man pages section 1M: System Administration Commands

ORACLE®

Contents

Preface

Both novice users and those familar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question "What does it do?" The man pages in general comprise a reference manual. They are not intended to be a tutorial.

Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.

- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.

- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.

- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.

- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.

- Section 5 contains miscellaneous documentation such as character-set tables.

- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.

- Section 9E describes the DDI (Device Driver Interface)/DKI (Driver/Kernel Interface), DDI-only, and DKI-only entry-point routines a developer can include in a device driver.

- Section 9F describes the kernel functions available for use by device drivers.

- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report,

there is no BUGS section. See the intro pages for more information and detail about each section, and man(1) for more information about man pages in general.

NAME	This section gives the names of the commands or functions documented, followed by a brief description of what they do.
SYNOPSIS	This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.

The following special characters are used in this section:

[ ]	Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.
. . .	Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename...".
|	Separator. Only one of the arguments separated by this character can be specified at a time.
{ }	Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.

PROTOCOL	This section occurs only in subsection 3R to indicate the protocol description file.
DESCRIPTION	This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are described under USAGE.
IOCTL	This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the ioctl(2) system call is called ioctl and generates its own heading. ioctl calls for a specific device are listed alphabetically (on the man page for that specific device).

ioctl calls are used for a particular class of devices all of which have an io ending, such as mtio(7I).

OPTIONS | This section lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.

OPERANDS | This section lists the command operands and describes how they affect the actions of the command.

OUTPUT | This section describes the output – standard output, standard error, or output files – generated by the command.

RETURN VALUES | If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or –1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.

ERRORS | On failure, most functions place an error code in the global variable errno indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph under the error code.

USAGE | This section lists special rules, features, and commands that require in-depth explanations. The subsections listed here are used to explain built-in functionality:

Commands
Modifiers
Variables
Expressions
Input Grammar

EXAMPLES | This section provides examples of usage or of how to use a command or function. Wherever possible a complete

example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as example%, or if the user must be superuser, example#. Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.

ENVIRONMENT VARIABLES   This section lists any environment variables that the command or function affects, followed by a brief description of the effect.

EXIT STATUS   This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.

FILES   This section lists all file names referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.

ATTRIBUTES   This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See attributes(5) for more information.

SEE ALSO   This section lists references to other man pages, in-house documentation, and outside publications.

DIAGNOSTICS   This section lists diagnostic messages with a brief explanation of the condition causing the error.

WARNINGS   This section lists warnings about special conditions which could seriously affect your working conditions. This is not a list of diagnostics.

NOTES   This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.

BUGS   This section describes known bugs and, wherever possible, suggests workarounds.

REFERENCE

Introduction

Name Intro – introduction to maintenance commands and application programs

Description This section describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.

Because of command restructuring for the Virtual File System architecture, there are several instances of multiple manual pages that begin with the same name. For example, the mount, pages – mount(1M), mount_hsfs(1M), mount_nfs(1M), mount_tmpfs(1M), and mount_ufs(1M). In each such case the first of the multiple pages describes the syntax and options of the generic command, that is, those options applicable to all FSTypes (file system types). The succeeding pages describe the functionality of the FSType-specific modules of the command. These pages list the command followed by an underscore (_) and the FSType to which they pertain. Note that the administrator should not attempt to call these modules directly. The generic command provides a common interface to all of them. Thus the FSType-specific manual pages should not be viewed as describing distinct commands, but rather as detailing those aspects of a command that are specific to a particular FSType.

Command Syntax Unless otherwise noted, commands described in this section accept options and other arguments according to the following syntax:

name [*option*(*s*)] [*cmdarg*(*s*)]

where:

name	The name of an executable file.
option	– *noargletter*(*s*) or,
	– *argletter*< >*optarg*
	where < > is optional white space.
noargletter	A single letter representing an option without an argument.
argletter	A single letter representing an option requiring an argument.
optarg	Argument (character string) satisfying preceding *argletter*.
cmdarg	Pathname (or other command argument) *not* beginning with – or, – by itself indicating the standard input.

Attributes See attributes(5) for a discussion of the attributes listed in this section.

Acknowledgments Oracle America, Inc. gratefully acknowledges The Open Group for permission to reproduce portions of its copyrighted documentation. Original documentation from The Open Group can be obtained online at http://www.opengroup.org/bookstore/.

The Institute of Electrical and Electronics Engineers and The Open Group, have given us permission to reprint portions of their documentation.

In the following statement, the phrase "this text" refers to portions of the system documentation.

Portions of this text are reprinted and reproduced in electronic form in the SunOS Reference Manual, from IEEE Std 1003.1, 2004 Edition, Standard for Information Technology -- Portable Operating System Interface (POSIX), The Open Group Base Specifications Issue 6, Copyright (C) 2001-2004 by the Institute of Electrical and Electronics Engineers, Inc and The Open Group. In the event of any discrepancy between these versions and the original IEEE and The Open Group Standard, the original IEEE and The Open Group Standard is the referee document. The original Standard can be obtained online at http://www.opengroup.org/unix/online.html.

This notice shall appear on any product containing this material.

See Also   getopt(1), getopt(3C), attributes(5)

Diagnostics   Upon termination, each command returns 0 for normal termination and non-zero to indicate troubles such as erroneous parameters, bad or inaccessible data, or other inability to cope with the task at hand. It is called variously "exit code," "exit status," or "return code," and is described only where special conventions are involved.

Notes   Unfortunately, not all commands adhere to the standard syntax.

System Administration Commands – Part 1

Name   6to4relay – administer configuration for 6to4 relay router communication

Synopsis   /usr/sbin/6to4relay

/usr/sbin/6to4relay [-e] [-a *addr*]

/usr/sbin/6to4relay [-d]

/usr/sbin/6to4relay [-h]

Description   The 6to4relay command is used to configure 6to4 relay router communication. Relay router communication support is enabled by setting the value of a variable that stores an IPv4 address within the tun module. This variable is global to all tunnels and defines the policy for communication with relay routers. By default, the address is set to INADDR_ANY (0.0.0.0), and the kernel interprets the value to indicate that support for relay router communication is disabled. Otherwise, support is enabled, and the specified address is used as the IPv4 destination address when packets destined for native IPv6 (non-6to4) hosts are sent through the 6to4 tunnel interface. The 6to4relay command uses a project private ioctl to set the variable.

6to4relay used without any options outputs the current, in-kernel, configuration status. Use the -a option to send packets to a specific relay router's unicast address instead of the default anycast address. The address specified with the -a option does not specify the policy for receiving traffic from relay routers. The source relay router on a received packet is non-deterministic, since a different relay router may be chosen for each sending native IPv6 end-point.

Configuration changes made by using the 6to4relay are not persistent across reboot. The changes will persist in the kernel only until you take the tunnel down

Options   The 6to4relay command supports the following options:

-a *addr*   Use the specified address, *addr*.

-e   Enable support for relay router. Use -a *addr* if it is specified. Otherwise, use the default anycast address, 192.88.99.1.

-d   Disable support for the relay router.

-h   Help

Operands   The following operands are supported:

addr   A specific relay router's unicast address. *addr* must be specified as a dotted decimal representation of an IPv4 address. Otherwise, an error will occur, and the command will fail.

Examples   EXAMPLE 1   Printing the In-Kernel Configuration Status

Use /usr/sbin/6to4relay without any options to print the in-kernel configuration status.

example# **/usr/sbin/6to4relay**

EXAMPLE 1 Printing the In-Kernel Configuration Status   *(Continued)*

If 6to4 relay router communication is disabled, the administrator will see the following message:

```
6to4relay: 6to4 Relay Router communication support is disabled.
```

If 6to4 router communication is enabled, the user will see this message:

```
6to4relay: 6to4 Relay Router communication support is enabled.
IPv4 destination address of Relay Router = 192.88.99.1
```

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Files   /usr/sbin/6to4relay   The default installation root

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also   ifconfig(1M), attributes(5)

Huitema, C. *RFC 3068, An Anycast Prefix for 6to4 Relay Routers*. Network Working Group. June, 2001.

Carpenter, B. and Moore, K. *RFC 3056, Connection of IPv6 Domains via IPv4 Clouds*. Network Working Group. February, 2001.

Diagnostics   The 6to4relay reports the following messages:

```
6to4relay: input (0.0.0.0) is not a valid IPv4 unicast address
```
    Example: The following example provides an incorrect unicast address.

```
example# 6to4relay -e -a 0.0.0.0
```

    Description: The address specified with the -a option must be a valid unicast address.

```
6to4relay: option requires an argument —a
usage:
    6to4relay
    6to4relay -e [-a <addr>]
```

```
 6to4relay -d
 6to4relay -h
```
Example: The following example does not include an argument for the -a option.

```
example# 6to4relay -e -a
```

Description: The -a option requires an argument.

```
usage:
   6to4relay
   6to4relay -e [-a <addr>]
   6to4relay -d
   6to4relay -h
```
Example: The following example specifies options that are not permitted.

```
example# 6to4relay -e -d
```

Description: The options specified are not permitted. A usage message is output to the screen.

```
usage:
   6to4relay
   6to4relay -e [-a <addr>]
   6to4relay -d
   6to4relay -h
```
Example: The following example specifies the -a option without specifying the -e option.

```
example# 6to4relay -a 1.2.3.4
```

Description: The -e option is required in conjunction with the -a option. A usage message is output to the screen.

```
6to4relay: ioctl (I_STR) : Invalid argument
```
Example: The following example specifies an invalid address.

```
example# 6to4relay -e -a 239.255.255.255
```

Description: The address specified with the -a option must not be a class d *addr*.

Name acct, acctdisk, acctdusg, accton, acctwtmp, closewtmp, utmp2wtmp – overview of accounting and miscellaneous accounting commands

Synopsis /usr/lib/acct/acctdisk

/usr/lib/acct/acctdusg [-u *filename*] [-p *filename*]

/usr/lib/acct/accton [*filename*]

/usr/lib/acct/acctwtmp *reason filename*

/usr/lib/acct/closewtmp

/usr/lib/acct/utmp2wtmp

Description Accounting software is structured as a set of tools (consisting of both C programs and shell procedures) that can be used to build accounting systems. acctsh(1M) describes the set of shell procedures built on top of the C programs.

Connect time accounting is handled by various programs that write records into /var/adm/wtmpx, as described in utmpx(4). The programs described in acctcon(1M) convert this file into session and charging records, which are then summarized by acctmerg(1M).

Process accounting is performed by the system kernel. Upon termination of a process, one record per process is written to a file (normally /var/adm/pacct). The programs in acctprc(1M) summarize this data for charging purposes; acctcms(1M) is used to summarize command usage. Current process data may be examined using acctcom(1).

Process accounting records and connect time accounting records (or any accounting records in the tacct format described in acct.h(3HEAD)) can be merged and summarized into total accounting records by acctmerg (see tacct format in acct.h(3HEAD)). prtacct (see acctsh(1M)) is used to format any or all accounting records.

acctdisk reads lines that contain user ID, login name, and number of disk blocks and converts them to total accounting records that can be merged with other accounting records. acctdisk returns an error if the input file is corrupt or improperly formatted.

acctdusg reads its standard input (usually from find / -print) and computes disk resource consumption (including indirect blocks) by login.

accton without arguments turns process accounting off. If *filename* is given, it must be the name of an existing file, to which the kernel appends process accounting records (see acct(2) and acct.h(3HEAD)).

acctwtmp writes a utmpx(4) record to *filename*. The record contains the current time and a string of characters that describe the *reason*. A record type of ACCOUNTING is assigned (see utmpx(4)) *reason* must be a string of 11 or fewer characters, numbers, $, or spaces. For example, the following are suggestions for use in reboot and shutdown procedures, respectively:

```
acctwtmp "acctg on" /var/adm/wtmpx
acctwtmp "acctg off" /var/adm/wtmpx
```

For each user currently logged on, closewtmp puts a false DEAD_PROCESS record in the /var/adm/wtmpx file. runacct (see runacct(1M)) uses this false DEAD_PROCESS record so that the connect accounting procedures can track the time used by users logged on before runacct was invoked.

For each user currently logged on, runacct uses utmp2wtmp to create an entry in the file /var/adm/wtmpx, created by runacct. Entries in /var/adm/wtmpx enable subsequent invocations of runacct to account for connect times of users currently logged in.

Options The following options are supported:

-u *filename* Places in *filename* records consisting of those filenames for which acctdusg charges no one (a potential source for finding users trying to avoid disk charges).

-p *filename* Specifies a password file, *filename*. This option is not needed if the password file is /etc/passwd.

Environment Variables If any of the LC_* variables (LC_TYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of acct for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how acct behaves.

LC_CTYPE Determines how acct handles characters. When LC_CTYPE is set to a valid value, acct can display and handle text and filenames containing valid characters for that locale. acct can display and handle Extended Unix Code (EUC) characters where any character can be 1, 2, or 3 bytes wide. acct can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_TIME Determines how acct handles date and time formats. In the "C" locale, date and time handling follows the U.S. rules.

Files /etc/passwd Used for login name to user ID conversions.

/usr/lib/acct Holds all accounting commands listed in sub-class 1M of this manual.

/var/adm/pacct Current process accounting file.

/var/adm/wtmpx History of user access and administration information..

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/accounting/legacy-accounting

See Also   acctcom(1), acctcms(1M), acctcon(1M), acctmerg(1M), acctprc(1M), acctsh(1M),

environ(5)

Oracle Solaris Administration: Common Tasks

Name acctadm – configure extended accounting facility

Synopsis /usr/sbin/acctadm [-DEsrux] [-d *resource_list*]
        [-e *resource_list*] [-f *filename*]
        [task | process | flow | net]

Description acctadm configures various attributes of the extended accounting facility. Without arguments, acctadm displays the current status of the extended accounting facility.

Options The following options are supported:

-d *resource_list*
    Disable reporting of resource usage for resource. Specify *resource_list* as a comma-separated list of resources or resource groups.

    This option requires an operand. See OPERANDS.

-D
    Disable accounting of the given operand type without closing the accounting file. This option can be used to temporarily stop writing accounting records to the accounting file without closing it. To close the file use the -x option. See -x.

-e *resource_list*
    Enable reporting of resource usage for resource. Specify *resource_list* as a comma-separated list of resources or resource groups.

    This option requires an operand. See OPERANDS.

-E
    Enable accounting of the given operand type without sending the accounting output to a file. This option requires an operand. See OPERANDS.

-f *filename*
    Send the accounting output for the given operand type to *filename*. If *filename* exists, its contents must be of the given accounting type.

    This option requires an operand. See OPERANDS.

-r
    Display available resource groups.

    When this option is used with an operand, it displays resource groups available for a given accounting type. When no operand is specified, this option displays resource groups for all available accounting types. See OPERANDS.

-s
    Start method for the smf(5) instance. This option is used to restore the extended accounting configuration at boot.

-x

    Deactivate accounting of the given operand type. This option also closes the accounting file for the given accounting type if it is currently open.

    This option requires an operand. See OPERANDS.

Operands The -d, -D, -e, -E, -f, and -x options require an operand.

The following operands are supported:

process

    Run acctadm on the process accounting components of the extended accounting facility.

task

    Run acctadm on the task accounting components of the extended accounting facility.

flow

    Run acctadm on the IPQoS accounting components of the extended accounting facility.

net

    Run acctadm on links and flows administered by dladm(1M) and flowadm(1M), respectively. Basic network accounting relates only to links, while extended network accounting includes both link and flow accounting.

The optional final parameter to acctadm represents whether the command should act on the process, system task, IPQoS, or network accounting components of the extended accounting facility.

Examples **EXAMPLE 1** Displaying the Current Status

The following command displays the current status. In this example, system task accounting is active and tracking only CPU resources. Process and flow accounting are not active.

```
$ acctadm
            Task accounting: active
       Task accounting file: /var/adm/exacct/task
     Tracked task resources: extended
   Untracked task resources: host
         Process accounting: inactive
    Process accounting file: none
  Tracked process resources: none
Untracked process resources: extended,host
            Flow accounting: inactive
       Flow accounting file: none
     Tracked flow resources: none
   Untracked flow resources: extended
             Net accounting: inactive
        Net accounting file: none
      Tracked Net resources: none
    Untracked Net resources: extended
```

EXAMPLE 2 Activating Basic Process Accounting

The following command activates basic process accounting:

```
$ acctadm -e basic -f /var/adm/exacct/proc process
```

EXAMPLE 3 Displaying Available Resource Groups

The following command displays available resource groups:

```
$ acctadm -r
  process:
  extended pid,uid,gid,cpu,time,command,tty,projid, \
  taskid,ancpid,wait-status,zone,flag,memory,mstate
  basic    pid,uid,gid,cpu,time,command,tty,flag
  task:
  extended taskid,projid,cpu,time,host,mstate,anctaskid,zone
  basic    taskid,projid,cpu,time
  flow:
  extended saddr,daddr,sport,dport,proto,dsfield,nbytes,npkts, \
  action,ctime,lseen,projid,uid
  basic    saddr,daddr,sport,dport,proto,nbytes,npkts,action
  net:
  extended name,devname,edest,vlan_tpid,vlan_tci,sap,cpuid, \
  priority,bwlimit,curtime,ibytes,obytes,ipkts,opks,ierrpkts \
  oerrpkts,saddr,daddr,sport,dport,protocol,dsfield
  basic    name,devname,edest,vlan_tpid,vlan_tci,sap,cpuid, \
  priority,bwlimit,curtime,ibytes,obytes,ipkts,opks,ierrpkts \
  oerrpkts
```

In the output above, the lines beginning with extended are shown with a backslash character. In actual acctadm output, these lines are displayed as unbroken, long lines.

EXAMPLE 4 Displaying Resource Groups for Task Accounting

The following command displays resource groups for task accounting:

```
$ acctadm -r task
  extended taskid,projid,cpu,time,host,mstate,anctaskid,zone
  basic    taskid,projid,cpu,time
```

Exit Status The following exit values are returned:

0

Successful completion.

The modifications to the current configuration were valid and made successfully.

1

An error occurred.

A fatal error occured either in obtaining or modifying the accounting configuration.

2

Invalid command line options were specified.

95

A fatal, non-configuration error occurred during the start of the smf(5) service instance.

96

A fatal configuration error occurred during the start of the smf(5) service instance.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also dladm(1M), flowadm(1M), acct(2), attributes(5), smf(5), ipqos(7ipp)

Notes Both extended accounting and regular accounting can be active.

Available resources can vary from system to system, and from platform to platform.

Extended accounting configuration is stored in the service management facility (smf(5)) repository. The configuration is restored at boot by a transient service instance, one per accounting type:

```
svc:/system/extended-accounting:flow       Flow accounting
svc:/system/extended-accounting:process    Process accounting
svc:/system/extended-accounting:task       Task accounting
svc:/system/extended-accounting:net        Network accounting
```

The instances are enabled or disabled by acctadm as needed. Configuration changes are made using acctadm; service properties should not be modified directly using svccfg(1M).

Users can manage extended accounting (start accounting, stop accounting, change accounting configuration parameters) if they have the appropriate RBAC Rights profile for the accounting type to be managed:

- Extended Accounting Flow Management
- Extended Accounting Process Management
- Extended Accounting Task Management
- Extended Accounting Network Management

The preceding profiles are for, respectively, flow accounting, process accounting, task accounting, and network accounting.

Name acctcms – command summary from process accounting records

Synopsis /usr/lib/acct/acctcms [-a [-o] [-p]] [-c] [-j] [-n] [-s]
[-t] *filename*...

Description acctcms reads one or more *filename*s, normally in the form described in acct.h(3HEAD). It adds all records for processes that executed identically named commands, sorts them, and writes them to the standard output, normally using an internal summary format.

Options -a Print output in ASCII rather than in the internal summary format. The output includes command name, number of times executed, total kcore-minutes, total CPU minutes, total real minutes, mean size (in K), mean CPU minutes per invocation, "hog factor," characters transferred, and blocks read and written, as in acctcom(1). Output is normally sorted by total kcore-minutes.

Use the following options only with the -a option:

-o Output a (non-prime) offshift-time-only command summary.

-p Output a prime-time-only command summary.

When -o and -p are used together, a combination prime-time and non-prime-time report is produced. All the output summaries are total usage except number of times executed, CPU minutes, and real minutes, which are split into prime and non-prime.

-c Sort by total CPU time, rather than total kcore-minutes.

-j Combine all commands invoked only once under "***other".

-n Sort by number of command invocations.

-s Any file names encountered hereafter are already in internal summary format.

-t Process all records as total accounting records. The default internal summary format splits each field into prime and non-prime-time parts. This option combines the prime and non-prime time parts into a single field that is the total of both, and provides upward compatibility with old style acctcms internal summary format records.

Examples EXAMPLE 1 Using the acctcms command.

A typical sequence for performing daily command accounting and for maintaining a running total is:

```
example% acctcms filename ... > today
example% cp total previoustotal
example% acctcms -s today previoustotal > total
example% acctcms -a -s today
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/accounting/legacy-accounting

See Also acctcom(1), acct(1M), acctcon(1M), acctmerg(1M), acctprc(1M), acctsh(1M), fwtmp(1M), runacct(1M), acct(2), acct.h(3HEAD), utmpx(4), attributes(5)

Notes Unpredictable output results if -t is used on new style internal summary format files, or if it is not used with old style internal summary format files.

Name acctcon, acctcon1, acctcon2 – connect-time accounting

Synopsis /usr/lib/acct/acctcon [-l *lineuse*] [-o *reboot*]

/usr/lib/acct/acctcon1 [-p] [-t] [-l *lineuse*] [-o *reboot*]

/usr/lib/acct/acctcon2

Description acctcon converts a sequence of login/logoff records to total accounting records (see the tacct format in acct.h(3HEAD)). The login/logoff records are read from standard input. The file /var/adm/wtmpx is usually the source of the login/logoff records; however, because it might contain corrupted records or system date changes, it should first be fixed using wtmpfix. The fixed version of file /var/adm/wtmpx can then be redirected to acctcon. The tacct records are written to standard output.

acctcon is a combination of the programs acctcon1 and acctcon2. acctcon1 converts login/logoff records, taken from the fixed /var/adm/wtmpx file, to ASCII output. acctcon2 reads the ASCII records produced by acctcon1 and converts them to tacct records. acctcon1 can be used with the -l and -o options, described below, as well as with the -p and -t options.

Options -p   Print input only, showing line name, login name, and time (in both numeric and date/time formats).

-t   acctcon1 maintains a list of lines on which users are logged in. When it reaches the end of its input, it emits a session record for each line that still appears to be active. It normally assumes that its input is a current file, so that it uses the current time as the ending time for each session still in progress. The -t flag causes it to use, instead, the last time found in its input, thus assuring reasonable and repeatable numbers for non-current files.

-l *lineuse*   *lineuse* is created to contain a summary of line usage showing line name, number of minutes used, percentage of total elapsed time used, number of sessions charged, number of logins, and number of logoffs. This file helps track line usage, identify bad lines, and find software and hardware oddities. Hangup, termination of login(1) and termination of the login shell each generate logoff records, so that the number of logoffs is often three to four times the number of sessions. See init(1M) and utmpx(4).

-o *reboot*   reboot is filled with an overall record for the accounting period, giving starting time, ending time, number of reboots, and number of date changes.

Examples EXAMPLE 1 Using the acctcon command.

The acctcon command is typically used as follows:

example% acctcon -l lineuse -o reboots < tmpwtmp > ctacct

The acctcon1 and acctcon2 commands are typically used as follows:

EXAMPLE 1 Using the acctcon command.   *(Continued)*

```
example% acctcon1 -l lineuse -o reboots < tmpwtmp | sort +1n +2 > ctmp
example% acctcon2 < ctmp > ctacct
```

Files /var/adm/wtmpx   History of user access and administration information

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/accounting/legacy-accounting

See Also acctcom(1), login(1), acct(1M), acctcms(1M), acctmerg(1M), acctprc(1M), acctsh(1M), fwtmp(1M), init(1M), runacct(1M), acct(2), acct.h(3HEAD), utmpx(4), attributes(5)

Oracle Solaris Administration: Common Tasks

Notes The line usage report is confused by date changes. Use wtmpfix (see fwtmp(1M)), with the /var/adm/wtmpx file as an argument, to correct this situation.

During a single invocation of any given command, the acctcon, acctcon1, and acctcon2 commands can process a maximum of:

- 6000 distinct session
- 1000 distinct terminal lines
- 2000 distinct login names

If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

Name acctmerg – merge or add total accounting files

Synopsis `/usr/lib/acct/acctmerg [-a] [-i] [-p] [-t] [-u] [-v]`
        `[`*filename*`] ...`

Description `acctmerg` reads its standard input and up to nine additional files, all in the `tacct` format (see
`acct.h(3HEAD)`) or an ASCII version thereof. It merges these inputs by adding records
whose keys (normally user ID and name) are identical, and expects the inputs to be sorted on
those keys.

Options   `-a`   Produce output in ASCII version of `tacct`.

          `-i`   Produce input in ASCII version of `tacct`.

          `-p`   Print input with no processing.

          `-t`   Produce a single record that totals all input.

          `-u`   Summarize by user ID, rather than by user ID and name.

          `-v`   Produce output in verbose ASCII format, with more precise notation for floating-point
numbers.

Examples EXAMPLE 1 Using the `acctmerg` command.

The following sequence is useful for making "repairs" to any file kept in this format:

`example% acctmerg     -v   <`*filename1* `>`*filename2*

Edit *filename2* as you want:

`example% acctmerg     -i   <`*filename2* `>`*filename1*

Oracle Solaris Administration: Common Tasks

Name acctprc, acctprc1, acctprc2 – process accounting

Synopsis /usr/lib/acct/acctprc

/usr/lib/acct/acctprc1 [*ctmp*]

/usr/lib/acct/acctprc2

Description acctprc reads the standard input and converts it to total accounting records (see the tacct record in acct.h(3HEAD)). acctprc divides CPU time into prime time and non-prime time and determines mean memory size (in memory segment units). acctprc then summarizes the tacct records, according to user IDs, and adds login names corresponding to the user IDs. The summarized records are then written to the standard output. acctprc1 reads input in the form described by acct.h(3HEAD), adds login names corresponding to user IDs, then writes for each process an ASCII line giving user ID, login name, prime CPU time (tics), non-prime CPU time (tics), and mean memory size (in memory segment units). If *ctmp* is given, it should contain a list of login sessions sorted by user ID and login name. If this file is not supplied, it obtains login names from the password file, just as acctprc does. The information in *ctmp* helps it distinguish between different login names that share the same user ID.

From the standard input, acctprc2 reads records in the form written by acctprc1, summarizes them according to user ID and name, then writes the sorted summaries to the standard output as total accounting records.

Examples EXAMPLE 1 Examples of acctprc.

The acctprc command is typically used as shown below:

example% acctprc < /var/adm/pacct > ptacct

The acctprc1 and acctprc2s commands are typically used as shown below:

example% acctprc1 ctmp </var/adm/pacct
example% acctprc2 > ptacct

Files /etc/passwd   system password file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/accounting/legacy-accounting

See Also acctcom(1), acct(1M), acctcms(1M), acctcon(1M), acctmerg(1M), acctsh(1M), cron(1M), fwtmp(1M), runacct(1M), acct(2), acct.h(3HEAD), utmpx(4), attributes(5)

Notes Although it is possible for acctprc1 to distinguish among login names that share user IDs for commands run from a command line, it is difficult for acctprc1 to make this distinction for commands invoked in other ways. A command run from cron(1M) is an example of where

acctprc1 might have difficulty. A more precise conversion can be done using the acctwtmp program in acct(1M). acctprc does not distinguish between users with identical user IDs.

A memory segment of the mean memory size is a unit of measure for the number of bytes in a logical memory segment on a particular processor.

During a single invocation of any given command, the acctprc, acctprc1, and acctprc2 commands can process a maximum of

- 6000 distinct sessions
- 1000 distinct terminal lines
- 2000 distinct login names

If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

Name acctsh, chargefee, ckpacct, dodisk, lastlogin, monacct, nulladm, prctmp, prdaily, prtacct, shutacct, startup, turnacct – shell procedures for accounting

Synopsis /usr/lib/acct/chargefee *login-name number*

/usr/lib/acct/ckpacct [*blocks*]

/usr/lib/acct/dodisk [-o] [*filename*]...

/usr/lib/acct/lastlogin

/usr/lib/acct/monacct *number*

/usr/lib/acct/nulladm *filename*...

/usr/lib/acct/prctmp *filename*

/usr/lib/acct/prdaily [-c] [-l] [*mmdd*]

/usr/lib/acct/prtacct *filename* ['' *heading* '']

/usr/lib/acct/shutacct ['' *reason* '']

/usr/lib/acct/startup

/usr/lib/acct/turnacct on | off | switch

Description

chargefee Command chargefee can be invoked to charge a *number* of units to *login-name*. A record is written to /var/adm/fee, to be merged with other accounting records by runacct(1M).

ckpacct Command ckpacct should be initiated using cron(1M) to periodically check the size of /var/adm/pacct. If the size exceeds *blocks*, 500 by default, turnacct will be invoked with argument switch. To avoid a conflict with turnacct switch execution in runacct, do not run ckpacct and runacct simultaneously. If the number of free disk blocks in the /var file system falls below 500, ckpacct will automatically turn off the collection of process accounting records via the off argument to turnacct. When at least 500 blocks are restored, the accounting will be activated again on the next invocation of ckpacct. This feature is sensitive to the frequency at which ckpacct is executed, usually by the cron(1M) command.

dodisk Command dodisk should be invoked by cron(1M) to perform the disk accounting functions.

lastlogin Command lastlogin is invoked by runacct(1M) to update /var/adm/acct/sum/loginlog, which shows the last date on which each person logged in.

monacct Command monacct should be invoked once each month or each accounting period. *number* indicates which month or period it is. If *number* is not given, it defaults to the current month (01–12). This default is useful if monacct is to executed using cron(1M) on the first day of each month. monacct creates summary files in /var/adm/acct/fiscal and restarts the summary files in /var/adm/acct/sum.

nulladm Command   nulladm creates *filename* with mode 664 and ensures that owner and group are adm. It is called by various accounting shell procedures.

prctmp Command   prctmp can be used to print the session record file (normally /var/adm/acct/nite/ctmp created by acctcon1 (see acctcon(1M)).

prdaily Command   prdaily is invoked by runacct(1M) to format a report of the previous day's accounting data. The report resides in /var/adm/acct/sum/rprt/mmdd where *mmdd* is the month and day of the report. The current daily accounting reports may be printed by typing prdaily. Previous days' accounting reports can be printed by using the *mmdd* option and specifying the exact report date desired.

prtacct Command   prtacct can be used to format and print any total accounting (tacct)file.

shutacct Command   shutacct is invoked during a system shutdown to turn process accounting off and append a *reason* record to /var/adm/wtmpx.

startup Command   startup can be invoked when the system is brought to a multi-user state to turn process accounting on.

turnacct Command   turnacct is an interface to accton (see acct(1M)) to turn process accounting on or off. The switch argument moves the current /var/adm/pacct to the next free name in /var/adm/pacct.*incr* (where *incr* is a number starting with 0 and incrementing by one for each additional pacct file), then turns accounting back on again. This procedure is called by ckpacct and thus can be taken care of by the cron(1M) command and used to keep pacct to a reasonable size. shutacct uses turnacct to stop process accounting. startup uses turnacct to start process accounting.

Options   The following options are supported:

-c   This option prints a report of exceptional resource usage by command, and may be used on current day's accounting data only.

-l   This option prints a report of exceptional usage by login id for the specified date. Previous daily reports are cleaned up and therefore inaccessible after each invocation of monacct.

-o   This option uses acctdusg (see acct(1M)) to do a slower version of disk accounting by login directory. *filename*s specifies the one or more filesystem names where disk accounting will be done. If *filename*s are used, disk accounting will be done on these filesystems only. If the -o option is used, *filename*s should be mount points of mounted filesystems. If the -o option is omitted, *filename*s should be the special file names of mountable filesystems.

Files   /etc/logadm.conf   Configuration file for the logadm(1M) command

            /usr/lib/acct   Holds all accounting commands listed in section 1M of this manual

/usr/lib/acct/ptecms.awk	Contains the limits for exceptional usage by command name
/usr/lib/acct/ptelus.awk	Contains the limits for exceptional usage by login ID
/var/adm/acct/fiscal	Fiscal reports directory
/var/adm/acct/nite	Working directory
/var/adm/acct/sum	Summary directory that contains information for monacct
/var/adm/acct/sum/loginlog	File updated by last login
/var/adm/fee	Accumulator for fees
/var/adm/pacct	Current file for per-process accounting
/var/adm/pacct*incr*	Used if pacct gets large and during execution of daily accounting procedure
/var/adm/wtmpx	History of user access and administration information

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/accounting/legacy-accounting

See Also acctcom(1), acct(1M), acctcms(1M), acctcon(1M), acctmerg(1M), acctprc(1M), cron(1M), fwtmp(1M), logadm(1M), runacct(1M), acct(2), acct.h(3HEAD), utmpx(4), attributes(5)

Notes See runacct(1M) for the main daily accounting shell script, which performs the accumulation of connect, process, fee, and disk accounting on a daily basis. It also creates summaries of command usage.

Name acpihpd – ACPI hot plug daemon

Synopsis `/usr/platform/i86pc/lib/acpihpd`

Description The ACPI hot plug daemon, `acpihpd`, is a daemon process that runs on x86 platforms. The daemon is started by the service management facility. It communicates with the syseventd(1M) and cfgadm(1M) subsystems to handle ACPI events from hotpluggable devices.

The service FMRI for `acpihpd` is:

`svc:/platform/i86pc/acpihpd:default`

Note that `acpihpd` is a private interface.

Options The `acpihpd` daemon does not support any options.

Errors `acpihpd` uses syslog(3C) to report status and error messages. All of the messages are logged with the `LOG_DAEMON` facility.

Error messages are logged with the `LOG_ERR` and `LOG_NOTICE` priorities, and informational messages are logged with the `LOG_DEBUG` priority. The default entries in the `/etc/syslog.conf` file log all of the error messages to the `/var/adm/messages` log.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/kernel/dynamic-reconfiguration/i86pc
Interface Stability	Private

See Also svcs(1), cfgadm(1M), inetadm(1M), svcadm(1M), syseventd(1M), syslog(3C), syslog.conf(4), attributes(5), smf(5)

Notes The `acpihpd` service is managed by the service management facility, smf(5), under the service identifier:

`svc:/platform/i86pc/acpihpd:default`

Name adbgen – generate adb script

Synopsis /usr/lib/adb/adbgen [-m *model*] *filename*.adb . . .

Description adbgen makes it possible to write adb(1) scripts that do not contain hard-coded dependencies on structure member offsets. The input to adbgen is a file named *filename*.adb that contains header information, then a null line, then the name of a structure, and finally an adb script. adbgen only deals with one structure per file; all member names are assumed to be in this structure. The output of adbgen is an adb script in *filename*. adbgen operates by generating a C program which determines structure member offsets and sizes, which in turn generate the adb script.

The header lines, up to the null line, are copied verbatim into the generated C program. Typically, these are #include statements, which include the headers containing the relevant structure declarations.

The adb script part may contain any valid adb commands (see adb(1)), and may also contain adbgen requests, each enclosed in braces ({ }). Request types are:

- Print a structure member. The request form is {*member*, *format*}. *member* is a member name of the *structure* given earlier, and format is any valid adb format request or any of the adbgen format specifiers (such as {POINTER}) listed below. For example, to print the p_pid field of the *proc* structure as a decimal number, you would write {p_pid,d}.

- Print the appropriate adb format character for the given adbgen format specifier. This action takes the data model into consideration. The request form is {*format specifier*}. The valid adbgen format specifiers are:

  {POINTER}   pointer value in hexadecimal

  {LONGDEC}   long value in decimal

  {ULONGDEC}   unsigned long value in decimal

  {ULONGHEX}   unsigned long value in hexadecimal

  {LONGOCT}   long value in octal

  {ULONGOCT}   unsigned long value in octal

- Reference a structure member. The request form is {**member*, *base*}. *member* is the member name whose value is desired, and *base* is an adb register name which contains the base address of the structure. For example, to get the p_pid field of the *proc* structure, you would get the *proc* structure address in an adb register, for example <f, and write {*p_pid,<f}.

- Tell adbgen that the offset is valid. The request form is {OFFSETOK}. This is useful after invoking another adb script which moves the adb *dot*.

- Get the size of the *structure*. The request form is {SIZEOF}. adbgen replaces this request with the size of the structure. This is useful in incrementing a pointer to step through an array of structures.

- Calculate an arbitrary C expression. The request form is {EXPR, *expression*}. adbgen replaces this request with the value of the expression. This is useful when more than one structure is involved in the script.

- Get the offset to the end of the structure. The request form is {END}. This is useful at the end of the structure to get adb to align the *dot* for printing the next structure member.

adbgen keeps track of the movement of the adb *dot* and generates adb code to move forward or backward as necessary before printing any structure member in a script. adbgen's model of the behavior of adb's *dot* is simple: it is assumed that the first line of the script is of the form *struct_address*/*adb text* and that subsequent lines are of the form +/*adb text*. The adb *dot* then moves in a sane fashion. adbgen does not check the script to ensure that these limitations are met. adbgen also checks the size of the structure member against the size of the adb format code and warns if they are not equal.

Options The following option is supported:

-m *model*   Specifies the data type model to be used by adbgen for the macro. This affects the outcome of the {*format specifier*} requests described under DESCRIPTION and the offsets and sizes of data types. *model* can be ilp32 or lp64. If the -m option is not given, the data type model defaults to ilp32.

Operands The following operand is supported:

filename.adb   Input file that contains header information, followed by a null line, the name of the structure, and finally an adb script.

Examples EXAMPLE 1   A sample adbgen file.

For an include file x.h which contained

```
struct x {
        char    *x_cp;
        char    x_c;
        int     x_i;
};
```

then, an adbgen file (call it script.adb) to print the file x.h would be:

```
#include "x.h"
x
./"x_cp"16t"x_c"8t"x_i"n{x_cp,{POINTER}}{x_c,C}{x_i,D}
```

After running adbgen as follows,

```
% /usr/lib/adb/adbgen  script.adb
```

the output file script contains:

```
./"x_cp"16t"x_c"8t"x_i"nXC3+D
```

EXAMPLE 1 A sample adbgen file. *(Continued)*

For a macro generated for a 64-bit program using the lp64 data model as follows,

```
% /usr/lib/adb/adbgen/ -m lp64  script.adb
```

the output file script would contain:

```
./"x_cp"16t"x_c"8t"x_i"nJC3+D
```

To invoke the script, type:

```
example% adb program
x$<script
```

Files   /usr/platform/*platform-name*/lib/adb/*
    platform-specific adb scripts for debugging the 32-bit kernel

/usr/platform/*platform-name*/lib/adb/sparcv9/*
    platform-specific adb scripts for debugging the 64-bit SPARC V9 kernel

/usr/lib/adb/*
    adb scripts for debugging the 32-bit kernel

/usr/lib/adb/sparcv9/*
    adb scripts for debugging the 64-bit SPARC V9 kernel

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/debug/mdb

See Also   adb(1), kmdb(1), uname(1), attributes(5)

Diagnostics   Warnings are given about structure member sizes not equal to adb format items and about badly formatted requests. The C compiler complains if a structure member that does not exist is referenced. It also complains about an ampersand before array names; these complaints may be ignored.

Notes   *platform-name* can be found using the -i option of uname(1).

Bugs   adb syntax is ugly; there should be a higher level interface for generating scripts.

Structure members which are bit fields cannot be handled because C will not give the address of a bit field. The address is needed to determine the offset.

Name   add_allocatable – add entries to allocation databases

Synopsis   /usr/sbin/add_allocatable [-f] [-s] [-d] -n *name* -t *type* -l *device-list*
        [-a *authorization*] [-c *clean*] [-o *key=value*]

Description   add_allocatable creates new entries for user allocatable devices that are to be managed by the device allocation mechanism. add_allocatable can also be used to update existing entries of such devices.

add_allocatable can also create and update entries for non-allocatable devices, such as printers, whose label range is managed by the device allocation mechanism.

add_allocatable can be used in shell scripts, such as installation scripts for driver packages, to automate the administrative work of setting up a new device.

Use list_devices(1) to see the names and types of allocatable devices, their attributes, and device paths.

Options

-f	Force an update of an already-existing entry with the specified information. add_allocatable exits with an error if this option is not specified when an entry with the specified device name already exists.
-s	Turn on silent mode. add_allocatable does not print any error or warning messages.
-d	If this option is present, add_allocatable updates the system-supplied default attributes of the device type specified with -t.
-n *name*	Adds or updates an entry for device that is specified by *name*.
-t *type*	Adds or updates device entries that are of a type that are specified by *type*.
-l *device-list*	Adds or updates device paths to the device that is specified with -n. Multiple paths in *device-list* must be separated by white spaces and the list must be quoted.
-a *authorization*	Adds or updates the authorization that is associated with either the device that is specified with -n or with devices of the type that is specified with -t. When more than one authorization is specified, the list must be separated by commas and must be quoted. When the device is not allocatable, *authorization* is specified with an asterisk (*) and must be quoted. When the device is allocatable by any user, *authorization* is specified with the at sign (@) and must be quoted. Default authorization is '@'.
-c *clean*	Specifies the device_clean(5) program *clean* to be used with the device that is specified with -n or with devices of the type that is specified with -t. The default clean program is /bin/true.

-o *key=value*   Accepts a string of colon-separated *key=value* pairs for a device that is specified with -n or with devices of the type that is specified with -t. The following keys are currently interpreted by the system:

minlabel   The minimum label at which the device can be used.

maxlabel   The maximum label at which the device can be used.

class   Specifies a logical grouping of devices. For example, all Sun Ray devices of all device types is a logical grouping. The class keyword has no default value.

xdpy   Specifies the display name of the X session. This keyword is used to identify devices that are associated with the X session. The xdpy keyword has no default value.

Exit Status   When successful, add_allocate returns an exit status of 0 (true). add_allocate returns a nonzero exit status in the event of an error. The exit codes are as follows:

1   Invocation syntax error

2   Unknown system error

3   An entry already exists for the specified device. This error occurs only when the -f option is not specified.

4   Permission denied. User does not have DAC or MAC access record updates.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/trusted
Interface Stability	See below.

The invocation is Uncommitted. The options are Uncommitted. The output is Not-an-Interface.

See Also   allocate(1), deallocate(1), list_devices(1), remove_allocatable(1M), attributes(5), device_clean(5)

Notes   The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name addbadsec – map out defective disk blocks

Synopsis addbadsec [-p] [-a *blkno* [*blkno*]...] [-f *filename*] *raw_device*

Description addbadsec is used by the system administrator to map out bad disk blocks. Normally, these blocks are identified during surface analysis, but occasionally the disk subsystem reports unrecoverable data errors indicating a bad block. A block number reported in this way can be fed directly into addbadsec, and the block will be remapped. addbadsec will first attempt hardware remapping. This is supported on SCSI drives and takes place at the disk hardware level. If the target is an IDE drive, then software remapping is used. In order for software remapping to succeed, the partition must contain an alternate slice and there must be room in this slice to perform the mapping.

It should be understood that bad blocks lead to data loss. Remapping a defective block does not repair a damaged file. If a bad block occurs to a disk-resident file system structure such as a superblock, the entire slice might have to be recovered from a backup.

Options The following options are supported:

-a   Adds the specified blocks to the hardware or software map. If more than one block number is specified, the entire list should be quoted and block numbers should be separated by white space.

-f   Adds the specified blocks to the hardware or software map. The bad blocks are listed, one per line, in the specified file.

-p   Causes addbadsec to print the current software map. The output shows the defective block and the assigned alternate. This option cannot be used to print the hardware map.

Operands The following operand is supported:

raw_device   The address of the disk drive (see FILES).

Files The raw device should be /dev/rdsk/c?[t?]d?p0. See disks(1M) for an explanation of SCSI and IDE device naming conventions.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	x86
Availability	system/core-os

See Also disks(1M), diskscan(1M), fdisk(1M), fmthard(1M), format(1M), attributes(5)

Notes The format(1M) utility is available to format, label, analyze, and repair SCSI disks. This utility is included with the addbadsec, diskscan(1M), fdisk(1M), and fmthard(1M) commands available for x86. To format an IDE disk, use the DOS "format" utility; however, to label, analyze, or repair IDE disks on x86 systems, use the Solaris format(1M) utility.

Name add_drv – add a new device driver to the system

Synopsis add_drv [-b *basedir*] [-c *class_name*]
      [-i '*identify_name...*'] [-m '*permission*','...']
      [-p '*policy*'] [-P *privilege*] [-n] [-f] [-u] [-v] *device_driver*

Description The add_drv command is used to inform the system about newly installed device drivers.

Each device on the system has a name associated with it. This name is represented by the name property for the device. Similarly, the device may also have a list of driver names associated with it. This list is represented by the compatible property for the device.

The system determines which devices will be managed by the driver being added by examining the contents of the name property and the compatible property (if it exists) on each device. If the value in the name property does not match the driver being added, each entry in the compatible property is tried, in order, until either a match occurs or there are no more entries in the compatible property.

In some cases, adding a new driver may require a reconfiguration boot. See the NOTES section.

Aliases might require quoting (with double-quotes) if they contain numbers. See EXAMPLES.

The /etc/minor_perm File add_drv and update_drv(1M) read the /etc/minor_perm file to obtain permission information. The permission specified is applied to matching minor nodes created when a device bound to the driver is attached. A minor node's permission may be manually changed by chmod(1). For such nodes, the specified permissions apply, overriding the default permissions specified via add_drv or update_drv(1M).

The format of the /etc/minor_perm file is as follows:

name:*minor_name permissions owner group*

minor_name may be the actual name of the minor node, or contain shell metacharacters to represent several minor nodes (see sh(1)).

For example:

```
sd:* 0640 root sys
zs:[a-z],cu 0600 uucp uucp
mm:kmem 0640 root bin
```

The first line sets all devices exported by the sd node to 0640 permissions, owned by root, with group sys. In the second line, devices such as a,cu and z,cu exported by the zs driver are set to 0600 permission, owned by uucp, with group uucp. In the third line the kmem device exported by the mm driver is set to 0640 permission, owned by root, with group bin.

Running add_drv from a postinstall Script When running add_drv from within the context of a package's postinstall script, you must consider whether the package is being added to a system image or to a running system. When a package is being installed on a system image, the BASEDIR variable refers to the image's base

directory. In this situation, add_drv should be invoked with -b $BASEDIR. This causes add_drv only to update the image's system files; a reboot of the system or client would be required to make the driver operational.

When a package is being installed on the running system itself, the system files need to be updated, as in the case above. However, the running kernel can be informed of the existence of the new driver without requiring a reboot. To accomplish this, the postinstall script must invoke add_drv without the -b option. Accordingly, postinstall scripts invoking add_drv should be written thusly:

```
if [ "${BASEDIR:=/}" = "/" ]
then
        ADD_DRV="add_drv"
else
        ADD_DRV="add_drv -b ${BASEDIR}"
fi
$ADD_DRV [<options>] <driver>
```

...or, alternatively:

```
if [ "${BASEDIR:=/}" != "/" ]
then
        BASEDIR_OPT="-b $BASEDIR"
fi
        add_drv $BASEDIR_OPT [<options>] <driver>
```

The -b option is described below.

Options -b *basedir*

Installs the driver on the system with a root directory of *basedir* rather than installing on the system executing add_drv. This option is typically used in package post-installation scripts when the package is not being installed on the system executing the pkgadd command. The system using *basedir* as its root directory must reboot to complete the driver installation.

Note – The root file system of any non-global zones must not be referenced with the -b option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-c *class_name*

The driver being added to the system exports the class *class_name*.

-f

Normally if a reconfiguration boot is required to complete the configuration of the driver into the system, add_drv will not add the driver. The force flag forces add_drv to add the driver even if a reconfiguration boot is required. See the -v flag.

-i '*identify_name*'

A white-space separated list of aliases for the driver *device_driver*.

-m *'permission'*

Specify the file system permissions for device nodes created by the system on behalf of *device_driver*.

-n

Do not try to load and attach *device_driver*, just modify the system configuration files for the *device_driver*.

-p *'policy'*

Specify an additional device security policy.

The device security policy constists of several whitespace separated tokens:

{*minorspec* {token=value}+}+

minorspec is a simple wildcard pattern for a minor device. A single * matches all minor devices. Only one * is allowed in the pattern.

Patterns are matched in the following order:

- entries without a wildcard
- entries with wildcards, longest wildcard first

The following tokens are defined: read_priv_set and write_priv_set. read_priv_set defines the privileges that need to be asserted in the effective set of the calling process when opening a device for reading. write_priv_set defines the privileges that need to be asserted in the effective set of the calling process when opening a device for writing. See privileges(5).

A missing minor spec is interpreted as a *.

-P *'privilege'*

Specify additional, comma separated, privileges used by the driver. You can also use specific privileges in the device's policy.

-u

Add the driver to the system, leaving it in an inactive state for later configuration with devfsadm(1M) -u. The -u behavior differs from -n in that -n only updates the system files, requiring a reboot to attach the driver. Drivers added with -u can be attached by running devfsadm -u without rebooting. Driver writers should verify their driver with this behavior. See NOTES for additional considerations. The -u option cannot be used together with -n or -b.

-v

The verbose flag causes add_drv to provide additional information regarding the success or failure of a driver's configuration into the system. See the EXAMPLES section.

Examples **EXAMPLE 1** Adding SUNW Example Driver to the System

The following example adds the SUNW,example driver to a 32–bit system, with an alias name of SUNW,alias. It assumes the driver has already been copied to /usr/kernel/drv.

```
example# add_drv -m '* 0666 bin bin','a 0644 root sys' \
      -p 'a write_priv_set=sys_config  * write_priv_set=none' \
      -i 'SUNW,alias' SUNW,example
```

Every minor node created by the system for the SUNW,example driver will have the permission 0666, and be owned by user bin in the group bin, except for the minor device a, which will be owned by root, group sys, and have a permission of 0644. The specified device policy requires no additional privileges to open all minor nodes, except minor device a, which requires the sys_config privilege when opening the device for writing.

EXAMPLE 2 Adding Driver to the Client /export/root/sun1

The following example adds the driver to the client /export/root/sun1. The driver is installed and loaded when the client machine, sun1, is rebooted. This second example produces the same result as the first, except the changes are on the diskless client, sun1, and the client must be rebooted for the driver to be installed.

```
example# add_drv -m '* 0666 bin bin','a 0644 root sys' \
        -i 'SUNW,alias' -b /export/root/sun1 \
    SUNW,example
```

See the note in the description of the -b option, above, specifying the caveat regarding the use of this option with the Solaris zones feature.

EXAMPLE 3 Adding Driver for a Device Already Managed by an Existing Driver

The following example illustrates the case where a new driver is added for a device that is already managed by an existing driver. Consider a device that is currently managed by the driver dumb_framebuffer. The name and compatible properties for this device are as follows:

```
name="display"
compatible="whizzy_framebuffer", "dumb_framebuffer"
```

If add_drv is used to add the whizzy_framebuffer driver, the following will result.

```
example# add_drv whizzy_framebuffer
Error: Could not install driver (whizzy_framebuffer)
Device managed by another driver.
```

If the -v flag is specified, the following will result.

```
example# add_drv -v whizzy_framebuffer
Error: Could not install driver (whizzy_framebuffer)
Device managed by another driver.
Driver installation failed because the following
entries in /devices would be affected:
```

EXAMPLE 3 Adding Driver for a Device Already Managed by an Existing Driver   *(Continued)*

```
/devices/iommu@f,e0000000/sbus@f,e0001000/display[:*]
(Device currently managed by driver "dumb_framebuffer")
```

The following entries in /dev would be affected:

```
/dev/fbs/dumb_framebuffer0
```

If the -v and -f flags are specified, the driver will be added resulting in the following.

```
example# add_drv -vf whizzy_framebuffer
A reconfiguration boot must be performed to complete the
installation of this driver.
```

The following entries in /devices will be affected:

```
/devices/iommu@f,e0000000/sbus@f,e0001000/display[:*]
(Device currently managed by driver "dumb_framebuffer"
```

The following entries in /dev will be affected:

```
/dev/fbs/dumb_framebuffer0
```

The above example is currently only relevant to devices exporting a generic device name.

EXAMPLE 4 Use of Double Quotes in Specifying Driver Alias

The following example shows the use of double quotes in specifying a driver alias that contains numbers.

```
example# add_drv -i '"pci10c5,25"' smc
```

Exit Status add_drv returns 0 on success and 1 on failure.

Writing Device Drivers

Notes It is possible to add a driver for a device already being managed by a different driver, where the driver being added appears in the device's compatible list before the current driver. In such cases, a reconfiguration boot is required (see boot(1M) and kernel(1M)). After the reconfiguration boot, device links in /dev and references to these files may no longer be valid (see the -v flag). If a reconfiguration boot would be required to complete the driver installation, add_drv will fail unless the -f option is specified. See Example 3 in the EXAMPLES section.

With the introduction of the device policy several drivers have had their minor permissions changed and a device policy instated. The typical network driver should use the following device policy:

```
add_drv -p 'read_priv_set=net_rawaccess\
   write_priv_set=net_rawaccess' -m '* 666 root sys'\
   mynet
```

This document does not constitute an API. /etc/minor_perm, /etc/name_to_major, /etc/driver_classes, and /devices may not exist or may have different contents or interpretations in a future release. The existence of this notice does not imply that any other documentation that lacks this notice constitutes an API.

/etc/minor_perm can only be updated by add_drv(1M), rem_drv(1M) or update_drv(1M).

In the current version of add_drv, the use of double quotes to specify an alias is optional when used from the command line. However, when using add_drv from packaging scripts, you should continue to use double quotes to specify an alias.

Some drivers should not be added and configured on the system directly, but should only be configured as the system boots. The reasons for this restriction include, but are not limited to, a driver dependency on configuration early during boot or a dependency on some kernel component being installed or updated at the same time as the driver is being added. Such drivers should only be added to the system with the -n flag, so the driver is only loaded and configured when the system is rebooted, thus assuring an environment in which the driver can be configured properly.

Bugs Previous versions of add_drv accepted a pathname for *device_driver*. This feature is no longer supported and results in failure.

Name arp – address resolution display and control

Synopsis arp *hostname*

arp -a [-n]

arp -d *hostname*

arp -f *filename*

arp -s *hostname ether_address* [temp] [pub] [trail]
        [permanent]

Description The arp program displays and modifies the Internet-to-MAC address translation tables used by the address resolution protocol (see arp(7P)).

With no flags, the program displays the current ARP entry for *hostname*. The host may be specified by name or by number, using Internet dot notation.

Options that modify the ARP translation tables (-d, -f, and -s) can be used only when the invoked command is granted the sys_net_config privilege. See privileges(5).

Options -a Display all of the current ARP entries. The definition for the flags in the table are:

d Unverified; this is a local IP address that is currently undergoing Duplicate Address Detection. ARP will not respond to requests for this address until Duplicate Address Detection completes.

o Old; this entry is aging away. If IP requests it again, a new ARP query will be generated. This state is used for detecting peer address changes.

y Delayed; periodic address defense and conflict detection was unable to send a packet due to internal network use limits for non-traffic-related messages (100 packets per hour per interface). This occurs only on interfaces with very large numbers of aliases.

A Authority; this machine is authoritative for this IP address. ARP will not accept updates from other machines for this entry.

L Local; this is a local IP address configured on one of the machine's logical interfaces. ARP will defend this address if another node attempts to claim it.

M Mapping; only used for the multicast entry for 224.0.0.0

P Publish; includes IP address for the machine and the addresses that have explicitly been added by the -s option. ARP will respond to ARP requests for this address.

S Static; entry cannot be changed by learned information. This indicates that the permanent flag was used when creating the entry.

U Unresolved; waiting for ARP response.

You can use the -n option with the -a option to disable the automatic numeric IP address-to-name translation. Use arp -an or arp -na to display numeric IP addresses. The arp -a option is equivalent to:

```
# netstat -p -f inet
```

...and -an and -na are equivalent to:

```
# netstat -pn -f inet
```

-d   Delete an entry for the host called *hostname*.

Note that ARP entries for IPMP (IP Network Multipathing) data and test addresses are managed by the kernel and thus cannot be deleted.

-f   Read the file named *filename* and set multiple entries in the ARP tables. Entries in the file should be of the form:

hostname MACaddress [temp] [pub] [trail] [permanent]

See the -s option for argument definitions.

-s   Create an ARP entry for the host called *hostname* with the MAC address *MACaddress*. For example, an Ethernet address is given as six hexadecimal bytes separated by colons. The entry will not be subject to deletion by aging unless the word temp is specified in the command. If the word pub is specified, the entry will be published, which means that this system will respond to ARP requests for *hostname* even though the *hostname* is not its own. The word permanent indicates that the system will not accept MAC address changes for *hostname* from the network.

Solaris does not implement trailer encapsulation, and the word trail is accepted on entries for compatibility only.

arp -s can be used for a limited form of proxy ARP when a host on one of the directly attached networks is not physically present on a subnet. Another machine can then be configured to respond to ARP requests using arp -s. This is useful in certain SLIP configurations.

Non-temporary proxy ARP entries for an IPMP (IP Network Multipathing) group are automatically managed by the kernel. Specifically, if the hardware address in an entry matches the hardware address of an IP interface in an IPMP group, and the IP address is not local to the system, this will be regarded as an IPMP proxy ARP entry. This entry will have its hardware address automatically adjusted in order to keep the IP address reachable so long as the IPMP group has not entirely failed.

ARP entries must be consistent across an IPMP group. Therefore, ARP entries cannot be associated with individual underlying IP interfaces in an IPMP group, and must instead be associated with the corresponding IPMP IP interface.

Note that ARP entries for IPMP data and test addresses are managed by the kernel and thus cannot be changed.

Name   asradm – Auto Service Request registration utility

Synopsis   `asradm list`

`asradm send [-n] [activate|audit|deactivate|fault|heartbeat|test]`

`asradm register -u` *username* `[-p` *password-file*`] [-e` *endpoint_URL*`]`

`asradm set-proxy [-i] | [-h` *host*`[:`*port*`]] [-u` *username*`] [-p` *password-file*`]`

`asradm unregister`

Description   The `asradm` utility is used by a privileged system administrator to register hosts for enrollment in the Oracle Auto Service Request (ASR) for Oracle Sun systems. Using auto-case generation improves system availability and expedites the diagnostic process when specific hardware faults occur.

Once the system has been registered with a valid My Oracle Support (MOS) account the [smf(5)](#) service, asr-notify, will start to send HTTPS/XML telemetry either directly to the configured endpoint or through an optional HTTP proxy.

The `asradm` utility can also list the current registration state as seen from the registered server. This only confirms that messages are being sent to the Oracle ASR service and does not mean the system is actively being monitored. The user must log into their MOS account and activate the service for the system. An email should be sent to the user after registration that will describe the specific details needed to complete enrollment.

ASR messages can be sent manually using the `send` subcommand. The content of ASR messages can also be viewed without actually sending the messages as well. The generation of messages can be done even if the system has not been registered.

The system can also be unregistered from the ASR service, which will remove the system from being monitored and will disable all telemetry sent by the system.

Options   The following options are supported:

-e *endpoint_URL*

   Sets the endpoint URL used for registration and all message telemetry. The default value is `transport.sun.com` sends all telemetry directly to Oracle service. A different URL can be used to support a local instance of an ASR Manager solution. The local ASR Manager can be used to aggregate telemetry from many hosts instances.

-h *host*[:*port*]

   Sets the HTTPS proxy host and optional port number to use for connecting to the internet. If a port is not specified, the default port value of `80` is used.

-i

   Sets the HTTPS connection to be a direct internet connection and thus not use any proxy host. This option will clear any previously set HTTPS proxy information.

-n
> Do a dry run of sending an event, which displays the message data to stdout that would have been sent.

-u *username*
> When used with the register subcommand, this specifies the MOS user name to be associated with registrations of products on this system. When used with the set-proxy subcommand this specifies the HTTPS proxy user name used for message transport.

-p *password-file*
> This should be a single-line file containing a password value. It can be immediately removed after running this command. When used with the register subcommand, this specifies the password associated with the MOS user name. When used with the set-proxy subcommand, this option specifies the password associated with the HTTPS proxy used to connect to the internet. If the -p option is not entered and the -u option was set, the user will be prompted for the password.

Sub-commands The asradm subcommands are described as follows.

register
> Registers the system with MOS using the supplied authentication credentials. The MOS password will be used only for initial registration, to obtain a token used for all future telemetry and will not be stored anywhere on the system.
>
> If the host system is behind a firewall, then the HTTP proxy settings must be set using the set-proxy command before registering the system.
>
> Once registered, an ASR activation message will be sent that will request support for automated support call generation. Subsequently, an email will be sent to the registered user giving the status of the service request.

list
> Shows the current authenticated MOS user name and the network connectivity information needed for HTTPS communication with MOS. If no registration has yet been done (by means of the register command), then the status of Unregistered is displayed.

set-proxy
> Sets up the HTTPS connection information to be used for sending all ASR messages. Either a direct connection can be made or an HTTPS proxy can be defined.

unregister
> Sends an ASR deactivation event and removes all configured registration information. No further telemetry will be sent and the Oracle ASR service will no longer generate any automated support calls.

send
> Manually sends a specified ASR message to the Oracle ASR service or, with the dry run option (-n), display ASR messages.

Examples   EXAMPLE 1   Setup Internet Connection to Use an HTTPS Proxy

The following command will route all messages through an HTTPS proxy host
webproxy.example.com on port 8080.

```
# asradm set-proxy -h webproxy.example.com:8080
```

EXAMPLE 2   Registering an MOS ID

The following command is used to interactively authenticate and register this system with the
given MOS ID for use with ASR. Following this, you will be prompted for your support user
name and password.

```
# asradm register
```

EXAMPLE 3   Authenticating Non-interactively

This is similar to set–proxy example, above. The difference is that the MOS user name and
password are specified by means of the command line.

```
# asradm register -u joe.admin@example.com -p mypassword
```

EXAMPLE 4   Viewing Contents of Audit Message

The command below will display an audit message without sending the event. This will work
even if the ASR service has not been registered.

```
# asradm send -n audit
```

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/fault-management/asr-notify
Interface Stability	Uncommitted

See Also   svcs(1), asr-notify(1M), svcadm(1M), svccfg(1M), syslogd(1M), attributes(5), smf(5)

Name asr-notify – auto service request notification daemon for Fault Management events

Synopsis `/usr/lib/fm/notify/asr-notify [- ]`

Description `asr-notify` is a daemon that subscribes to Fault Management life cycle events and produces HTTPS/XML notifications based on a set of notification preferences that are stored in the SMF service configuration repository.

The messages will be sent to the Oracle Auto Service Request (ASR) service offering once the service has been registered using the asradm(1M) command or by setting SMF auto registration properties. If the auto registration properties are set, the service will attempt to register on either startup or refresh. If registration fails, the service will go into maintenance mode. If registration is successful, the SMF auto registration properties will be deleted.

`asr-notify` is managed by the service management facility, smf(5), under the service FMRI:

`svc:/system/fm/asr-notify:default`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

ASR notification preferences are set using svccfg(1M).

Properties The following service properties can be set:

config/*rootdir*
This is an `astring` property that defaults to `/`. When set, the specified root directory will be used for all pathnames evaluated by `asr-notify`.

config/*http_timeout*
This is an integer property that sets the number of seconds to wait for HTTP connections before generating an error.

config/*endpoint*
This is an `astring` property that sets the endpoint URL used for registration and all message telemetry. The endpoint URL can be set to a local ASR Manager that will aggregate telemetry from many hosts instances. If not set, then all telemetry will be sent directly to the Oracle Auto Service Request service.

autoreg/*user*
This is an `astring` property that is used to set the My Oracle Support user name used for auto registration.

autoreg/*password*
This is an `astring` property that is used to set the My Oracle Support password used for auto registration.

autoreg/*proxy-host*
This is an `astring` property that is used to set the HTTP proxy *hostname*:*port* and needs to be set only if an HTTP proxy is used to connect to the internet.

autoreg/*proxy-user*
 This is an `astring` property that is used to set the HTTP proxy user name and needs to be
 set only if the HTTP proxy requires credentials.

autoreg/*proxy-password*
 This is an `astring` property that is used to set the HTTP proxy password and needs to be
 set only if the HTTP proxy requires credentials.

Messages The service will send the following types of messages:

- fault messages when an FMA fault is created

- daily heartbeat messages to indicate that the system is still active

- running and weekly audit messages to provide a full inventory of operational components

The contents of each message are an XML document that adheres to the ASR message XML
schema. Each message starts with a common message header followed by event specific
content.

ASR event header information:

```
XML Element     Description
------------    -----------
site-id         the serial number of the host sending
                the event
host-id         the hostname(1) of the system that the
                message is about
message-uuid    a unique id generated for each message
message-time    local time on the system that generated
                the message
system-id       the serial number of the system that the
                message is about
asset-id        the registered service tag for the system
product-id      the unique product identifier for the system
product-name    the name of the product for the system
event           element containing fault specific event
                information
```

The fault-specific content in the event will be contained within the
primary-event-information XML element.

```
XML Element     Description
-----------     -----------
message-id      the knowledge article message ID
event-uuid      the FMA event UUID
event-time      the time that the FMA event was generated
severity        the severity of the FMA event
component       element containing list of suspects
summary         a short summary of the event
```

```
description     event description
payload         the raw FMA event contents
```

For each suspect FRU associated with a fault event, a hardware-component element will be included within the component.

```
XML Element             Description
-----------             -----------
name                    the component path name of the FRU
serial                  the FRU serial number
part                    the FRU part number
revision                the FRU revision level
additional-information  a list of additional properties
                        containing values such as FRU
                        manufacturer and FRU model
```

Some faults might be associated with a software issue instead of a hardware issue. In this case, the fault event will contain a software-module element within the component list.

```
XML Element             Description
-----------             -----------
name                    the name or FMRI of the software
                        module in error
description             a description of the software
                        module error
```

Heartbeat events do not contain any additional data and audit events contain a list of all hardware-component, software-package, and software-module elements available to the system.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/fault-management/asr-notify

Name atohexlabel – convert a human readable label to its internal text equivalent

Synopsis /usr/sbin/atohexlabel [*human-readable-sensitivity-label*]

/usr/sbin/atohexlabel -c [*human-readable-clearance*]

Description atohexlabel converts a human readable label into an internal text representation that is safe for storing in a public object. If no option is supplied, the label is assumed to be a sensitivity label.

Internal conversions can later be parsed to their same value. This internal form is often hexadecimal. The converted label is written to the standard output file. If no human readable label is specified, the label is read from the standard input file. The expected use of this command is emergency repair of labels that are stored in internal databases.

Options -c   Identifies the human readable label as a clearance.

Exit Status The following exit values are returned:

0   On success.

1   On failure, and writes diagnostics to the standard error file.

Files /etc/security/tsol/label_encodings
  The label encodings file contains the classification names, words, constraints, and values for the defined labels of this system.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/trusted
Interface Stability	See below.

The command output is Committed for systems with the same label_encodings file. The command invocation is Committed for systems that implement the DIA MAC policy.

See Also hextoalabel(1M), label_to_str(3TSOL), str_to_label(3TSOL), label_encodings(4), attributes(5)

Oracle Solaris Trusted Extensions Configuration and Administration

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

This file is part of the Defense Intelligence Agency (DIA) Mandatory Access Control (MAC) policy. This file might not be applicable to other MAC policies that might be developed for future releases of Solaris Trusted Extensions software.

Name audit – control the behavior of the audit daemon

Synopsis audit -n | -s | -t | -v

Description The audit command is the system administrator's interface to start, stop, and refresh the audit service auditd(1M). Refreshing the audit service rereads the system and plugin configuration.

Options -n Notify the audit service audit_binfile plugin to close the current audit file and open a new audit file in the current audit directory.

-s Start (enable) the audit service if it is not running, or refresh the audit service, if it is currently running.

-t Terminate (disable) the audit service. The audit service will close out the active plugins, stop auditing and exit. Use -s to restart auditing.

-v Verify that at least one plugin is active. Verify the directory parameters of audit_binfile(5).

Diagnostics The audit command will exit with 0 upon success and a positive integer upon failure.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also auditconfig(1M), auditd(1M), attributes(5), audit_binfile(5)

See the section on Solaris Auditing in *Oracle Solaris Administration: Security Services*.

Notes The audit command does not modify a process's preselection mask. Its functions are limited to performing control actions of the auditing subsystem. See auditconfig(1M) for configuration.

The -s option validates the audit plugin configuration. If it is not valid an error message is displayed and the audit service is not started or refreshed. The -v option may be used to validate the audit plugin configuration before using the -s option to start or refresh the audit service.

The -s option also checks state of the audit service. In case the audit service is found in the maintenance state (thus not able to be enabled or refreshed) the audit command returns with an appropriate message and exit code.

All options are valid in the global zone. Unless per-zone is enabled, only the -v option is valid in a local zone. See auditconfig(1M) for per-zone audit configuration.

Name auditconfig – configure auditing

Synopsis `auditconfig` *subcommand*...

Description `auditconfig` provides a command line interface to get and set kernel audit parameters.

Except for getting or setting the persistent audit service values, this functionality is available only if the Solaris Auditing feature has been enabled.

A zero (`0`) queue value indicates that the system default is in effect.

The setting of the `perzone` policy determines the scope of the audit setting controlled by `auditconfig`. If `perzone` is set, then the values reflect the local zone except as noted. Otherwise, the settings are for the entire system. Any restriction based on the `perzone` setting is noted for each option to which it applies.

A non-global zone administrator can set all audit policy options except `perzone` and `ahlt`. `perzone` and `ahlt` apply only to the global zone; setting these policies requires the privileges of a global zone administrator. `perzone` and `ahlt` are described under the `-setpolicy` option, below.

This command is available to administrators who have been granted the Audit Control Rights Profile.

Options The following option is supported:

`-t`

Display or set the values on the running system in addition to the persistent values of the audit service.

This option is available only for the subcommands that list it below.

Sub-commands `-aconf`

Set the configured non-attributable audit mask. For example:

```
# auditconfig -aconf
Configured non-attributable event mask.
```

`-audit` *event sorf retval string*

This command constructs an audit record for audit event *event* using the process's audit characteristics containing a text token *string*. The return token is constructed from the *sorf* (success/failure flag) and the *retval* (return value). The event is type char*, the *sorf* is 0/1 for success/failure, *retval* is an errno value, *string* is type *char. This command is useful for constructing an audit record with a shell script. An example of this option:

```
# auditconfig -audit AUE_ftpd 0 0 "test string"
#

audit record from audit trail:
    header,76,2,ftp access,,Fri Dec 08 08:44:02 2000, + 669 msec
```

```
        subject,abc,root,other,root,other,104449,102336,235 197121 elbow
        text,test string
        return,success,0
```

-chkaconf

   Checks the configuration of the non-attributable events set in the kernel against the entries
   configured in the audit service (-setnaflags). If the active class mask of a kernel audit
   event does not match the configured class mask, a mismatch is reported.

-chkconf

   Check the configuration of kernel audit event to class mappings. If the runtime class mask
   of a kernel audit event does not match the configured class mask, a mismatch is reported.

-conf

   Configure kernel audit event to class mappings. Runtime class mappings are changed to
   match those in the audit event to class database file.

-getasid

   Prints the audit session ID of the current process. For example:

   # **auditconfig -getasid**
   audit session id = 102336

-getaudit

   Returns the audit characteristics of the current process.

   # **auditconfig -getaudit**
   audit id = abc(666)
   process preselection mask = lo(0x1000,0x1000)
   terminal id (maj,min,host) = 235,197121,elbow(172.146.89.77)
   audit session id = 102336

-getauid

   Prints the audit ID of the current process. For example:

   # **auditconfig -getauid**
   audit id = abc(666)

-getcar

   Prints current active root location (anchored from root [or local zone root] at system boot).
   For example:

   # **auditconfig -getcar**
   current active root = /

-getclass *event*

   Display the preselection mask associated with the specified kernel audit event. *event* is the
   kernel event number or event name.

-getcond

   Display the kernel audit condition. The condition displayed is the literal string auditing
   meaning auditing is enabled and turned on (the kernel audit module is constructing and

queuing audit records, audit daemon is running); `noaudit`, meaning auditing is enabled but turned off (the kernel audit module is not constructing and queuing audit records, audit daemon is not running); `disabled`, meaning that the audit module has not been enabled (the module has been excluded in `system(4)`). See `auditd(1M)` for further information.

-getestate *event*
    For the specified event (string or event number), print out classes *event* has been assigned. For example:

```
# auditconfig -getestate 20
audit class mask for event AUE_REBOOT(20) = 0x800
# auditconfig -getestate AUE_RENAME
audit class mask for event AUE_RENAME(42) = 0x30
```

-getflags
    Display the user default audit preselection flags.

-getkaudit
    Get audit characteristics of the current zone. For example:

```
# auditconfig -getkaudit
audit id = unknown(-2)
process preselection mask = lo,na(0x1400,0x1400)
terminal id (maj,min,host) = 0,0,(0.0.0.0)
audit session id = 0
```

If the audit policy `perzone` is not set, the terminal id is that of the global zone. Otherwise, it is the terminal id of the local zone.

-getkmask
    Get non-attributable pre-selection mask for the current zone. For example:

```
# auditconfig -getkmask
audit flags for non-attributable events = lo,na(0x1400,0x1400)
```

If the audit policy `perzone` is not set, the kernel mask is that of the global zone. Otherwise, it is that of the local zone.

-getnaflags
    Display the non-attributable audit flags.

-getpinfo *pid*
    Display the audit ID, preselection mask, terminal ID, and audit session ID for the specified process.

-getplugin [*name*]
    Display information about the plugin name. If *name* is not specified, display all plugins.

[-t] -getpolicy
  Display the kernel audit policy. The `ahlt` and `perzone` policies reflect the settings from the global zone. If `perzone` is set, all other policies reflect the local zone's settings. If `perzone` is not set, the policies are machine-wide.

-getcwd
  Prints current working directory (anchored from zone root at system boot). For example:

  ```
  # cd /usr/tmp
  # auditconfig -getcwd
  current working directory = /var/tmp
  ```

[-t] -getqbufsz
  Get audit queue write buffer size. For example:

  ```
  # auditconfig -getqbufsz
  no configured audit queue size
  audit queue buffer size (bytes) = 1024
  ```

[-t] -getqctrl
  Get audit queue write buffer size, audit queue `hiwater` mark, audit queue `lowater` mark, audit queue `prod` interval (ticks).

  ```
  # auditconfig -getqctrl
  no configured audit queue lowater mark
  no configured audit queue hiwater mark
  no configured audit queue size
  no configured audit queue delay
  audit queue hiwater mark (records) = 100
  audit queue lowater mark (records) = 10
  audit queue buffer size (bytes) = 1024
  audit queue delay (ticks) = 20

  # auditconfig -setqbufsz 8192
  # auditconfig -t -setqbufsz 12288
  # auditconfig -setqdelay 20
  # auditconfig -t -setqdelay 25
  # auditconfig -getqctrl
  no configured audit queue lowater mark
  no configured audit queue hiwater mark
  configured audit queue buffer size (bytes) = 8192
  configured audit queue delay (ticks) = 20
  active audit queue hiwater mark (records) =     100
  active audit queue lowater mark (records) =     10
  active audit queue buffer size (bytes) = 12288
  active audit queue delay (ticks) = 25
  ```

[-t] -getqdelay
  Get interval at which audit queue is prodded to start output. For example:

```
                       # auditconfig -getqdelay
                       no configured audit queue delay
                       audit queue delay (ticks) = 20
```

[-t] -getqhiwater

Get high water point in undelivered audit records when audit generation will block. For example:

```
                       # ./auditconfig -getqhiwater
                       no configured audit queue hiwater mark
                       audit queue hiwater mark (records) = 100
```

[-t] -getqlowater

Get low water point in undelivered audit records where blocked processes will resume. For example:

```
                       # auditconfig -getqlowater
                       no configured audit queue lowater mark
                       audit queue lowater mark (records) = 10
```

-getstat

Print current audit statistics information. For example:

```
                       # auditconfig -getstat
                       gen nona kern  aud  ctl  enq wrtn wblk rblk drop  tot  mem
                       910    1  725  184    0  910  910    0  231    0   88   48
```

See auditstat(1M) for a description of the headings in -getstat output.

-gettid

Print audit terminal ID for current process. For example:

```
                       # auditconfig -gettid
                       terminal id (maj,min,host) = 235,197121,elbow(172.146.89.77)
```

-lsevent

Display the currently configured (runtime) kernel and user level audit event information.

-lspolicy

Display the kernel audit policies with a description of each policy.

-setasid *session-ID* [*cmd*]

Execute shell or *cmd* with specified *session-ID*. For example:

```
                       # ./auditconfig -setasid 2000 /bin/ksh
                       #
                       # ./auditconfig -getpinfo 104485
                       audit id = abc(666)
                       process preselection mask = lo(0x1000,0x1000)
                       terminal id (maj,min,host) = 235,197121,elbow(172.146.89.77)
                       audit session id = 2000
```

-setaudit *audit-ID preselect_flags term-ID session-ID* [*cmd*]
    Execute shell or *cmd* with the specified audit characteristics.

-setauid *audit-ID* [*cmd*]
    Execute shell or *cmd* with the specified *audit–ID*.

-setclass *event audit_flag*[,*audit_flag*...]
    Map the kernel event *event* to the classes specified by audit_flag list. *event* is an event
    number or name. An *audit_flag* is a character string representing an audit class. See
    audit_flags(5) for further information. If perzone is not set, this option is valid only in
    the global zone.

-setflags *audit_flags*
    Set the default user audit preselection flags; see audit_flags(5). The default preselection
    flags are combined with the user's specific audit flags to form the user's audit preselection
    mask.

-setkaudit *IP-address_type IP_address*
    Set IP address of machine to specified values. *IP-address_type* is ipv6 or ipv4.

    If perzone is not set, this option is valid only in the global zone.

-setkmask *audit_flags*
    Set non-attributable preselection flags of machine.

    If perzone is not set, this option is valid only in the global zone.

-setnaflags *audit_flags*
    Set the non-attributable audit flags; see audit_flags(5). Non-attributable audit flags
    define which classes of events are to be audited when the action cannot be attributed to an
    authenticated user. Failed login is an example of an event that is non-attributable.

-setpmask *pid flags*
    Set the preselection mask of the specified process. *flags* is the ASCII representation of the
    flags similar to that in audit_flags(5).

    If perzone is not set, this option is valid only in the global zone.

-setplugin *name* active|inactive [*attributes* [*qsize*]]
    Configure the plugin name to be active or inactive. Optionally configure the attributes
    and number of unprocessed audit records to queue for the plugin. See the relevant audit
    plugin man pages and auditd(1M).

[-t] -setpolicy [+|-]*policy_flag*[,*policy_flag*...]
    Set the kernel audit policy. A policy *policy_flag* is literal strings that denotes an audit policy.
    A prefix of + adds the policies specified to the current audit policies. A prefix of - removes
    the policies specified from the current audit policies. No policies can be set from a local
    zone unless the perzone policy is first set from the global zone. The following are the valid
    policy flag strings (auditconfig -lspolicy also lists the current valid audit policy flag
    strings):

all   Include all policies that apply to the current zone.

ahlt   Panic is called and the system dumps core if an asynchronous audit event occurs that cannot be delivered because the audit queue has reached the high-water mark or because there are insufficient resources to construct an audit record. By default, records are dropped and a count is kept of the number of dropped records.

arge   Include the execv(2) system call environment arguments to the audit record. This information is not included by default.

argv   Include the execv(2) system call parameter arguments to the audit record. This information is not included by default.

cnt   Do not suspend processes when audit resources are exhausted. Instead, drop audit records and keep a count of the number of records dropped. By default, process are suspended until audit resources become available.

group   Include the supplementary group token in audit records. By default, the group token is not included.

none   Include no policies. If used in other than the global zone, the ahlt and perzone policies are not changed.

path   Add secondary path tokens to audit record. These are typically the pathnames of dynamically linked shared libraries or command interpreters for shell scripts. By default, they are not included.

perzone   Maintain separate configuration, queues, and logs for each zone and execute a separate version of auditd(1M) for each zone.

public   Audit public files. By default, read-type operations are not audited for certain files which meet *public* characteristics: owned by root, readable by all, and not writable by all.

trail   Include the trailer token in every audit record. By default, the trailer token is not included.

seq   Include the sequence token as part of every audit record. By default, the sequence token is not included. The sequence token attaches a sequence number to every audit record.

windata_down   Include in an audit record any downgraded data moved between windows. This policy is available only if the system is configured with Trusted Extensions. By default, this information is not included.

windata_up   Include in an audit record any upgraded data moved between windows. This policy is available only if the system is configured with Trusted Extensions. By default, this information is not included.

zonename Include the zonename token as part of every audit record. By default, the zonename token is not included. The zonename token gives the name of the zone from which the audit record was generated.

[-t] -setqbufsz *buffer_size*
Set the audit queue write buffer size (bytes). Zero (0), indicates reset to no configured value.

[-t] -setqctrl *hiwater lowater bufsz interval*
Set the audit queue write buffer size (bytes), hiwater audit record count, lowater audit record count, and wakeup interval (ticks). Valid within a local zone only if perzone is set. Zero (0), indicates reset to no configured value.

[-t] -setqdelay *interval*
Set the audit queue wakeup interval (ticks). This determines the interval at which the kernel pokes the audit queue, to write audit records to the audit trail. Valid within a local zone only if perzone is set. Zero (0), indicates reset to no configured value.

[-t] -setqhiwater *hiwater*
Set the number of undelivered audit records in the audit queue at which audit record generation blocks. Valid within a local zone only if perzone is set. Zero (0), indicates reset to no configured value.

[-t] -setqlowater *lowater*
Set the number of undelivered audit records in the audit queue at which blocked auditing processes unblock. Valid within a local zone only if perzone is set. Zero (0), indicates reset to no configured value.

-setsmask *asid flags*
Set the preselection mask of all processes with the specified audit session ID. Valid within a local zone only if perzone is set.

-setstat
Reset audit statistics counters. Valid within a local zone only if perzone is set.

-setumask *username|auid flags*
Set the preselection mask of all processes with the specified username or audit ID. Valid within a local zone only if perzone is set.

Examples

EXAMPLE 1 Using auditconfig

The following is an example of an auditconfig command:

```
#
# map kernel audit event number 10 to the "fr" audit class
#
% auditconfig -setclass 10 fr

#
# turn on inclusion of exec arguments in exec audit records
#
```

EXAMPLE 1   Using auditconfig   *(Continued)*

```
% auditconfig -setpolicy +argv
```

EXAMPLE 2   Setting Only the Number of Unprocessed Audit Records

The following sequence of commands sets only the number of unprocessed audit records to queue for the audit_binfile plugin:

```
#
# see if audit_binfile is active
#
% auditconfig -getplugin audit_binfile

#
# set to queue 20 unprocessed audit records
#
% auditconfig -setplugin active "" 20
```

EXAMPLE 3   Resetting Queue Control Parameters

The following commands reset active and configured queue control parameters:

```
#
# reset configured audit queue control parameters
#
% auditconfig -setqctrl 0 0 0 0

#
# reset active audit queue control parameters
#
% auditconfig -t -setqctrl 0 0 0 0
```

Exit Status 0   Successful completion.

1   An error occurred.

Files /etc/security/audit_event   Stores event definitions used in the audit system.

/etc/security/audit_class   Stores class definitions used in the audit system.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also   audit(1M), auditd(1M), auditstat(1M), praudit(1M), execv(2), audit_class(4), audit_event(4), system(4), attributes(5), audit_binfile(5), audit_flags(5), audit_remote(5), audit_syslog(5)

See the section on Solaris Auditing in *Oracle Solaris Administration: Security Services*.

Notes   If plugin output is selected using the -setplugin option, the behavior of the system with respect to the -setpolicy +cnt and the -setqhiwater options is modified slightly. If -setpolicy +cnt is set, data will continue to be sent to the selected plugin, even though output of the audit_binary plugin is stopped, pending the freeing of disk space. If -setpolicy –cnt is used, the blocking behavior is as described under SUBCOMMANDS, above. The queue high water mark value is used within auditd as the upper bound for its queue limits unless overridden by means of the qsize attribute, as described in the explanation of the -setplugin option, above.

The auditconfig options that modify or display process-based information are not affected by the perzone policy. Those that modify system audit data such as the terminal id and audit queue parameters are valid only in the global zone, unless the perzone policy is set. The display of a system audit reflects the local zone if perzone is set. Otherwise, it reflects the settings of the global zone.

The change to plugins (-setplugin) settings do not take effect (such as becoming active or inactive, or changing the active attribute or queue size values) until the audit service is refreshed. Use audit(1M) to refresh the audit service.

Name auditd – audit daemon

Synopsis `/usr/sbin/auditd`

Description The audit daemon, `auditd`, controls the generation and location of audit trail files and the generation of `syslog` messages based on its configuration (see `auditconfig(1M)`). If auditing is enabled, `auditd` reads its configuration to do the following:

- Configure audit policy.

- Configure the audit queue control parameters.

- Configure the event-to-class mappings.

- Set the default audit masks.

- Load one or more plugins.

  Solaris provides three plugins. `audit_binfile(5)` writes binary audit data to a file. `audit_remote(5)` sends binary audit data to an authenticated server with privacy and integrity protection. `audit_syslog(5)` sends text summaries of audit records to the `syslog` daemon.

- Read audit data from the kernel and pass that data to each of the active plugins.

- Execute the `audit_warn(1M)` script to warn of various conditions.

`audit(1M)` is used to control `auditd`. It can cause `auditd` to:

- Close the current audit file and open a new one.
- Start and refresh the service based on the current properties.
- Close the audit trail and terminate auditing.

`auditconfig(1M)` is used to configure `auditd`. It can configure the active and permanent:

- audit policy
- audit queue control parameters
- default audit masks
- which plugins are to be loaded
- plugin attributes

Audit Record Queue The maximum number of records to queue for audit data sent to the plugin is specified by the `qsize` parameter specified for the plugin. If omitted, the current `hiwater` mark is used. See the `-getqctrl` option in `auditconfig(1M)`. When this maximum is reached, `auditd` will either block processes or discard data, depending on the `cnt` audit policy as described in `auditconfig(1M)`.

Auditing Conditions The audit daemon and audit plugins invoke the program `audit_warn(1M)` under certain conditions. See `audit_warn(1M)` for more information.

Files ▪ etc/security/audit/audit_class
▪ etc/security/audit/audit_event

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also audit(1M), audit_warn(1M), auditconfig(1M), praudit(1M), audit_class(4), audit_class(4), audit_event(4), attributes(5), audit_binfile(5), audit_flags(5), audit_remote(5), audit_syslog(5), smf(5)

See the section on Solaris Auditing in *Oracle Solaris Administration: Security Services*.

Notes auditd is loaded in the global zone at boot time if auditing is enabled.

If the audit policy perzone is set, auditd runs in each zone, starting automatically when the local zone boots. If a zone is running when the perzone policy is set, auditing must be started manually in local zones. It is not necessary to reboot the system or the local zone to start auditing in a local zone. auditd can be started with audit -s and will start automatically with future boots of the zone.

When auditd runs in a local zone, the configuration is taken from the local zone's smf(5) repository and the /etc/security directory's files: audit_class, user_attr, and audit_event.

Configuration changes do not affect audit sessions that are currently running, as the changes do not modify a process's preselection mask. To change the preselection mask on a running process, use the –setpmask option of the auditconfig command (see auditconfig(1M)). If the user logs out and logs back in, the new configuration changes will be reflected in the next audit session.

The audit service FMRI is svc:/system/auditd:default.

Name auditrecord – display Solaris audit record formats

Synopsis `/usr/sbin/auditrecord [-d] [ [-a] | [-e string] | [-c class] |`
`[-i id] | [-p programname] | [-s systemcall] | [-h]]`

Description The auditrecord utility displays the event ID, audit class and selection mask, and record format for audit record event types defined in audit_event(4). You can use auditrecord to generate a list of all audit record formats, or to select audit record formats based on event class, event name, generating program name, system call name, or event ID.

There are two output formats. The default format is intended for display in a terminal window; the optional HTML format is intended for viewing with a web browser.

Tokens contained in square brackets ([ ]) are optional and might not be present in every record.

Options The following options are supported:

-a
    List all audit records.

-c *class*
    List all audit records selected by *class*. *class* is one of the two-character class codes from the file /etc/security/audit_class.

-d
    Debug mode. Display number of audit records that are defined in audit_event, the number of classes defined in audit_class, any mismatches between the two files, and report which defined events do not have format information available to auditrecord.

-e *string*
    List all audit records for which the event ID label contains the string *string*. The match is case insensitive.

-h
    Generate the output in HTML format.

-i *id*
    List the audit records having the numeric event ID *id*.

-p *programname*
    List all audit records generated by the program *programname*, for example, audit records generated by a user-space program.

-s *systemcall*
    List all audit records generated by the system call *systemcall*, for example, audit records generated by a system call.

The -p and -s options are different names for the same thing and are mutually exclusive. The -a option is ignored if any of -c, -e, -i, -p, or -s are given. Combinations of -c, -e, -i, and either -p or -s are ANDed together.

Examples **EXAMPLE 1** Displaying an Audit Record with a Specified Event ID

The following example shows how to display the contents of a specified audit record.

```
% auditrecord -i 6152
  terminal login
  program     /usr/sbin/login      see login(1)
              /usr/dt/bin/dtlogin  See dtlogin
  event ID    6152                 AUE_login
  class       lo                   (0x00001000)
      header
      subject
      [text]                       error message
      return
```

EXAMPLE 2 Displaying an Audit Record with an Event ID Label that Contains a Specified String

The following example shows how to display the contents of a audit record with an event ID label that contains the string login.

```
# auditrecord -e login
terminal login
  program     /usr/sbin/login      see login(1)
              /usr/dt/bin/dtlogin  See dtlogin
  event ID    6152                 AUE_login
  class       lo                   (0x00001000)
      header
      subject
      [text]                       error message
      return

rlogin
  program     /usr/sbin/login      see login(1) - rlogin

Error

Files /etc/security/audit_class
Provides the list of valid classes and the associated audit mask.

/etc/security/audit_event
Provides the numeric event ID, the literal event name, and the name of the associated system call or program.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
CSI	Enabled
Interface Stability	Uncommitted

See Also auditconfig(1M), praudit(1M), audit.log(4), audit_class(4), audit_event(4), attributes(5)

See the section on Solaris Auditing in *Oracle Solaris Administration: Security Services*.

Diagnostics If unable to read either of its input files or to write its output file, auditrecord shows the name of the file on which it failed and exits with a non-zero return.

If no options are provided, if an invalid option is provided, or if both -s and -p are provided, an error message is displayed and auditrecord displays a usage message then exits with a non-zero return.

Notes This command was formerly known as bsmrecord.

If /etc/security/audit_event has been modified to add user-defined audit events, auditrecord displays the record format as undefined.

The audit records displayed by auditrecord are the core of the record that can be produced. Various audit policies and optional tokens, such as those shown below, might also be present.

The following is a list of praudit(1M) token names with their descriptions.

group
Present if the group audit policy is set.

sensitivity label
Present when Trusted Extensions is enabled and represents the label of the subject or object with which it is associated. The mandatory_label token is noted in the basic audit record where a label is explicitly part of the record.

sequence
Present when the seq audit policy is set.

trailer
Present when the trail audit policy is set.

zone

The name of the zone generating the record when the `zonename` audit policy is set. The zonename token is noted in the basic audit record where a zone name is explicitly part of the record.

Name auditreduce – merge and select audit records from audit trail files

Synopsis auditreduce [*options*] [*audit-trail-file*]...

Description auditreduce allows you to select or merge records from audit trail files. Audit files can be from one or more machines.

The merge function merges together audit records from one or more input audit trail files into a single output file. The records in an audit trail file are assumed to be sorted in chronological order (oldest first) and this order is maintained by auditreduce in the output file.

Unless instructed otherwise, auditreduce will merge the entire audit trail, which consists of all the audit trail files in the directory structure *audit_root_dir*/* (see audit.log(4) for details of the structure of the audit root). Unless specified with the -R or -S option, *audit_root_dir* defaults to /var/audit. By using the file selection options it is possible to select some subset of these files, or files from another directory, or files named explicitly on the command line.

The select function allows audit records to be selected on the basis of numerous criteria relating to the record's content (see audit.log(4) for details of record content). A record must meet all of the *record-selection-option* criteria to be selected.

Audit Trail Filename Format Any audit trail file not named on the command line must conform to the audit trail filename format. Files produced by the audit system already have this format. Output file names produced by auditreduce are in this format. It is:

start-time. *end-time*. *suffix*

where *start-time* is the 14-character timestamp of when the file was opened, *end-time* is the 14-character timestamp of when the file was closed, and *suffix* is the name of the machine which generated the audit trail file, or some other meaningful suffix (for example, all, if the file contains a combined group of records from many machines). The *end-time* can be the literal string not_terminated, to indicate that the file is still being written to by the audit system. Timestamps are of the form *yyyymmddhhmmss* (year, month, day, hour, minute, second). The timestamps are in Coordinated Universal Time (UTC).

Options

File Selection Options The file selection options indicate which files are to be processed and certain types of special treatment.

-A

All of the records from the input files will be selected regardless of their timestamp. This option effectively disables the -a, -b, and -d options. This is useful in preventing the loss of records if the -D option is used to delete the input files after they are processed. Note, however, that if a record is *not* selected due to another option, then -A will not override that.

-C

Only process complete files. Files whose filename *end-time* timestamp is not_terminated are not processed (such a file is currently being written to by the audit system). This is useful in preventing the loss of records if -D is used to delete the input files after they are processed. It does not apply to files specified on the command line.

-D *suffix*

Delete input files after they are read if the entire run is successful. If auditreduce detects an error while reading a file, then that file is not deleted. If -D is specified, -A, -C and -O are also implied. *suffix* is given to the -O option. This helps prevent the loss of audit records by ensuring that all of the records are written, only complete files are processed, and the records are written to a file before being deleted. Note that if both -D and -O are specified in the command line, the order of specification is significant. The *suffix* associated with the latter specification is in effect.

-M *machine*

Allows selection of records from files with *machine* as the filename suffix. If -M is not specified, all files are processed regardless of suffix. -M can also be used to allow selection of records from files that contain combined records from many machines and have a common suffix (such as all).

-N

Select objects in *new mode*. This flag is off by default, thus retaining backward compatibility. In the existing, *old mode*, specifying the -e, -f, -g, -r, or -u flags would select not only actions taken with those IDs, but also certain objects owned by those IDs. When running in *new mode*, only actions are selected. In order to select objects, the -o option must be used.

-O *suffix*

Direct output stream to a file in the current audit_root_dir with the indicated suffix. *suffix* can alternatively contain a full pathname, in which case the last component is taken as the suffix, ahead of which the timestamps will be placed, ahead of which the remainder of the pathname will be placed. If the -O option is not specified, the output is sent to the standard output. When auditreduce places timestamps in the filename, it uses the times of the first and last records in the merge as the *start-time* and *end-time*.

-Q

Quiet. Suppress notification about errors with input files.

-R *pathname*

Specify the pathname of an alternate audit root directory *audit_root_dir* to be *pathname*. Therefore, rather than using /var/audit by default, *pathname*/* will be examined instead.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-S *specific_directory*

This option causes auditreduce to read audit trail files from a specific location (*specific_directory*). *specific_directory* is normally interpreted as the name of a subdirectory of the audit root, therefore auditreduce will look in *audit_root_dir*/*specific_directory* for the audit trail files. But if *specific_directory* contains any backslash characters (/), it is the name of a directory not necessarily contained in the audit root. In this case, *specific_directory* will be consulted. This option allows archived files to be manipulated easily, without requiring that they be physically located in a directory structure like that of /var/audit.

-V

Verbose. Display the name of each file as it is opened, and how many records total were written to the output stream.

Record Selection Options

The record selection options listed below are used to indicate which records are written to the output file produced by auditreduce.

Multiple arguments of the same type are not permitted.

-a *date-time*

Select records that occurred at or after *date-time*. The *date-time* argument is described under Option Arguments, below. *date-time* is in local time. The -a and -b options can be used together to form a range.

-b *date-time*

Select records that occurred before *date-time*.

-c *audit-classes*

Select records by audit class. Records with events that are mapped to the audit classes specified by *audit-classes* are selected. Audit class names are defined in audit_class(4). The *audit-classes* can be a comma separated list of audit *flags* like those described in audit_flags(5). Using the audit *flags,* one can select records based upon success and failure criteria.

-d *date-time*

Select records that occurred on a specific day (a 24-hour period beginning at 00:00:00 of the day specified and ending at 23:59:59). The day specified is in local time. The time portion of the argument, if supplied, is ignored. Any records with timestamps during that day are selected. If any hours, minutes, or seconds are given in *time,* they are ignored. -d can not be used with -a or -b.

-e *effective-user*

Select records with the specified *effective-user*.

-f *effective-group*

Select records with the specified *effective-group*.

-g *real-group*

Select records with the specified *real-group*.

-j *subject-ID*

    Select records with the specified *subject-ID* where *subject-ID* is a process ID.

-l *label*

    Select records with the specified label (or label range), as explained under "Option Arguments," below. This option is available only if the system is configured with Trusted Extensions.

-m *event*

    Select records with the indicated *event*. The *event* is the literal string or the *event* number.

-o *object_type=objectID_value*

    Select records by object type. A match occurs when the record contains the information describing the specified *object_type* and the object ID equals the value specified by *objectID_value*. The allowable object types and values are as follows:

    file=*pathname*

        Select records containing file system objects with the specified pathname, where pathname is a comma separated list of regular expressions. If a regular expression is preceded by a tilde (~), files matching the expression are excluded from the output. For example, the option file=~/usr/openwin,/usr,/etc would select all files in /usr or /etc except those in /usr/openwin. The order of the regular expressions is important because auditreduce processes them from left to right, and stops when a file is known to be either selected or excluded. Thus the option file= /usr,/etc, ~/usr/openwin would select all files in /usr and all files in /etc. Files in /usr/openwin are not excluded because the regular expression /usr is matched first. Care should be given in surrounding the *pathname* with quotes so as to prevent the shell from expanding any tildes.

    filegroup=*group*

        Select records containing file system objects with *group* as the owning group.

    fileowner=*user*

        Select records containing file system objects with *user* as the owning user.

    fmri=*service_instance*

        Select records containing fault management resource identifier (FMRI) objects with the specified *service instance*. See `smf(5)`.

    msgqid=*ID*

        Select records containing message queue objects with the specified *ID* where *ID* is a message queue ID.

    msgqgroup=*group*

        Select records containing message queue objects with *group* as the owning or creating group.

    msgqowner=*user*

        Select records containing message queue objects with *user* as the owning or creating user.

pid=*ID*

    Select records containing process objects with the specified *ID* where *ID* is a process ID. Process are objects when they are receivers of signals.

procgroup=*group*

    Select records containing process objects with *group* as the real or effective group.

procowner=*user*

    Select records containing process objects with *user* as the real or effective user.

semid=*ID*

    Select records containing semaphore objects with the specified *ID* where *ID* is a semaphore ID.

semgroup=*group*

    Select records containing semaphore objects with *group* as the owning or creating group.

semowner=*user*

    Select records containing semaphore objects with *user* as the owning or creating user.

shmid=*ID*

    Select records containing shared memory objects with the specified *ID* where *ID* is a shared memory ID.

shmgroup=*group*

    Select records containing shared memory objects with *group* as the owning or creating group.

shmowner=*user*

    Select records containing shared memory objects with *user* as the owning or creating user.

sock=*port_number*|*machine*

    Select records containing socket objects with the specified *port_number* or the specified *machine* where *machine* is a machine name as defined in `hosts(4)`.

user=*user_name*

    Select records containing the user object whose name is specified. User objects are generally specified for administrative actions on a user.

-r *real-user*

    Select records with the specified *real-user*.

-s *session-id*

    Select audit records with the specified *session-id*.

-u *audit-user*

    Select records with the specified *audit-user*.

-z *zone-name*

    Select records from the specified zone name. The zone name selection is case-sensitive.

When one or more *filename* arguments appear on the command line, only the named files are processed. Files specified in this way need not conform to the audit trail filename format. However, -M, -S, and -R must not be used when processing named files. If the *filename* is "−" then the input is taken from the standard input.

Option Arguments **audit-trail-file**

An audit trail file as defined in audit.log(4). An audit trail file not named on the command line must conform to the audit trail file name format. Audit trail files produced as output of auditreduce are in this format as well. The format is:

start-time . end-time . suffix

start-time is the 14 character time stamp denoting when the file was opened. *end-time* is the 14 character time stamp denoting when the file was closed. *end-time* can also be the literal string not_terminated, indicating the file is still be written to by the audit daemon or the file was not closed properly (a system crash or abrupt halt occurred). *suffix* is the name of the machine that generated the audit trail file (or some other meaningful suffix; for example, all would be a good suffix if the audit trail file contains a combined group of records from many machines).

date-time

The *date-time* argument to -a, -b, and -d can be of two forms: An absolute *date-time* takes the form:

yyyymmdd [*hh* [*mm* [*ss*]]]

where *yyyy* specifies a year (with 1970 as the earliest value), *mm* is the month (01-12), dd is the day (01-31), *hh* is the hour (00-23), *mm* is the minute (00-59), and *ss* is the second (00-59). The default is 00 for *hh*, *mm* and *ss*.

An offset can be specified as: +*n* d|h|m| s where *n* is a number of units, and the tags d, h, m, and s stand for days, hours, minutes and seconds, respectively. An offset is relative to the starting time. Thus, this form can only be used with the -b option.

event

The literal string or ordinal event number as found in audit_event(4). If *event* is not found in the audit_event file it is considered invalid.

group

The literal string or ordinal group ID number as found in group(4). If *group* is not found in the group file it is considered invalid. *group* can be negative.

label

The literal string representation of a MAC label or a range of two valid MAC labels. To specify a range, use x;y where x and y are valid MAC labels. Only those records that are fully bounded by x and y will be selected. If x or y is omitted, the default uses ADMIN_LOW or ADMIN_HIGH respectively. Notice that quotes must be used when specifying a range.

pathname
> A regular expression describing a pathname.

user
> The literal username or ordinal user ID number as found in passwd(4). If the username is not found in the passwd file it is considered invalid. *user* can be negative.

Examples   EXAMPLE 1   Using auditreduce

praudit(1M) is available to display audit records in a human-readable form.

This will display the entire audit trail in a human-readable form:

% **auditreduce | praudit**

If all the audit trail files are being combined into one large file, then deleting the original files could be desirable to prevent the records from appearing twice:

% **auditreduce -V -D /var/audit/combined/all**

This displays what user milner did on April 13, 1988. The output is displayed in a human-readable form to the standard output:

% **auditreduce -d 19880413 -u milner | praudit**

The above example might produce a large volume of data if milner has been busy. Perhaps looking at only login and logout times would be simpler. The -c option will select records from a specified class:

% **auditreduce -d 19880413 -u milner -c lo | praudit**

To see milner's login/logout activity for April 13, 14, and 15, the following is used. The results are saved to a file in the current working directory. Notice that the name of the output file will have milnerlo as the *suffix*, with the appropriate timestamp prefixes. Notice also that the long form of the name is used for the -c option:

% **auditreduce -a 19880413 -b +3d -u milner -c login_logout -O milnerlo**

To follow milner's movement about the file system on April 13, 14, and 15 the chdir record types could be viewed. Notice that in order to get the same time range as the above example we needed to specify the -b time as the day *after* our range. This is because 19880416 defaults to midnight of that day, and records before that fall on 0415, the end-day of the range.

% **auditreduce -a 19880413 -b 19880416 -u milner -m AUE_CHDIR | praudit**

In this example, the audit records are being collected in summary form (the login/logout records only). The records are being written to a summary file in a different directory than the normal audit root to prevent the selected records from existing twice in the audit root.

% **auditreduce -d 19880330 -c lo -O /var/audit/audit_summary/logins**

EXAMPLE 1 Using `auditreduce` *(Continued)*

If activity for user ID 9944 has been observed, but that user is not known to the system administrator, then the command in the following example searches the entire audit trail for any records generated by that user. `auditreduce` queries the system about the current validity of ID 9944 and displays a warning message if it is not currently active:

```
% auditreduce -O /var/audit/audit_suspect/user9944 -u 9944
```

To get an audit log of only the global zone:

```
% auditreduce -z global
```

Files /var/audit/*   default location of audit trails, when stored

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

The command invocation is Stable. The binary file format is Stable. The binary file contents is Unstable.

See Also praudit(1M), audit.log(4), audit_class(4), group(4), hosts(4), passwd(4), attributes(5), audit_flags(5), smf(5)

See the section on Solaris Auditing in *Oracle Solaris Administration: Security Services*.

Diagnostics `auditreduce` displays error messages if there are command line errors and then exits. If there are fatal errors during the run, `auditreduce` displays an explanatory message and exits. In this case, the output file might be in an inconsistent state (no trailer or partially written record) and `auditreduce` displays a warning message before exiting. Successful invocation returns 0 and unsuccessful invocation returns 1.

Since `auditreduce` might be processing a large number of input files, it is possible that the machine-wide limit on open files will be exceeded. If this happens, `auditreduce` displays a message to that effect, give information on how many file there are, and exit.

If `auditreduce` displays a record's timestamp in a diagnostic message, that time is in local time. However, when filenames are displayed, their timestamps are in UTC.

Bugs Conjunction, disjunction, negation, and grouping of record selection options should be allowed.

Notes   The -z option should be used only if the audit policy zonename is set. If there is no zonename token, then no records will be selected.

Name auditstat – display kernel audit statistics

Synopsis auditstat [-c *count*] [-h *numlines*] [-i *interval*] [-n]
          [-T u | d] [-v]

Description auditstat displays kernel audit statistics. The fields displayed are as follows:

aud   The total number of audit records processed by the userland audit.

ctl   This field is obsolete.

drop   The total number of audit records that have been dropped. Records are dropped
       according to the kernel audit policy. See auditconfig(1M), AUDIT_CNT policy for
       details.

enq   The total number of audit records put on the kernel audit queue.

gen   The total number of audit records that have been constructed (not the number
       written).

kern   The total number of audit records produced by user processes (as a result of system
       calls).

mem   The total number of Kbytes of memory currently in use by the kernel audit module.

nona   The total number of non-attributable audit records that have been constructed.
       These are audit records that are not attributable to any particular user.

rblk   The total number of times that the audit queue has blocked waiting to process audit
       data.

tot   The total number of Kbytes of audit data written to the audit trail.

wblk   The total number of times that user processes blocked on the audit queue at the high
       water mark.

wrtn   The total number of audit records written. The difference between enq and wrtn is
       the number of outstanding audit records on the audit queue that have not been
       written.

Options -c *count*   Display the statistics a total of *count* times. If *count* is equal to zero, statistics
                 are displayed indefinitely. A time interval must be specified.

-h *numlines*   Display a header for every *numlines* of statistics printed. The default is to
                 display the header every 20 lines. If *numlines* is equal to zero, the header is
                 never displayed.

-i *interval*   Display the statistics every *interval* where *interval* is the number of seconds to
                 sleep between each collection.

-n   Display the number of kernel audit events currently configured.

-T u | d   Display a time stamp.

Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See date(1).

-v   Display the version number of the kernel audit module software.

Exit Status   auditstat returns 0 upon success and 1 upon failure.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   auditconfig(1M), praudit(1M), attributes(5)

Name audit_warn – audit daemon warning script

Synopsis /etc/security/audit_warn [*option* [*arguments*]]

Description The audit_warn utility processes warning or error messages from the audit daemon. When a problem is encountered, the audit daemon, auditd(1M) calls audit_warn with the appropriate arguments. The *option* argument specifies the error type.

The system administrator can specify a list of mail recipients to be notified when an audit_warn situation arises by defining a mail alias called audit_warn in aliases(4). The users that make up the audit_warn alias are typically the audit and root users.

Options The following options are supported:

allhard *count* Indicates that the hard limit for all filesystems has been exceeded *count* times. The default action for this option is to send mail to the audit_warn alias only if the *count* is 1, and to write a message to the machine console every time. It is recommended that mail *not* be sent every time as this could result in a the saturation of the file system that contains the mail spool directory.

allsoft Indicates that the soft limit for all filesystems has been exceeded. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.

auditoff Indicates that someone other than the audit daemon changed the system audit state to something other than AUC_AUDITING. The audit daemon will have exited in this case. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.

ebusy Indicates that the audit daemon is already running. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.

hard *filename* Indicates that the hard limit for the file has been exceeded. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.

hostname Indicates that the audit service could not find an IP address to associate with the local hostname. It has fallen back to using the "loopback" address. The audit trail might not

	translate properly. See `/var/audit/debug` for more information. The audit service can be refreshed (`audit -s`) to retry to find an IP address.
nostart	Indicates that auditing could not be started. The default action for this option is to send mail to the `audit_warn` alias and to write a message to the machine console. Some administrators may prefer to modify `audit_warn` to reboot the system when this error occurs.
plugin *name error count text*	Indicates that an error occurred during execution of the `auditd` plugin *name*. The default action for this option is to send mail to the `audit_warn` alias only if *count* is 1, and to write a message to the machine console every time. (Separate counts are kept for each error type.) It is recommended that mail not be sent every time as this could result in the saturation of the file system that contains the mail spool directory. The *text* field provides the detailed error message passed from the plug-in. The *error* field is one of the following strings:

	load_error	Unable to load the plugin *name*.
	sys_error	The plugin *name* is not executing due to a system error such as a lack of resources.
	config_error	No plug-ins loaded (including the binary file plug-in, audit_binfile(5)) due to configuration errors (see the `-setplugin` option of the auditconfig(1M) command). The name string is `--`, to indicate that no plug-in name applies.
	retry	The plugin *name* reports it has encountered a temporary failure. For example, the `audit_binfree.so` plugin uses `retry` to indicate that all directories are full.
	no_memory	The plugin *name* reports a failure due to lack of memory.
	invalid	The plugin *name* reports it received an invalid input.
	failure	The plugin *name* has reported an error as described in *text*.

postsigterm	Indicates that an error occurred during the orderly shutdown of the audit daemon. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.
soft *filename*	Indicates that the soft limit for *filename* has been exceeded. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.
tmpfile	Indicates that the temporary audit file already exists indicating a fatal error. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

The interface stability is Evolving. The file content is Unstable.

See Also   audit(1M), auditconfig(1M), auditd(1M), aliases(4), audit.log(4), attributes(5)

See the section on Solaris Auditing in *Oracle Solaris Administration: Security Services*.

Notes   This functionality is available only if the Solaris Auditing feature has been enabled.

If the audit policy perzone is set, the /etc/security/audit_warn script for the local zone is used for notifications from the local zone's instance of auditd. If the perzone policy is not set, all auditd errors are generated by the global zone's copy of /etc/security/audit_warn.

Name automount – install automatic mount points

Synopsis `/usr/sbin/automount [-t `*`duration`*`] [-v]`

Description The `automount` utility installs `autofs` mount points and associates an automount map with each mount point. It starts the automountd(1M) daemon if it finds any non-trivial entries in either local or distributed automount maps and if the daemon is not already running. The `autofs` file system monitors attempts to access directories within it and notifies the automountd(1M) daemon. The daemon uses the map to locate a file system, which it then mounts at the point of reference within the `autofs` file system. A map can be assigned to an `autofs` mount using an entry in the `/etc/auto_master` map or a direct map.

If the file system is not accessed within an appropriate interval (`10` minutes by default), the `automountd` daemon unmounts the file system.

The file `/etc/auto_master` determines the locations of all `autofs` mount points. By default, this file contains three entries:

```
# Master map for automounter
#
+auto_master
/net           -hosts    -nosuid
/home          auto_home
```

The `+auto_master` entry is a reference to an external NIS master map. If one exists, then its entries are read as if they occurred in place of the `+auto_master` entry. The remaining entries in the master file specify a directory on which an `autofs` mount will be made followed by the automounter map to be associated with it. Optional mount options may be supplied as an optional third field in the each entry. These options are used for any entries in the map that do not specify mount options explicitly. The `automount` command is usually run without arguments. It compares the entries `/etc/auto_master` with the current list of `autofs` mounts in `/etc/mnttab` and adds, removes or updates `autofs` mounts to bring the `/etc/mnttab` up to date with the `/etc/auto_master`. At boot time it installs all `autofs` mounts from the master map. Subsequently, it may be run to install `autofs` mounts for new entries in the master map or the direct map, or to perform unmounts for entries that have been removed from these maps.

SMF Management The `automount` service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/filesystem/autofs:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Startup autofs SMF parameters for `automount` can be manipulated using sharectl(1M). Refer to sharectl(1M) for instructions for viewing and updating these parameters. Supported parameters are:

timeout=*num*
  Specifies a duration, in seconds, that a file system is to remain mounted when not in use. The default value is 600 (10 minutes). Equivalent to the -t option in automount.

automount_verbose=TRUE | FALSE
  Verbose mode. Causes you to be notified of non-critical events, suchs as autofs mounts and unmounts. The default value is FALSE. Equivalent to the -v option in automount.

Automount with Oracle Solaris Trusted Extensions If a system is configured with Oracle Solaris Trusted Extensions, users have home directories at each label within their clearance. Therefore a home directory needs to be available in each corresponding labeled zone. Instead of using the auto_home map, a special map is automatically generated, using the zone's name as a suffix. By default the map contains the single entry:

```
-fstype=lofs    :/export/home/&
```

When a home directory is referenced and the name does not match any other keys in the zone's auto_home_*zonename* map, it will match this loopback mount specification. If this loopback match occurs and the name corresponds to a valid user whose home directory does not exist in the zone, the directory is automatically created on behalf of the user.

It is also possible to share home directories in a zone, in read-only mode, with higher-level zones, using NFS. In this case, the higher-level zone needs to have an automap entry for each lower-level zone that is to be imported. A typical map entry for the public zone, to be interpreted in the internal zone, would be called auto_home_public, and would look like this:

```
+auto_home_public
```

public-zone-IP-address:/export/home/&

This automap entry would then be included in /etc/auto_master, as follows:

```
/zone/public/home      auto_home_public      -nobrowse
```

Users in higher-level zones can use the updatehome(1) utility to synchronize specific startup files using their minimum labeled zone as the source.

Options The following options are supported:

-t *duration*   Specifies a *duration*, in seconds, that a file system is to remain mounted when not in use. The default is 10 minutes.

-v   Verbose mode. Notifies of autofs mounts, unmounts, or other non-essential information.

Usage

Map Entry Format   A simple map entry (mapping) takes the form:

key [-*mount-options*] *location* . . .

where key is the full pathname of the directory to mount when used in a direct map, or the simple name of a subdirectory in an indirect map. *mount-options* is a comma-separated list of mount options, and *location* specifies a file system from which the directory may be mounted. In the case of a simple NFS mount, the options that can be used are as specified in mount_nfs(1M), and *location* takes the form:

host: *pathname*

host is the name of the host from which to mount the file system, and *pathname* is the absolute pathname of the directory to mount.

Options to other file systems are documented on the other mount_* reference manual pages, for example, mount_nfs(1M).

Replicated File Systems   Multiple *location* fields can be specified for replicated NFS file systems, in which case automount and the kernel will each try to use that information to increase availability. If the read-only flag is set in the map entry, automountd mounts a list of locations that the kernel may use, sorted by several criteria. Only locations available at mount time will be mounted, and thus be available to the kernel. When a server does not respond, the kernel will switch to an alternate server. The sort ordering of automount is used to determine how the next server is chosen. If the read-only flag is not set, automount will mount the best single location, chosen by the same sort ordering, and new servers will only be chosen when an unmount has been possible, and a remount is done. Servers on the same local subnet are given the strongest preference, and servers on the local net are given the second strongest preference. Among servers equally far away, response times will determine the order if no weighting factors (see below) are used.

If the list includes server locations using both the NFS Version 2 Protocol and the NFS Version 3 Protocol, automount will choose only a subset of the server locations on the list, so that all entries will be the same protocol. It will choose servers with the NFS Version 3 Protocol so long as an NFS Version 2 Protocol server on a local subnet will not be ignored. See the *Oracle Solaris Administration: IP Services* for additional details.

If each *location* in the list shares the same *pathname* then a single *location* may be used with a comma-separated list of hostnames:

hostname,hostname . . . : *pathname*

Requests for a server may be weighted, with the weighting factor appended to the server name as an integer in parentheses. Servers without a weighting are assumed to have a value of zero (most likely to be selected). Progressively higher values decrease the chance of being selected. In the example,

man -ro alpha,bravo,charlie(1),delta(4) : /usr/man

hosts `alpha` and `bravo` have the highest priority; host `delta` has the lowest.

Server proximity takes priority in the selection process. In the example above, if the server `delta` is on the same network segment as the client, but the others are on different network segments, then `delta` will be selected; the weighting value is ignored. The weighting has effect only when selecting between servers with the same network proximity. The automounter always selects the localhost over other servers on the same network segment, regardless of weighting.

In cases where each server has a different export point, the weighting can still be applied. For example:

```
man -ro alpha:/usr/man  bravo,charlie(1):/usr/share/man
    delta(3):/export/man
```

A mapping can be continued across input lines by escaping the NEWLINE with a backslash (\) Comments begin with a number sign (#) and end at the subsequent NEWLINE.

Map Key Substitution
The ampersand (&) character is expanded to the value of the `key` field for the entry in which it occurs. In this case:

```
jane sparcserver : /home/&
```

the & expands to `jane`.

Wildcard Key
The asterisk (*) character, when supplied as the `key` field, is recognized as the catch-all entry. Such an entry will match any key not previously matched. For instance, if the following entry appeared in the indirect map for `/config`:

```
*        & : /export/config/&
```

this would allow automatic mounts in `/config` of any remote file system whose location could be specified as:

```
hostname : /export/config/hostname
```

Note that the wildcard key does not work in conjunction with the `-browse` option.

Variable Substitution
Client specific variables can be used within an `automount` map. For instance, if $HOST appeared within a map, `automount` would expand it to its current value for the client's host name. Supported variables are:

ARCH	The output of `arch`	The architecture name. For example, sun4 on a sun4u machine.
CPU	The output of `uname -p`	The processor type.

		For example, "sparc"
HOST	The output of uname -n	The host name.
		For example, myhost.
KARCH	The output of arch -k or uname –m	The kernel architecture name or machine hardware name. For example, sun4u.
OSNAME	The output of uname -s	The OS name.
		For example, "SunOS"
OSREL	The output of uname -r	The OS release name.
		For example "5.3"
OSVERS	The output of uname -v	The OS version.
		For example, "beta1.0"
NATISA	The output of isainfo -n	The native instruction set architecture for the system.
		For example, "sparcv9"
PLATFORM	The output of uname -i	The platform name. For example, SUNW,Sun-Fire-V240.

If a reference needs to be protected from affixed characters, you can surround the variable name with curly braces ({ }).

Multiple Mounts A multiple mount entry takes the form:

key [-*mount-options*] [[*mountpoint*] [-*mount-options*] *location*. . .] . . .

The initial /[*mountpoint*] is optional for the first mount and mandatory for all subsequent mounts. The optional *mountpoint* is taken as a pathname relative to the directory named by key. If *mountpoint* is omitted in the first occurrence, a *mountpoint* of / (root) is implied.

Given an entry in the indirect map for /src

```
beta      -ro\
  /          svr1,svr2:/export/src/beta  \
  /1.0       svr1,svr2:/export/src/beta/1.0  \
  /1.0/man   svr1,svr2:/export/src/beta/1.0/man
```

All offsets must exist on the server under beta. automount will automatically mount /src/beta, /src/beta/1.0, and /src/beta/1.0/man, as needed, from either svr1 or svr2, whichever host is nearest and responds first.

Other File System Types   The automounter assumes NFS mounts as a default file system type. Other file system types can be described using the fstype mount option. Other mount options specific to this file system type can be combined with the fstype option. The location field must contain information specific to the file system type. If the location field begins with a slash, a colon character must be prepended, for instance, to mount a CD file system:

```
cdrom -fstype=hsfs,ro   : /dev/sr0
```

or to perform an autofs mount:

```
src -fstype=autofs    auto_src
```

Use this procedure only if you are not using Volume Manager.

See the NOTES section for information on option inheritance.

Indirect Maps   An indirect map allows you to specify mappings for the subdirectories you wish to mount under the directory indicated on the command line. In an indirect map, each key consists of a simple name that refers to one or more file systems that are to be mounted as needed.

Direct Maps   Entries in a direct map are associated directly with autofs mount points. Each *key* is the full pathname of an autofs mount point. The direct map as a whole is not associated with any single directory.

Direct maps are distinguished from indirect maps by the /- key. For example:

```
# Master map for automounter
#
+auto_master
/net            -hosts          -nosuid,nobrowse
/home           auto_home       -nobrowse
/-              auto_direct
```

Included Maps   The contents of another map can be included within a map with an entry of the form

+*mapname*

If *mapname* begins with a slash, it is assumed to be the pathname of a local file. Otherwise, the location of the map is determined by the policy of the name service switch according to the entry for the automounter in /etc/nsswitch.conf, such as

```
automount: files nis
```

If the name service is files, then the name is assumed to be that of a local file in /etc. If the key being searched for is not found in the included map, the search continues with the next entry.

Special Maps
There are three special maps available: -hosts, -fedfs and -null. The -hosts map is used with the /net directory and assumes that the map key is the hostname of an NFS server. The automountd daemon dynamically constructs a map entry from the server's list of exported file systems. References to a directory under /net/hermes will refer to the corresponding directory relative to hermes root.

The -fedfs map is used with the /nfs4 directory and assumes that the map key is the DNS domain for which the domain root filesystem is needed. The automountd daemon looks up the domain root servers with a query equivalent to:

% **nslookup -q=srv _nfs4._domainroot._tcp.***domain*

...and mounts *server-list*:/.domainroot-*domain* at /nfs4/*domain*.

This supports the pending IETF standard documented in:

```
http://datatracker.ietf.org/doc/\
draft-ietf-nfsv4-federated-fs-dns-srv-namespace/
```

The -null map cancels a previous map for the directory indicated. This is most useful in the /etc/auto_master for cancelling entries that would otherwise be inherited from the +auto_master include entry. To be effective, the -null entries must be inserted before the included map entry.

Executable Maps
Local maps that have the execute bit set in their file permissions will be executed by the automounter and provided with a key to be looked up as an argument. The executable map is expected to return the content of an automounter map entry on its stdout or no output if the entry cannot be determined. A direct map cannot be made executable.

Configuration and the auto_master Map
When initiated without arguments, automount consults the master map for a list of autofs mount points and their maps. It mounts any autofs mounts that are not already mounted, and unmounts autofs mounts that have been removed from the master map or direct map.

The master map is assumed to be called auto_master and its location is determined by the name service switch policy. Normally the master map is located initially as a local file /etc/auto_master.

Browsing
The automount daemon supports browsability of indirect maps. This allows all of the potential mount points to be visible, whether or not they are mounted. The -nobrowse option can be added to any indirect autofs map to disable browsing. For example:

```
/net      -hosts        -nosuid,nobrowse
/home     auto_home
```

In this case, any *hostnames* would only be visible in /net after they are mounted, but all potential mount points would be visible under /home. The -browse option enables browsability of autofs file systems. This is the default for all indirect maps.

The -browse option does not work in conjunction with the wildcard key.

Restricting Mount Maps

Options specified for a map are used as the default options for all the entries in that map. They are ignored when map entries specify their own mount options.

In some cases, however, it is desirable to force nosuid, nodevices, nosetuid, or noexec for a complete mount map and its submounts. This can be done by specifying the additional mount option, -restrict.

```
/home    auto_home        -restrict,nosuid,hard
```

The -restrict option forces the inheritance of all the restrictive options nosuid, nodevices, nosetuid, and noexec as well as the restrict option itself. In this particular example, the nosuid and restrict option are inherited but the hard option is not. The restrict option also prevents the execution of "executable maps" and is enforced for auto mounts established by programs with fewer than all privileges available in their zone.

Exit Status The following exit values are returned:

0   Successful completion.

1   An error occurred.

Files /etc/auto_master   Master automount map.

/etc/auto_home   Map to support automounted home directories.

/etc/nsswitch.conf   Name service switch configuration file. See nsswitch.conf(4).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also isainfo(1), ls(1), svcs(1), uname(1), updatehome(1), automountd(1M), mount(1M), mount_nfs(1M), sharectl(1M), svcadm(1M), attributes(5), nfssec(5), smf(5)

Oracle Solaris Administration: Network Services

Notes autofs mount points must not be hierarchically related. automount does not allow an autofs mount point to be created within another autofs mount.

Since each direct map entry results in a new autofs mount such maps should be kept short.

Entries in both direct and indirect maps can be modified at any time. The new information is used when automountd next uses the map entry to do a mount.

New entries added to a master map or direct map will not be useful until the automount command is run to install them as new autofs mount points. New entries added to an indirect map may be used immediately.

As of the Solaris 2.6 release, a listing (see ls(1)) of the autofs directory associated with an indirect map shows all potential mountable entries. The attributes associated with the potential mountable entries are temporary. The real file system attributes will only be shown once the file system has been mounted.

Default mount options can be assigned to an entire map when specified as an optional third field in the master map. These options apply only to map entries that have no mount options. Note that map entities with options override the default options, as at this time, the options do not concatenate. The concatenation feature is planned for a future release.

When operating on a map that invokes an NFS mount, the default number of retries for the automounter is 0, that is, a single mount attempt, with no retries. Note that this is significantly different from the default (10000) for the mount_nfs(1M) utility.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same.

Name automountd – autofs mount/unmount daemon

Synopsis automountd [-Tvn] [-D *name=value*]

Description automountd is an RPC server that answers file system mount and unmount requests from the autofs file system. It uses local files or name service maps to locate file systems to be mounted. These maps are described with the automount(1M) command.

If automount finds any non-trivial entries in either the local or distributed automount maps and if the daemon is not running already, the automountd daemon is automatically invoked by automount(1M). automountd enables the svc:/network/nfs/nlockmgr service (lockd(1M)), and the svc:/network/nfs/status service (statd(1M)), if NFS mounts need to be done.

SMF Management The automountd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/filesystem/autofs

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using svcs(1). If it is disabled, it is enabled by automount(1M) unless the application/auto_enable property is set to false.

Values for parameters for automountd are stored in SMF and manipulated using sharectl(1M). The following are the supported parameters.

automountd_verbose=TRUE | FALSE
  Verbose mode. Causes status messages to be logged to:

  /var/svc/log/system-filesystem-autofs:default.log

  See smf(5). The default value is FALSE. Equivalent to the -v option.

nobrowse=ON | OFF
  Turn on or off browsing for all autofs mount points. The default value is OFF. Equivalent to the -n option.

trace=*num*
  Expands each RPC call and logs it to:

  /var/svc/log/system-filesystem-autofs:default.log

  See smf(5). The default value, 0, turns off such tracing. Starting with 1, with each higher value, the verbosity of trace output increases. This property is equivalent to the -T option.

environment=*name=value*
  Environment variables. You can specify multiple *name=value* pairs with a comma separator. If there is more than one value for a name, use the double forward slash to indicate that. See EXAMPLES. There are no environment variable settings supplied. This property is equivalent to the -D option.

All the above parameters can be changed using the sharectl(1M) command.

Options The following options are supported:

-D *name=value*   Assign *value* to the indicated `automount` map substitution variable. These assignments cannot be used to substitute variables in the master map `auto_master`.

-n   Turn off browsing for all `autofs` mount points. This option overrides the `-browse` autofs map option on the local host.

-T   Trace. Expand each RPC call and display it on the standard output.

-v   Verbose. Log status messages to the console.

Usage See largefile(5) for the description of the behavior of `automountd` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1**   Setting Verbose Mode

The following command turns on verbose mode, causing status messages to be logged to the location specified in "SMF Management," above. See that section for a description of the properties specified in this and following examples.

```
# sharectl set -p automountd_verbose=true autofs
```

EXAMPLE 2   Turning on Browsing for Mount Points

The following command turns on browsing for all `autofs` mount points.

```
# sharectl set -p nobrowse=off autofs
```

EXAMPLE 3   Specifying and Displaying Environment Variables

The following commands set and display the value for an environment variable named `DAY`.

```
# sharectl set -p environment=DAY=TUES autofs
% sharectl get -p environment autofs
environment=DAY=TUES
```

The following command sets multiple parameters for an environment variable. The subsequent command displays the result.

```
# sharectl set -p environment=DAY=TUES,TIME=NOON autofs
% sharectl get -p environment autofs
environment=DAY=TUES,TIME=NOON
```

The following command set multiple values for name that is assigned to an environment variable. The subsequent command displays the result.

```
# sharectl set -p environment=DAY=MON\\,TUE,TIME=NOON autofs
% sharectl get -p environment autofs
environment=DAY=MON\,TUE,TIME=NOON
```

Files /etc/auto_master   Master map for automounter.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also svcs(1), automount(1M), sharectl(1M), svcadm(1M), attributes(5), largefile(5), smf(5)

Name   autopush – configures lists of automatically pushed STREAMS modules

Synopsis   autopush -f *filename*

autopush -g -M *major* -m *minor*

autopush -r -M *major* -m *minor*

Description   The autopush command configures the list of modules to be automatically pushed onto the stream when a device is opened. It can also be used to remove a previous setting or get information on a setting.

Options   The following options are supported:

-f *filename*
Sets up the autopush configuration for each driver according to the information stored in *filename*. An autopush file consists of lines of four or more fields, separated by spaces as shown below:

major minor last-minor module1 module2 . . . module8

The first field is a string that specifies the *major* device name, as listed in the /kernel/drv directory. The next two fields are integers that specify the *minor* device number and *last-minor* device number. The fields following represent the names of modules. If *minor* is −1, then all minor devices of a major driver specified by *major* are configured, and the value for *last-minor* is ignored. If *last-minor* is 0, then only a single minor device is configured. To configure a range of minor devices for a particular major, *minor* must be less than *last-minor*.

The remaining fields list the names of modules to be automatically pushed onto the stream when opened, along with the position of an optional anchor. The maximum number of modules that can be pushed is eight. The modules are pushed in the order they are specified. The optional special character sequence [anchor] indicates that a STREAMS anchor should be placed on the stream at the module previously specified in the list; it is an error to specify more than one anchor or to have an anchor first in the list.

A nonzero exit status indicates that one or more of the lines in the specified file failed to complete successfully.

-g
Gets the current configuration setting of a particular *major* and *minor* device number specified with the -M and -m options respectively and displays the autopush modules associated with it. It will also return the starting minor device number if the request corresponds to a setting of a range (as described with the -f option).

-m *minor*
Specifies the minor device number.

-M *major*
Specifies the major device number.

-r

Removes the previous configuration setting of the particular *major* and *minor* device number specified with the -M and -m options respectively. If the values of *major* and *minor* correspond to a previously established setting of a range of minor devices, where *minor* matches the first minor device number in the range, the configuration would be removed for the entire range.

Exit Status The following exit values are returned:

0

Successful completion.

non-zero

An error occurred.

Examples EXAMPLE 1   Using the autopush command.

The following example gets the current configuration settings for the *major* and *minor* device numbers as indicated and displays the autopush modules associated with them for the character-special device /dev/term/a:

```
example# autopush -g -M 29 -m 0
Major     Minor     Lastminor     Modules
  29        0         1           ldterm  ttcompat
```

Files /etc/iu.ap

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also dladm(1M), ttymon(1M), attributes(5), ldterm(7M), sad(7D), streamio(7I), ttcompat(7M)

STREAMS Programming Guide

Notes The use of the autopush command is obsolete for networking data-links. The preferred method of configuring a list of automatically pushed STREAMS modules on a given networking data-link interface is the dladm(1M) autopush link property.

Because network devices are self-cloning, the autopush command is inadequate for networking devices. The granularity of the autopush command's configuration is driver-wide, and not per-interface as one might expect. Another reason not to use autopush is that administrators are more familiar with the names of their network interfaces than with device major and minor numbers. The dladm(1M) command allows the configuration using data-link interface names.

Name   bart – basic audit reporting tool

Synopsis   /usr/bin/bart create [-n] [-R *root_directory*]
       [-r *rules_file* | -] [-a md5|sha1|sha256|sha384|sha512]

/usr/bin/bart create [-n] [-R *root_directory*] -I
       [-a md5|sha1|sha256|sha384|sha512] [*file_name*]...

/usr/bin/bart compare [-i *attribute*] [-p]
       [-r *rules_file* | -] *control-manifest test-manifest*

Description   bart(1M) is a tool that performs a file-level check of the software contents of a system.

You can also specify the files to track and the types of discrepancies to flag by means of a rules file, bart_rules. See bart_rules(4).

The bart utility performs two basic functions:

bart create   The manifest generator tool takes a file-level *snapshot* of a system. The output is a catalog of file attributes referred to as a *manifest*. See bart_manifest(4).

                    You can specify that the list of files be cataloged in three ways. Use bart create with no options, specify the files by name on the command line, or create a rules file with directives that specify which the files to monitor. See bart_rules(4).

                    By default, the manifest generator catalogs all attributes of all files in the root (/) file system. File systems mounted on the root file system are cataloged only if they are of the same type as the root file system.

                    For example, /, /usr, and /opt are separate UFS file systems. /usr and /opt are mounted on /. Therefore, all three file systems are cataloged. However, /tmp, also mounted on /, is not cataloged because it is a TMPFS file system. Mounted CD-ROMs are not cataloged since they are HSFS file systems.

bart compare   The report tool compares two manifests. The output is a list of per-file attribute discrepancies. These discrepancies are the differences between two manifests: a control manifest and a test manifest.

                    A discrepancy is a change to any attribute for a given file cataloged by both manifests. A new file or a deleted file in a manifest is reported as a discrepancy.

                    The reporting mechanism provides two types of output: verbose and programmatic. Verbose output is localized and presented on multiple lines, while programmatic output is more easily parsable by other programs. See OUTPUT.

By default, the report tool generates verbose output where all discrepancies are reported except for modified directory timestamps (dirmtime attribute).

To ensure consistent and accurate comparison results, *control-manifest* and *test-manifest* must be built with the same rules file.

Use the rules file to ignore specified files or subtrees when you generate a manifest or compare two manifests. Users can compare manifests from different perspectives by re-running the bart compare command with different rules files.

Options The following options are supported:

-i *attribute* ...
Specify the file attributes to be ignored globally. Specify attributes as a comma separated list.

This option produces the same behavior as supplying the file attributes to a global IGNORE keyword in the rules file. See bart_rules(4).

-I [*file_name*...]
Specify the input list of files. The file list can be specified at the command line or read from standard input.

-n
Prevent computation of content signatures for all regular files in the file list.

-p
Display manifest comparison output in "programmatic mode," which is suitable for programmatic parsing. The output is not localized.

-r *rules_file*
Use *rules_file* to specify which files and directories to catalog, and to define which file attribute discrepancies to flag. If *rules_file* is -, then the rules are read from standard input. See bart_rules(4) for the definition of the syntax.

-R *root_directory*
Specify the root directory for the manifest. All paths specified by the rules, and all paths reported in the manifest, are relative to *root_directory*.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-a [*hash*]
Specify the cryptographic digest algorithm to use for the hash of the file contents: md5, sha1, sha256, sha512 are the currently supported values. If -a is not specified, sha256 is used and a Version 1.1 manifest is created that indicates which hash algorithm is used. If md5 is specified then a Version 1.0 manifest is created.

Operands bart allows quoting of operands. This is particularly important for white-space appearing in subtree and subtree modifier specifications.

The following operands are supported:

control-manifest Specify the manifest created by bart create on the control system.

test-manifest Specify the manifest created by bart create on the test system.

Output The bart create and bart compare commands write output to standard output, and write error messages to standard error.

The bart create command generates a system manifest. See bart_manifest(4).

When the bart compare command compares two system manifests, it generates a list of file differences. By default, the comparison output is localized. However, if the -p option is specified, the output is generated in a form that is suitable for programmatic manipulation.

Default Format *filename*
attribute control:*xxxx* test:*yyyy*

filename Name of the file that differs between *control-manifest* and *test-manifest*. For file names that contain embedded whitespace or newline characters, see bart_manifest(4).

attribute The name of the file attribute that differs between the manifests that are compared. *xxxx* is the attribute value from *control-manifest*, and *yyyy* is the attribute value from *test-manifest*. When discrepancies for multiple attributes occur for the same file, each difference is noted on a separate line.

The following attributes are supported:

acl ACL attributes for the file. For a file with ACL attributes, this field contains the output from acltotext().

all All attributes.

contents Checksum value of the file. This attribute is only specified for regular files. If you turn off context checking or if checksums cannot be computed, the value of this field is -.

dest Destination of a symbolic link.

devnode Value of the device node. This attribute is for character device files and block device files only.

dirmtime Modification time in seconds since 00:00:00 UTC, January 1, 1970 for directories.

gid Numerical group ID of the owner of this entry.

lnmtime   Creation time for links.

mode   Octal number that represents the permissions of the file.

mtime   Modification time in seconds since 00:00:00 UTC, January 1, 1970 for files.

size   File size in bytes.

type   Type of file.

uid   Numerical user ID of the owner of this entry.

The following default output shows the attribute differences for the /etc/passwd file. The output indicates that the size, mtime, and contents attributes have changed.

```
/etc/passwd:
  size  control:74  test:81
  mtime  control:3c165879  test:3c165979
  contents  control:daca28ae0de97afd7a6b91fde8d57afa
test:84b2b32c4165887355317207b48a6ec7
```

Programmatic Format   *filename attribute control-val test-val* [*attribute control-val test-val*]*

filename   Same as *filename* in the default format.

attribute control-val test-val   A description of the file attributes that differ between the control and test manifests for each file. Each entry includes the attribute value from each manifest. See bart_manifest(4) for the definition of the attributes.

Each line of the programmatic output describes all attribute differences for a single file.

The following programmatic output shows the attribute differences for the /etc/passwd file. The output indicates that the size, mtime, and contents attributes have changed.

```
/etc/passwd size 74 81 mtime 3c165879 3c165979
contents daca28ae0de97afd7a6b91fde8d57afa 84b2b32c4165887355317207b48a6ec7
```

Exit Status

Manifest Generator   The manifest generator returns the following exit values:

0   Success

1   Non-fatal error when processing files; for example, permission problems

>1   Fatal error; for example, invalid command-line options

Report Tool   The report tool returns the following exit values:

0   No discrepancies reported

1   Discrepancies found

>1   Fatal error executing comparison

Examples   **EXAMPLE 1**   Creating a Default Manifest Without Computing Checksums

The following command line creates a default manifest, which consists of all files in the / file system. The -n option prevents computation of checksums, which causes the manifest to be generated more quickly.

```
bart create -n
```

EXAMPLE 2   Creating a Manifest for a Specified Subtree

The following command line creates a manifest that contains all files in the /home/nickiso subtree.

```
bart create -R /home/nickiso
```

EXAMPLE 3   Creating a Manifest by Using Standard Input

The following command line uses output from the find(1) command to generate the list of files to be cataloged. The find output is used as input to the bart create command that specifies the -I option.

```
find /home/nickiso -print | bart create -I
```

EXAMPLE 4   Creating a Manifest by Using a Rules File

The following command line uses a rules file, rules, to specify the files to be cataloged.

```
bart create -r rules
```

EXAMPLE 5   Comparing Two Manifests and Generating Programmatic Output

The following command line compares two manifests and produces output suitable for parsing by a program.

```
bart compare -p manifest1 manifest2
```

EXAMPLE 6   Comparing Two Manifests and Specifying Attributes to Ignore

The following command line compares two manifests. The dirmtime, lnmtime, and mtime attributes are not compared.

```
bart compare -i dirmtime,lnmtime,mtime manifest1 manifest2
```

EXAMPLE 7   Comparing Two Manifests by Using a Rules File

The following command line uses a rules file, rules, to compare two manifests.

```
bart compare -r rules manifest1 manifest2
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	security/bart
Interface Stability	Committed

See Also cksum(1), digest(1), find(1), bart_manifest(4), bart_rules(4), attributes(5)

Notes The file attributes of certain system libraries can be temporarily altered by the system as it boots. To avoid triggering false warnings, you should compare manifests only if they were both created with the system in the same state; that is, if both were created in single-user or both in multi-user.

Name beadm – manage ZFS boot environments

Synopsis beadm create [-a] [-d *description*]
         [-e *non-activeBeName* | *beName@snapshot*]
         [-o *property=value*] ... [-p *zpool*] *beName*

beadm create *beName@snapshot*

beadm destroy [-fF] *beName* | *beName@snapshot*

beadm list [-a | -ds] [-H] [*beName*]

beadm mount *beName* *mountpoint*

beadm unmount [-f] *beName*

beadm rename *beName* *newBeName*

beadm activate *beName*

Description The beadm command is the user interface for managing ZFS Boot Environments (BEs). This
utility is intended to be used by system administrators who want to manage multiple Oracle
Solaris instances on a single system.

Using beadm, you can do the following:

- Create a new BE, based on the active BE.
- Create a new BE, based on an inactive BE.
- Create a snapshot of an existing BE.
- Create a new BE, based on an existing snapshot.
- Create a new BE, and copy it to a different zpool.
- Activate an existing, inactive BE.
- Mount a BE.
- Unmount a BE.
- Destroy a BE.
- Destroy a snapshot of a BE.
- Rename an existing, inactive BE.
- Display information about your snapshots and datasets.

Sub-commands The beadm command has the subcommands and options listed below. Usage of many of these
subcommands and options is illustrated in EXAMPLES, below.

beadm *(no arguments)*
    Displays command usage.

beadm create [-a] [-d *description*] [-e *non-activeBeName* | *beName@snapshot*] [-o
property=value] ... [-p *zpool*] *beName*
    Creates a new boot environment named *beName*. If the -e option is not provided, the new
    boot environment will be created as a clone of the currently running boot environment. If
    the -d option is provided, then the description is also used as the title for the BE's entry in
    the GRUB menu for x86 systems or in the boot menu for SPARC systems. If the -d option is

not provided, *beName* will be used as the title. Nested BEs do not support the use of the -p option. Also, non-bootable, nested BEs and snapshots of non-bootable, nested BEs cannot be used with the -e option.

-a

    Activate the newly created BE upon creation. The default is to not activate the newly created BE.

-d *description*

    Create a new BE with a description associated with it.

-e *non-activeBeName*

    Create a new BE from an existing inactive BE. In a nested BE, only bootable BEs can be used with this option.

-e *beName@snapshot*

    Create a new BE from an existing snapshot of the BE named *beName*. In a nested BE, only snapshots of bootable BEs can be used with this option.

-o *property=value*

    Create the datasets for a new BE with specific ZFS properties. Multiple -o options can be specified. See zfs(1M) for more information on the -o option.

-p *zpool*

    Create the new BE in the specified *zpool*. If this is not provided, the default behavior is to create the new BE in the same pool as the origin BE. This option is not supported inside of a nested BE.

beadm create *beName@snapshot*

    Creates a snapshot of the existing BE named *beName*. Inside a nested BE, only bootable BEs can be snapshotted. When inside of a nested BE, only BEs that are bootable or BEs that are not bootable but are not marked as active on reboot can be destroyed.

beadm destroy [-fF] *beName* | *beName@snapshot*

    Destroys the boot environment named *beName* or destroys an existing snapshot of the boot environment named *beName@snapshot*. Destroying a boot environment will also destroy all snapshots of that boot environment. Use this command with caution.

-f

    Forcefully unmount the boot environment if it is currently mounted.

-F

    Force the action without prompting to verify the destruction of the boot environment.

beadm list [-a | -ds] [-H] [*beName*]

    Lists information about the existing boot environment named *beName*, or lists information for all boot environments if *beName* is not provided. The Active field indicates whether the boot environment is active now, represented by N; active on reboot, represented by R; or both, represented by NR. Unbootable BEs inside of a nested BE are represented by an exclamation point (!)

Each line in the machine-parsable output has the boot environment name as the first field. The Space field is displayed in bytes and the Created field is displayed in UTC format. The -H option used with no other options gives the boot environment's UUID in the second field. This field will be blank if the boot environment does not have a UUID. See the EXAMPLES section. Inside of a nested BE, the UUID field actually represents the parent id with which the nested BE is associated.

-a

    Lists all available information about the boot environment. This includes subordinate file systems and snapshots.

-d

    Lists information about all subordinate file systems belonging to the boot environment.

-s

    Lists information about the snapshots of the boot environment.

-H

    Do not list header information. Each field in the list information is separated by a semicolon.

beadm mount *beName mountpoint*

    Mounts a boot environment named *beName* at *mountpoint*. *mountpoint* must be an already existing empty directory.

beadm unmount [-f] *beName*

    Unmounts a boot environment named *beName*.

-f

    Forcefully unmount the boot environment even if it is currently busy.

beadm rename *beName newBeName*

    Renames the boot environment named *beName* to *newBeName*. In a nested BE, only bootable BEs can be renamed.

beadm activate *beName*

    Makes *beName* the active BE on next reboot. In a nested BE, only bootable BEs can be activated.

Nested BE Support   beadm supports the concept of a nested BE, specifically, as it pertains to BEs for non-global zones. Currently, beadm can only manage nested BEs from inside of a non-global zone.

beadm functions inside of a non-global zone much the same as it does from the global zone, with a few exceptions. First, the -p (alternate pool) option to beadm create is not supported within a non-global zone. Second, there is a distinction made for any given nested BE (or snapshot of a BE) to determine if it is bootable or not bootable. A nested BE is bootable if it is associated (that is, shares the same parent id as the active global zone BE's UUID) with the currently active global zone BE. It is unbootable—and marked with an '!' in the active column in beadm list)—otherwise. Note that, while the non-global zone administrator could mark

such a BE as active by means of beadm activate, rebooting the non-global zone would not result in the BE being loaded, because the BE is associated with a non-active global zone BE. Based on these conditions, beadm restricts some actions on unbootable BEs thusly:

- You cannot destroy a nested BE that is both unbootable and marked as active on reboot.
- You cannot activate an unbootable BE.
- You cannot snapshot an unbootable BE.
- You cannot use an unbootable BE or BE snapshot with the -e option to beadm create.
- You cannot rename an unbootable BE.

Examples **EXAMPLE 1** Creating a New BE Using Active BE

The following command creates a new BE, BE1, by cloning the current BE.

```
# beadm create BE1
```

EXAMPLE 2 Creating a New BE Using Inactive BE

The following command creates a new BE, BE2, by cloning the existing inactive BE named BE1.

```
# beadm beadm create -e BE1 BE2
```

EXAMPLE 3 Creating a Snapshot of Existing BE

The following command creates a snapshot named now of the existing BE named BE1.

```
# beadm create BE1@now
```

EXAMPLE 4 Cloning a Snapshot to Create a New BE

The following command creates a new BE named BE3, by cloning an existing snapshot of BE1.

```
# beadm create -e BE1@now BE3
```

EXAMPLE 5 Creating a New BE in Specified zpool

The following command creates a new BE named BE4, based on the currently running BE. The command creates the new BE in the zpool rpool2.

```
# beadm create -p rpool2 BE4
```

EXAMPLE 6 Creating a New BE in Specified zpool with Compression Enabled

The following command creates a new BE named BE5, based on the currently running BE. The command creates the new BE in the zpool rpool2 and creates its datasets with compression turned on.

```
# beadm create -p rpool2 -o compression=on BE5
```

EXAMPLE 7   Creating a New BE and Providing a Description

The following command creates a new BE named BE6, based on the currently running BE, and provides a description for it.

```
# beadm create -d "BE6 used as test environment" BE6
```

EXAMPLE 8   Activating a BE

The following command activates an existing, inactive BE named BE3.

```
# beadm activate BE3
```

EXAMPLE 9   Mounting a BE

The following command mounts the BE named BE3 at /mnt.

```
# beadm mount BE3 /mnt
```

EXAMPLE 10   Unmounting a BE

The following command unmounts the BE named BE3.

```
# beadm unmount BE3
```

EXAMPLE 11   Destroying a BE

The following command destroys the BE named BE3 without asking for confirmation.

```
# beadm destroy -F BE3
```

EXAMPLE 12   Destroying a Snapshot

The following command destroys the snapshot named now of BE1.

```
# beadm destroy BE1@now
```

EXAMPLE 13   Renaming a BE

The following command renames the existing, inactive BE named BE1 to BE3.

```
# beadm rename BE1 BE3
```

EXAMPLE 14   Listing All BEs

The following command lists all existing BEs.

```
# beadm list
BE   Active Mountpoint Space  Policy Created
--   ------ ---------- -----  ------ -------
BE2  -      -          72.0K  static 2008-05-21 12:26
BE3  -      -          332.0K static 2008-08-26 10:28
BE4  -      -          15.78M static 2008-09-05 18:20
BE5  NR     /          7.25G  static 2008-09-09 16:53
```

EXAMPLE 15 Listing All BEs with Dataset and Snapshot Info

The following command lists all existing BEs and list all dataset and snapshot information about those boot environments.

```
# beadm list -d -s
BE/Dataset/Snapshot     Active Mountpoint Space   Policy Created

   p/ROOT/BE5@foo       -      -          912.85M static 2008-06-10 16:37
```

EXAMPLE 16 Listing Dataset and Snapshot Info for a BE

The following command lists all dataset and snapshot information about BE5.

```
# beadm list -a BE5
BE/Dataset/Snapshot     Active Mountpoint Space   Policy Created
------------------      ------ ---------- -----   ------ -------
BE5
   p/ROOT/BE5           NR     /          6.10G   static 2008-09-09 16:53
   p/ROOT/BE5/opt       -      /opt       24.55M  static 2008-09-09 16:53
   p/ROOT/BE5/opt@bar   -      -          18.38M  static 2008-09-10 00:59
   p/ROOT/BE5/opt@foo   -      -          18.38M  static 2008-06-10 16:37
   p/ROOT/BE5@bar       -      -          139.44M static 2008-09-10 00:59
   p/ROOT/BE5@foo       -      -          912.85M static 2008-06-10 16:37
```

EXAMPLE 17 Listing in Machine-Parseable Format

The following command lists information about all BEs in machine-parseable format.

```
# beadm list -H
BE2;;;;;55296;static;1211397974
BE3;;;;;339968;static;1219771706
BE4;;;;;16541696;static;1220664051
BE5;215b8387-4968-627c-d2d0-f4a011414bab;NR;/;7786206208;static;1221004384
```

EXAMPLE 18 Displaying Non-bootable BEs

The following command lists all BEs. When run inside of a non-global zone, it displays both bootable and non-bootable BEs. Non-bootable BEs are designated with an exclamation point (!) in the active column.

```
# beadm list
BE     Active Mountpoint Space   Policy Created
--     ------ ---------- -----   ------ -------
zbe-0 -      -          29.22M  static 2011-03-04 09:14
zbe-1 NR     /          815.10M static 2011-03-04 09:28
zbe-2 -      -          35.0K   static 2011-03-04 09:28
zbe-3 -      -          35.0K   static 2011-03-04 09:28
zbe-4 -      -          35.0K   static 2011-03-04 09:28
zbe-5 !      -          35.0K   static 2011-03-04 11:47
zbe-6 !      -          54.0K   static 2011-03-07 14:37
```

Exit Status 0

Success.

>0

Failure.

Files /var/log/beadm/*beName*/create.log.*yyyymmdd_hhmmss*

Log used for capturing beadm create output. The time designation portion of the file name is explained as follows.

- *yyyymmdd_hhmmss* — for example, 20071130_140558.
- *yyyy* — year, 2007
- *mm* — month, 11
- *dd* — day, 30
- *hh* — hour, 14
- *mm* — minute, 05
- *ss* — second, 58

Name boot – start the system kernel or a standalone program

Synopsis

SPARC boot [*OBP names*] [*file*] [-aLV] [-F *object*] [-D *default-file*]
            [-Z *dataset*] [*boot-flags*] [––] [*client-program-args*]

x86 kernel$ /platform/i86pc/kernel/$ISADIR/unix [*boot-args*]
            [-B *prop*=*val* [,*val*...]]

Description Bootstrapping is the process of loading and executing a standalone program. For the purpose of this discussion, bootstrapping means the process of loading and executing the bootable operating system. Typically, the standalone program is the operating system kernel (see kernel(1M)), but any standalone program can be booted instead. On a SPARC-based system, the diagnostic monitor for a machine is a good example of a standalone program other than the operating system that can be booted.

If the standalone is identified as a dynamically-linked executable, boot will load the interpreter (linker/loader) as indicated by the executable format and then transfer control to the interpreter. If the standalone is statically-linked, it will jump directly to the standalone.

Once the kernel is loaded, it starts the UNIX system, mounts the necessary file systems (see vfstab(4)), and runs /usr/sbin/init to bring the system to the "initdefault" state specified in /etc/inittab. See inittab(4).

SPARC Bootstrap Procedure On SPARC based systems, the bootstrap procedure on most machines consists of the following basic phases.

After the machine is turned on, the system firmware (in PROM) executes power-on self-test (POST). The form and scope of these tests depends on the version of the firmware in your system.

After the tests have been completed successfully, the firmware attempts to autoboot if the appropriate flag has been set in the non-volatile storage area used by the firmware. The name of the file to load, and the device to load it from can also be manipulated.

These flags and names can be set using the eeprom(1M) command from the shell, or by using PROM commands from the ok prompt after the system has been halted.

The second level program is either a fileystem-specific boot block (when booting from a disk), or inetboot or wanboot (when booting across the network).

Network Booting

Network booting occurs in two steps: the client first obtains an IP address and any other parameters necessary to permit it to load the second-stage booter. The second-stage booter in turn loads the boot archive from the boot device.

An IP address can be obtained in one of three ways: RARP, DHCP, or manual configuration, depending on the functions available in and configuration of the PROM. Machines of the sun4u and sun4v kernel architectures have DHCP-capable PROMs.

The boot command syntax for specifying the two methods of network booting are:

```
boot net:rarp
boot net:dhcp
```

The command:

```
boot net
```

without a rarp or dhcp specifier, invokes the default method for network booting over the network interface for which net is an alias.

The sequence of events for network booting using RARP/bootparams is described in the following paragraphs. The sequence for DHCP follows the RARP/bootparams description.

When booting over the network using RARP/bootparams, the PROM begins by broadcasting a reverse ARP request until it receives a reply. When a reply is received, the PROM then broadcasts a TFTP request to fetch the first block of inetboot. Subsequent requests will be sent to the server that initially answered the first block request. After loading, inetboot will also use reverse ARP to fetch its IP address, then broadcast bootparams RPC calls (see bootparams(4)) to locate configuration information and its root file system. inetboot then loads the boot archive by means of NFS and transfers control to that archive.

When booting over the network using DHCP, the PROM broadcasts the hardware address and kernel architecture and requests an IP address, boot parameters, and network configuration information. After a DHCP server responds and is selected (from among potentially multiple servers), that server sends to the client an IP address and all other information needed to boot the client. After receipt of this information, the client PROM examines the name of the file to be loaded, and will behave in one of two ways, depending on whether the file's name appears to be an HTTP URL. If it does not, the PROM downloads inetboot, loads that file into memory, and executes it. inetboot loads the boot archive, which takes over the machine and releases inetboot. Startup scripts then initiate the DHCP agent (see dhcpagent(1M)), which implements further DHCP activities.

If the file to be loaded is an HTTP URL, the PROM will use HTTP to load the referenced file. If the client has been configured with an HMAC SHA-1 key, it will check the integrity of the loaded file before proceeding to execute it. The file is expected to be the wanboot binary. The WAN boot process can be configured to use either DHCP or NVRAM properties to discover the install server and router and the proxies needed to connect to it. When wanboot begins executing, it determines whether sufficient information is available to it to allow it to proceed. If any necessary information is missing, it will either exit with an appropriate error or bring up a command interpreter and prompt for further configuration information. Once wanboot has obtained the necessary information, it loads the boot loader into memory by means of HTTP.

If an encryption key has been installed on the client, wanboot will verify the boot loader's signature and its accompanying hash. Presence of an encryption key but no hashing key is an error.

The wanboot boot loader can communicate with the client using either HTTP or secure HTTP. If the former, and if the client has been configured with an HMAC SHA-1 key, the boot loader will perform an integrity check of the root file system. Once the root file system has been loaded into memory (and possibly had an integrity check performed), the boot archive is transferred from the server. If provided with a boot_logger URL by means of the wanboot.conf(4) file, wanboot will periodically log its progress.

Not all PROMs are capable of consuming URLs. You can determine whether a client is so capable using the list-security-keys OBP command (see monitor(1M)).

WAN booting is not currently available on the x86 platform.

The wanboot Command Line

When the client program is wanboot, it accepts client-program-args of the form:

boot ... -o *opt1*[,*opt2*[,...]]

where each option may be an action:

dhcp
    Require wanboot to obtain configuration parameters by means of DHCP.

prompt
    Cause wanboot to enter its command interpreter.

<cmd>
    One of the interpreter commands listed below.

...or an assignment, using the interpreter's parameter names listed below.

The wanboot Command Interpreter

The wanboot command interpreter is invoked by supplying a client-program-args of "-o prompt" when booting. Input consists of single commands or assignments, or a comma-separated list of commands or assignments. The configuration parameters are:

host-ip
    IP address of the client (in dotted-decimal notation)

router-ip
    IP address of the default router (in dotted-decimal notation)

subnet-mask
    subnet mask (in dotted-decimal notation)

client-id
    DHCP client identifier (a quoted ASCII string or hex ASCII)

hostname
> hostname to request in DHCP transactions (ASCII)

http-proxy
> HTTP proxy server specification (IPADDR[:PORT])

The key names are:

3des
> the triple DES encryption key (48 hex ASCII characters)

aes
> the AES encryption key (32 hex ASCII characters)

sha1
> the HMAC SHA-1 signature key (40 hex ASCII characters)

Finally, the URL or the WAN boot CGI is referred to by means of:

bootserver
> URL of WAN boot's CGI (the equivalent of OBP's file parameter)

The interpreter accepts the following commands:

help
> Print a brief description of the available commands

var=val
> Assign *val* to *var*, where *var* is one of the configuration parameter names, the key names, or bootserver.

var=
> Unset parameter *var*.

list
> List all parameters and their values (key values retrieved by means of OBP are never shown).

prompt
> Prompt for values for unset parameters. The name of each parameter and its current value (if any) is printed, and the user can accept this value (press Return) or enter a new value.

go
> Once the user is satisfied that all values have been entered, leave the interpreter and continue booting.

exit
> Quit the boot interpreter and return to OBP's ok prompt.

Any of these assignments or commands can be passed on the command line as part of the -o options, subject to the OBP limit of 128 bytes for boot arguments. For example, -o list,go would simply list current (default) values of the parameters and then continue booting.

iSCSI Boot   iSCSI boot is supported on both x86 and SPARC.

iSCSI Boot on x86

For iSCSI boot on x86, the host being booted must be equipped with NIC(s) capable of iBFT (iSCSI Boot Firmware Table) or have the mainboard's BIOS be iBFT-capable. iBFT, defined in the Advanced Configuration and Power Interface (ACPI) 3.0b specification, specifies a block of information that contains various parameters that are useful to the iSCSI Boot process.

Firmware implementing iBFT presents an iSCSI disk in the BIOS during startup as a bootable device by establishing the connection to the iSCSI target. The rest of the process of iSCSI booting is the same as booting from a local disk.

To configure the iBFT properly, users need to refer to the documentation from their hardware vendors.

iSCSI Boot on SPARC

iSCSI boot on SPARC is supported with OpenBoot level 4.31 and above, and does not require a specific NIC.

The boot command in OpenBoot takes a series of keywords to identify the destination iSCSI target, following the *keyword=value* format. The complete form of the iSCSI boot command is:

```
boot net:iscsi-target-ip=t-ip,iscsi-target-name=name
     host-ip=h-ip[,router-ip=r-ip]
     [,subnet-mask=m-ip]
     [,iscsi-port=port]
     [,iscsi-lun=lun]
     [,iscsi-partition=partition]
```

The descriptions of the preceding keywords are as follows:

host-ip   IP address of booting host.

router-ip   IP address of routing gateway.

subnet-mask   Subnet mask of host-ip.

iscsi-target-ip   IP address of iSCSI target storing OS.

iscsi-target-name   Name of iSCSI target storing OS.

iscsi-partition   Partition containing the bootable root.

iscsi-port   IP port of the target.

iscsi-lun   LUN to be booted off on target.

The values of iscsi-target-ip, route-ip, and subnet-mask are in standard, IPv4 dotted-decimal format; for example, 255.255.255.0 for subnet-mask. IPv6 is not supported in the current OpenBoot implementation.

The value of iscsi-port, a decimal number, is in the range of 1 to 65535.

The value of iscsi-lun is in the format of a dashed hexadecimal LUN, *ffff-ffff-ffff-ffff*. Please refer to section 5 of RFC 4173 for details. Leading zeroes and trailing dashes can be excluded, thus, 3, for example, is equivalent to 0003-0000-0000-0000.

The value of iscsi-partition is one ASCII character, used to specify the root partition. Most commonly, it is a.

The value of iscsi-target-name is in the format of a string, as specified by RFC 3720 and RFC 3722.

Two security keys are added to provide CHAP authentication on the target side. These are:

chap-user   CHAP name

chap-password   CHAP secret

Currently these two keys can be set with the command set-ascii-security-key at the Open Boot PROM (ok) prompt. For example:

```
ok set-ascii-security-key chap-user chap name
ok set-ascii-security-key chap-password chap password
```

Bi-directional authentication is not yet supported. These two variables can be changed only under the Open Boot PROM prompt.

RFC 4173 is supported, to retrieve iSCSI boot information from a DHCP server. The DHCP server must specify the Root Path option for the booting client, after which the client can do an iSCSI boot by means of the simple command:

```
boot net:dhcp
```

Currently the key boot-device is used to retrieve the physical boot device path during iSCSI boot. This key is setup during the Solaris installation. A manually modified key value might break iSCSI boot.

Booting from Disk   When booting from disk, the OpenBoot PROM firmware reads the boot blocks from blocks 1 to 15 of the partition specified as the boot device. This standalone booter usually contains a file system-specific reader capable of reading the boot archive.

If the pathname to the standalone is relative (does not begin with a slash), the second level boot will look for the standalone in a platform-dependent search path. This path is guaranteed to contain /platform/*platform-name*. Many SPARC platforms next search the platform-specific path entry /platform/*hardware-class-name*. See filesystem(5). If the pathname is absolute, boot will use the specified path. The boot program then loads the standalone at the appropriate address, and then transfers control.

Once the boot archive has been transferred from the boot device, Solaris can initialize and take over control of the machine. This process is further described in the "Boot Archive Phase," below, and is identical on all platforms.

If the filename is not given on the command line or otherwise specified, for example, by the `boot-file` NVRAM variable, boot chooses an appropriate default file to load based on what software is installed on the system and the capabilities of the hardware and firmware.

The path to the kernel must not contain any whitespace.

Booting from ZFS Booting from ZFS differs from booting from UFS in that, with ZFS, a device specifier identifies a storage pool, not a single root file system. A storage pool can contain multiple bootable datasets (that is, root file systems). Therefore, when booting from ZFS, it is not sufficient to specify a boot device. One must also identify a root file system within the pool that was identified by the boot device. By default, the dataset selected for booting is the one identified by the pool's `bootfs` property. This default selection can be overridden by specifying an alternate bootable dataset with the `-Z` option. Use the `-L` option to list the bootable datasets within a ZFS pool.

Boot Archive Phase The boot archive contains a file system image that is mounted using an in-memory disk. The image is self-describing, specifically containing a file system reader in the boot block. This file system reader mounts and opens the RAM disk image, then reads and executes the kernel contained within it. By default, this kernel is in:

```
/platform/'uname -i'/kernel/unix
```

If booting from ZFS, the pathnames of both the archive and the kernel file are resolved in the root file system (that is, dataset) selected for booting as described in the previous section.

The initialization of the kernel continues by loading necessary drivers and modules from the in-memory filesystem until I/O can be turned on and the root filesystem mounted. Once the root filesystem is mounted, the in-memory filesystem is no longer needed and is discarded.

OpenBoot PROM boot Command Behavior The OpenBoot boot command takes arguments of the following form:

```
ok boot [device-specifier] [arguments]
```

The default boot command has no arguments:

```
ok boot
```

If no *device-specifier* is given on the boot command line, OpenBoot typically uses the *boot-device* or *diag-device* NVRAM variable. If no optional *arguments* are given on the command line, OpenBoot typically uses the *boot-file* or *diag-file* NVRAM variable as default boot arguments. (If the system is in diagnostics mode, *diag-device* and *diag-file* are used instead of *boot-device* and *boot-file*).

arguments may include more than one string. All *argument* strings are passed to the secondary booter; they are not interpreted by OpenBoot.

If any *arguments* are specified on the boot command line, then neither the *boot-file* nor the *diag-file* NVRAM variable is used. The contents of the NVRAM variables are not merged with command line arguments. For example, the command:

```
ok boot -s
```

ignores the settings in both *boot-file* and *diag-file*; it interprets the string "-s" as *arguments*. boot will not use the contents of *boot-file* or *diag-file*.

With older PROMs, the command:

```
ok boot net
```

took no arguments, using instead the settings in *boot-file* or *diag-file* (if set) as the default file name and arguments to pass to boot. In most cases, it is best to allow the boot command to choose an appropriate default based upon the system type, system hardware and firmware, and upon what is installed on the root file system. Changing *boot-file* or *diag-file* can generate unexpected results in certain circumstances.

This behavior is found on most OpenBoot 2.x and 3.x based systems. Note that differences may occur on some platforms.

The command:

ok **boot cdrom**

...also normally takes no arguments. Accordingly, if *boot-file* is set to the 64-bit kernel filename and you attempt to boot the installation CD or DVD with boot cdrom, boot will fail if the installation media contains only a 32-bit kernel.

Because the contents of *boot-file* or *diag-file* can be ignored depending on the form of the boot command used, reliance upon *boot-file* should be discouraged for most production systems.

When executing a WAN boot from a local (CD or DVD) copy of wanboot, one must use:

ok **boot cdrom -F wanboot - install**

Modern PROMs have enhanced the network boot support package to support the following syntax for arguments to be processed by the package:

[*protocol*,] [*key=value*,]*

All arguments are optional and can appear in any order. Commas are required unless the argument is at the end of the list. If specified, an argument takes precedence over any default values, or, if booting using DHCP, over configuration information provided by a DHCP server for those parameters.

protocol, above, specifies the address discovery protocol to be used.

Configuration parameters, listed below, are specified as *key=value* attribute pairs.

tftp-server
   IP address of the TFTP server

file
   file to download using TFTP or URL for WAN boot

host-ip
   IP address of the client (in dotted-decimal notation)

router-ip
   IP address of the default router

subnet-mask
   subnet mask (in dotted-decimal notation)

client-id
   DHCP client identifier

hostname
   hostname to use in DHCP transactions

http-proxy
   HTTP proxy server specification (IPADDR[:PORT])

tftp-retries
   maximum number of TFTP retries

dhcp-retries
   maximum number of DHCP retries

The list of arguments to be processed by the network boot support package is specified in one of two ways:

- As arguments passed to the package's open method, or
- arguments listed in the NVRAM variable network-boot-arguments.

Arguments specified in network-boot-arguments will be processed only if there are no arguments passed to the package's open method.

Argument Values

protocol specifies the address discovery protocol to be used. If present, the possible values are rarp or dhcp.

If other configuration parameters are specified in the new syntax and style specified by this document, absence of the *protocol* parameter implies manual configuration.

If no other configuration parameters are specified, or if those arguments are specified in the positional parameter syntax currently supported, the absence of the *protocol* parameter causes the network boot support package to use the platform-specific default address discovery protocol.

Manual configuration requires that the client be provided its IP address, the name of the boot file, and the address of the server providing the boot file image. Depending on the network configuration, it might be required that subnet-mask and router-ip also be specified.

If the *protocol* argument is not specified, the network boot support package uses the platform-specific default address discovery protocol.

tftp-server is the IP address (in standard IPv4 dotted-decimal notation) of the TFTP server that provides the file to download if using TFTP.

When using DHCP, the value, if specified, overrides the value of the TFTP server specified in the DHCP response.

The TFTP RRQ is unicast to the server if one is specified as an argument or in the DHCP response. Otherwise, the TFTP RRQ is broadcast.

file specifies the file to be loaded by TFTP from the TFTP server, or the URL if using HTTP. The use of HTTP is triggered if the file name is a URL, that is, the file name starts with http: (case-insensitive).

When using RARP and TFTP, the default file name is the ASCII hexadecimal representation of the IP address of the client, as documented in a preceding section of this document.

When using DHCP, this argument, if specified, overrides the name of the boot file specified in the DHCP response.

When using DHCP and TFTP, the default file name is constructed from the root node's name property, with commas (,) replaced by periods (.).

When specified on the command line, the filename must not contain slashes (/).

The format of URLs is described in RFC 2396. The HTTP server must be specified as an IP address (in standard IPv4 dotted-decimal notation). The optional port number is specified in decimal. If a port is not specified, port 80 (decimal) is implied.

The URL presented must be "safe-encoded", that is, the package does not apply escape encodings to the URL presented. URLs containing commas must be presented as a quoted string. Quoting URLs is optional otherwise.

host-ip specifies the IP address (in standard IPv4 dotted-decimal notation) of the client, the system being booted. If using RARP as the address discovery protocol, specifying this argument makes use of RARP unnecessary.

If DHCP is used, specifying the `host-ip` argument causes the client to follow the steps required of a client with an "Externally Configured Network Address", as specified in RFC 2131.

`router-ip` is the IP address (in standard IPv4 dotted-decimal notation) of a router on a directly connected network. The router will be used as the first hop for communications spanning networks. If this argument is supplied, the router specified here takes precedence over the preferred router specified in the DHCP response.

`subnet-mask` (specified in standard IPv4 dotted-decimal notation) is the subnet mask on the client's network. If the subnet mask is not provided (either by means of this argument or in the DHCP response), the default mask appropriate to the network class (Class A, B, or C) of the address assigned to the booting client will be assumed.

`client-id` specifies the unique identifier for the client. The DHCP client identifier is derived from this value. Client identifiers can be specified as:

- The ASCII hexadecimal representation of the identifier, or
- a quoted string

Thus, `client-id="openboot"` and `client-id=6f70656e626f6f74` both represent a DHCP client identifier of 6F70656E626F6F74.

Identifiers specified on the command line must must not include slash (`/`) or spaces.

The maximum length of the DHCP client identifier is 32 bytes, or 64 characters representing 32 bytes if using the ASCII hexadecimal form. If the latter form is used, the number of characters in the identifier must be an even number. Valid characters are 0-9, a-f, and A-F.

For correct identification of clients, the client identifier must be unique among the client identifiers used on the subnet to which the client is attached. System administrators are responsible for choosing identifiers that meet this requirement.

Specifying a client identifier on a command line takes precedence over any other DHCP mechanism of specifying identifiers.

`hostname` (specified as a string) specifies the hostname to be used in DHCP transactions. The name might or might not be qualified with the local domain name. The maximum length of the hostname is 255 characters.

Note – The `hostname` parameter can be used in service environments that require that the client provide the desired hostname to the DHCP server. Clients provide the desired hostname to the DHCP server, which can then register the hostname and IP address assigned to the client with DNS.

`http-proxy` is specified in the following standard notation for a host:

host [`":""` *port*]

...where *host* is specified as an IP ddress (in standard IPv4 dotted-decimal notation) and the optional *port* is specified in decimal. If a port is not specified, port 8080 (decimal) is implied.

`tftp-retries` is the maximum number of retries (specified in decimal) attempted before the TFTP process is determined to have failed. Defaults to using infinite retries.

`dhcp-retries` is the maximum number of retries (specified in decimal) attempted before the DHCP process is determined to have failed. Defaults to of using infinite retries.

x86 Bootstrap Procedure
On x86 based systems, the bootstrapping process consists of two conceptually distinct phases, kernel loading and kernel initialization. Kernel loading is implemented in GRUB (GRand Unified Bootloader) using the BIOS ROM on the system board, and BIOS extensions in ROMs on peripheral boards. The BIOS loads GRUB, starting with the first physical sector from a hard disk, DVD, or CD. If supported by the ROM on the network adapter, the BIOS can also download the pxegrub binary from a network boot server. Once GRUB is located, it executes a command in a menu to load the unix kernel and a pre-constructed boot archive containing kernel modules and data.

If the device identified by GRUB as the boot device contains a ZFS storage pool, the menu.lst file used to create the GRUB menu will be found in the dataset at the root of the pool's dataset hierarchy. This is the dataset with the same name as the pool itself. There is always exactly one such dataset in a pool, and so this dataset is well-suited for pool-wide data such as the menu.lst file. After the system is booted, this dataset is mounted at /*poolname* in the root file system.

There can be multiple bootable datasets (that is, root file systems) within a pool. By default, the file system in which file name entries in a menu.lst file are resolved is the one identified by the pool's bootfs property (see zpool(1M)). However, a menu.lst entry can contain a bootfs command, which specifies an alternate dataset in the pool. In this way, the menu.lst file can contain entries for multiple root file systems within the pool.

Kernel initialization starts when GRUB finishes loading the boot archive and hands control over to the unix binary. At this point, GRUB becomes inactive and no more I/O occurs with the boot device. The Unix operating system initializes, links in the necessary modules from the boot archive and mounts the root file system on the real root device. At this point, the kernel regains storage I/O, mounts additional file systems (see vfstab(4)), and starts various operating system services (see smf(5)).

Enabling Automatic Rebooting (x86)
The Solaris operating system supports an smf(5) property that enables a system to automatically reboot from the current boot device, to recover from conditions such as an out-of-date boot archive.

The service svc:/system/boot-config:default contains the boolean property auto-reboot-safe, which is set to false by default. Setting it to true communicates that both the system's BIOS and default GRUB menu entry are set to boot from the current boot device. The value of this property can be changed using svccfg(1M) and svcadm(1M). For example, to set auto-reboot-safe to enable automatic rebooting, enter a command such as:

```
example# svccfg -s svc:/system/boot-config:default \
    setprop config/auto-reboot-safe = true
```

Most systems are configured for automatic reboot from the current boot device. However, in some instances, automatic rebooting to an unknown operating system might produce undesirable results. For these instances, the auto-reboot-safe property allows you to specify the behavior you want.

Failsafe Mode   A requirement of booting from a root filesystem image built into a boot archive then remounting root onto the actual root device is that the contents of the boot archive and the root filesystem must be consistent. Otherwise, the proper operation and integrity of the machine cannot be guaranteed.

The term "consistent" means that all files and modules in the root filesystem are also present in the boot archive and have identical contents. Since the boot strategy requires first reading and mounting the boot archive as the first-stage root image, all unloadable kernel modules and initialization derived from the contents of the boot archive are required to match the real root filesystem. Without such consistency, it is possible that the system could be running with a kernel module or parameter setting applied to the root device before reboot, but not yet updated in the root archive. This inconsistency could result in system instability or data loss.

Once the root filesystem is mounted, and before relinquishing the in-memory filesystem, Solaris performs a consistency verification against the two file systems. If an inconsistency is detected, Solaris suspends the normal boot sequence and falls back to failsafe mode. Correcting this state requires the administrator take one of two steps. The recommended procedure is to reboot to the failsafe archive and rebuild the boot archive. This ensures that a known kernel is booted and functioning for the archive rebuild process. Alternatively, the administrator can elect to clear the inconsistent boot archive service state and continue system bring-up if the inconsistency is such that correct system operation will not be impaired. See svcadm(1M).

If the boot archive service is cleared and system bring-up is continued (the second alternative above), the system may be running with unloadable kernel drivers or other modules that are out-of-date with respect to the root filesystem. As such, correct system operation may be compromised.

To ensure that the boot archive is consistent, the normal system shutdown process, as initiated by reboot(1M) and shutdown(1M), checks for and applies updates to the boot archive at the conclusion of the umountall(1M) milestone.

An update to any kernel file, driver, module or driver configuration file that needs to be included in the boot archive after the umountall service is complete will result in a failed boot archive consistency check during the next boot. To avoid this, it is recommended to always shut down a machine cleanly.

If an update is required to the kernel after completion of the umountall service, the administrator may elect to rebuild the archive by invoking:

```
# bootadm update-archive
```

Failsafe Boot Archive   The failsafe archive can be used to boot the machine at any time for maintenance or troubleshooting. The failsafe boot archive is installed on the machine, sourced from the miniroot archive. Booting the failsafe archive causes the machine to boot using the in-memory filesystem as the root device.

SPARC

The SPARC failsafe archive is:

```
/platform/'uname -i'/failsafe
```

...and can be booted as follows:

ok **boot [***device-specifier***] -F failsafe**

If a user wishes to boot a failsafe archive from a particular ZFS bootable dataset, this can be done as follows:

ok **boot [***device-specifier***] -Z** *dataset* **-F failsafe**

x86

The x86 failsafe archive is:

```
/boot/x86.miniroot-safe
```

...and can be booted by selecting the Solaris failsafe item from the GRUB menu.

Options

SPARC   The following SPARC options are supported:

-a
> The boot program interprets this flag to mean ask me, and so it prompts for the name of the standalone. The '-a' flag is then passed to the standalone program.

-D *default-file*
> Explicitly specify the *default-file*. On some systems, boot chooses a dynamic default file, used when none is otherwise specified. This option allows the *default-file* to be explicitly set and can be useful when booting kmdb(1) since, by default, kmdb loads the default-file as exported by the boot program.

-F *object*
> Boot using the named object. The object must be either an ELF executable or bootable object containing a boot block. The primary use is to boot the failsafe or wanboot boot archive.

-L
    List the bootable datasets within a ZFS pool. You can select one of the bootable datasets in the list, after which detailed instructions for booting that dataset are displayed. Boot the selected dataset by following the instructions. This option is supported only when the boot device contains a ZFS storage pool.

-V
    Display verbose debugging information.

boot-flags
    The boot program passes all *boot-flags* to file. They are not interpreted by boot. See the kernel(1M) and kmdb(1) manual pages for information about the options available with the default standalone program.

client-program-args
    The boot program passes all *client-program-args* to *file*. They are not interpreted by boot.

file
    Name of a standalone program to boot. If a filename is not explicitly specified, either on the boot command line or in the *boot-file* NVRAM variable, boot chooses an appropriate default filename.

OBP names
    Specify the open boot prom designations. For example, on Desktop SPARC based systems, the designation /sbus/esp@0,800000/sd@3,0:a indicates a SCSI disk (sd) at target 3, lun0 on the SCSI bus, with the esp host adapter plugged into slot 0.

-Z *dataset*
    Boot from the root file system in the specified ZFS dataset.

x86   The following x86 options are supported:

-B *prop=val*...
    One or more property-value pairs to be passed to the kernel. Multiple property-value pairs must be separated by a comma. Use of this option is the equivalent of the command: eeprom *prop=val*. See eeprom(1M) for available properties and valid values.

    If the root file system corresponding to this menu entry is a ZFS dataset, the menu entry needs the following option added:

    -B $ZFS-BOOTFS

boot-args
    The boot program passes all *boot-args* to file. They are not interpreted by boot. See kernel(1M) and kmdb(1) for information about the options available with the kernel.

    Unless otherwise specified, an x86 system will boot /platform/i86pc/kernel/amd64/unix.

x86 Boot Sequence Details After a PC-compatible machine is turned on, the system firmware in the BIOS ROM executes a power-on self test (POST), runs BIOS extensions in peripheral board ROMs, and invokes software interrupt INT 19h, Bootstrap. The INT 19h handler typically performs the standard PC-compatible boot, which consists of trying to read the first physical sector from the first hard disk. The processor then jumps to the first byte of the sector image in memory.

x86 Primary Boot The first sector on a disk medium contains the master boot block (GRUB stage1). The stage 1 is responsible for loading GRUB stage2. Now GRUB is fully functional. It reads and executes the menu file /boot/grub/menu.lst. A similar sequence occurs for DVD or CD boot, but the master boot block location and contents are dictated by the El Torito specification. The El Torito boot also leads to strap.com, which in turn loads boot.bin.

The first sector on a hard disk contains the master boot block, which contains the master boot program and the FDISK table, named for the PC program that maintains it. The master boot finds the active partition in the FDISK table, loads its first sector (GRUB stage1), and jumps to its first byte in memory. This completes the standard PC-compatible hard disk boot sequence. If GRUB stage1 is installed on the master boot block (see the -m option of installgrub(1M)), then stage2 is loaded directly from the Solaris FDISK partition regardless of the active partition.

An x86 FDISK partition for the Solaris software begins with a one-cylinder boot slice, which contains GRUB stage1 in the first sector, the standard Solaris disk label and volume table of contents (VTOC) in the second and third sectors, and GRUB stage2 in the fiftieth and subsequent sectors. The area from sector 4 to 49 might contain boot blocks for older versions of Solaris. This makes it possible for multiple Solaris releases on the same FDISK to coexist. When the FDISK partition for the Solaris software is the active partition, the master boot program (mboot) reads the partition boot program in the first sector into memory and jumps to it. It in turn reads GRUB stage2 program into memory and jumps to it. Once the GRUB menu is displayed, the user can choose to boot an operating system on a different partition, a different disk, or possibly from the network.

For network booting, the supported method is Intel's Preboot eXecution Environment (PXE) standard. When booting from the network using PXE, the system or network adapter BIOS uses DHCP to locate a network bootstrap program (pxegrub) on a boot server and reads it using Trivial File Transfer Protocol (TFTP). The BIOS executes the pxegrub by jumping to its first byte in memory. The pxegrub program downloads a menu file and presents the entries to user.

x86 Kernel Startup The kernel startup process is independent of the kernel loading process. During kernel startup, console I/O goes to the device specified by the console property.

When booting from UFS, the root device is specified by the bootpath property, and the root file system type is specified by the fstype property. These properties should be setup by the Solaris Install/Upgrade process in /boot/solaris/bootenv.rc and can be overridden with the -B option, described above (see the eeprom(1M) man page).

When booting from ZFS, the root device is specified by a boot parameter specified by the `-B` `$ZFS-BOOTFS` parameter on either the kernel or module line in the GRUB menu entry. This value (as with all parameters specified by the `-B` option) is passed by GRUB to the kernel.

If the console properties are not present, console I/O defaults to `screen` and `keyboard`. The root device defaults to `ramdisk` and the file system defaults to `ufs`.

Examples

SPARC **EXAMPLE 1** To Boot the Default Kernel In Single-User Interactive Mode

To boot the default kernel in single-user interactive mode, respond to the `ok` prompt with one of the following:

```
boot -as
```

```
boot disk3 -as
```

EXAMPLE 2 Network Booting with WAN Boot-Capable PROMs

To illustrate some of the subtle repercussions of various boot command line invocations, assume that the `network-boot-arguments` are set and that `net` is devaliased as shown in the commands below.

In the following command, device arguments in the device alias are processed by the device driver. The network boot support package processes arguments in `network-boot-arguments`.

boot net

The command below results in no device arguments. The network boot support package processes arguments in `network-boot-arguments`.

boot net:

The command below results in no device arguments. `rarp` is the only network boot support package argument. `network-boot-arguments` is ignored.

boot net:rarp

In the command below, the specified device arguments are honored. The network boot support package processes arguments in `network-boot-arguments`.

boot net:speed=100,duplex=full

EXAMPLE 3 Using wanboot with Older PROMs

The command below results in the `wanboot` binary being loaded from DVD or CD, at which time `wanboot` will perform DHCP and then drop into its command interpreter to allow the user to enter keys and any other necessary configuration.

boot cdrom -F wanboot -o dhcp,prompt

x86   **EXAMPLE 4**   To Boot the Default Kernel in Single-User Interactive Mode

To boot the default kernel in single-user interactive mode, edit the GRUB kernel command line to read:

```
kernel /platform/i86pc/kernel/amd64/unix -as
```

Files   /etc/inittab

Table in which the initdefault state is specified

/usr/sbin/init

Program that brings the system to the initdefault state

SPARC Only   /platform/*platform-name*/kernel/sparcv9/unix

Default program to boot system.

x86 Only   /boot

Directory containing boot-related files.

/rpool/boot/grub/menu.lst

Menu of bootable operating systems displayed by GRUB. /rpool is a common convention. The pathname is configurable, depending on the capabilities of your installer.

/platform/i86pc/kernel/amd64/unix

Default program to boot system.

Oracle Solaris Administration: Common Tasks

Sun Hardware Platform Guide

OpenBoot Command Reference Manual

Warnings   The boot utility is unable to determine which files can be used as bootable programs. If the booting of a file that is not bootable is requested, the boot utility loads it and branches to it. What happens after that is unpredictable.

Notes   *platform-name* can be found using the -i option of uname(1). *hardware-class-name* can be found using the -m option of uname(1).

The current release of the Solaris operating system does not support machines running an UltraSPARC-I CPU.

Name bootadm – manage bootability of GRUB-enabled operating system

Synopsis `/usr/sbin/bootadm update-archive [-vn] [-R` *altroot* `[-p` *platform*`]]`

`/usr/sbin/bootadm list-archive [-vn] [-R` *altroot* `[-p` *platform*`]]`

  `x86 only`

`/usr/sbin/bootadm set-menu [-R` *altroot* `[-p` *platform*`]]` *key=value*

`/usr/sbin/bootadm list-menu [-R` *altroot* `[-p` *platform*`]]`

Description The `bootadm` command manages the boot archive and, with x86 boot environments, the GRUB (GRand Unified Bootloader) menu. The `update–archive` option provides a way for user to update the boot archive as a preventative measure or as part of a recovery procedure. The `set-menu` subcommand allows you to switch the `auto-boot` timeout and default boot entry in the GRUB menu.

The `list-menu` subcommand displays the location of the GRUB menu and the current GRUB menu entries. While the typical location of the GRUB menu under ZFS is `/rpool/boot/grub/menu.lst`, depending on the install method used, the active GRUB menu might be located somewhere else. Use the `list-menu` subcommand to locate the active GRUB menu. For example, if a system was installed using Live Upgrade, the GRUB menu might not be located in the current boot environment. See the EXAMPLES section for typical output from the `list-menu` option.

Note that OpenBoot PROM (OBP)-based machines, such as SPARC systems, do not use GRUB and have no boot menu manageable by `bootadm`.

The `bootadm` command determines dynamically the options supported by the image to be managed, so that `bootadm` invoked on one platform can be used to manage diskless clients of a different platform type.

Subcommands The `bootadm` command has the following subcommands:

`update-archive`
    Updates current boot archive if required. Applies to both SPARC and x86 platforms.

`list-archive`
    Lists the files and directories to be included in the boot archive. Applies to both SPARC and x86 platforms.

`set-menu`
    Maintain the GRUB menu. The current GRUB menu is `boot/grub/menu.lst`, relative to root. Do not depend on this location, because it is subject to change. Applies to x86 platforms only.

`list-menu`
    Lists the location of the active GRUB menu, as well as the current GRUB menu entries. This includes the autoboot-timeout, the default entry number, and the title of each entry. Applies to x86 platforms only.

Options The bootadm command has the following options:

-v

In an update-archive operation, stale files are displayed on stderr.

-n

In an update-archive operation, archive content is checked but not updated.

-p *platform*

The platform, or machine hardware class, of the client. The platform type can only be specified together with -R, and is generally useful only for managing a diskless client where the client is of a different platform class than the server. Platform must be one of i86pc, sun4u, or sun4v.

-R *altroot*

Operation is applied to an alternate root path.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

key=value

Possible values are:

default=*entrynum*

The item number (for example, 0, 1, or 2) in the GRUB menu designating the operating system to boot when the timer expires.

timeout=*seconds*

The number of seconds before the operating system designated by the default item number is booted. If the value is –1, auto boot is disabled.

Examples **EXAMPLE 1** Updating the Current Boot Archive

The following command updates the current boot archive:

```
# bootadm update-archive
```

EXAMPLE 2 Updating the Boot Archive on an Alternate Root

The following command updates the boot archive on an alternate root:

```
# bootadm update-archive -R /a
```

EXAMPLE 3 Listing Installed OS Instances

The following command lists the installed operating system instances in a GRUB menu:

```
# bootadm list-menu

default=0
```

EXAMPLE 3 Listing Installed OS Instances   *(Continued)*

```
timeout=10
(0) Solaris10
(1) Solaris10 Failsafe
(2) Linux
```

EXAMPLE 4 Switching Default Boot Entry

The following command refers to the menu displayed in the previous example. The user selects Linux (item 2).

```
# bootadm set-menu default=2
```

EXAMPLE 5 Listing GRUB Menu Entries and Location of GRUB Menu

The following command lists the GRUB menu entries and the location of the GRUB menu:

```
# bootadm list-menu
The location for the active GRUB menu is: /stubboot/boot/grub/menu.lst
default 0
timeout 10
0 Solaris10
1 Solaris10 failsafe
2 Linux
```

EXAMPLE 6 Displaying Location of GRUB Menu

The following command displays the location of the GRUB menu:

```
# bootadm list-menu
The location for the active GRUB menu is: /dev/dsk/c0t1d0s0 (not mounted)
The filesystem type of the menu device is <ufs>
default 2
timeout 10
0 c0t1d0s3
1 c0t1d0s3 failsafe
2 Solaris10
3 Solaris10 failsafe
```

In this example, the active GRUB menu is located on a device which is *not* mounted. To access the GRUB menu, mount the device and access the GRUB menu at *<mountpoint>*/boot/grub/menu.lst.

Exit Status The following exit values are returned:

0

   The command completed successfully.

1

   The command exited due to an error.

Attributes   See attributes(5) for descriptions of the following attributes:

Consult the GRUB home page, under:

http://www.gnu.org/

Name bootconfchk – verify the integrity of a network boot configuration file

Synopsis /usr/sbin/bootconfchk [*bootconf-file*]

Description The bootconfchk command checks that the file specified is a valid network boot configuration file as described in wanboot.conf(4).

Any discrepancies are reported on standard error.

Exit Status 0 Successful completion.

1 An error occurred.

2 Usage error.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/boot/wanboot
Interface Stability	Committed

See Also wanboot.conf(4), attributes(5)

Name busstat – report bus-related performance statistics

Synopsis busstat -e *device-inst* | -h | -l

busstat [-a] [-n]
    [-w *device-inst* [,pic0=*event*,pic*n*=*event*]]...
    [-r *device-inst*]... [*interval* [*count*]]

Description busstat provides access to the bus-related performance counters in the system. These performance counters allow for the measurement of statistics like hardware clock cycles, bus statistics including DMA and cache coherency transactions on a multiprocessor system. Each bus device that supports these counters can be programmed to count a number of events from a specified list. Each device supports one or more Performance Instrumentation Counters (PIC) that are capable of counting events independently of each other.

Separate events can be selected for each PIC on each instance of these devices. busstat summarizes the counts over the last interval seconds, repeating forever. If a count is given, the statistics are repeated count times.

Only root users can program these counters. Non-root users have the option of reading the counters that have been programmed by a root user.

The default value for the *interval* argument is 1 second, and the default *count* is unlimited.

The devices that export these counters are highly platform-dependent and the data may be difficult to interpret without an in-depth understanding of the operation of the components that are being measured and of the system they reside in.

Options The following options are supported:

-a	Display absolute counter values. The default is delta values.
-e *device-inst*	Display the list of events that the specified device supports for each pic.
	Specify *device-inst* as device (name) followed by an optional instance number. If an instance number is specified, the events for that instance are displayed. If no instance number is specified, the events for the first instance of the specified device are displayed.
-h	Print a usage message.
-l	List the devices in the system which support performance counters.
-n	Do not display a title in the output. The default is to display titles.

-r *device-inst*	Read and display all pic values for the specified device
	Specify *device-inst* as *device* (name) followed by *instance number*, if specifying an instance number of a device whose counters are to be read and displayed. If all instances of this device are to be read, use *device* (name) without an instance number. All pic values will be sampled when using the -r option.
-w *device-inst* [,pic0=*event*] [,pic*n*=*event*]	Program (write) the specified devices to count the specified events. Write access to the counters is restricted to root users only. Non-root users can use -r option.
	Specify *device-inst* as *device* (name) followed by an optional *instance number*. If specifying an instance number of a device to program these events on. If all instances of this device are to be programmed the same, then use *device* without an instance number. Specify an event to be counted for a specified pic by providing a comma separated list of pic*n*=*event* values.

The -e option displays all valid event names for each device. Any devices that are programmed will be sampled every interval seconds and repeated count times. It is recommended that the interval specified is small enough to ensure that counter wraparound will be detected. The rate at which counters wraparound varies from device to device. If a user is programming events using the -w option and busstat detects that another user has changed the events that are being counted, the tool will terminate as the programmed devices are now being controlled by another user. Only one user can be programming a device instance at any one time. Extra devices can be sampled using the -r option. Using multiple instances of the -w option on the same command line, with the same *device-inst* specifying a different list of events for the pics will give the effect of multiplexing for that device. busstat will

switch between the list of events for that device every interval seconds. Event can be a string representing the event name, or even a number representing the bit pattern to be programmed into the Performance Control Register (PCR). This assumes explicit knowledge of the meaning of the control register bits for a device. The number can be specified in hexadecimal, decimal, or octal, using the usual conventions of strtol(3C).

Exit Status The following exit values are returned:

0   Successful completion.

1   An error occurred.

2   Another user is writing to the same devices.

Examples

SPARC Only   **EXAMPLE 1** Programming and monitoring the Address Controller counters

In this example, ac0 refers to the Address Controller instance 0. The counters are programmed to count Memory Bank stalls on an Ultra Enterprise system at 10 second intervals with the values displayed in absolute form instead of deltas.

```
# busstat -a -w ac0,pic0=mem_bank0_stall,pic1=mem_bank1_stall 10
time  dev   event0          pic0   event1          pic1
10    ac0   mem_bank0_stall  1234   mem_bank1_stall   5678
20    ac0   mem_bank0_stall  5678   mem_bank1_stall  12345
30    ac0   mem_bank0_stall 12345   mem_bank1_stall  56789
...
```

For a complete list of the supported events for a device, use the -e option.

EXAMPLE 2 Programming and monitoring the counters on all instances of the Address Controller

In this example, ac refers to all ac instances. This example programs all instances of the Address Controller counters to count_clock cycles and mem_bank0_rds at 2 second intervals, 100 times, displaying the values as deltas.

```
# busstat -w ac,pic0=clock_cycles,pic1=mem_bank0_rds 2 100
time  dev    event0         pic0          event1         pic1
2     ac0    clock_cycles   167242902     mem_bank0_rds   3144
2     ac1    clock_cycles   167254476     mem_bank0_rds   1392
4     ac0    clock_cycles   168025190     mem_bank0_rds  40302
4     ac1    clock_cycles   168024056     mem_bank0_rds  40580
...
```

EXAMPLE 3 Monitoring the events being counted

This example monitors the events that are being counted on the sbus1 device, 100 times at 1 second intervals. It suggests that a root user has changed the events that sbus1 was counting to be dvma_tlb_misses and interrupts instead of pio_cycles.

```
% busstat -r sbus0 1 100

time    dev     event0              pic0        event1          pic1
1       sbus1   pio_cycles          2321        pio_cycles      2321
2       sbus1   pio_cycles          48          pio_cycles      48
3       sbus1   pio_cycles          49          pio_cycles      49
4       sbus1   pio_cycles          2281        pio_cycles      2281
5       sbus1   dvma_tlb_misses     0           interrupts      0
6       sbus1   dvma_tlb_misses     6           interrupts      2
7       sbus1   dvma_tlb_misses     8           interrupts      11
...
```

EXAMPLE 4 Event Multiplexing

This example programs ac0 to alternate between counting (clock cycles, mem_bank0_rds) and (addr_pkts, data_pkts) at 2 second intervals while also monitoring what ac1 is counting :

It shows the expected output of the above busstat command. Another root user on the machine has changed the events that this user had programmed and busstat has detected this and terminates the command with a message.

```
# busstat -w ac0,pic0=clock_cycles,pic1=mem_bank0_rds \
          -w ac0,pic0=addr_pkts,pic1=data_pkts \
          -r ac1 2

time    dev     event0          pic0        event1          pic1
2       ac0     addr_pkts       12866       data_pkts       17015
2       ac1     rio_pkts        385         rio_pkts        385
4       ac0     clock_cycles    168018914   mem_bank0_rds   2865
4       ac1     rio_pkts        506         rio_pkts        506
6       ac0     addr_pkts       144236      data_pkts       149223
6       ac1     rio_pkts        522         rio_pkts        522
8       ac0     clock_cycles    168021245   mem_bank0_rds   2564
8       ac1     rio_pkts        387         rio_pkts        387
10      ac0     addr_pkts       144292      data_pkts       159645
10      ac1     rio_pkts        506         rio_pkts        506
12      ac0     clock_cycles    168020364   mem_bank0_rds   2665
12      ac1     rio_pkts        522         rio_pkts        522
busstat: events changed (possibly by another busstat).
#
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also iostat(1M), mpstat(1M), vmstat(1M), strtol(3C), attributes(5)

Name captoinfo – convert a termcap description into a terminfo description

Synopsis `captoinfo [-1] [-v]... [-V] [-w width] filename...`

Description captoinfo looks in *filename* for termcap descriptions. For each one found, an equivalent terminfo description is written to standard output, along with any comments found. A description which is expressed as relative to another description (as specified in the termcap tc = field) is reduced to the minimum superset before being displayed.

If no *filename* is given, then the environment variable TERMCAP is used for the filename or entry. If TERMCAP is a full pathname to a file, only the terminal whose name is specified in the environment variable TERM is extracted from that file. If the environment variable TERMCAP is not set, then the file /usr/share/lib/termcap is read.

Options −1 Display the fields one to a line. Otherwise, the fields are printed several to a line, with a maximum width of 60 characters.

-v Display tracing information on the standard error as the program runs. Specifying additional -v options displays more detailed information.

-V Display the version of the program in use on the standard error and then exit.

-w *width* Change the output to *width* characters.

Files /usr/share/lib/terminfo/?/* compiled terminal description database

/usr/share/lib/termcap

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also infocmp(1M), curses(3CURSES), terminfo(4), attributes(5)

Notes captoinfo should be used to convert termcap entries to terminfo entries because the termcap database may not be supplied in future releases.

Name catman – create the formatted files for the reference manual

Synopsis /usr/bin/catman [-c] [-n] [-p] [-t] [-w] [-M *directory*]
        [-T *macro-package*] [*sections*]

/usr/bin/catman [-M *directory*] -w

Description The catman utility creates the preformatted versions of the on-line manual from the nroff(1) or sgml(5) input files. This feature allows easy distribution of the preformatted manual pages among a group of associated machines, since it makes the directories of preformatted manual pages self-contained and independent of the unformatted entries.

With the -w option, catman also creates index files, in the directories specified by the MANPATH or the -M option. If there is no MANPATH or -M option specified, unless -n is specified, catman creates index files at the /usr/share/man/ and /usr/gnu/share/man/ directories by default. When any specified or default directory is read-only, catman fails and displays an error message to stderr, indicating that writing is not allowed to the directory.

Each manual page is examined and those whose preformatted versions are missing or out of date are recreated. If any changes are made, catman recreates the index files.

If a manual page is a *shadow* page, that is, it sources another manual page for its contents, a symbolic link is made in the cat*x* or fmt*x* directory to the appropriate preformatted manual page.

Shadow files in an unformatted nroff source file are identified by the first line being of the form .so man*x*/yyy.*x*.

Shadow files in the SGML sources are identified by the string SHADOW_PAGE. The file entity declared in the shadow file identifies the file to be sourced.

Options The following options are supported:

-c

Create unformatted nroff source files in the appropriate man subdirectories from the SGML sources. This option will overwrite any existing file in the man directory of the same name as the SGML file.

-n

Do not create (or recreate) the index files. If the -n option is specified, the index files are not created and the apropos(1) and whatis(1) commands might run more slowly than otherwise.

-p

Dry—run option. That is, display what would be done instead of doing it.

-t

Create troffed entries in the appropriate fmt subdirectories instead of nroffing into the cat subdirectories.

-w

    Create the index files that are used by apropos(1), whatis(1) and the man(1) -f, -k, and -K options, in the directories specified by the MANPATH environment variable or the -M option. If no MANPATH or -M option is specified, index files are created in the /usr/share/man/ and /usr/gnu/share/man/ directories by default. No manual reformatting is done.

-M *directory*

    Update manual pages located in the specified *directory*, (/usr/share/man by default). If the -M option is specified, the directory argument must not contain a ',' (comma), since a comma is used to delineate section numbers. See man(1).

-T *macro-package*

    Use *macro-package* in place of the standard manual page macros, (man(5) by default).

Operands The following operand is supported:

sections

    If there is one parameter not starting with a '−', it is taken to be a space separated list of manual sections to be processed by catman. If this operand is specified, only the manual sections in the list will be processed. For example,

    catman 1 2 3

    only updates manual sections 1, 2, and 3. If specific sections are not listed, all sections in the man directory specified by the environment variable MANPATH are processed.

Environment Variables TROFF

    The name of the formatter to use when the -t flag is given. If not set, troff(1) is used.

MANPATH

    A colon-separated list of directories that are processed by catman and man(1). Each directory can be followed by a comma-separated list of sections. If set, its value overrides /usr/share/man as the default directory search path, and the man.cf file as the default section search path. The -M and -s flags, in turn, override these values.

Examples EXAMPLE 1 Creating an Index File

The following command creates an index file in the /usr/local/share/man directory.

    # catman -M /usr/local/share/man -w

Files /usr/share/man

    default manual directory location

/usr/share/man/man*/*.*

    raw nroff input files

/usr/share/man/sman*/*.*

    raw SGML input files

/usr/share/man/cat*/*.*

    preformatted nroffed manual pages

/usr/share/man/fmt*/*.*
   preformatted troffed manual pages

/usr/share/lib/tmac/an
   default macro package

/usr/share/man/man_index/*
/usr/share/man/man_index/man.idx
/usr/share/man/man_index/man.dic
/usr/share/man/man_index/man.frq
/usr/share/man/man_index/man.pos
   index file for -K query

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	text/doctools
CSI	Enabled
Interface Stability	Committed

See Also apropos(1), man(1), nroff(1), rm(1), troff(1), whatis(1), attributes(5), man(5), sgml(5)

Diagnostics man?/xxx.? (.so'ed from man?/yyy.?): No such file or directory
   The file outside the parentheses is missing, and is referred to by the file inside them.

target of .so in man?/xxx.? must be relative to /usr/man
   catman only allows references to filenames that are relative to the directory /usr/man.

opendir:man?: No such file or directory
   A harmless warning message indicating that one of the directories catman normally looks
   for is missing.

.: No such file or directory
   A harmless warning message indicating catman came across an empty directory.

Warnings If a user, who has previously run catman to install the cat* directories, upgrades the operating
system, the entire cat* directory structure should be removed prior to running catman. See
rm(1).

Do not re-run catman to rebuild the index files unless the complete set of man* directories is
present. catman builds the index files based on the man* directories.

Notes The windex database has been replaced by index files. Unlike the case with windex, index file
generation does not pose any specific restrictions or prerequisites on what can be indexed.

Name   cfgadm – configuration administration

Synopsis /usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o *hardware_options*]
              -c *function ap_id*...

/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o *hardware_options*]
              -x *hardware_function ap_id*...

/usr/sbin/cfgadm [-v] [-a] [-s *listing_options*]
              [-o *hardware_options*] [-l [*ap_id* | *ap_type*]]

/usr/sbin/cfgadm [-v] [-o *hardware_options*] -t *ap_id*...

/usr/sbin/cfgadm [-v] [-o *hardware_options*] -h
              [*ap_id* | *ap_type*]

Description The cfgadm command provides configuration administration operations on dynamically
reconfigurable hardware resources. These operations include displaying status, (-l), initiating
testing, (-t), invoking configuration state changes, (-c), invoking hardware specific functions,
(-x), and obtaining configuration administration help messages (-h). Configuration
administration is performed at *attachment points*, which are places where system software
supports dynamic reconfiguration of hardware resources during continued operation of
Solaris.

Configuration administration makes a distinction between hardware resources that are
physically present in the machine and hardware resources that are configured and visible to
Solaris. The nature of configuration administration functions are hardware specific, and are
performed by calling hardware specific libraries.

Configuration administration operates on an *attachment point*. Hardware resources located at
attachment points can or can not be physically replaceable during system operation, but are
dynamically reconfigurable by way of the configuration administration interfaces.

An attachment point defines two unique elements, which are distinct from the hardware
resources that exist beyond the attachment point. The two elements of an attachment point
are a *receptacle* and an *occupant*. Physical insertion or removal of hardware resources occurs
at attachment points and results in a receptacle gaining or losing an occupant. Configuration
administration supports the physical insertion and removal operations as well as other
configuration administration functions at an attachment point.

Attachment points have associated state and condition information. The configuration
administration interfaces provide control for transitioning attachment point states. A
receptacle can exist in one of three states: empty, disconnected or connected, while an
occupant can exist in one of two states: configured or unconfigured.

A receptacle can provide the empty state, which is the normal state of a receptacle when the
attachment point has no occupants. A receptacle can also provide the disconnected state if it
has the capability of isolating its occupants from normal system access. Typically this state is
used for various hardware specific testing prior to bringing the occupant's resources into full

use by the system, or as a step in preparing an occupant for physical removal or reconfiguration. A receptacle in the disconnected state isolates its occupant from the system as much as its hardware allows, but can provide access for testing and setup. A receptacle must provide the connected state, which allows normal access to hardware resources contained on any occupants. The connected state is the normal state of a receptacle that contains an occupant and that is not currently undergoing configuration administration operations.

The hardware resources contained on an occupant in the unconfigured state are not represented by normal Solaris data structures and are thus not available for use by Solaris. Operations allowed on an unconfigured occupant are limited to configuration administration operations. The hardware resources of an occupant in the configured state are represented by normal Solaris data structures and thus some or all of those hardware resources can be in use by Solaris. All occupants provide both the configured and unconfigured states,

An attachment point can be in one of five conditions: unknown, ok, failing, failed, or unusable. An attachment point can enter the system in any condition depending upon results of power-on tests and non-volatile record keeping.

An attachment point with an occupant in the configured state is in one of four conditions: unknown, ok, failing, or failed. If the condition is not failing or failed an attachment point can change to failing during the course of operation if a hardware dependent recoverable error threshold is exceeded. If the condition is not failed an attachment point can change to failed during operation as a result of an unrecoverable error.

An attachment point with an occupant in the unconfigured state can be in any of the defined conditions. The condition of an attachment point with an unconfigured occupant can decay from ok to unknown after a machine dependent time threshold. Initiating a test function changes the attachment point's condition to ok, failing or failed depending on the outcome of the test. An attachment point that does not provide a test function can leave the attachment point in the unknown condition. If a test is interrupted, the attachment point's condition can be set to the previous condition, unknown or failed. An attachment point in the unknown, ok, failing, or failed conditions can be re-tested.

An attachment point can exist in the unusable condition for a variety of reasons, such as inadequate power or cooling for the receptacle, an occupant that is unidentifiable, unsupported, incorrectly configured, etc. An attachment point in the unusable condition can never be used by the system. It typically remains in this condition until the physical cause is remedied.

An attachment point also maintains busy information that indicates when a state change is in progress or the condition is being reevaluated.

Attachment points are referred to using hardware specific identifiers (*ap_id*s) that are related to the type and location of the attachment points in the system device hierarchy. An *ap_id* can not be ambiguous, it must identify a single attachment point. Two types of *ap_id*

specifications are supported: physical and logical. A physical *ap_id* contains a fully specified pathname, while a logical *ap_id* contains a shorthand notation that identifies an attachment point in a more user-friendly way.

For example, an attachment point representing a system's backplane slot number 7 could have a physical *ap_id* of /devices/central/fhc/sysctrl:slot7 while the logical *ap_id* could be system:slot7. Another example, the third receptacle on the second PCI I/O bus on a system could have a logical *ap_id* of pci2:plug3.

Attachment points may also be created dynamically. A dynamic attachment point is named relative to a base attachment point which is present in the system. ap_ids for dynamic attachment points consist of a base component followed by two colons (::) and a dynamic component. The base component is the base attachment point ap_id. The dynamic component is hardware specific and generated by the corresponding hardware specific library.

For example, consider a base attachment point, which represents a SCSI HBA, with the physical ap_id /devices/sbus@1f,0/SUNW,fas@e,8800000:scsi and logical ap_id c0. A disk attached to this SCSI HBA could be represented by a dynamic attachment point with logical ap_id c0::dsk/c0t0d0 where c0 is the base component and dsk/c0t0d0 is the hardware specific dynamic component. Similarly the physical ap_id for this dynamic attachment point would be: /devices/sbus@1f,0/SUNW,fas@e,8800000:scsi::dsk/c0t0d0

An *ap_type* is a partial form of a logical ap_id that can be ambiguous and not specify a particular attachment point. An *ap_type* is a substring of the portion of the logical ap_id up to but not including the colon (:) separator. For example, an *ap_type* of pci would show all attachment points whose logical *ap_id*s begin with pci.

The use of *ap_types* is discouraged. The new select sub-option to the -s option provides a more general and flexible mechanism for selecting attachment points. See OPTIONS.

The cfgadm command interacts primarily with hardware dependent functions contained in hardware specific libraries and thus its behavior is hardware dependent.

For each configuration administration operation a service interruption can be required. Should the completion of the function requested require a noticeable service interruption to interactive users, a prompt is output on the standard error output for confirmation on the standard input before the function is started. Confirmation can be overridden using the -y or -n options to always answer yes or no respectively. Hardware specific options, such as test level, are supplied as sub-options using the -o option.

Operations that change the state of the system configuration are audited by the system log daemon syslogd(1M).

The arguments for this command conform to the getopt(3C) and getsubopt(3C) syntax convention.

Options The following options are supported:

-a
: Specifies that the -l option must also list dynamic attachment points.

-c*function*
: Performs the state change *function* on the attachment point specified by *ap_id*.

  Specify *function* as insert, remove, disconnect, connect, configure or unconfigure. These functions cause state transitions at the attachment point by calling hardware specific library routines and are defined in the following list.

  insert
  : Performs operations that allows the user to manually insert an occupant or to activate a hardware supplied mechanism that performs the physical insertion. insert can have hardware specific side effects that temporarily suspend activity in portions of the system. In such cases the hardware specific library generates appropriate warning messages and informs the user of any special considerations or procedures unique to that hardware. Various hardware specific errors can cause this function to fail and set the receptacle condition to unusable.

  remove
  : Performs operations that allow the user to manually remove an occupant or to activate a hardware supplied mechanism to perform the physical removal. remove can have hardware specific side effects that temporarily suspend activity in portions of the system. In such cases the hardware specific library generates appropriate warning messages and informs the user of any special considerations or procedures unique to that hardware. Various hardware specific errors can cause this function to fail and set the receptacle condition to unusable.

  disconnect
  : Performs hardware specific operations to put a receptacle in the disconnected state, which can prevent an occupant from operating in a normal fashion through the receptacle.

connect   Performs hardware specific operations to put
                    the receptacle in the connected state, which
                    allows an occupant to operate in a normal
                    fashion through the receptacle.

configure   Performs hardware specific operations that
                    allow an occupant's hardware resources to be
                    usable by Solaris. Occupants that are
                    configured are part of the system configuration
                    and are available for manipulation by Solaris
                    device manipulation maintenance commands
                    (eg: psradm(1M), mount(1M), ifconfig(1M)).

unconfigure   Performs hardware specific operations that
                    logically remove an occupant's hardware
                    resources from the system. The occupant must
                    currently be configured and its hardware
                    resources must not be in use by Solaris.

State transition functions can fail due to the condition of the
attachment point or other hardware dependent considerations.
All state change *function*s in the direction of adding resources,
(insert, connect and configure) are passed onto the hardware
specific library when the attachment point is in the ok or unknown
condition. All other conditions require the use of the force option
to allow these *function*s to be passed on to the hardware specific
library. Attachment point condition does not prevent a hardware
specific library being called for related to the removal (remove,
disconnect and unconfigure), of hardware resources from the
system. Hardware specific libraries can reject state change
*function*s if the attachment point is in the unknown condition.

The condition of an attachment point is not necessarily changed
by the state change functions, however errors during state change
operations can change the attachment point condition. An
attempt to override a condition and force a state change that
would otherwise fail can be made by specifying the force option
(-f). Hardware specific safety and integrity checks can prevent
the force option from having any effect.

-f   Forces the specified action to occur. Typically, this is a hardware
            dependent override of a safety feature. Forcing a state change
            operation can allow use of the hardware resources of occupant
            that is not in the ok or unknown conditions, at the discretion of
            any hardware dependent safety checks.

-h [*ap_id* | *ap_type* . . .]	Prints out the help message text. If *ap_id* or *ap_type* is specified, the help routine of the hardware specific library for the attachment point indicated by the argument is called.
-l [*ap_id* | *ap_type* . . .]	Lists the state and condition of attachment points specified. Attachment points can be filtered by using the -s option and select sub-option. Invoking cfgadm without one of the action options is equivalent to -l without an argument. The format of the list display is controlled by the -v and -s options. When the -a option is specified attachment points are dynamically expanded.
-n	Suppress any interactive confirmation and assume that the answer is *no*. If neither -n or -y is specified, interactive confirmation is obtained through the standard error output and the standard input. If either of these standard channels does not correspond to a terminal (as determined by isatty(3C)) then the -n option is assumed.
-o*hardware_options*	Supplies hardware specific options to the main command option. The format and content of the hardware option string is completely hardware specific. The option string *hardware_options* conforms to the getsubopt(3C) syntax convention.
-s*listing_options*	Supplies listing options to the list (-l) command. *listing_options* conforms to the getsubopt(3C) syntax convention. The sub-options are used to specify the attachment point selection criteria (select=*select_string*), the type of matching desired (match=*match_type*), order of listing (sort=*field_spec*), the data that is displayed (cols=*field_spec* and cols2=*field_spec*), the column delimiter (delim=*string*) and whether to suppress column headings (noheadings).

When the select sub-option is specified, only attachment points which match the specified criteria will be listed. The select sub-option has the following syntax:

```
cfgadm -s select=attr1(value1):attr2(value2)...
```

where an *attr* is one of ap_id, class or type. ap_id refers to the logical *ap_id* field, class refers to attachment point class and type refers to the type field. *value1*, *value2*, etc. are the corresponding values to be matched. The type of match can be specified by the match sub-option as follows:

```
cfgadm -s match=match_type,select=attr1(value1)...
```

where *match_type* can be either exact or partial. The default
value is exact.

Arguments to the select sub-option can be quoted to protect
them from the shell.

A *field_spec* is one or more *data-field*s concatenated using colon
(:), as in *data-field*:*data-field*:*data-field*. A *data-field* is one of
ap_id, physid, r_state, o_state, condition, type, busy,
status_time, status_time_p, class, and info. The ap_id field
output is the logical name for the attachment point, while the
physid field contains the physical name. The r_state field can
be empty, disconnected or connected. The o_state field can be
configured or unconfigured. The busy field can be either y if
the attachment point is busy, or n if it is not. The type and info
fields are hardware specific. The status_time field provides the
time at which either the r_state, o_state, or condition of the
attachment point last changed. The status_time_p field is a
parsable version of the status_time field. If an attachment point
has an associated class, the class field lists the class name. If an
attachment point does not have an associated class, the class
field lists none.

The order of the fields in *field_spec* is significant: For the sort
sub-option, the first field given is the primary sort key. For the
cols and cols2 sub-options, the fields are printed in the order
requested. The order of sorting on a *data-field* can be reversed by
placing a minus (−) before the *data-field* name within the
field_sec for the sort sub-option. The default value for sort is
ap_id. The defaults values for cols and cols2 depend on
whether the -v option is given: Without it cols is
ap_id:r_state:o_state:condition and cols2 is not set. With
-v cols is ap_id:r_state:o_state:condition:info and cols2
is status_time:type:busy:physid:. The default value for
delim is a single space. The value of delim can be a string of
arbitrary length. The delimiter cannot include comma (,)
character, see getsubopt(3C). These listing options can be used
to create parsable output. See NOTES.

-t   Performs a test of one or more attachment points. The test
function is used to re-evaluate the condition of the attachment
point. Without a test level specifier in *hardware_options*, the
fastest test that identifies hard faults is used.

More comprehensive tests are hardware specific and are selected using the *hardware_options*.

The results of the test is used to update the condition of the specified occupant to either `ok` if no faults are found, `failing` if recoverable faults are found or `failed` if any unrecoverable faults are found.

If a test is interrupted, the attachment point's condition can be restored to its previous value or set to `unknown` if no errors were found or `failing` if only recoverable errors were found or to `failed` if any unrecoverable errors were found. The attachment point should only be set to `ok` upon normal completion of testing with no errors.

-v   Executes in verbose mode. For the -c, -t and -x options outputs a message giving the results of each attempted operation. Outputs detailed help information for the -h option. Outputs verbose information for each attachment point for the -l option.

-x*hardware_function*   Performs hardware specific functions. Private hardware specific functions can change the state of a receptacle or occupant. Attachment point conditions can change as the result of errors encountered during private hardware specific functions. The format and content of the *hardware_function* string is completely hardware specific. The option string *hardware_function* conforms to the getsubopt(3C) syntax convention.

-y   Suppresses any interactive confirmation and assume that the answer is `yes`.

Usage The required privileges to use this command are hardware dependent. Typically, a default system configuration restricts all but the list option to the superuser.

Examples EXAMPLE 1   Listing Attachment Points in the Device Tree

The following example lists all attachment points except dynamic attachment points.

```
example# cfgadm

  Ap_Id        Type       Receptacle     Occupant       Cond
system:slot0   cpu/mem    connected      configured     ok
system:slot1   sbus-upa   connected      configured     ok
system:slot2   cpu/mem    connected      configured     ok
system:slot3   unknown    connected      unconfigured   unknown
system:slot4   dual-sbus  connected      configured     failing
system:slot5   cpu/mem    connected      configured     ok
system:slot6   unknown    disconnected   unconfigured   unusable
```

EXAMPLE 1   Listing Attachment Points in the Device Tree   *(Continued)*

```
system:slot7    unknown     empty                 unconfigured   ok
c0              scsi-bus    connected             configured     unknown
c1              scsi-bus    connected             configured     unknown
```

EXAMPLE 2   Listing All Configurable Hardware Information

The following example lists all current configurable hardware information, including those represented by dynamic attachment points:

```
example# cfgadm -al

  Ap_Id           Type        Receptacle     Occupant       Cond
system:slot0      cpu/mem     connected      configured     ok
system:slot1      sbus-upa    connected      configured     ok
system:slot2      cpu/mem     connected      configured     ok
system:slot3      unknown     connected      unconfigured   unknown
system:slot4      dual-sbus   connected      configured     failing
system:slot5      cpu/mem     connected      configured     ok
system:slot6      unknown     disconnected   unconfigured   unusable
system:slot7      unknown     empty          unconfigured   ok
c0                scsi-bus    connected      configured     unknown
c0::dsk/c0t14d0   disk        connected      configured     unknown
c0::dsk/c0t11d0   disk        connected      configured     unknown
c0::dsk/c0t8d0    disk        connected      configured     unknown
c0::rmt/0         tape        connected      configured     unknown
c1                scsi-bus    connected      configured     unknown
```

EXAMPLE 3   Listing Selectively, Based on Attachment Point Attributes

The following example lists all attachment points whose class begins with scsi, ap_id begins with c and type field begins with scsi. The argument to the -s option is quoted to protect it from the shell.

```
example# cfgadm -s "match=partial,select=class(scsi):ap_id(c):type(scsi)"

Ap_Id         Type        Receptacle     Occupant       Cond
 c0           scsi-bus    connected      configured     unknown
 c1           scsi-bus    connected      configured     unknown
```

EXAMPLE 4   Listing Current Configurable Hardware Information in Verbose Mode

The following example lists current configurable hardware information for *ap-type* system in verbose mode:

```
example# cfgadm -v -l system
Ap_Id                   Receptacle Occupant   Condition Information
When        Type      Busy     Phys_Id
```

EXAMPLE 4 Listing Current Configurable Hardware Information in Verbose Mode   *(Continued)*

```
system:slot1                connected  configured ok
Apr  4 23:50 sbus-upa  n       /devices/central/fhc/sysctrl:slot1
system:slot3                connected  configured ok       non-detachable
Apr 17 11:20 cpu/mem   n       /devices/central/fhc/sysctrl:slot3
system:slot5                connected  configured ok
Apr  4 23:50 cpu/mem   n       /devices/central/fhc/sysctrl:slot5
system:slot7                connected  configured ok
Apr  4 23:50 dual-sbus n       /devices/central/fhc/sysctrl:slot7
```

The When column represents the status_time field.

EXAMPLE 5 Testing Two Occupants Using the Hardware Specific Extended Test

The following example tests two occupants using the hardware specific extended test:

```
example# cfgadm -v -o extended -t system:slot3 system:slot5
Testing attachment point system:slot3 ... ok
Testing attachment point system:slot5 ... ok
```

EXAMPLE 6 Configuring an Occupant Using the Force Option

The following example configures an occupant in the failing state to the system using the force option:

```
example# cfgadm -f -c configure system:slot3
```

EXAMPLE 7 Unconfiguring an Occupant From the System

The following example unconfigures an occupant from the system:

```
example# cfgadm -c unconfigure system:slot4
```

EXAMPLE 8 Configuring an Occupant at an Attachment Point

The following example configures an occupant:

```
example# cfgadm -c configure c0::dsk/c0t0d0
```

Environment Variables   See environ(5) for descriptions of the following environment variables that affect the execution of cfgadm: LC_TIME, LC_MESSAGES, NLSPATH and TZ.

LC_MESSAGES   Determines how cfgadm displays column headings and error messages. Listing output data is not affected by the setting of this variable.

LC_TIME   Determines how cfgadm displays human readable status changed time (status_time).

TZ   Specifies the timezone used when converting the status changed time. This applies to both the human readable (status_time) and parsable

(status_time_p) formats.

Exit Status The following exit values are returned:

0   Successful completion.

1   An error occurred.

2   Configuration administration not supported on specified target.

3   Usage error.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also cfgadm_fp(1M), cfgadm_ib(1M), cfgadm_pci(1M), cfgadm_sata(1M), cfgadm_sbd(1M), cfgadm_scsi(1M), cfgadm_usb(1M), ifconfig(1M), mount(1M), prtdiag(1M), psradm(1M), syslogd(1M), config_admin(3CFGADM), getopt(3C), getsubopt(3C), isatty(3C), attributes(5), environ(5)

Diagnostics Diagnostic messages appear on the standard error output. Other than options and usage errors, the following are diagnostic messages produced by this utility:

cfgadm: Configuration administration not supported on *ap_id*

cfgadm: No library found for *ap_id*

cfgadm: *ap_id* is ambiguous

cfgadm: *operation*: Insufficient privileges

cfgadm: Attachment point is busy, try again

cfgadm: No attachment points with specified attributes found

cfgadm: System is busy, try again

cfgadm: *operation*: Operation requires a service interruption

cfgadm: *operation*: Data error: *error_text*

cfgadm: *operation*: Hardware specific failure: *error_text*

See config_admin(3CFGADM) for additional details regarding error messages.

Notes Hardware resources enter the unconfigured pool in a hardware specific manner. This can occur at various times such as: system initialization or as a result of an unconfigure operation. An occupant that is in the unconfigured state is not available for use by the system until specific intervention occurs. This intervention can be manifested as an operator initiated command or it can be by way of an automatic configuring mechanism.

The listing option of the cfgadm command can be used to provide parsable input for another command, for example within a shell script. For parsable output, the -s option must be used to select the fields required. The -s option can also be used to suppress the column headings. The following fields always produce parsable output: ap_id, physid, r_state, o_state, condition, busy status_time_p, class, and type. Parsable output never has white-space characters embedded in the field value.

The following shell script fragment finds the first good unconfigured occupant of type CPU.

```
found=
cfgadm -l -s "noheadings,cols=ap_id:r_state:condition:type" | \
while read ap_id r_state cond type
do
     if [ "$r_state" = unconfigured -a "$cond" = ok -a "$type" = CPU ]
     then
          if [ -z "$found" ]
          then
               found=$ap_id
          fi
     fi
done
if [ -n "$found" ]
then
        echo "Found CPU $found"
fi
```

The format of the parsable time field (status_time_p) is *YYYYMMDDhhmmss*, giving the year, month, day, hour, minute and second in a form suitable for string comparison.

Reference should be made to the hardware specific documentation for details of System Configuration Administration support.

Name cfgadm_ac – EXX00 memory system administration

Synopsis /usr/sbin/cfgadm [-c configure] [-f]
        [-o disable-at-boot | enable-at-boot] ac#:bank# ...

/usr/sbin/cfgadm [-c unconfigure]
        [-o disable-at-bootp | enable-at-boot] ac#:bank# ...

/usr/sbin/cfgadm [-v]
        [-o quick | normal | extended, [max_errors=#]] -t ac#:bank#...

/usr/sbin/cfgadm -x relocate-test ac#:bank# ...

/usr/sbin/cfgadm [-l] -o disable-at-boot | enable-at-boot ac#:bank# ...

Description The ac hardware specific library /usr/platform/sun4u/lib/cfgadm/cfgadm_ac.so.1
provides the functionality for configuring and unconfiguring memory banks on E6X00, E5X00,
E4X00 and E3X00 systems as part of the Dynamic Reconfiguration of CPU/Memory boards
using cfgadm_sysctrl(1M).

Memory banks appear as attachment points in the device tree. For each CPU/Memory board,
two attachment points are published, one for each bank on the board: bank0 and bank1. If the
bank is unpopulated, the receptacle state is empty. If the bank is populated, the receptacle state
is connected. The receptacle state of a memory bank can never be disconnected. The occupant
state of a connected memory bank can be configured or unconfigured. If the occupant state is
configured, the memory is in use by Solaris, if unconfigured it is not.

Options Refer to cfgadm(1M) for complete descriptions of the command options.

The following options are supported:

-c configure | unconfigure   Change the occupant state. The configure argument
                                      ensures that the memory is initialized and adds the
                                      memory to the Solaris memory pool. The
                                      unconfigure argument removes the memory from use
                                      by Solaris. When a CPU/Memory board is to be
                                      removed from a system, both banks of memory must
                                      be unconfigured.

                                      cfgadm refuses the configure operation if the memory
                                      on the board is marked disabled-at-boot (see info
                                      field), unless either the -f (force) option or the enable
                                      at boot flag, (-o enable-at-boot), is given. The
                                      configure operation takes a short time proportional to
                                      the size of memory that must be initialized.

                                      cfgadm refuses the unconfigure operation if there is
                                      not enough uncommitted memory in the system (VM
                                      viability error) or if the bank to be unconfigured has
                                      memory that can't be removed (non-relocatable

pages error). The presence of non-relocatable pages is indicated by the word permanent in the info listing field. Removing memory from use by Solaris may take a significant time due to factors such as system load and how much paging to secondary storage is required. The unconfigure operation can be cancelled at any time and the memory returned to the fully configured state by interrupting the command invocation with a signal. The unconfigure operation self-cancels if no memory can be removed within a timeout period. The default timeout period of 60 seconds can be changed using the -o timeout=# option, with a value of 0 disabling the timeout.

-f   Force option. Use this option to override the block on configuring a memory bank marked as disabled at boot in the non-volatile disabled-memory-list variable. See *Platform Notes:Sun Enterprise 6x00/5x00/4x00/3x00 Systems*

-l   List option. This option is supported as described in cfgadm(1M).

The type field is always *memory*.

The *info* field has the following information for empty banks:

slot# empty

The slot# indicates the system slot into which the CPU/Memory board is inserted. For example, if this were slot11 the attachment point for use with cfgadm to manipulate the associated board would be sysctrl0:slot11. The info field has the following information for connected banks:

```
slot# sizeMb|sizeGb [(sizeMb|sizeGb used)] base 0x###
      [interleaved #-way] [disabled at boot] [permanent]
```

The size of the bank is given in Mb or Gb as appropriate. If the memory is less than completely used, the used size is reported. The physical base address is given in hexadecimal. If the memory bank is interleaved with some other bank, the interleave factor is reported. If the memory on the board is disabled at boot using the non-volatile disabled-memory-list

	variable, this is reported. If the bank has memory that cannot be removed this is reported as permanent.
-o disable-at-boot | enable-at-boot	These options allow the state of the non-volatile disabled-memory-list variable to be modified. These options can be used in conjunction with the issuing of a -c option or with the explicit or implied listing command, -l, if no command is required. Use of -o enable-at-boot with the configure command to override the block on configuring memory on a board in the disabled memory list.
-o extended | normal | quick	Use with the -t option to specify test level.
	The normal test level ensures that each memory cell stores both a 0 and a 1, and checks that all cells are separately addressable. The quick test level only does the 0s and 1s test, and typically misses address line problems. The extended test uses patterns to test for adjacent cell interference problems. The default test level is normal. See -t option.
-o max_errors=#	Use with the -t option to specify the maximum number of allowed errors. If not specified, a default of 32 is assumed.
-o timeout=#	Use with the unconfigure command to set the self-cancelling timeout. The default value is 60 and the unit is seconds. A value of 0 means no timeout.
-t	Test an unconfigured bank of memory. Specify the test level using the -o quick | normal | extended option.
	cfgadm exits with a 0 (success) if the *test* was able to run on the memory bank. The result of the test is available in the condition for the attachment point.
-v	Verbose option. Use this option in combination with the -t option to display detailed progress and results of tests.
-x relocate-test	For all pages of memory in use on the specified memory bank, a relocation operation as used in the unconfigure command is attempted. The success of this operation does not guarantee that the bank can be unconfigured. Failure indicates that it probably cannot be unconfigured. This option is for test purposes only.

Operands The following operand is supported:

ac#:bank#   The attachment points for memory banks are published by instances of the address controller (ac) driver (*ac#*). One instance of the ac driver is created for each system board, but only those instances associated with CPU/Memory boards publish the two bank attachment points, bank0 and bank1.

This form conforms to the logical ap_id specification given in cfgadm(1M). The corresponding physical ap_ids are listed in the FILES section.

The ac driver instance numbering has no relation to the slot number for the corresponding board. The full physical attachment point identifier has the slot number incorporated into it as twice the slot number in hexadecimal directly following the fhc@ part.

Files /devices/fhc@*,f8800000/ac@0,1000000:bank?   attachment points

/usr/platform/sun4u/lib/cfgadm/cfgadm_ac.so.1   hardware specific library file

/usr/sbin/cfgadm [-v] [-o *hardware_function*] -h
        [*ap_id*| *ap_type*]

Description The CardBus slots in Solaris are hot plug capable. This capability is supported by the PCI
hardware specific library /usr/lib/cfgadm/pci.so.1 through the cfgadm command (see
cfgadm(1M)).

The hot plug administrative models between CardBus, PCI, CompactPCI, and PCI Express
operate the same fashion. Please refer to cfgadm_pci(1M) for the usage information.

Description The fp port driver plug-in /usr/lib/cfgadm/fp.so.1 provides the functionality for Fibre Channel Fabric device node management through cfgadm(1M). cfgadm operates on attachment points. Attachment points are locations in the system where hardware resources can be dynamically reconfigured. Refer to cfgadm(1M) for additional details on attachment points.

For Fibre Channel Fabric device node management, each fp port node is represented by an attachment point in the device tree. In addition, each Fibre Channel device is represented by a dynamic attachment point. Attachment points are named through ap_ids. Two types of ap_ids are defined: logical and physical. The physical ap_id is based on the physical pathname. The logical ap_id is a shorter, more user-friendly name. For fp port nodes, the logical ap_id is the corresponding disk controller number. For example, c0 is a typical logical ap_id.

Fibre Channel devices are named with a port World Wide Name (WWN). If a disk device is connected to controller c0, its ap_id can be:

c0::50020f2300006077

where 50020f2300006077 identifies the port WWN of a specific Fibre Channel device.

Each device on the Fibre Channel private loop port, Fabric port or public loop port is probed and made available to Solaris by default. Devices connected to the Fibre Channel Fabric port or public loop port can be made unavailable to Solaris by initiating an application or an end user operation. The operation is similar to the hot unplugging of devices by way of management user interfaces. Applications or users can use the /usr/lib/cfgadm/fp.so.1 library to enable libcfgadm to provide interfaces to accomplish this task.

The list of currently connected Fabric devices is generated in the form of the attachment point.

A simple listing of attachment points in the system includes attachment points at fp port nodes but not Fibre Channel devices. The following example uses the -a flag to the list option (-l) to list Fibre Channel devices:

```
# cfgadm -l
    Ap_Id               Type          Receptacle   Occupant      Condition
    c0                  fc-fabric     connected    configured    unknown
    c1                  fc-private    connected    configured    unknown
    c2                  fc-pt_to_pt   connected    configured    unknown
    c3                  fc            connected    unconfigured  unknown
```

```
sysctrl0:slot0      cpu/mem     connected    configured   ok
sysctrl0:slot1      sbus-upa    connected    configured   ok
```

The following example lists Fibre Channel devices connected to fp ports.

```
# cfgadm -al
    Ap_Id               Type        Receptacle   Occupant     Condition
    c0                  fc-fabric   connected    configured   unknown
    c0::50020f2300006077 disk       connected    configured   unknown
    c0::50020f23000063a9 disk       connected    configured   unknown
    c0::50020f2300005f24 disk       connected    configured   unknown
    c0::50020f2300006107 disk       connected    configured   unknown
    c1                  fc-private  connected    configured   unknown
    c1::220000203708b69c disk       connected    configured   unknown
    c1::220000203708ba7d disk       connected    configured   unknown
    c1::220000203708b8d4 disk       connected    configured   unknown
    c1::220000203708b9b2 disk       connected    configured   unknown
    c2                  fc-pt_to_pt connected    configured   unknown
    c2::500104f000937528 tape       connected    configured   unknown
    c3                  fc          connected    unconfigured unknown
    sysctrl0:slot0      cpu/mem     connected    configured   ok
    sysctrl0:slot1      sbus-upa    connected    configured   ok
```

In this example, the fc-fabric type of ap_id c0 indicates that the fp port is connected to
Fabric. For an fp port with a Fabric-related type such as fc-fabric and fc-public, device
node creation happens by default at the boot time and can be managed by the cfgadm
configure and unconfigure operations. The fc-private type of ap_id c1 indicates that fp
port is connected to private-loop and device node creation happens by default as well. The
fc-pt_to_pt type of ap_id c2 indicates that the fp port is directly connected to another
N_port and device node creation also happens by default. The fc type of ap_id c3 indicates
that nothing is attached to fp port c2. The Type field of a Fibre Channel device ap_id shows
the SCSI device type of LUN 0 in the device.

A Fibre Channel device with multiple FCP SCSI LUNs is configured into Solaris and each FCP
SCSI LUN is available as a Solaris device. Suppose that ap_ids c0::50020f2300006077 and
c0::50020f23000063a9 represent Fibre Channel devices with multiple FCP SCSI LUNs.

The following example shows how to list ap_ids with FCP SCSI LUN information:

```
# cfgadm -al -o show_SCSI_LUN
    Ap_Id                   Type        Receptacle   Occupant     Condition
    c0                      fc-fabric   connected    configured   unknown
    c0::50020f2300006077,0 disk        connected    configured   unknown
    c0::50020f2300006077,1 disk        connected    configured   unknown
    c0::50020f2300006077,2 disk        connected    configured   unknown
    c0::50020f2300006077,3 disk        connected    configured   unknown
    c0::50020f23000063a9,0 disk        connected    configured   unknown
    c0::50020f23000063a9,1 disk        connected    configured   unknown
    c0::50020f23000063a9,2 disk        connected    configured   unknown
```

```
c0::50020f23000063a9,3 disk           connected   configured   unknown
c0::50020f2300005f24,0 disk           connected   unconfigured unknown
c0::50020f2300005f24,1 disk           connected   unconfigured unknown
c0::50020f2300006107,0 disk           connected   unconfigured unknown
c0::50020f2300006107,1 disk           connected   unconfigured unknown
c1                     fc-private     connected   configured   unknown
c1::220000203708b69c,0 disk           connected   configured   unknown
c1::220000203708ba7d,0 disk           connected   configured   unknown
c1::220000203708b8d4,0 disk           connected   configured   unknown
c1::220000203708b9b2,0 disk           connected   configured   unknown
c2                     fc-pt_to_pt    connected   configured   unknown
c2::500104f000937528,0 tape           connected   configured   unknown
c3                     fc             connected   unconfigured unknown
```

In this example, the ap_id c0::50020f2300006077,0 identifies the FCP SCSI LUN 0 of the Fibre Channel device which is represented by port WWN 50020f2300006077. The Fibre Channel device is reported to have 4 FCP SCSI LUNs and they are all configured. 4 FCP SCSI LUN level ap_ids associated with port WWN 50020f2300006077 are listed. The listing also displays FCP SCSI LUNs for unconfigured Fibre Channel devices. The Fibre Channel device represented by c0::50020f2300005f24 is reported to have two FCP SCSI LUNs. The configure operation on c0::50020f2300005f24 creates two Solaris devices. The Type field of FCP SCSI LUN level ap_ids show the SCSI device type of each LUN. When a Fibre Channel device has different device type LUNs, the Type field reflects that.

The receptacle and occupant state for attachment points at the fp port have the following meanings:

configured
    One or more devices configured on the fp port

connected
    fp port active

disconnected
    fp port quiesced (IO activity is suspended)

empty
    Not applicable

unconfigured
    No devices configured on the fp port

The state for individual Fibre Channel devices on an fp port:

configured
    Device is configured into Solaris and is available for use

connected
    fp port to which the device is connected to is active

disconnected
    fp port to which the device is attached is quiesced

unconfigured
    Device is available to be configured

The condition field for attachment points at the fp port has the following meanings:

failed
    An error condition has prevented the fp port from being able to detect the presence or type
    of a Fibre Channel connection.

The condition field for individual Fibre Channel devices on an fp port has the following
meanings:

failed
    An error is encountered while probing a device on Fabric.

failing
    A device was configured on a host and its state as seen by Solaris appears to be normal (i.e.,
    online) but it is either not currently present or visible in the fabric or its presence could not
    be verified due to an error condition on the local port through which the device was
    configured.

unusable
    A device has been configured on the host, but is currently offline or failed.

The unknown condition indicates that probing a device on Fabric completed without an
error and the device state within Solaris host is normal if the device was configured previously.
The internal condition of the device cannot be guaranteed.

Options cfgadm defines several types of operations in addition to listing (-l). These operations include
invoking configuration state changes and obtaining configuration administration help
messages (-h).

The following options are supported:

-c *function*
    The following generic commands are defined for the fp-transport-specific library:

    For Fibre Channel device attachment points on the fc-fabric type fp port attachment
    point, the following configuration state change operations are supported:

    configure
        Configure a connected Fibre Channel Fabric device to a host. When a Fibre Channel
        device is listed as an unknown type in the output of the list operation the device might
        not be configurable. No attempt is made to configure devices with unknown types. The
        force option (-f) can be used to force the fp port driver plug-in to make an attempt to
        configure any devices. Any errors in the process are reported. By default, each FCP SCSI

LUN that is discovered on a Fibre channel Fabric device is configured. However, FCP SCSI LUNs that are specified in the "pwwn-lun-blacklist" property in the `fp.conf` file will remain unconfigured. The FCP SCSI LUN level listing reflects the state of such FCP SCSI LUNs. They stay in the "unconfigured" state after reboot or Solaris Dynamic Reconfiguration on the controller that they are connected through. Refer to `fp(7d)` for additional details on the "pwwn-lun-blacklist" property.

unconfigure

Unconfigure a Fibre Channel Fabric device from a host. This device stays unconfigured until the next reboot or Solaris Dynamic Reconfiguration on the controller that the device is connected, at which time all fabric devices are automatically enumerated. The default behavior may be changed through the use of the "manual_configuration_only" property in the `fp.conf` file. If the property is set, the device remains unconfigured after reboot. Refer to `fp(7d)` for additional details on the "manual_configuration_only" property.

For Fibre Channel private loop devices and N_Port point-to-point devices, the configure command returns success without doing any operation. The unconfigure command is not supported on the private loop devices and N_Port point-to-point devices. The private loop devices and N_Port point-to-point devices are configured by Solaris Fibre Channel drivers by default and are not managed through end user- or application-initiated operations. The pwwn-lun-blacklist property in the `fp.conf` file is applied to the private loop device and N_Port point-to-point device in the same way it is applied to a Fabric device.

-f

Force the configure change state operation to occur irrespective of the condition or type. Refer to the above description of the configure change state operation.

-h *ap_id*

Obtain fp—transport-specific help. Specify any fp attachment point.

-o *hardware_options*

The following hardware options are supported.

show_SCSI_LUN

Lists ap_ids associated with each FCP SCSI LUN for discovered Fibre Channel devices when specified with the list option -al. Refer to the previously mentioned description and example of FCP SCSI LUN level listing. Device node creation is not supported on the FCP SCSI LUN level. See NOTES.

All Fibre Channel devices are available to Solaris by default. Enabling only a subset of Fabric devices available to Solaris by default can be accomplished by setting the property "manual_configuration_only" in /kernel/drv/fp.conf file. When "manual_configuration_only" in `fp.conf` is set, all Fabric devices are not available to Solaris unless an application or an end user had previously requested the device be configured into Solaris. The configure state-change command makes the device available

to Solaris. After a successful `configure` operation on a Fabric device, the associated links are added to the /dev namespace. The `unconfigure` state-change command makes a device unavailable to Solaris.

When a Fibre Channel Fabric device is configured successfully to a host using the `-c configure` operation, its physical ap_id is stored in a repository. When a Fibre Channel Fabric device is unconfigured using the `-c unconfigure` operation, its physical ap_id is deleted from the same repository. All fabric devices are automatically enumerated by default and the repository is used only if the `fp.conf` "manual_configuration_only" property is set. Refer to fp(7d) for additional details on the "manual_configuration_only" property.

You can specify the following commands with the `-c` option to control the update behavior of the repository:

force_update
    For `configure`, the attachment point is unconditionally added to the repository; for `unconfigure`, the attachment point is unconditionally deleted.

no_update
    No update is made to the repository regardless of the operation.

These options should not be used for normal `configure` and `unconfigure` operations. See WARNINGS.

When a Fibre Channel device has multiple FCP SCSI LUNs configured and any Solaris device associated with its FCP SCSI LUN is in the unusable condition, the whole Fibre Channel device is reported as unusable. The following option with the `-c unconfigure` command removes only Solaris devices with the unusable condition for a Fibre Channel device.

unusable_SCSI_LUN
    For `unconfigure` operation, any offlined device nodes for a target device is removed.

-s *listing_options*
    Refer to cfgadm(1M) for usage information.

-t *ap_id*
    No test commands are available at present.

-x *hardware_function*
    No hardware specific functions are available at present.

All other options have the same meaning as defined in the cfgadm(1M) man page.

Examples   EXAMPLE 1   Unconfiguring a Disk

The following command unconfigures a disk:

```
# cfgadm -c unconfigure c0::210000203708b606
```

EXAMPLE 2 Unconfigure all the Configured Disks under Single Attachment Point

The following command unconfigures all configured disks under the attachment point c0.

```
# cfgadm -c unconfigure c0
```

EXAMPLE 3 Configuring a Disk

The following command configures a disk:

```
# cfgadm -c configure c0::210000203708b606
```

EXAMPLE 4 Configure all the Unconfigured Disks under Single Attachment Point

The following command configures all unconfigured disks under the attachment point c0.

```
# cfgadm -c configure c0
```

EXAMPLE 5 Removing the Fibre Channel Fabric Device Attachment Point from Repository

The following command unconditionally removes the fibre channel fabric device attachment point from the Fabric device repository.

```
# cfgadm -c unconfigure -o force_update c0::210000203708b606
```

EXAMPLE 6 Removing Offlined Solaris Device Nodes for a Target Device

The following command removes offlined Solaris device nodes for a target device:

```
# cfgadm -c unconfigure -o unusable_SCSI_LUN c0::210000203708b606
```

Files /usr/lib/cfgadm/fp.so.1
   Hardware-specific library for Fibre Channel Fabric device node management.

/etc/cfg/fp/fabric_WWN_map
   Repository of physical ap_ids of Fabric devices currently configured. It is used only to reconfigure those Fabric devices at boot time. This repository is only used when the "manual_configuration_only" /kernel/drv/fp.conf file is set.

/etc/rcS.d/fdevattach
   Reconfigures Fabric device(s) of which physical ap_id is listed in /etc/cfg/fp/fabric_WWN_map on boot time.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/storage/fibre-channel/fc-fabric, service/storage/fibre-channel/fc-fabricx

See Also svcs(1), cfgadm(1M), svcadm(1M), config_admin(3CFGADM), libcfgadm(3LIB),
attributes(5), smf(5), fp(7d)

Warnings Do not use hardware-specific options for the repository update under normal
configure/unconfigure operations. The hardware-specific options are expected to be used
when the node creation of a Fabric device fails at boot time and the error condition is
considered to be permanent. The unconfigure command with force_update
hardware-specific option unconditionally removes the attachment point of a failing Fabric
device from the repository.

Notes For devices with unknown or no SCSI device type (for example, a Fibre Channel Host Bus
Adapter), the configure operation might not be applicable.

The configure and unconfigure commands operate on the Fibre Channel device level which
is represented by port WWN ap_id. If a Fibre Channel device has multiple FCP SCSI LUNs
configured, the configure command on the associated port WWN ap_id results in creating a
Solaris device for each FCP SCSI LUN unless it is specified in the "pwwn-lun-blacklist"
property in the fp.conf file. The unconfigure command removes all Solaris devices
associated with the port WWN ap_id. The FCP SCSI LUN level ap_id is not valid for the
configure and unconfigure commands.

The deprecated show_FCP_dev option has been replaced by the new show_SCSI_LUN option,
and the deprecated unusable_FCP_dev option has been replaced by the new
unusable_SCSI_LUN option.

The cfgadm_fp service is managed by the service management facility, smf(5), under the
service identifier:

```
svc:/system/device/fc-fabric:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can
be performed using svcadm(1M). The service's status can be queried using the svcs(1)
command.

No administrative actions on this service are required for Fabric device configuration once
this service is started on boot time.

Name cfgadm_ib – InfiniBand hardware specific commands for cfgadm

Synopsis `/usr/sbin/cfgadm -f [-y | -n] [-v] -c` *function ap_id*...

`/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o` *hardware_options*`]`
`    -x` *hardware_function ap_id*...

`/usr/sbin/cfgadm -v [-a] [-s` *listing_option*`] [-] [`*ap_id* `|` *ap_type*...`]`

`/usr/sbin/cfgadm -v -h [`*ap_id*`]`...

Description The InfiniBand hardware specific library `/usr/lib/cfgadm/ib.so.1` provides the
functionality for administering its fabric through the cfgadm(1M) utility. cfgadm operates on
attachment points. See cfgadm(1M).

An InfiniBand (IB) device is enumerated by the IB nexus driver, ib(7D), based on the services
from the IB Device Manager (IBDM).

The IB nexus driver creates and initializes five types of child device nodes:

- IB Port devices
- IB HCA service (HCA_SVC) devices
- IB Virtual Physical Point of Attachment (VPPA) devices
- I/O Controller (IOC)
- IB Pseudo devices

See ib(7D) for details on enumeration of IB Port, IB VPPA, and IB HCA_SVC devices. For
additional information on IBDM, see ibdm(7D). See ib(4) for details on IB Pseudo devices.

For IB administration, two types of static attachment point are created for the fabric
administration as seen by the given host. There is one static attachment point ib and all IB
devices (either an IOC, Port, VPPA, HCA_SVC, or a Pseudo device) in the fabric are
represented as dynamic attachment points based off of it. There is another static attachment
point for each Host Channel Adapter (HCA) in the host based on its node Globally Unique
Identifier (GUID) value.

Attachment points are named through ap_ids. There are two types of ap_ids: logical and
physical. The physical ap_id is based on the physical path name. For the IB fabric it is
`/devices/ib:fabric`. The logical ap_id is a shorter, and has a more user friendly name.

The static ap_id for the IB fabric is ib. The IB devices are dynamic attachment points and have
no physical ap_id. The logical ap_id of an IOC contains its GUID, ib::*IOC-GUID*. An
example of an IOC ap_id is ib::80020123456789a. The logical ap_id of a Pseudo device, see
ib(4) for details, is of the format ib::*driver_name,unit-address*. An example of a pseudo
ap_id would be ib::sdp,0 where "sdp" is the driver name and "0" is its *unit-address* property.
The logical ap_id of Port, VPPA and HCA_SVC device contains its Partition Key (*P_Key*),
Port GUID / *Node GUID* and a communication service-name. The format of ap_id is as below:

Port device
    ib::*PORT_GUID*,*0*,*service-name*

VPPA device
   ib::*PORT_GUID*,*P_Key*,*service-name*

HCA_SVC device
   ib::*HCA_GUID*,0,*servicename*

The Partition Key (*P_Key*) is 0 for Port and HCA_SVC devices. The *P_Key* helps determine
the partition to which this port belongs for a VPPA device node. A port might have more than
one *P_Key*. An example of a VPPA device logical ap_id point is ib::80245678,ffff,ipib.
The *port-GUID* is 80245678, the *P_Key* is 0xffff, and the service name is ipib. The
service-name information is obtained from the file /kernel/drv/ib.conf which contains
service-name strings. The HCA's logical ap_id contains its node GUID value,
hca:HCA-GUID. An example is hca:21346543210a987.

A listing of the IB attachment points includes information on all IB devices (IOC, VPPA,
HCA_SVC, Pseudo, and Port devices seen by the IBDM and the IB nexus driver) in the fabric
even if they are not seen by the host and configured for use.

The following shows a listing of five IB devices (two IOC, one VPPA, one Port, one
HCA_SVC) and one HCA:

```
example# cfgadm -al
Ap_Id                 Type         Receptacle   Occupant       Condition
hca:21346543210a987   IB-HCA       connected    configured     ok
ib                    IB-FABRIC    connected    configured     ok
ib::80020123456789a   IB-IOC       connected    configured     ok
ib::802abc9876543     IB-IOC       connected    unconfigured   unknown
ib::80245678,ffff,ipib IB-VPPA     connected    configured     ok
ib::12245678,0,nfs    IB-PORT      connected    configured     ok
ib::21346543,0,hnfs   IB-HCA_SVC   connected    configured     ok
ib::sdp,0             IB-PSEUDO    connected    configured     ok
```

The ap_id ib::802abc9876543 shows an IOC device that is not yet configured by the host for
use or had been previously offlined by an explicit

```
cfgadm -c unconfigure
```

operation. The distinction was made by the information displayed under the Condition
column. The IB device with a zero P_Key and HCA GUID is a HCA_SVC device. Refer to
cfgadm(1M) for more information regarding listing attachment points.

The receptacle state for attachment points have the following meanings:

connected
   For an IOC/VPPA/Port/Pseudo/HCA_SVC device, connected implies that it has been seen
   by the host. The device might not have been configured for use by Solaris.

   For a HCA attachment point, connected implies that it has been configured and is in use.

   All IB ap_ids are always shown as connected.

The occupant state for attachment points have the following meanings:

configured
   The IB device, and the HCA ap_id, are configured and usable by Solaris.

unconfigured
   The IB device at the ap_id was explicitly offlined using cfgadm -c unconfigure, was not
   successfully configured. This could be because it wasn not successfully configuref for use
   with Solaris (no driver, or a device problem), or because it was never configured for use by
   the IB nexus driver.

   The unconfigured operation is not supported for the HCA attachment point. The IB static
   apid, ib, is shown unconfigured if the system has no IB hardware.

The attachment point conditions are:

failed
   Not used.

failing
   Not used.

ok
   Normal state. Ready for use.

unknown
   This state is only valid for IB device that have been probed by IBDM but not yet configured
   for use by Solaris. It is also shown for devices that have been explicitly offlined by a cfgadm
   -c unconfigure operation. This condition does not apply to a HCA attachment point.

unusable
   Not used.

Options   The following options are supported:

-c *function*
   The IB hardware specific library supports two generic commands (*function*s). These
   commands are not supported on the static attachment points (that is, the HCA ap_ids and
   the IB static ib ap_id).

   The following generic commands are supported:

   configure
      Configure the IB device to be used by Solaris.

   unconfigure
      Unconfigure the IB device. If successful, cfgadm reports the condition of this ap_id as
      unknown.

-f
   Not supported.

-h *ap_id*

Obtain IB specific help for an IB attachment point.

-l

List the state and condition of IB attachment points. The -l option works as described in cfgadm(1M).

When paired with the -a option, displays the dynamic attachment points as well (IOC, VPPA, Port, Pseudo, and HCA_SVC devices).

When paired with -v option, displays verbose data about the ap_ids. For an IOC, the Info field in the

cfgadm -avl

output displays the following information: VendorID, IOCDeviceID, DeviceVersion, SubsystemVendorID, SubsystemID, Class, Subclass, Protocol, ProtocolVersion and IDString from the IOCControllerProfile. If the ID string isn't provided then nothing is displayed in its place. These fields are defined in the InfiniBand Specification Volume 1 (http://www.infinibandta.org).

For a VPPA, Port, or HCA_SVC device the Info field in the cfgadm -lav display shows the service name information to which this device is bound. If no such information exists, nothing is displayed.

For a Pseudo device cfgadm -alv displays the driver name and its unit-address information. For a HCA the verbose listing displays the VendorID, ProductID of the HCA, number of ports it has, and the PortGUID value of its ports. See EXAMPLES.

-o *hardware_option*

This option is not currently defined.

-s *listing_option*

Attachment points of class ib can be listed by using the select sub-option. Refer to the cfgadm(1M) man page for more information.

-x *hardware_function*

Perform a hardware specific function. Note that the *name* can not be more than 4 characters long.

The following hardware specific functions are supported:

add_service -ocomm=[port|vppa|hca_svc],service=*name*

This hardware specific function is supported on the static IB attachment point. It can be used to add a new service to /kernel/drv/ib.conf file and to update the ib(7D) driver.

You must use the service=*name* option to indicate the new service to be added. You must use the option comm=[port|vppa|hca_svc] option to add the name service to either port-svc-list or to the hca-svc-list in the /kernel/drv/ib.conf file. See EXAMPLES.

delete_service -ocomm=[port|vppa|hca_svc],service=*name*

This hardware specific function is supported on the static IB attachment point only. It can be used to delete an existing service from the /kernel/drv/ib.conf file and also from the ib(7D) driver's data base. You must use the service=name option to indicate which service to delete. You must use the comm=[port|vppa|hca_svc] option to delete this service from the port-svc-list, vppa-svc-list, or vppa-svc-list of the /kernel/drv/ib.conf file. See EXAMPLES.

list_clients

Supported on HCA attachment points. Displays all the kernel IB clients using this HCA. It also displays the respective ap_ids of these kernel IB clients and if they have opened an alternate HCA device. See EXAMPLES.

.

If a given kernel IB client does not have a valid ap_id then a - is displayed in that column.

list_services

This hardware specific function is supported on the static IB attachment point only. It lists all the Port and VPPA services as read from the /kernel/drv/ib.conf file. See EXAMPLES.

unconfig_clients

This hardware specific function is supported on the static HCA attachment point only. It can be used to unconfigure all IB kernel clients of this given HCA. Only IB kernel clients that do not have an alternate HCA are unconfigured. See EXAMPLES.

update_ioc_config

This hardware specific function is supported on static ib attachment point and the IOC attachment points. For the ib APID, this function updates properties of all the IOC device nodes. For the IOC APID, this function updates the properties of specified IOC device node. This command updates the port-list, port-entries, service-id, and service-name IOC node properties .

See ib(7D).

update_pkey_tbls

Supported on the static ib attachment point. Updates the PKEY information inside IBTL. IBTL re-reads the P_Key tables for all the ports on each HCA present on the host.

See ibtl(7D).

Examples   EXAMPLE 1   Listing the State and Condition of IB Devices

The following command lists the state and condition of IB devices on the system. It only shows the static attachment points.

EXAMPLE 1   Listing the State and Condition of IB Devices   *(Continued)*

```
example# cfgadm
hca:21346543210a987      IB-HCA      connected    configured   ok
ib                       IB-FABRIC   connected    configured   ok
```

The -a option lists all attachment points. The following example uses the -a option and lists all attachment points:

```
example# cfgadm -a
hca:21346543210a987      IB-HCA      connected    configured    ok
ib                       IB-FABRIC   connected    configured    ok
ib::80020123456789a      IB-IOC      connected    unconfigured ok
ib::80245678,ffff,ipib   IB-VPPA     connected    configured    ok
ib::21346543,0,hnfs      IB-HCA_SVC  connected    configured    ok
ib::12245678,0,nfs       IB-PORT     connected    configured    ok
ib::sdp,0                IB-PSEUDO   connected    configured    ok
```

EXAMPLE 2   Listing the Verbose Status of a IB VPPA Device

The following command lists the verbose status of a IB VPPA device:

```
example# cfgadm -alv ib::80245678,ffff,ipib
Ap_Id                 Receptacle Occupant   Condition Information
When      Type    Busy  Phys_Id
ib::80245678,ffff,ipib    connected    configured    ok       ipib
unavailable  IB-VPPA  n   /devices/ib:fabric::80245678,ffff,ipib
```

A verbose listing of an IOC shows additional information. The following command shows a verbose listing:

```
example# cfgadm -alv ib::80020123456789a
Ap_Id     Receptacle   Occupant    Condition Information
When      Type    Busy  Phys_Id
ib::80020123456789a     connected    configured    ok        VID: 0xeaea
DEVID: 0xeaea VER: 0x5 SUBSYS_VID: 0x0 SUBSYS_ID: 0x0 CLASS: 0xffff
SUBCLASS: 0xff PROTO: 0xff PROTOVER: 0x1 ID_STRING: Sample Host Adapter
unavailable IB-IOC   n    /devices/ib:fabric::80020123456789a
```

A verbose listing of a Pseudo device shows:

```
example# cfgadm -alv ib::sdp,0
Ap_Id                 Receptacle  Occupant    Condition Information
When      Type    Busy  Phys_Id
ib::sdp,0         connected   configured   ok       Driver = "sd
p" Unit-address = "0"
unavailable  IB-PSEUDO  n /devices/ib:fabric::sdp,0
```

A verbose listing of a HCA shows:

EXAMPLE 2 Listing the Verbose Status of a IB VPPA Device   *(Continued)*

```
example# cfgadm -alv hca:21346543210a987
Ap_Id              Receptacle   Occupant     Condition Information
When       Type    Busy  Phys_Id
hca:21346543210a987 connected   configured   ok          VID: 0x15b3,
PID: 0x5a44, #ports: 0x2, port1 GUID: 0x80245678, port2 GUID: 0x80245679
unavailable  IB-HCA    n /devices/ib:21346543210a987
```

You can obtain more user-friendly output if you specify these following cfgadm class and field
selection options: -s "select=class(ib),cols=ap_id:info"

The following command displays only IB ap_ids. The output only includes the ap_id and
Information fields.

```
# cfgadm -al -s "cols=ap_id:info" ib::80245678,ffff,ipib
Ap_Id                           Information
ib::80245678,ffff,ipib          ipib
```

EXAMPLE 3 Unconfiguring an Existing IB IOC

The following command unconfigures the IB IOC attached to ib::80020123456789a, then
displays the status of the ap_id:

```
# cfgadm -c unconfigure ib::80020123456789a
Unconfigure the device: /devices/ib:fabric::80020123456789a
This operation will suspend activity on the IB device
Continue (yes/no)?
```

Enter: y

```
IB device unconfigured successfully.
# cfgadm -al ib::80020123456789a
Ap_Id              Type     Receptacle Occupant     Condition
ib::80020123456789  IB-IOC   connected   unconfigured unknown
#
```

The condition unknown implies that the device node doesn't exist anymore and this IB
device's existence is known only to the IB Device Manager.

EXAMPLE 4 Configuring an IB IOC

The following series of commands configures an IB device attached to ib::80020123456789a:

```
# cfgadm -yc configure ib::80020123456789a
# cfgadm -al ib::80020123456789a
Ap_Id              Type     Receptacle Occupant     Condition
ib::80020123456789a IB-IOC   connected   configured   ok
```

EXAMPLE 5 Listing All Kernel IB Clients of a HCA

The following command lists all kernel IB clients of an HCA attached to
`hca:21346543210a987`:

```
# cfgadm -x list_clients hca:21346543210a987
Attachment Point       Clients              Alternate HCA
ib::80020123456789a    ioc1                 Yes
ib::80245678,ffff,ipib ipib                 No
ib::21346543,0,hnfs    hnfs                 No
-                      ibdm                 No
-                      ibmf                 No
```

EXAMPLE 6 Adding a Port Service

The following command adds a new Port service called `srp`:

```
 # cfgadm -o comm=port,service=srp -x add_service ib
```

EXAMPLE 7 Deleting a VPPA Service

The following command deletes the `ibd` VPPA service `ibd`:

```
# cfgadm -o comm=vppa,service=ipib -x delete_service ib
```

EXAMPLE 8 Listing Port, VPPA, HCA_SVC Services

The following command lists all Port, VPPA, and HCA_SVC services:

```
# cfgadm -x list_services ib
Port communication services:
        srp

VPPA communication services:
        ipib
        nfs

HCA_SVC communication services:
        hnfs
```

EXAMPLE 9 Reprobing IOC Devices

The following command reprobes all IOC device nodes.

```
# cfgadm -x update_ioc_config ib
This operation can update properties of IOC devices.
Continue (yes/no)?

Enter: y

#
```

EXAMPLE 10 Unconfiguring All Kernel Clients of a HCA

The following command unconfigures all kernel clients of a HCA

```
# cfgadm -x unconfig_clients hca:21346543
 This operation will unconfigure clients of this HCA.
 Continue (yes/no)?

 Enter: y
```

InfiniBand Specification Volume 1 (http://www.infinibandta.org)

Notes Apart from the listing (cfgadm -l or cfgadm -x list_clients), only the superuser can execute any functions on an attachment point.

Name   cfgadm_pci – PCI, CompactPCI, and PCI Express Hotplug hardware specific commands for
cfgadm

Synopsis   /usr/sbin/cfgadm [-f] [-y | -n] [-v]
        [-o *hardware_options*] -c *function ap_id* [*ap_id*]

/usr/sbin/cfgadm [-f] [-y | -n] [-v]
        [-o *hardware_options*] -x *hardware_function ap_id*
        [*ap_id*]

/usr/sbin/cfgadm [-v] [-s *listing_options*]
        [-o *hardware_options*] [-l [*ap_id* | *ap_type*]]

/usr/sbin/cfgadm [-v] [-o *harware_options*] -t *ap_id* [*ap_id*]

/usr/sbin/cfgadm [-v] [-o *hardware_function*] -h
        [*ap_id*| *ap_type*]

Description   The PCI hardware specific library, /usr/lib/cfgadm/pci.so.1, provides the support for
hotplugging PCI and CompactPCI adapter cards into the respective hotpluggable slots in a
system that is hotplug capable, through the cfgadm command (see cfgadm(1M)). This library
does not include support for PCI Express Hotplug or Standard PCI Hotplug adapter cards,
which are provided by a different library (see cfgadm_shp(1M)). Hotplug administrative
models between PCI, CompactPCI remain the same except where noted in this document.

For PCI Hot Plug, each hotplug slot on a specific PCI bus is represented by an attachment
point of that specific PCI bus.

An attachment point consist of two parts: a receptacle and an occupant. The receptacle
under PCI Hot Plug is usually referred to as the physical hotpluggable slot; and the occupant
is usually referred to as the PCI adapter card that plugs into the slot.

Attachment points are named through ap_ids. There are two types of ap_ids: logical and
physical. The physical ap_id is based on the physical pathname, that is,
/devices/pci@1/hpc0_slot3, whereas the logical ap_id is a shorter, and more user-friendly
name. For PCI hotpluggable slots, the logical ap_id is usually the corresponding hotplug
controller driver name plus the logical slot number, that is, pci0:hpc0slot1; PCI nexus
driver, with hotplug controller driver named hpc and slot number 1. The ap_type for PCI Hot
Plug is pci.

Note that the ap_type is not the same as the information in the Type field.

See the *Oracle Solaris Administration: Common Tasks* for a detailed description of the hotplug
procedure.

Options   The following options are supported:

-c *function*
    The following *function*s are supported for PCI hotpluggable slots:

configure

    Configure the PCI device in the slot to be used by Solaris.

connect

    Connect the slot to PCI bus.

disconnect

    Disconnect the slot from the PCI bus.

insert

    Not supported.

remove

    Not supported.

unconfigure

    Logically remove the PCI device's resources from the system.

-f

    Not supported.

-h *ap_id* | *ap_type*

    Print out PCI Hot Plug-specific help message.

-l *list*

    List the values of PCI Hot Plug slots.

-o *hardware_options*

    No hardware specific options are currently defined.

-s *listing_options*

    Same as the generic cfgadm(1M).

-t *ap_id*

    This command is only supported on platforms which support testing capability on the slot.

-v

    Execute in verbose mode.

    When the -v option is used with the -l option, the cfgadm command outputs information about the attachment point. For PCI Hotplug attachment points located in a PCI PCI Express hierarchy, see cfgadm_shp(1M) for details. For PCI Hot Plug attachment points not located in a PCI Express hieararchy, the Information field will be the slot's system label, if any. This string will be obtained from the slot-name property of the slot's bus node. The information in the Type field is printed with or without the v option. The occupant Type field will describe the contents of the slot. There are 2 possible values:

unknown

    The slot is empty. If a card is in the slot, the card is not configured or there is no driver for the device on the card.

subclass/*board*
    The card in the slot is either a single-function or multi-function device.

    subclass is a string representing the subclass code of the device, for example, SCSI,
    ethernet, pci-isa, and so forth. If the card is a multi-functional device, MULT will get
    printed instead.

    board is a string representing the board type of the device. For example, hp is the string
    used for a PCI Hot Plug adapter, hs is used for a Hot Swap Board, nhs for a Non—Hot
    Swap cPCI Board, bhs for a Basic Hot Swap cPCI Board, and fhs for a Full Hot Swap
    cPCI Board.

    Most PCI cards with more than one device are not multi-function devices, but are
    implemented as a PCI bridge with arbitrary devices behind them. In those cases, the
    subclass displayed is that of the PCI bridge. Most commonly, the bridges are pci-pci, a
    generic PCI to PCI bridge or stpci, a semi-transparent PCI bridge.

-x *hardware_function*
    Perform hardware specific function. These hardware specific functions should not
    normally change the state of a receptacle or occupant.

    The following *hardware_functions* are supported:

    enable_slot | disable_slot
        Change the state of the slot and preserve the state of slot across reboot. Preservation of
        state across reboot is only supported on select platforms.

        enable_slot enables the addition of hardware to this slot for hotplugging and at boot
        time.

        disable_slot disables the addition of hardware to this slot for hotplugging and at boot
        time. When a slot is disabled its condition is shown as unusable.

    enable_autoconfig | disable_autoconfig
        Change the ability to autoconfigure the occupant of the slot. Only platforms that
        support auto configuration support this feature.

        enable_autoconfig enables the ability to autoconfigure the slot.

        diable_autoconfig disables the ability to autoconfigure the slot.

        Autoconfiguration is done through the attention button on the PCI Express platforms
        and through the injector/ejector latch on the CompactPCI platforms. When
        autoconfiguration is disabled, the attention button or latch mechanism cannot be used
        to configure the occupant of the slot.

    led=[*led_sub_arg*],mode=[*mode_sub_arg*]
        Without sub-arguments, print a list of the current LED settings. With sub-arguments,
        set the mode of a specific LED for a slot.

Specify *led_sub_arg* as fault, power, attn, or active.

Specify *mode_sub_arg* as on, off or blink.

Changing the state of the LED does not change the state of the receptacle or occupant. Normally, the LEDs are controlled by the hotplug controller, no user intervention is necessary. Use this command for testing purposes.

Caution: Changing the state of the LED can misrepresent the state of occupant or receptacle.

The following command prints the values of LEDs:

```
example# cfgadm -x led pci0:hpc0_slot1
Ap_Id           Led
pci0:hpc0_slot1  power=on,fault=off,active=off,attn=off
```

The following command turns on the Fault LED:

```
example# cfgadm -x led=fault,mode=on pci0:hpc0_slot1
```

The following command turns off the Power LED:

```
example# cfgadm -x led=power,mode=off pci0:hpc0_slot0
```

The following command sets the *active* LED to blink to indicate the location of the slot:

```
example# cfgadm -x led=active,mode=on pci0:hpc0_slot3
```

Examples   EXAMPLE 1   Printing out the Value of Each Slot

The following command prints out the values of each slot:

```
example# cfgadm -l
Ap_Id           Type        Receptacle   Occupant       Condition
c0              scsi-bus    connected    configured     unknown
c1              scsi-bus    connected    unconfigured   unknown
c2              scsi-bus    connected    unconfigured   unknown
cpci_slot1      stpci/fhs   connected    configured     ok
cpci_slot2      unknown     empty        unconfigured   unknown
cpci_slot4      stpci/fhs   connected    configured     ok
cpci_slot5      stpci/fhs   connected    configured     ok
```

EXAMPLE 2   Replacing a Card

The following command lists all DR-capable attachment points:

```
example# cfgadm

Type            Receptacle  Occupant     Condition
c0              scsi-bus    connected    configured     unknown
c1              scsi-bus    connected    unconfigured   unknown
```

EXAMPLE 2 Replacing a Card   *(Continued)*

```
c2              scsi-bus    connected    unconfigured  unknown
cpci_slot1      stpci/fhs   connected    configured    ok
cpci_slot2      unknown     empty        unconfigured  unknown
cpci_slot4      stpci/fhs   connected    configured    ok
cpci_slot5      stpci/fhs   connected    configured    ok
```

The following command unconfigures and electrically disconnects the card:

example# **cfgadm -c disconnect cpci_slot4**

The change can be verified by entering the following command:

example# **cfgadm cpci_slot4**

```
Ap_Id                   Type        Receptacle   Occupant    Condition
cpci_slot4              unknown     disconnected unconfigured unknown
```

Now the card can be swapped. The following command electrically connects and configures the card:

example# **cfgadm -c configure cpci_slot4**

The change can be verifed by entering the following command:

example# **cfgadm cpci_slot4**

```
Ap_Id                   Type        Receptacle   Occupant    Condition
cpci_slot4              stpcipci/fhs connected   configured  ok
```

Oracle Solaris Administration: Common Tasks

Name cfgadm_sata – SATA hardware-specific commands for cfgadm

Synopsis /usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o *hardware_options*]
        -c *function ap_id*...

/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o *hardware_options*]
        -x *hardware_function ap_id*...

/usr/sbin/cfgadm [-v] [-a] [-s *listing_options*]
        [-o *hardware_options*] [-l [*ap_id* | *ap_type*]...]

/usr/sbin/cfgadm [-v] [-o *harware_options*] -t *ap_id*...

/usr/sbin/cfgadm [-v] [-o *hardware_options*] -h [*ap_id*]...

Description The SATA hardware specific library, /usr/lib/cfgadm/sata.so.1, provides the functionality for SATA hot plugging through the cfgadm command. cfgadm operates on attachment points, which are locations in the system where hardware resources can be dynamically reconfigured. See cfgadm(1M) for information regarding attachment points.

Each SATA controller's and port multiplier's device port is represented by an attachment point in the device tree. SATA devices, connected and configured in the system are shown as the attachment point name extension. The terms "attachment point" and "SATA port" are used interchangeably in the following description.

Attachment points are named through ap_ids. All the SATA attachment points ap_id consist of a string in the following form:

sataX/P[.M][::dsk/cXtYd0]

where

X	is the SATA controller number
P	is the SATA controller's device port number (0 to 31)
M	is the port multiplier's device port number (0 to 14) the port multiplier host port number (15). It is used only when the port multiplier is attached to the SATA controller's device port.
dev/cXtYd0	identifies the attached SATA device
Y	is a target number

In general, the device identifier is derived from the corresponding logical link for the device in /*dev*. Because only one LUN (LUN 0) is supported by the SATA device, the "d" component of the device string will always have number 0 (zero).

For example, the logical ap_id of the device port 4 of the port multiplier connected to the device port 5 of the SATA controller 2 would be:

sata2/5.4

If the SATA disk or CD/DVD device is connected to this attachment point, and the device is configured, the *ap_id* would be:

```
sata2/5.4::dsk/c2t645d0
```

The *cXtYd0* string identifying a device has one-to-one correspondence to the device attachment point.

A simple listing of attachment points in the system will include all SATA device ports and attached devices. For example:

```
#cfgadm -l
Ap_Id                        Type         Receptacle    Occupant      Condition
  sata0/0::dev/c0t0d0        disk         connected     configured    ok
  sata0/1::dev/c0t1d0        disk         connected     configured    ok
  sata0/2::dev/c0t2d0        cd-dvd       connected     configured    ok
  sata0/3                    sata-port    empty         unconfigured  ok
  sata1/0                    sata-port    disconnected  unconfigured  unknown
  sata1/1                    sata port    disconnected  unconfigured  unknown
  sata1/2                    sata port    empty         unconfigured  ok
  sata1/3.15                 sata-pmult   connected     configured    ok
  sata1/3.0::dev/c0t512d0    disk         connected     configured    ok
  sata1/3.1                  sata-port    empty         unconfigured  ok
  sata1/3.2                  sata-port    empty         unconfigured  ok
  sata1/3.3                  sata-port    empty         unconfigured  ok
  usb0/1                     unknown      empty         unconfigured  ok
  usb0/2                     unknown      empty         unconfigured  ok
```

See cfgadm(1M) for more information regarding listing of attachment points.

The receptacle state for attachment point at the SATA port have the following meanings:

empty   The SATA port is powered-on and enabled. No device presence was detected on this port.

disconnected   The SATA port is not enabled or the SATA device presence was detected but no communication with the device was established, or the port has failed.

connected   The SATA device is detected on the port the communication with the device is established.

The occupant (device attached to the SATA port) state have the following meanings:

configured   The attached SATA device is configured and ready to use by the operating system.

unconfigured   No device is attached, or the SATA device attached to the SATA port was not yet configured. To configure it, run the command "cfgadm -c configure ap_id".

The attachment point (SATA port) condition have the following meanings:

ok   The SATA port is powered-on and enabled, and is ready for use.

failed   The SATA port failed. It may be disabled and/or powered-off by the system. It is
            unusable and its condition is unknown. It may be due to the device plugged-in.

unknown   The SATA port is disabled and its condition is unknown.

A "state table" is the combination of an attachment point receptacle state, an occupant state,
and an attachment point (SATA port) condition. The valid states are:

empty/unconfigured/ok	The SATA port is enabled and active. No device presence was detected.
disconnected/unconfigured/ok	The SATA port is enabled and a device presence was detected but no communications with the device was established.
disconnected/unconfigured/unknown	The SATA Port is disabled and its condition is unknown.
disconnected/unconfigured/failed	The SATA Port is disabled and unusable. The port was disabled by the system due to a system-detected failure.
connected/unconfigured/ok	The SATA Port is enabled and active. A device presence was detected and the communication with a device was established. The device is not configured to be used by the OS.
connected/configured/ok	The device is present and configured, and is ready to use by the OS.

Options cfgadm defines several types of operations besides listing (-l). These operations include
testing, (-t), invoking configuration state changes, (-c), invoking hardware specific functions
(-x), and obtaining configuration administration help messages (-h).

-c *function*
    The following generic *function*s are defined for the SATA hardware specific library. For
    SATA port attachment point, the following configuration state change operations are
    supported:

    connect
        Enable (activate) the SATA port and establish the communication with an attached
        device. This operation implies powering-on the port if necessary.

    disconnect
        Unconfigure the attached device, if it is not already unconfigured, and disable
        (deactivate) the SATA port. A subsequent "connect" command enables SATA port

operation but does not bring a device to the "configured" state.

For a SATA device attached to the SATA port following state change operations are supported:

configure   Configure new device for use by the operating system if it is not already configured. This command also implies connect operation, if necessary.

unconfigure   Unconfigure the device connected to the SATA port if it is not already unconfigured.

The `configure` and `unconfigure` operations cannot be used for an attachment point where the port multiplier is connected. Port multipliers are configured and unconfigured automatically by the system. However, configure and unconfigure operations apply to all SATA devices connected to the port multiplier's device ports.

-f

Not supported.

-h *ap_id*

SATA specific help can be obtained by using the help option with any SATA attachment point.

-l [-v]

The -l option works as described in cfgadm(1M). When paired with the -v option, the "Information" field contains the following SATA-specific information:

- Mfg: manufacturer string
- Product: product string
- No: product Serial Number

-o *hardware_options*

No hardware specific options are currently defined.

-s *listing_options*

Attachment points of class SATA can be listed by using the select suboption. See cfgadm(1M).

-t *ap_id*

Perform self-test of the SATA port, if supported by the SATA controller. If a port self-test operation is not supported by the SATA controller, an error message is issued.

-x *hardware_function*

Perform hardware specific function.

Some of the following commands used on the SATA ports or the SATA controller may affect any SATA devices that have been attached, as noted. ap_id refers to SATA port or the entire SATA controller, as noted. If the operation implies unconfiguring a device, but it cannot be unconfigured (that is, the device contains a mounted filesystem), an error

message is issued and the operation is not performed. An error message will be also issued if the SATA controller does not support specified operation.

sata_reset_device ap_id
Reset the SATA device attached to ap_id SATA port. The SATA port state does not change.

sata_reset_port ap_id
Reset the SATA port specified by ap_id. If a SATA device is attached to the port, it is also reset. This operation may be also performed on the port to which a port multiplier is connected. If a port multiplier is connected to the SATA controller port, the SATA devices attached to the port multiplier may not be reset

sata_reset_all ap_id
Reset SATA controller specified by the controller number part in ap_id and all attached devices and re-enumerate all connected devices, including port multipliers and devices connected to port multipliers' device ports.

This operations implies unconfiguring all attached devices prior to the operation. Any newly enumerated devices will be left unconfigured.

sata_port_deactivate ap_id
Force the deactivation of the port when all else fails. This is meant as an emergency step; use with caution.

sata_port_activate ap_id
Force the activation of a port. This is meant for emergency situations on a port which was deactivated to recover from errors.

sata_port_self_test ap_id
Perform self-test operation on the SATA controller. This operation implies unconfiguring all devices and resetting the SATA controller.

-v

Execute in verbose mode.

The following Transitions table reports the state transitions resulting from the -c operations and hotplugging actions:

```
current state     operation        possible new state
-------------     ---------        ------------------
empty/
unconfigured/ok   device plug-in   connected/unconfigured/ok, or
                                   disconnected/unconfigured/ok, or
                                   disconnected/unconfigured/failed

empty/
unconfigured/ok   -c unconfigure   error message, no state change

empty/
```

```
                unconfigured/ok    -c configure    error message, no state change

                empty/
                unconfigured/ok    -c connect      error message, no state change

                empty/
                unconfigured/ok    -c disconnect   disconnected/unconfigured/unknown, or
                                                   disconnected/unconfigured/failed

                disconnected/
                unconfigured/ok    device unplug   no state change

                disconnected/
                unconfigured/ok    -c unconfigure  error message, no state change

                disconnected/
                unconfigured/ok    -c configure    error message, no state change

                disconnected/
                unconfigured/ok    -c connect      error message, no state change

                disconnected/
                unconfigured/ok    -c disconnect   error message, no state change

                disconnected/
                unconfigured/
                unknown
                (no disk plugged)  -c configure    error message, state change to
                                                   empty/unconfigured/ok, or
                                                   disconnected/unconfigured/failed

                disconnected/
                unconfigured/
                unknown            -c configure    state change to
                (disk plugged)                     connected/configured/ok or,
                                                   connected/unconfigured/ok, or
                                                   disconnected/unconfigured/failed and
                                                   possible error message

                disconnected/
                unconfigured/
                unknown            -c connect      empty/unconfigured/ok, or
                                                   connected/unconfigured/ok, or
                                                   disconnected/unconfigured/ok, or
                                                   disconnected/unconfigured/unknown, or
                                                   disconnected/unconfigured/failed

                disconnected/
```

```
unconfigured/
unknown          -c disconnect   error message, no state change

disconnected/
unconfigured/
failed           any command     error message, no state change
                 other than
                 -x commands

connected/
unconfigured/ok  disk unplug     error message and state:
                                 empty/unconfigured/ok, or
                                 disconnected/unconfigured/failed

connected/
unconfigured/ok  -c configure    connected/unconfigured/ok, or
                                 connected/configured/ok, or
                                 disconnected/unconfigured/ok, or
                                 disconnected/unconfigured/failed

connected/
unconfigured/ok  -c unconfigure  error message, no state change

connected/
unconfigured/ok  -c connect      error message, no state change

connected/
unconfigured/ok  -c disconnect   disconnected/unconfigured/unknown, or
                                 disconnected/unconfigured/failed

connected/
configured/ok    disk unplug     error message and state:
                                 empty/unconfigured/ok, or
                                 disconnected/unconfigured/failed

connected/
configured/ok    -c configure    error message, no state change

connected/
configured/ok    -c unconfigure  error message, if device cannot be
                                 unconfigured, no state change, or
                                 connected/unconfigured/ok, or
                                 disconnected/unconfigured/ok, or
                                 disconnected/unconfigured/failed

connected/
configured/ok    -c connect      error message, no state change
```

```
connected/
configured/ok        -c disconnect    error message, if device cannot be
                                      unconfigured, no state change, or
                                      disconnected/unconfigured/unknown, or
                                      disconnected/unconfigured/failed
```

Examples   **EXAMPLE 1**   Configuring a Disk

The following command configures a disk attached to SATA controller 0, port 0:

```
example# cfgadm -c configure sata0/0
```

This command should be issued only when there is a device connected to the SATA port.

EXAMPLE 2   Unconfiguring a Disk

The following command unconfigures a disk attached to SATA controller 0, port 3:

```
example# cfgadm -c unconfigure sata0/3
```

The device identifying string is shown when the attachment point receptacle state is
"connected" and occupant state is "configured".

EXAMPLE 3   Encountering a Mounted File System While Unconfiguring a Disk

The following command illustrates encountering a mounted file system while unconfiguring a
disk:

```
example# cfgadm -c unconfigure sata1/5
```

The system responds with the following:

```
cfgadm: Component system is busy, try again: failed to offline:
/devices/pci@0,0/pci8086,244e@1e/pci1095,3124@1/sd@5,0
     Resource              Information
-----------------    --------------------------
/dev/dsk/c1t5d0s0    mounted filesystem "/mnt"
```

Files   /usr/lib/cfgadm/sata.so.1   Hardware specific library for generic SATA hot plugging.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library

See Also   cfgadm(1M), config_admin(3CFGADM), libcfgadm(3LIB), attributes(5)

Notes   The emergency "sata_port_deactivate" operation is not supported on ports with attached
disks containing critical partitions such as root (/), /usr, swap, or /var. The deactivate
operation should not be attempted on such ports. Incorrect usage can result in a system hang
and require a reboot.

Hotplugging operations are not supported by all SATA controllers.

If SATA connectors are the hot-pluggable type and the SATA controller supports hotplugging, a SATA device can be hotplugged at any time. The system detects the event and establishes the communication with the device. The device has to be configured by the explicit "`cfgadm -c configure ap_id`" command.

If the SATA connectors are the hot-pluggable type and the SATA controller supports hotplugging, unplugging a device without unconfiguring it may result in system hang or data loss. If a device is unconfigured but receptacle state is not in a disconnected state, unplugging a device from the SATA port will result in error message.

Warnings   The connectors on some SATA devices do not conform to SATA hotplug specifications. Performing hotplug operations on such devices can cause damage to the SATA controller and/or the SATA device.

Name cfgadm_sbd – cfgadm commands for system board administration

Synopsis cfgadm -l [-a] [-o parsable] *ap_id*...

cfgadm -c *function* [-f] [-y | -n]
    [-o unassign | nopoweroff] [-v] *ap_id*...

cfgadm -t [-v] *ap_id*...

cfgadm -x [-f] [-v] *function ap_id*...

Description The cfgadm_sbd plugin provides dynamic reconfiguration functionality for connecting, configuring, unconfiguring, and disconnecting class sbd system boards. It also enables you to connect or disconnect a system board from a running system without having to reboot the system.

The cfgadm command resides in /usr/sbin. See cfgadm(1M). The cfgadm_sbd plugin resides /usr/platform/sun4u/lib/cfgadm.

Each board slot appears as a single attachment point in the device tree. Each component appears as a dynamic attachment point. You can view the type, state, and condition of each component, and the states and condition of each board slot by using the -a option.

The cfgadm options perform differently depending on the platform. Additionally, the form of the attachment points is different depending on the platform. See the Platform Notes section for more information.

Component Conditions The following are the names and descriptions of the component conditions:

failed
    The component failed testing.

ok
    The component is operational.

unknown
    The component has not been tested.

Component States The following is the name and description of the receptacle state for components:

connected
    The component is connected to the board slot.

The following are the names and descriptions of the occupant states for components:

configured
    The component is available for use by the Solaris operating environment.

unconfigured
    The component is not available for use by the Solaris operating environment.

Board Conditions The following are the names and descriptions of the board conditions.

failed
    The board failed testing.

ok
    The board is operational.

unknown
    The board has not been tested.

unusable
    The board slot is unusable.

Board States Inserting a board changes the receptacle state from empty to disconnected. Removing a board changes the receptacle state from disconnected to empty.

Caution: Removing a board that is in the connected state or that is powered on and in the disconnected state crashes the operating system and can result in permanent damage to the system.

The following are the names and descriptions of the receptacle states for boards:

connected
    The board is powered on and connected to the system bus. You can view the components on a board only after it is in the connected state.

disconnected
    The board is disconnected from the system bus. A board can be in the disconnected state without being powered off. However, a board must be powered off and in the disconnected state before you remove it from the slot.

empty
    A board is not present.

The occupant state of a disconnected board is always unconfigured. The following table contains the names and descriptions of the occupant states for boards:

configured
    At least one component on the board is configured.

unconfigured
    All of the components on the board are unconfigured.

Dynamic System Domains Platforms based on dynamic system domains (DSDs, referred to as domains in this document) divide the slots in the chassis into electrically isolated hardware partitions (that is, DSDs). Platforms that are not based on DSDs assign all slots to the system permanently.

A slot can be empty or populated, and it can be assigned or available to any number of domains. The number of slots available to a given domain is controlled by an available

component list (ACL) that is maintained on the system controller. The ACL is not the access control list provided by the Solaris operating environment.

A slot is visible to a domain only if the slot is in the domain's ACL and if it is not assigned to another domain. An unassigned slot is visible to all domains that have the slot in their ACL. After a slot has been assigned to a domain, the slot is no longer visible to any other domain.

A slot that is visible to a domain, but not assigned, must first be assigned to the domain before any other state changing commands are applied. The assign can be done explicitly using `-x assign` or implicitly as part of a connect. A slot must be unassigned from a domain before it can be used by another domain. The unassign is always explicit, either directly using `-x unassign` or as an option to disconnect using `-o unassign`.

State Change Functions

Functions that change the state of a board slot or a component on the board can be issued concurrently against any attachment point. Only one state changing operation is permitted at a given time. A Y in the Busy field in the state changing information indicates an operation is in progress.

The following list contains the functions that change the state:

- configure
- unconfigure
- connect
- disconnect

Availability Change Functions

Commands that change the availability of a board can be issued concurrently against any attachment point. Only one availability change operation is permitted at a given time. These functions also change the information string in the `cfgadm -l` output. A Y in the Busy field indicates that an operation is in progress.

The following list contains the functions that change the availability:

- assign
- unassign

Condition Change Functions

Functions that change the condition of a board slot or a component on the board can be issued concurrently against any attachment point. Only one condition change operation is permitted at a given time. These functions also change the information string in the `cfgadm -l` output. A Y in the Busy field indicates an operation is in progress.

The following list contains the functions that change the condition:

- poweron
- poweroff
- test

Unconfigure Process   This section contains a description of the unconfigure process, and illustrates the states of source and target boards at different stages during the process of moving permanent memory.

In the following code examples, the permanent memory on board 0 must be moved to another board in the domain. Thus, board 0 is the source, and board 1 is the target.

A status change operation cannot be initiated on a board while it is marked as busy. For brevity, the CPU information has been removed from the code examples.

The process is started with the following command:

```
# cfgadm -c unconfigure -y SB0::memory &
```

First, the memory on board 1 in the same address range as the permanent memory on board 0 must be deleted. During this phase, the source board, the target board, and the memory attachment points are marked as busy. You can display the status with the following command:

```
# cfgadm -a -s cols=ap_id:type:r_state:o_state:busy SB0 SB1

Ap_Id          Type      Receptacle    Occupant      Busy
SB0            CPU       connected     configured    y
SB0::memory    memory    connected     configured    y
SB1            CPU       connected     configured    y
SB1::memory    memory    connected     configured    y
```

After the memory has been deleted on board 1, it is marked as unconfigured. The memory on board 0 remains configured, but it is still marked as busy, as in the following example.

```
Ap_Id          Type      Receptacle    Occupant      Busy
SB0            CPU       connected     configured    y
SB0::memory    memory    connected     configured    y
SB1            CPU       connected     configured    y
SB1::memory    memory    connected     unconfigured  n
```

The memory from board 0 is then copied to board 1. After it has been copied, the occupant state for the memory is switched. The memory on board 0 becomes unconfigured, and the memory on board 1 becomes configured. At this point in the process, only board 0 remains busy, as in the following example.

```
Ap_Id          Type      Receptacle    Occupant      Busy
SB0            CPU       connected     configured    y
SB0::memory    memory    connected     unconfigured  n
SB1            CPU       connected     configured    n
SB1::memory    memory    connected     configured    n
```

After the entire process has been completed, the memory on board 0 remains unconfigured, and the attachment points are not busy, as in the following example.

```
Ap_Id         Type     Receptacle    Occupant       Busy
SB0           CPU      connected     configured     n
SB0::memory   memory   connected     unconfigured   n
SB1           CPU      connected     configured     n
SB1::memory   memory   connected     configured     n
```

The permanent memory has been moved, and the memory on board 0 has been unconfigured. At this point, you can initiate a new state changing operation on either board.

Platform-Specific Options You can specify platform-specific options that follow the options interpreted by the system board plugin. All platform-specific options must be preceded by the platform keyword. The following example contains the general format of a command with platform-specific options:

command -o *sbd_options*,platform=*platform_options*

Options This man page does not include the -v, -a, -s, or -h options for the cfgadm command. See cfgadm(1M) for descriptions of those options. The following options are supported by the cfgadm_sbd plugin:

-c *function*
  Performs a state change function. You can use the following functions:

  unconfigure
    Changes the occupant state to unconfigured. This function applies to system board slots and to all of the components on the system board.

    The unconfigure function removes the CPUs from the CPU list and deletes the physical memory from the system memory pool. If any device is still in use, the cfgadm command fails and reports the failure to the user. You can retry the command as soon as the device is no longer busy. If a CPU is in use, you must ensure that it is off line before you proceed. See pbind(1M), psradm(1M) and psrinfo(1M).

    The unconfigure function moves the physical memory to another system board before it deletes the memory from the board you want to unconfigure. Depending of the type of memory being moved, the command fails if it cannot find enough memory on another board or if it cannot find an appropriate physical memory range.

    For permanent memory, the operating system must be suspended (that is, quiesced) while the memory is moved and the memory controllers are reprogrammed. If the operating system must be suspended, you will be prompted to proceed with the operation. You can use the -y or -n options to always answer yes or no respectively.

    Moving memory can take several minutes to complete, depending on the amount of memory and the system load. You can monitor the progress of the operation by issuing a status command against the memory attachment point. You can also interrupt the memory operation by stopping the cfgadm command. The deleted memory is returned to the system memory pool.

disconnect

 Changes the receptacle state to disconnected. This function applies only to system board slots.

 If the occupant state is configured, the disconnect function attempts to unconfigure the occupant. It then powers off the system board. At this point, the board can be removed from the slot.

 This function leaves the board in the assigned state on platforms that support dynamic system domains.

 If you specify -o nopoweroff, the disconnect function leaves the board powered on. If you specify -o unassign, the disconnect function unassigns the board from the domain.

 If you unassign a board from a domain, you can assign it to another domain. However, if it is assigned to another domain, it is not available to the domain from which is was unassigned.

configure

 Changes the occupant state to configured. This function applies to system board slots and to any components on the system board.

 If the receptacle state is disconnected, the configure function attempts to connect the receptacle. It then walks the tree of devices that is created by the connect function, and attaches the devices if necessary. Running this function configures all of the components on the board, except those that have already been configured.

 For CPUs, the configure function adds the CPUs to the CPU list. For memory, the configure function ensures that the memory is initialized then adds the memory to the system memory pool. The CPUs and the memory are ready for use after the configure function has been completed successfully.

 For I/O devices, you must use the mount and the ifconfig commands before the devices can be used. See ifconfig(1M) and mount(1M).

connect

 Changes the receptacle state to connected. This function applies only to system board slots.

 If the board slot is not assigned to the domain, the connect function attempts to assign the slot to the domain. Next, it powers on and tests the board, then it connects the board electronically to the system bus and probes the components.

 After the connect function is completed successfully, you can use the -a option to view the status of the components on the board. The connect function leaves all of the components in the unconfigured state.

 The assignment step applies only to platforms that support dynamic system domains.

-f

Overrides software state changing constraints.

The -f option never overrides fundamental safety and availability constraints of the hardware and operating system.

-l

Lists the state and condition of attachment points specified in the format controlled by the -s, -v, and -a options as specified in cfgadm(1M). The cfgadm_sbd plugin provides specific information in the info field as described below. The format of this information might be altered by the -o parsable option.

The parsable info field is composed of the following:

cpu

The cpu type displays the following information:

cpuid=#[,#…]

Where # is a number, and represents the ID of the CPU. If more than one # is present, this CPU has multiple active virtual processors.

speed=#

Where # is a number and represents the speed of the CPU in MHz.

ecache=#

Where # is a number and represents the size of the ecache in MBytes. If the CPU has multiple active virtual processors, the ecache could either be shared among the virtual processors, or divided between them.

memory

The memory type displays the following information, as appropriate:

address=#

Where # is a number, representing the base physical address.

size=#

Where # is a number, representing the size of the memory in KBytes.

permanent=#

Where # is a number, representing the size of permanent memory in KBytes.

unconfigurable

An operating system setting that prevents the memory from being unconfigured.

inter-board-interleave

The board is participating in interleaving with other boards.

source=*ap_id*

Represents the source attachment point.

target=*ap_id*

Represents the target attachment point.

deleted=#
　　Where # is a number, representing the amount of memory that has already been
　　deleted in KBytes.

remaining=#
　　Where # is a number, representing the amount of memory to be deleted in KBytes.

io
　The io type displays the following information:

device=*path*
　　Represents the physical path to the I/O component.

referenced
　　The I/O component is referenced.

board
　The board type displays the following boolean names. If they are not present, then the
　opposite applies.

assigned
　　The board is assigned to the domain.

powered-on
　　The board is powered on.

　The same items appear in the info field in a more readable format if the -o parsable
　option is not specified.

-o parsable
　Returns the information in the info field as a boolean *name* or a set of name=value pairs,
　separated by a space character.

　The -o parsable option can be used in conjunction with the -s option. See the
　cfgadm(1M) man page for more information about the -s option.

-t
　Tests the board.

　Before a board can be connected, it must pass the appropriate level of testing.

　Use of this option always attempts to test the board, even if it has already passed the
　appropriate level of testing. Testing is also performed when a -c connect state change
　function is issued, in which case the test step can be skipped if the board already shows an
　appropriate level of testing. Thus the -t option can be used to explicitly request that the
　board be tested.

-x *function*
　Performs an sbd-class function. You can use the following functions:

assign
    Assigns a board to a domain.

    The receptacle state must be disconnected or empty. The board must also be listed in the
    domain available component list. See Dynamic System Domains.

unassign
    Unassigns a board from a domain.

    The receptacle state must be disconnected or empty. The board must also be listed in the
    domain available component list. See Dynamic System Domains.

poweron
    Powers the system board on.

    The receptacle state must be disconnected.

poweroff
    Powers the system board off.

    The receptacle state must be disconnected.

Operands   The following operands are supported:

Receptacle *ap_id*
    For the Sun Fire high-end systems such as the Sun Fire 15K , the receptacle attachment
    point ID takes the form SB*X* or IO*X*, where *X* equals the slot number.

    The exact format depends on the platform and typically corresponds to the physical
    labelling on the machine. See the platform specific information in the NOTES section.

Component *ap_id*
    The component attachment point ID takes the form *component_typeX*, where
    component_type equals one of the component types described in "Component Types" and
    X equals the component number. The component number is a board-relative unit number.

    The above convention does not apply to memory compontents. Any DR action on a
    memory attachment point affects all of the memory on the system board.

Examples   The following examples show user input and system output on a Sun Fire 15K system. User
    input, specifically references to attachment points and system output might differ on other
    Sun Fire systems, such as the Sun Fire midrange systems such as the 6800. Refer to the
    Platform Notes for specific information about using the cfgadm_sbd plugin on non-Sun Fire
    high-end models.

EXAMPLE 1   Listing All of the System Board

```
# cfgadm -a -s "select=class(sbd)"

Ap_Id        Type      Receptacle      Occupant        Condition
```

EXAMPLE 1   Listing All of the System Board   *(Continued)*

```
SB0          CPU        connected      configured    ok
SB0::cpu0    cpu        connected      configured    ok
SB0::memory  memory     connected      configured    ok
IO1          HPCI       connected      configured    ok
IO1::pci0    io         connected      configured    ok
IO1::pci1    io         connected      configured    ok
SB2          CPU        disconnected   unconfigured  failed
SB3          CPU        disconnected   unconfigured  unusable
SB4          unknown    empty          unconfigured  unknown
```

This example demonstrates the mapping of the following conditions:

- The board in Slot 2 failed testing.
- Slot 3 is unusable; thus, you cannot hot plug a board into that slot.

EXAMPLE 2   Listing All of the CPUs on the System Board

```
# cfgadm -a -s "select=class(sbd):type(cpu)"
```

```
Ap_Id        Type       Receptacle     Occupant      Condition
SB0::cpu0    cpu        connected      configured    ok
SB0::cpu1    cpu        connected      configured    ok
SB0::cpu2    cpu        connected      configured    ok
SB0::cpu3    cpu        connected      configured    ok
```

EXAMPLE 3   Displaying the CPU Information Field

```
# cfgadm -l -s noheadings,cols=info SB0::cpu0
```

```
cpuid 16, speed 400 MHz, ecache 8 Mbytes
```

EXAMPLE 4   Displaying the CPU Information Field in Parsable Format

```
# cfgadm -l -s noheadings,cols=info -o parsable SB0::cpu0
```

```
cpuid=16 speed=400 ecache=8
```

EXAMPLE 5   Displaying the Devices on an I/O Board

```
# cfgadm -a -s noheadings,cols=ap_id:info -o parsable IO1
```

```
IO1        powered-on assigned
IO1::pci0 device=/devices/saf@0/pci@0,2000 referenced
IO1::pci1 device=/devices/saf@0/pci@1,2000 referenced
```

EXAMPLE 6   Monitoring an Unconfigure Operation

In the following example, the memory sizes are displayed in Kbytes.

EXAMPLE 6 Monitoring an Unconfigure Operation   *(Continued)*

```
# cfgadm -c unconfigure -y SB0::memory &
# cfgadm -l -s noheadings,cols=info -o parsable SB0::memory SB1::memory

address=0x0 size=2097152 permanent=752592 target=SB1::memory
    deleted=1273680 remaining=823472
address=0x1000000 size=2097152 source=SB0::memory
```

EXAMPLE 7 Assigning a Slot to a Domain

```
# cfgadm -x assign SB2
```

EXAMPLE 8 Unassigning a Slot from a Domain

```
# cfgadm -x unassign SB3
```

Attributes See attributes(5) for a description of the following attribute:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	`system/library/platform`
Stability	See below.

The interface stability is evolving. The output stability is unstable.

See Also cfgadm(1M), devfsadm(1M), ifconfig(1M), mount(1M), pbind(1M), psradm(1M), psrinfo(1M), config_admin(3CFGADM), attributes(5)

Notes This section contains information on how to monitor the progress of a memory delete operation. It also contains platform specific information.

Memory Delete Monitoring The following shell script can be used to monitor the progress of a memory delete operation.

```
# cfgadm -c unconfigure -y SB0::memory &
# watch_memdel SB0

#!/bin/sh
# This is the watch_memdel script.

if [ -z "$1" ]; then
        printf "usage:  %s board_id\n" `basename $0`
        exit 1
fi

board_id=$1

cfgadm_info='cfgadm -s noheadings,cols=info -o parsable'
```

```
eval `$cfgadm_info $board_id::memory`

if [ -z "$remaining" ]; then
        echo no memory delete in progress involving $board_id
        exit 0
fi

echo deleting target $target

while true
do
        eval `$cfgadm_info $board_id::memory`

        if [ -n "$remaining" -a "$remaining" -ne 0 ]
        then
                echo $deleted KBytes deleted, $remaining KBytes remaining
                remaining=
        else
                echo memory delete is done
                exit 0
        fi
        sleep 1
done
exit 0
```

Sun Enterprise 10000 Platform Notes

The following syntax is used to refer to attachment points on the Sun Enterprise 10000 system:

board::*component*

...where *board* refers to the system board; and *component* refers to the individual component. System boards can range from SB0 (zero) to SB15. A maximum of sixteen system boards are available.

The DR 3.0 model running on a Sun Enterprise 10000 domain supports a limited subset of the functionality provided by the cfgadm_sbd plugin. The only supported operation is to view the status of attachment points in the domain. This corresponds to the -l option and all of its associated options.

Attempting to perform any other operation from the domain will result in an error that states that the operation is not supported. All operations to add or remove a system board must be initiated from the System Service Processor.

Sun Fire High-End System Platform Notes

The following syntax is used to refer to attachment points on the Sun Fire high-end systems:

board::*component*

where *board* refers to the system board or I/O board; and *component* refers to the individual component.

Depending on the system's configuration, system boards can range from `SB0` (zero) through `SB17`, and I/O boards can range from `IO0` (IO zero) through `IO17`. (A maximum of eighteen system and I/O boards are available).

The `-t` and `-x` options behave differently on the Sun Fire high-end system platforms. The following list describes their behavior:

`-t`
The system controller uses a CPU to test system boards by running `LPOST`, sequenced by the `hpost` command. To test I/O boards, the driver starts the testing in response to the `-t` option, and the test runs automatically without user intervention. The driver unconfigures a CPU and a stretch of contiguous physical memory. Then, it sends a command to the system controller to test the board. The system controller uses the CPU and memory to test the I/O board from inside of a transaction/error cage. You can only use CPUs from system boards (not MCPU boards) to test I/O boards.

`-x assign | unassign`
In the Sun Fire high-end system administration model, the platform administrator controls the platform hardware through the use of an available component list for each domain. This information is maintained on the system controller. Only the platform administrator can modify the available component list for a domain.

The domain administrator is only allowed to assign or unassign a board if it is in the available component list for that domain. The platform administrator does not have this restriction, and can assign or unassign a board even if it is not in the available component list for a domain.

Sun Fire 15K Component Types
The following are the names and descriptions of the component types:

`cpu`
CPU

`io`
I/O device

`memory`
Memory

Note: An operation on a memory component affects all of the memory components on the board.

Sun Fire Midrange Systems Platform Notes
References to attachment points are slightly different on Sun Fire midrange servers such as the 6800, 4810, 4800, and 3800 systems than on the Sun Fire high-end systems. The following syntax is used to refer to attachment points on Sun Fire systems other than the Sun Fire 15K:

N#.*board*::*component*

where **N#** refers to the node; *board* refers to the system board or I/O board; and *component* refers to the individual component.

Depending on the system's configuration, system boards can range from SB0 through SB5, and I/O boards can range from IB6 through IB9. (A maximum of six system and four I/O boards are available).

Sun Fire Midrange System Component Types

The following are the names and descriptions of the component types:

cpu
    CPU

pci
    I/O device

memory
    Memory

Note: An operation on a memory component affects all of the memory components on the board.

Name cfgadm_scsi – SCSI hardware specific commands for cfgadm

Synopsis /usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o *hardware_option*]
        -c *function* *ap_id*...

/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o *hardware_option*]
        -x *hardware_function* *ap_id*...

/usr/sbin/cfgadm [-v] [-a] [-s *listing_option*] [-o *hardware_option*]
        [-l [*ap_id* | *ap_type* ...]]

/usr/sbin/cfgadm [-v] [-o *hardware_option*] -t *ap_id*...

/usr/sbin/cfgadm [-v] [-o *hardware_option*] -h [*ap_id*]...

Description The SCSI hardware specific library /usr/lib/cfgadm/scsi.so.1 provides the functionality
for SCSI hot-plugging through the cfgadm(1M) command. cfgadm operates on attachment
points, which are locations in the system where hardware resources can be dynamically
reconfigured. Refer to cfgadm(1M) for information regarding attachment points.

For SCSI hot-plugging, each SCSI controller is represented by an attachment point in the
device tree. In addition, each SCSI device is represented by a dynamic attachment point.
Attachment points are named through ap_ids. Two types of ap_ids are defined: logical and
physical. The physical ap_id is based on the physical pathname, whereas the logical ap_id is a
shorter more user-friendly name. For SCSI controllers, the logical ap_id is usually the
corresponding disk controller number. For example, a typical logical ap_id would be c0.

SCSI devices are named relative to the controller ap_id. Thus if a disk device is attached to
controller c0, its ap_id can be:

c0::dsk/c0t0d0

where dsk/c0t0d0 identifies the specific device. In general, the device identifier is derived
from the corresponding logical link for the device in /dev. For example, a SCSI tape drive
logical ap_id could be c0::rmt/0. Here c0 is the logical ap_id for the SCSI controller and
rmt/0 is derived from the logical link for the tape drive in /dev/rmt. If an identifier can not be
derived from the link in /dev, a unique identifier will be assigned to it. For example, if the tape
device has no link in /dev, it can be assigned an ap_id of the form c0::st3 where st3 is a
unique internally generated identifier.

When a controller is capable of supporting the Solaris I/O multipathing feature (formerly
known as MPxIO or the Sun StorEdge Traffic Manager [STMS]) and is enabled, the controller
provides a path to a scsi_vhci(7D) multipath device. If a device attached to such controller is
supported by scsi_vhci(7D) its ap_id can be:

c0::0,0

...where 0,0 uniquely identifies the target and logical unit information. The Type field for a
path of such ap_ids indicates if it represent a path to the scsi_vhci(7D) multipath devices,
along with the type of device that is connected to through the path.

A simple listing of attachment points in the system will include attachment points at SCSI controllers but not SCSI devices. Use the -a flag to the list option (-l) to list SCSI devices as well. For example:

```
# cfgadm -l
  Ap_Id           Type        Receptacle    Occupant      Condition
  c0              scsi-bus    connected     configured    unknown
  sysctrl0:slot0  cpu/mem     connected     configured    ok
  sysctrl0:slot1  sbus-upa    connected     configured    ok
```

To list SCSI devices in addition to SCSI controllers:

```
# cfgadm -al

Ap_Id              Type        Receptacle    Occupant      Condition
c0                 scsi-bus    connected     configured    unknown
c0::dsk/c0t14d0    disk        connected     configured    unknown
c0::dsk/c0t11d0    disk        connected     configured    unknown
c0::dsk/c0t8d0     disk        connected     configured    unknown
c0::dsk/c0t0d0     disk        connected     configured    unknown
c0::rmt/0          tape        connected     configured    unknown
sysctrl0:slot0     cpu/mem     connected     configured    ok
sysctrl0:slot1     sbus-upa    connected     configured    ok
```

If the controller c0 was enabled with Solaris I/O multipathing and the connected disk and tape devices are supported by Solaris I/O multipathing the output would be:

```
# cfgadm -al

Ap_Id              Type        Receptacle    Occupant      Condition
c0                 scsi-bus    connected     configured    unknown
c0::11,0           disk-path   connected     configured    unknown
c0::14,0           disk-path   connected     configured    unknown
c0::8,0            disk-path   connected     configured    unknown
c0::0,0            disk-path   connected     configured    unknown
c0::a.0            tape-path   connected     configured    unknown
sysctrl0:slot0     cpu/mem     connected     configured    ok
sysctrl0:slot1     sbus-upa    connected     configured    ok
```

Refer to cfgadm(1M) for more information regarding listing attachment points. The receptacle and occupant state for attachment points at the SCSI controller have the following meanings:

empty
  not applicable

disconnected
  bus quiesced (I/O activity on bus is suspended)

connected
  bus active

configured
  one or more devices on the bus is configured

unconfigured
  no device on the bus is configured

The corresponding states for individual SCSI devices are:

empty
  not applicable

disconnected
  bus to which the device is attached is quiesced

connected
  bus to which device is attached is active

configured
  device or path to a multipath SCSI device is configured

unconfigured
  device or path to a multipath SCSI device is not configured

Options cfgadm defines several types of operations besides listing (-l).These operations include testing, (-t), invoking configuration state changes, (-c), invoking hardware specific functions (-x), and obtaining configuration administration help messages (-h).

-c *function*
  The following generic commands are defined for the SCSI hardware specific library:

  For SCSI controller attachment points, the following configuration state change operations are supported:

  connect
    Unquiesce the SCSI bus.

  disconnect
    Quiesce the bus (suspend I/O activity on bus).

    Incorrect use of this command can cause the system to hang. See NOTES.

  configure
    Configure new devices on SCSI bus.

  unconfigure
    Unconfigure all devices connected to bus.

  The following generic commands are defined for SCSI devices and for paths to multipath SCSI devices:

  configure
    Configure a specific device or a specific path to a multipath SCSI device.

unconfigure
    Unconfigure a specific device or a specific path to a multipath SCSI device.

-f
    When used with the disconnect command, forces a quiesce of the SCSI bus, if supported
    by hardware.

    Incorrect use of this command can cause the system to hang. See NOTES.

-h *ap_id*
    SCSI specific help can be obtained by using the help option with any SCSI attachment
    point.

-o *hardware_option*
    No hardware specific options are currently defined.

-s *listing_option*
    Attachment points of class scsi can be listed by using the select sub-option. Refer to the
    [cfgadm(1M)](#) man page for additional information.

-t *ap_id*
    No test commands are available at present.

-x *hardware_function*
    Some of the following commands can only be used with SCSI controllers and some only
    with SCSI devices.

    In the following, *controller_ap_id* refers to an ap_id for a SCSI controller, for example, c0.
    device_ap_id refers to an ap_id for a SCSI device, for example: c0::dsk/c0dt3d0.

    The following hardware specific functions are defined:

    insert_device *controller_ap_id*
        Add a new device to the SCSI controller, *controller_ap_id*.

        This command is intended for interactive use only.

    remove_device *device_ap_id*
        Remove device *device_ap_id*.

        This command is intended for interactive use only.

    replace_device *device_ap_id*
        Remove device *device_ap_id* and replace it with another device of the same kind.

        This command is intended for interactive use only.

    reset_device *device_ap_id*
        Reset *device_ap_id*.

    reset_bus *controller_ap_id*
        Reset bus *controller_ap_id* without resetting any devices attached to the bus.

reset_all *controller_ap_id*
    Reset bus *controller_ap_id* and all devices on the bus.

locator [=on|off] *device_ap_id*
    Sets or gets the hard disk locator LED, if it is provided by the platform. If the [on|off]
    suboption is not set, the state of the hard disk locator is printed.

led[=LED,mode=on|off|blink] *device_ap_id*
    If no sub-arguments are set, this function print a list of the current LED settings. If
    sub-arguments are set, this function sets the mode of a specific LED for a slot.

Examples

EXAMPLE 1 Configuring a Disk

The following command configures a disk attached to controller c0:

```
# cfgadm -c configure c0::dsk/c0t3d0
```

EXAMPLE 2 Unconfiguring a Disk

The following command unconfigures a disk attached to controller c0:

```
# cfgadm -c unconfigure c0::dsk/c0t3d0
```

EXAMPLE 3 Adding a New Device

The following command adds a new device to controller c0:

```
# cfgadm -x insert_device c0
```

The system responds with the following:

```
Adding device to SCSI HBA: /devices/sbus@1f,0/SUNW,fas@e,8800000
This operation will suspend activity on SCSI bus c0
Continue (yes/no)?
```

Enter:

y

The system responds with the following:

```
SCSI bus quiesced successfully.
It is now safe to proceed with hotplug operation.
Enter y if operation is complete or n to abort (yes/no)?
```

Enter:

y

EXAMPLE 4 Replacing a Device

The following command replaces a device attached to controller c0:

```
# cfgadm -x replace_device c0::dsk/c0t3d0
```

EXAMPLE 4 Replacing a Device   *(Continued)*

The system responds with the following:

```
Replacing SCSI device: /devices/sbus@1f,0/SUNW,fas@e,8800000/sd@3,0
This operation will suspend activity on SCSI bus: c0
Continue (yes/no)?
```

Enter:

y

The system responds with the following:

```
SCSI bus quiesced successfully.
It is now safe to proceed with hotplug operation.
Enter y if operation is complete or n to abort (yes/no)?
```

Enter:

y

EXAMPLE 5 Encountering a Mounted File System While Unconfiguring a Disk

The following command illustrates encountering a mounted file system while unconfiguring a disk:

cfgadm -c unconfigure c1::dsk/c1t0d0

The system responds with the following:

```
cfgadm: Component system is busy, try again: failed to offline:
/devices/pci@1f,4000/scsi@3,1/sd@1,0
    Resource              Information
-----------------  --------------------------
/dev/dsk/c1t0d0s0  mounted filesystem "/mnt"
```

EXAMPLE 6 Displaying the Value of the Locator for a Disk

The following command displays the value of the locator for a disk. This example is specific to the SPARC Enterprise Server family:

cfgadm -x locator c0::dsk/c0t6d0

The system responds with the following:

```
Disk                Led
c0t6d0              locator=on
```

EXAMPLE 7 Setting the Value of the Locator for a Disk

The following command sets the value of the locator for a disk. This example is specific to the SPARC Enterprise Server family:

EXAMPLE 7 Setting the Value of the Locator for a Disk   *(Continued)*

```
# cfgadm -x locator=off c0::dsk/c0t6d0
```

The system does not print anything in response.

EXAMPLE 8 Configuring a Path to a Multipath SCSI Disk

The following command configures a path connected through controller c0:

```
# cfgadm -c configure c0::2,0
```

EXAMPLE 9 Unconfiguring a Path to a Multipath SCSI Disk

The following command unconfigures a path connected through controller c0:

```
# cfgadm -c unconfigure c0::2,0
```

Files /usr/lib/cfgadm/scsi.so.1
    hardware-specific library for generic SCSI hot-plugging

/usr/platform/SPARC-Enterprise/lib/cfgadm/scsi.so.1
    platform-specific library for generic SCSI hot-plugging

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library

See Also cfgadm(1M), luxadm(1M), config_admin(3CFGADM), libcfgadm(3LIB), attributes(5), scsi_vhci(7D)

Notes The disconnect (quiesce) operation is not supported on controllers which control disks containing critical partitions such as root (/), /usr, swap, or /var. The disconnect operation should not be attempted on such controllers. Incorrect usage can result in a system hang and require a reboot.

When a controller is in the disconnected (quiesced) state, there is a potential for deadlocks occurring in the system. The disconnect operation should be used with caution. A controller should be kept in the disconnected state for the minimum period of time required to accomplish the DR operation. The disconnect command is provided only to allow the replacement of the SCSI cables while the system is running. It should not be used for any other purpose. The only fix for a deadlock (if it occurs) is to reboot the system.

Hotplugging operations are not supported by all SCSI controllers.

Warnings The connectors on some SCSI devices do not conform to SCSI hotplug specifications. Performing hotplug operations on such devices can cause damage to the hardware on the SCSI bus. Refer to your hardware manual for additional information.

Name cfgadm_sdcard – SD/MMC hardware-specific commands for cfgadm

Synopsis /usr/sbin/cfgadm [-f] [-y | -n] [-o *hardware_options*]
        -c *function ap_id*[...]

/usr/sbin/cfgadm [-f] [-y | -n] [-o *hardware_options*]
        -c *hardware_function ap_id*[...]

/usr/sbin/cfgadm [-v] [-a] [-s *listing_options*]
        [-o *hardware_options*] [-l [*ap_id* | *ap_type*[...]]]

/usr/sbin/cfgadm [-v] [-o *hardware_options*] -h [*ap_id*[...]]

Description The Secure Digital (SD) and MultiMediaCard (MMC) hardware specific library,
/usr/lib/cfgadm/sdcard.so.1, provides the functionality for SD/MMC hot-plugging
through the cfgadm(1M) command. The cfgadm command operates on attachment points,
which are locations in the system where hardware resources can be dynamically reconfigured.
See cfgadm(1M) for information on attachment points.

Each SD/MMC slot is represented by an attachment point in the device tree. Card devices that
are connected and configured in the system are shown as attachment point name extensions.
The terms "attachment point" and "SD/MMC slot" are used interchangeably throughout this
manpage.

Attachment points are named through ap_ids. All SD/MMC attachment points consist of a
string in the following form:

sdcardX/[S][::dsk/cXtYd0]

Where:

X is the SD/MMC controller number.

S is the slot number on the controller (0 to 8).

dev/cXtYd0 identifies the inserted memory card.

Y is a target number.

In general, the device identifier is derived from the corresponding logical link for the device in
/dev. Because only one LUN (LUN 0) is supported by the SD/MMC device, the "d"
component of the device string will always have number 0 (zero). For example, the logical
ap_id of slot 4 of SD/MMC controller 2 would be *sdcard2/4*. If the SD/MMC media card is
inserted in this attachment point and the device is configured, the *ap_id* might be
sdcard2/4::dsk/c2t0d0.

The c*X*t*Y*d*0* string identifying a device has one-to-one correspondence to the device
attachment point.

A simple listing of attachment points in the system includes all SD/MMC device slots and
attached devices. For example:

```
#cfgadm -l
Ap_Id                    Type        Receptacle   Occupant      Condition
 sdcard0/0::dev/c2t0d0    sdcard      connected    configured     ok
 sata0/1::dev/c0t1d0      disk        connected    configured     ok
 sata0/2::dev/c0t2d0      cd-dvd      connected    configured     ok
 sata0/3                  sata-port   empty        unconfigured   ok
 usb0/1                   unknown     empty        unconfigured   ok
 usb0/2                   unknown     empty        unconfigured   ok
```

See cfgadm(1M) for more information regarding listing of attachment points.

The receptacle state for an attachment point at the SD/MMC slot has the following meanings:

empty
   The SD/MMC slot is powered-on and enabled. No device presence was detected for this slot.

disconnected
   The SD/MMC slot is not enabled, or the SD/MMC device presence was detected but no communication with the device was established, or the slot has failed.

connected
   The SD/MMC device is detected in the slot and device communication is established.

The occupant (device inserted in the SD/MMC slot) state has the following meanings:

configured
   The attached SD/MMC device is configured and ready to use by the operating system.

unconfigured
   No device is attached, or the SD/MMC device inserted in the SD/MMC slot is not yet configured. To configure, run the command **cfgadm -c configure ap_id**.

The attachment point (SD/MMC slot) condition has the following meanings:

ok
   The SD/MMC slot is powered-on, enabled and ready for use.

failed
   The SD/MMC slot failed. It may be disabled and/or powered-off by the system. It is unusable and its condition is unknown. The failure may be due to the device inserted in the slot.

unknown
   The SD/MMC slot is disabled and its condition is unknown.

Options The cfgadm command defines several types of operations besides listing (-l). These operations include invoking configuration state changes (-c), invoking hardware specific functions (-x), and obtaining configuration administration help messages (-h).

-c: For SD/MMC slot attachment points, the following configuration state change operations are supported:

connect
> Enable (activate) the SD/MMC slot and establish the communication with an attached device. This operation implies powering-on the slot if necessary.

disconnect
> Unconfigure the inserted device if it is not already unconfigured and disable (deactivate) the SD/MMC slot. A subsequent "connect" command enables SD/MMC slot operation but does not bring a device to the "configured" state.

The following state change operations are supported for an SD/MMC card inserted in to the SD/MMC slot:

configure
> Configure new device for use by the operating system if it is not already configured. This command also implies connect operation, if necessary.

unconfigure
> Unconfigure the device inserted in the SD/MMC slot if it is not already unconfigured.

-f : Not supported.

-h *ap_id*: SD/MMC specific help can be obtained by using the help option with any SD/MMC attachment point.

-l [-v]: The -l option works as described in cfgadm(1M). When paired with the -v option, the "Information" field contains the following SD/MMC-specific information:

Mod: product model string
Rev: product revision number (major.minor)
Date: month and year of manufacture
SN: product serial number (hexadecimal)

-o hardware_options — No hardware specific options are currently defined.

-s listing_options: Attachment points of class SD/MMC can be listed by using the select suboption. See cfgadm(1M).

-t *ap_id*: Self-test functionality. Not supported by SD/MMC slots.

-x *hardware_function*: Perform hardware specific function. sdcard_reset_slot *ap_id* indicates reset of the SD/MMC slot specified by *ap_id*. If an SD/MMC device is inserted in the slot, it is also reset.

-v: Execute in verbose mode.

Examples Example 1 – Configuring an SD/MMC card:

The following command configures a card attached to SD/MMC controller 0, slot 0. It should be issued only when there is a device inserted in the SD/MMC slot.

```
# cfgadm -c configure sdcard0/0
```

Example 2 – Unconfiguring an SD/MMC card:

The following command unconfigures a card inserted in SD/MMC controller 0, slot 3:

```
# cfgadm -c unconfigure sdcard0/3
```

Example 3 — Encountering a mounted file system while unconfiguring a disk:

The following command illustrates encountering a mounted file system while unconfiguring a disk:

```
# cfgadm -c unconfigure sdcard1/5::dsk/c01t35d0
```

The system responds with the following:

```
cfgadm: Component system is busy, try again: failed to offline:
     /devices/pci@0,0/pci8086,244e@1e/pci1095,3124@1/sd@5,0
          Resource              Information
     -----------------  --------------------------
     /dev/dsk/c1t5d0s0   mounted filesystem "/mnt"
```

Files /usr/lib/cfgadm/sdcard.so.1
　　　Hardware specific library for generic SD/MMC hot plugging.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library

See Also cfgadm(1M), config_admin(3CFGADM), libcfgadm(3LIB), attributes(5), sda(7D), sdcard(7D), sdhost(7D)

Notes Under normal operation, SD/MMC media cards are automatically configured when a card is inserted. Most administrators do not find it necessary to use this command under normal use.

Removing an SD/MMC card without first unconfiguring it may result in data loss if the device is being written to when it's being removed. Devices that are mounted read-only can be safely removed at any time.

Devices that have filesystems other than pcfs(7FS) on them should always be explicitly unconfigured before removal.

Name cfgadm_shp – PCI Express and Standard PCI Hotplug hardware-specific commands for cfgadm

Synopsis /usr/sbin/cfgadm [-f] [-y | -n] [-v]
        [-o *hardware_options*] -c *function* *ap_id* [*ap_id*]

/usr/sbin/cfgadm [-f] [-y | -n] [-v]
        [-o *hardware_options*] -x *hardware_function* *ap_id* [*ap_id*]

/usr/sbin/cfgadm [-v] [-s *listing_options*]
        [-o *hardware_options*] -x *hardware_function* *ap_id* [*ap_id*]

/usr/sbin/cfgadm [-v] [-o *hardware_options*] -t*ap_id* [*ap_id*]

/usr/sbin/cfgadm [-v] [-o *hardware_function*]-h [*ap_id* | *ap_type*]

Description The PCI Express and Standard PCI Hotplug hardware-specific library, /usr/lib/cfgadm/shp.so.1, provides support for hotplugging PCI Express and Standard PCI Hotplug adapter cards into the respective hotpluggable slots in a system that is hotplug-capable, through the cfgadm command (see cfgadm(1M)). Support for the rest PCI Hotplug adapter cards (other than PCI Express and Standard PCI Hotplug cards) are provided by cfgadm_pci library (see cfgadm_pci(1M)). Hotplug administrative models between PCI Express Hotplug and Standard PCI Hotplug remain the same except where noted in this man page.

For PCI hotplug, each hotplug slot on a specific PCI bus is represented by an attachment point of that PCI bus.

An attachment point consist of two parts: a receptacle and an occupant. The receptacle under PCI hotplug is usually referred to as the physical hot pluggable slot; and the occupant is usually referred to as the PCI adapter card that plugs into the slot.

Attachment points are named through ap_ids. There are two types of ap_ids: logical and physical. The physical ap_id is based on the physical pathname, for example:

/devices/pci@7c,0/pci10de,5d@d:pcie2

Whereas the logical ap_id is a shorter, more user-friendly name, for example, pcie2. The ap_type for Hotplug PCI is pci.

Note that the ap_type is not the same as the information in the Type field.

PCI Express ap_id Naming For attachment points located in a PCI Express hierarchy (that is, the parent or an ancestor is a PCI Express device), including attachment points that are not PCI Express devices themselves, the naming scheme shown below is used.

Grammar:

APID : *absolute-slot-path*
    Fundamental term.

absolute-slot-path : *slot-path*[:*slot-path*[:*slotpath* ...]]
> ...where *fru-id* indicates the chassis FRU, if any, containing the *slot-id*.

fru-id : *fru-type*[*serialid#*]
> ...where *fru-type* is "iob" for a PCI Express expansion chassis, followed by its serial number *serialid#*, if available

slot-id : *slot-name* | *device-type physical-slot#* | \
nexus-driver-name nexus-driver-instance.\
device-type pci-device-number
> ...where *slot-name* is a name assigned by the platform or hardware itself. *device-type* is either `pcie` for PCI Express devices or `pci` for PCI devices. *nexus-driver-name* is the driver name for the device component; *physical-slot#* is the hardware slot number; and *pci-device-number* is the PCI device number in standard PCI nomenclature.

First, an *absolute-slot-path* is constructed that attempts to describe the attachment point's topological location in more physically identifiable terms for the user. This *absolute-slot-path* consists of *slot-path* components each separated by a : (colon). The leaf or leftmost *slot-path* component describes the device of the attachment point itself, while its right-adjacent *slot-path* component up to the rightmost or topmost *slot-path* component describes the parent up to the root devices, respectively.

Each *slot-path* consists of a *slot-id* optionally preceded by a *fru-id*, which identifies an expansion chassis containing the device described by *slot-id* (detailed below). *fru-id* consists of *fru-type* followed by an optional *serialid#*. *fru-type* is "iob" for PCI Express expansion chassis types, while *serialid#* is either a 64-bit hexadecimal number indicating a raw serial number obtained from the expansion chassis hardware, or an upper-case, ASCII four-character sequence for a Sun-branded expansion chassis.

Each slot-id consists of one of three possible forms:

slot-id form (1)
> *slot-names*

slot-id form (2)
> *device-type physical-slot#*

slot-id form (3)
> *nexus-driver-name nexus-driver-instance device-type pci-device-number*

The precedence of which form to select flows from the lowest form number to the highest form number, or from top to bottom as described above. If a form cannot be successfully constructed, then the next numerically higher form is attempted.

The *slot-names* in *slot-id* form (1) is taken from the `slot-names` property of the corresponding node in the device tree and is a name assigned by hardware or the platform. This format is not predefined or established.

In *slot-id* form (2), *device-type* indicates the device type of the component's slot, and is either `pcie` for PCI Express or `pci` for PCI, while *physical-slot#*, taken from the `physical-slot#` property of its corresponding device node, indicates the hardware slot number of the component.

slot-id form (3) is used when all other forms cannot be successfully constructed, and is considered to be the default form. *nexus-driver-name* is the component's driver name; *nexus-driver-instance* is this driver's instance; *device-type* is the same as described in form (2); *pci-device-number* is the PCI device number as described and used for device configuration cycles in standard PCI nomenclature.

In summary of the *slot-path* component, expanding the optional FRU component that might precede it, *slot-path* will consist one of the following forms in order:

(1) [iob[*serialid#*].]
    slot-names

(2) [iob[*serialid#*].]
    device_type physical_slot#

(2) [iob[*serialid#*].]
    nexus-driver-name nexus-driver-instance.

    device_type pci-device-number

Lastly, the final form of the actual ap_id name used in `cfgadm` is decided as follows, specified in order of precedence:

ap_id form (1)
    If the *absolute-slot-path* can fit within the fixed length limit of `cfgadm`'s ap_id field, then *absolute-slot-path* itself is used

ap_id form (2)
    (*absolute-slot-path* exceeds the ap_id length limit) If the last *slot_path* component is contained within an expansion chassis, and it contains a *serialid#*, then the last *slot_path* component is used. The requirement for a *serialid#* in this form is to ensure a globally unique ap_id.

ap_id form (3)
    (*absolute-slot-path* exceeds the ap_id length limit) The default form, *slot-id* form (3), of the last *slot_path* component is used.

Whichever final ap_id name is used, the *absolute-slot-path* is stored in the Information (`info`) field which can be displayed using the `-s` or `-v` options. This information can be used to physically locate any ap_ids named using ap_id form (2) or ap_id form (3). The *absolute-slot-path* is transformed slightly when stored in the information field, by the replacement of a colon (`:`) with forward slashes (`/`) to more closely denote a topological context. The *absolute-slot-path* can include *slot-path* components that are not hotpluggable above the leaf or rightmost *slot-path* component up to the onboard host slot.

See the Examples section for a list of hotpluggable examples.

Options The following options are supported:

-c *function*
  The following functions are supported for PCI hotpluggable slots:

  configure
    Configure the PCI device in the slot to be used by Solaris.

  connect
    Connect the slot to PCI bus.

  disconnect
    Disconnect the slot from the PCI bus.

  insert
    Not supported.

  remove
    Not supported.

  unconfigure
    Logically remove the PCI device's resources from the system.

-f
  Not supported.

-h *ap_id* | *ap_type*
  Display PCI hotplug-specific help message.

-l *list*
  List the values of PCI Hot Plug slots.

-o *hardware_options*
  No hardware specific options are currently defined.

-s *listing_options*
  Same as the generic cfgadm(1M).

-t *ap_id*
  This command is only supported on platforms that support testing capability on the slot.

-v
  Execute in verbose mode.

  When the -v option is used with the -l option, the cfgadm command outputs information about the attachment point. For attachment points located in a PCI Express hierarchy, the Information field will contain the attachment point's absolute slot path location, including any hardware– or platform-specific labeling information for each component in the slot path. Each component in the slot path will be separated by a / (forward slash). See "PCI Express ap_id Naming," above. For PCI Hot Plug attachment points not located in a PCI

Express hierarchy, see cfgadm_pci(1M). The information in the Type field is printed with or without the -v option. The occupant Type field will describe the contents of the slot. There are two possible values:

unknown
    The slot is empty. If a card is in the slot, the card is not configured or there is no driver for the device on the card.

subclass/*board*
    The card in the slot is either a single-function or multi-function device.

    subclass is a string representing the subclass code of the device, for example, SCSI, ethernet, pci-isa, and so forth. If the card is a multi-functional device, MULT will get displayed instead.

    board is a string representing the board type of the device. For example, hp is the string used for a PCI Hot Plug adapter.

-x *hardware_function*
Perform hardware-specific function. These hardware-specific functions should not normally change the state of a receptacle or occupant.

The following *hardware_function* is supported:

led=[*led_sub_arg*],mode=[*mode_sub_arg*]
Without subarguments, display a list of the current LED settings. With subarguments, set the mode of a specific LED for a slot.

Specify *led_sub_arg* as fault, power, attn, or active.

Specify *mode_sub_arg* as on, off, or blink.

For PCI Express, only the power and attn LEDs are valid and only the state of the attn LED can be changed.

Changing the state of the LED does not change the state of the receptacle or occupant. Normally, the LEDs are controlled by the hotplug controller, no user intervention is necessary. Use this command for testing purposes.

Caution – Changing the state of the LED can misrepresent the state of occupant or receptacle.

The following command displays the values of LEDs:

```
example# cfgadm -x led pcie2
Ap_Id           Led
pcie2      power=on,fault=off,active=off,attn=off
```

The following command sets the attn LED to blink to indicate the location of the slot:

```
example# cfgadm -x led=attn,mode=blink pcie2
```

Examples   EXAMPLE 1   Displaying the Value of Each Slot

The following command displays the values of each slot:

```
example# cfgadm -l
Ap_Id           Type          Receptacle    Occupant      Condition
c0              scsi-bus      connected     configured    unknown
c1              scsi-bus      connected     unconfigured  unknown
c2              scsi-bus      connected     unconfigured  unknown
pcie7           etherne/hp    connected     configured    ok
pcie8           unknown       empty         unconfigured  unknown
pcie9           fibre/hp      connected     configured    ok
```

EXAMPLE 2   Replacing a Card

The following command lists all DR-capable attachment points:

```
example# cfgadm
Type            Receptacle    Occupant      Condition
c0              scsi-bus      connected     configured    unknown
c1              scsi-bus      connected     unconfigured  unknown
c2              scsi-bus      connected     unconfigured  unknown
pcie7           etherne/hp    connected     configured    ok
pcie8           unknown       empty         unconfigured  unknown
pcie9           fibre/hp      connected     configured    ok
```

The following command unconfigures and electrically disconnects the card identified by pcie7:

```
example# cfgadm -c disconnect pcie7
```

The change can be verified by entering the following command:

```
example# cfgadm pcie7
Ap_Id     Type          Receptacle    Occupant      Condition
pcie7     unknown       disconnected unconfigured unknown
```

At this point the card can be swapped. The following command electrically connects and configures the replacement card:

```
example# cfgadm -c configure pcie7
```

The change can be verified by entering the following command:

```
example# cfgadm pcie7
Ap_Id     Type          Receptacle    Occupant      Condition
pcie7     etherne/hp    connected     configured    ok
```

EXAMPLE 3   Interpreting ApIds in a PCI Express Topology

The following command shows a listing for a topology with both PCI Express and PCI attachment points in an I/O expansion chassis connected to hotpluggable slots at the host level:

EXAMPLE 3 Interpreting ApIds in a PCI Express Topology   *(Continued)*

```
example# cfgadm -s cols=ap_id:info
Ap_Id                         Information
iou#0-pci#0                   Location: iou#0-pci#0
iou#0-pci#1                   Location: iou#0-pci#1
iou#0-pci#1:iob.pci3          Location: iou#0-pci#1/iob.pci3
iou#0-pci#1:iob.pci4          Location: iou#0-pci#1/iob.pci4
iou#0-pci#2                   Location: iou#0-pci#2
iou#0-pci#2:iob58071.pcie1    Location: iou#0-pci#2/iob58071.pcie1
iou#0-pci#2:iob58071.special  Location: iou#0-pci#2/iob58071.special
iou#0-pci#3                   Location: iou#0-pci#3
iou#0-pci#3:iobBADF.pcie1     Location: iou#0-pci#3/iobBADF.pcie1
iou#0-pci#3:iobBADF.pcie2     Location: iou#0-pci#3/iobBADF.pcie2
iou#0-pci#3:iobBADF.pcie3     Location: iou#0-pci#3/iobBADF.pcie3
iou#0-pci#3:iobBADF.pci1      Location: iou#0-pci#3/iobBADF.pci1
iou#0-pci#3:iobBADF.pci2      Location: iou#0-pci#3/iobBADF.pci2
```

In this example, the `iou#0-pci#[0-3]` entries represents the topmost hotpluggable slots in the system. Because the `iou#`*n*`-pci#`*n* form does not match any of the forms stated in the grammar specification section described above, we can infer that such a name for the base component in this hotplug topology is derived from the platform through the `slot-names` property.

The slots in the preceding output are described as follows:

Slot `iou#0-pci#0`
   This slot is empty or its occupant is unconfigured.

Slot `iou#0-pci#1`
   This slot contains an expansion chassis with two hotpluggable slots, `pci3` and `pci4`. `pci3` and `pci4` represent two PCI slots contained within that expansion chassis with physical slot numbers 3 and 4, respectively. The expansion chassis in this case does not have or export a serial-id.

Slot `iou#0-pci#2`
   This slot contains a third-party expansion chassis with a hexadecimal serial-id of `58071`. Within that expansion chassis are two hotpluggable slots, `pcie1` and `special`. `pcie1` represents a PCI Express slot with physical slot number 1. The slot `special` has a label which is derived from the platform, hardware, or firmware.

Slot `iou#0-pci#3`
   This slot contains a Sun expansion chassis with an FRU identifier of `BADF`. This expansion chassis contains three PCI Express slots, `pcie1`, `pcie2`, and `pcie3` with physical slot numbers 1, 2, and 3, respectively; and two PCI slots, `pci1` and `pci2`, with physical slot numbers 1 and 2, respectively.

The following command shows a listing for a topology with both PCI Express and PCI attachment points in an I/O expansion chassis with connected hotpluggable and non-hotpluggable host slots:

EXAMPLE 3 Interpreting ApIds in a PCI Express Topology   *(Continued)*

```
example# cfgadm -s cols=ap_id:info
Ap_Id                      Information
Slot1                      Location: Slot1
Slot2:iob4ffa56.pcie1      Location: Slot2/iob4ffa56.pcie1
Slot2:iob4ffa56.pcie2      Location: Slot2/iob4ffa56.pcie2
Slot5:iob3901.pci1         Location: Slot2/iob3901.pci1
Slot5:iob3901.pci2         Location: Slot2/iob3901.pci2
```

In this example, the host system only has one hotpluggable slot, Slot1. We can infer that Slot2 and Slot5 are not hotpluggable slots because they do not appear as attachment points themselves in cfgadm. However, Slot2 and Slot5 each contains a third party expansion chassis with hotpluggable slots.

The following command shows a listing for a topology with attachment points that are lacking in certain device properties:

```
example# cfgadm -s cols=ap_id:info
Ap_Id                      Information
px_pci7.pcie0              Location: px_pci7.pcie0
px_pci11.pcie0             Location: px_pci11.pcie0
px_pci11.pcie0:iob.pcie1   Location: px_pci11.pcie0/iob.pcie1
px_pci11.pcie0:iob.pcie2   Location: px_pci11.pcie0/iob.pcie2
px_pci11.pcie0:iob.pcie3   Location: px_pci11.pcie0/iob.pcie3
```

In this example, the host system contains two hotpluggable slots, px_pci7.pcie0 and px_pci11.pcie0. In this case, it uses slot-id form (3) (the default form) for the base *slot-path* component in the *absolute-slot-path*, because the framework could not obtain enough information to produce other more descriptive forms of higher precedence.

Interpreting right-to-left, attachment point px_pci7.pcie0 represents a PCI Express slot with PCIdevice number 0 (which does not imply a physical slot number of the same number), bound to nexus driver px_pci, instance 7. Likewise, attachment point px_pci11.pcie0 represents a PCI Express slot with PCI device number 0 bound to driver instance 11 of px_pci.

Under px_pci11.pcie0 is a third-party expansion chassis without a serial-id and with three hotpluggable PCI Express slots.

The following command shows a listing for a topology with attachment point paths exceeding the ApId field length limit:

```
example# cfgadm -s cols=ap_id:info
Ap_Id                      Information
pcie4                      Location: pcie4
pcie4:iobSUNW.pcie1        Location: pcie4/iobSUNW.pcie1
pcie4:iobSUNW.pcie2        Location: pcie4/iobSUNW.pcie2
```

EXAMPLE 3   Interpreting ApIds in a PCI Express Topology   *(Continued)*

```
iob8879c3f3.pci1
                 Location: pcie4/iobSUNW.pcie2/iob8879c3f3.pci1
iob8879c3f3.pci2
                 Location: pcie4/iobSUNW.pcie2/iob8879c3f3.pci2
iob8879c3f3.pci3
                 Location: pcie4/iobSUNW.pcie2/iob8879c3f3.pci3
```

In this example, there is only one hotpluggable slot, `pcie4` in the host. Connected under `pcie4` is a Sun expansion chassis with FRU identifier `SUNW`. Nested under PCI Express slot `pcie2` of that expansion chassis (ApId `pcie4:iobSUNW.pcie2`) lies another expansion chassis with three hotpluggable PCI slots.

Because the length of the absolute-slot-path form of:

```
pcie4/iobSUNW.pcie2/iob8879c3f3.pci1...3
```

...exceeds the `ApId` field length limit, and the leaf slot-path component is globally unique, `ap_id` form (2) is used, where the leaf *slot-path* component in the *absolute-slot-path* is used as the final `ApId`.

The following command shows a listing for a topology with attachment point paths exceeding the `ApId` field-length limit and lacking enough information to uniquely identify the leaf *slot-id* on its own (for example, missing the serial-id):

```
example# cfgadm -s cols=ap_id:info
Ap_Id                        Information
pcie4                        Location: pcie4
pcie4:iob4567812345678.pcie3  Location: pcie4/iob4567812345678.pcie3
px_pci20.pcie0
                Location: pcie4/iob4567812345678.pcie3/iob.pcie1
px_pci21.pcie0
                Location: pcie4/iob4567812345678.pcie3/iob.pcie2
```

In this example, there is only one hotpluggable slot, `pcie4` in the host. Connected under `pcie4` is a third-party expansion chassis with hexadecimal serial-id 4567812345678. Nested under the PCI Express slot `pcie3` of that expansion chassis (ApId `pcie4:iob4567812345678.pcie3`), lies another third-party expansion chassis without a serial- id and with two hotpluggable PCI Express slots.

Because the length of the absolute-slot-path form of:

```
pcie4/iob4567812345678.pcie3/iob.pcie1...2
```

exceeds the `ApId` field length limit, and the leaf *slot-path* component is not globally unique, `ap_id` form (3) is used. `ap_id` form (2) is where *slot-id* form (3) (the default form) of the leaf *slot-path* component in the *absolute-slot-path* is used as the final `ApId`.

EXAMPLE 3 Interpreting ApIds in a PCI Express Topology   *(Continued)*

The default form or slot-id form (3) of the leaf component .../iob.pcie1 represents a PCI Express slot with device number 0, bound to driver instance 20 of px_pci. Likewise, the default form of the leaf component .../iob.pcie2 represents a PCI Express slot with device number 0, bound to driver instance 21 of px_pci.

Files /usr/lib/cfgadm/shp.so.1
Hardware-specific library for PCI Express and Standard PCI hotplugging.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library
Interface Stability	Uncommitted

See Also cfgadm(1M), cfgadm_pci(1M), hotplugd(1M), config_admin(3CFGADM), libcfgadm(3LIB), attributes(5), smf(5)

Notes The cfgadm_shp library is dependent on the hotplug service, which is managed by smf(5) under FMRI:

svc:/system/hotplug:default

The service must be enabled for the cfgadm_shp library to function properly. See hotplugd(1M) for details.

Name cfgadm_sysctrl – EXX00 system board administration

Synopsis /usr/sbin/cfgadm -c *function* [-f]
       [-o disable-at-boot | enable-at-boot] [-n | -y] sysctrl0:slot# ...

/usr/sbin/cfgadm -x quiesce-test sysctrl0:slot#

/usr/sbin/cfgadm -x insert-test | remove-test sysctrl0:slot# ...

/usr/sbin/cfgadm -x set-condition-test=# sysctrl0:slot# ...

/usr/sbin/cfgadm [-l]
       -o disable-at-boot | enable-at-boot sysctrl0:slot# ...

Description The sysctrl hardware specific library /usr/platform/sun4u/lib/cfgadm/sysctrl.so.1
provides dynamic reconfiguration functionality for configuring and disconnecting system
boards on E6X00, E5X00, E4X00, and E3X00 systems. You can insert both I/O and CPU boards
into a slot on a running system that is configured for Solaris without rebooting. You can also
disconnect and remove both types of boards from a running system without rebooting.

System slots appear as attachment points in the device tree, one attachment point for each
actual slot in the system chassis. If a board is not in a slot, the receptacle state is empty. If a
board is powered-off and ready to remove, the receptacle state is disconnected. If a board is
powered-on and is connected to the system bus, the receptacle state is connected.

The occupant state is unconfigured when the receptacle state is empty or disconnected. The
occupant state is either unconfigured or configured when the receptacle state is connected.

In the configured state the devices on a board are available for use by Solaris. In the
unconfigured state, the devices on the board are not.

Inserting a board changes the receptacle state from empty to disconnected. Removing a
board changes the receptacle state from disconnected to empty. Removing a board that is in
the connected state crashes the operating system and can result in permanent damage to the
system.

Options Refer to cfgadm(1M) for a more complete description options.

The following options are supported:

-c *function*		Perform the state change function. Specify *function* as connect, disconnect, configure or unconfigure.
	configure	Change the occupant state to configure.
		If the receptacle state is disconnected, the configure function first attempts to connect the receptacle. The configure function walks the OBP device tree created as

part of the connect function and creates the Solaris device tree nodes, attaching devices as required. For CPU/Memory boards, configure adds CPUs to the CPU list in the powered-off state. These are visible to the psrinfo(1M) and psradm(1M) commands. Two memory attachment points are published for CPU/memory boards. Use mount(1M) and ifconfig(1M) to use I/O devices on the new board. To use CPUs, use psradm -n to on-line the new processors. Use cfgadm_ac(1M) to test and configure the memory banks.

connect   Change the receptacle state to connected.

Changing the receptacle state requires that the system bus be frozen while the bus signals are connected and the board tested. The bus is frozen by running a quiesce operation which stops all process activity and suspends all drivers. Because the quiesce operation and the subsequent resume can be time consuming, and are not supported by all drivers, the -x quiesce-test is provided. While the system bus is frozen, the board being connected is tested by firmware. This operation takes a short time for I/O boards and a significant time for CPU/Memory boards due to CPU external cache testing. This does not provide memory testing. The user is prompted for confirmation before proceeding with the quiesce. Use the -y or -n option to override the prompt. The connect operation is refused if the board is marked as

		disabled-at-boot, unless either the force flag, -f, or the enable at boot flag, -o enable-at-boot, is given. See -l.
	disconnect	Change the receptacle state to disconnected.
		If the occupant state is configure, the disconnect function first attempts to unconfigure the occupant. The disconnect operation does not require a quiesce operation and operates quickly. The board is powered-off ready for removal.
	unconfigure	Change the occupant state to unconfigureed.
		Devices on the board are made invisible to Solaris during this process. The I/O devices on an I/O board are removed from the Solaris device tree. Any device that is still in use stops the unconfigure process and be reported as in use. The unconfigure operation must be retried after the device is made non-busy. For CPU/Memory boards, the memory must have been changed to the unconfigured state prior to issuing the board unconfigure operation. The CPUs on the board are off-lined, powered off and removed from the Solaris CPU list. CPUs that have processes bound to them cannot be off-lined. See psradm(1M), psrinfo(1M), pbind(1M), and p_online(2) for more information on off-lining CPUs.
-f		Force a block on connecting a board marked as disabled-at-boot in the non-volatile

<table>
<tr>
<td></td>
<td>disabled-board-list variable. See *Platform Notes:Sun Enterprise 6x00/5x00/4x00/3x00 Systems*</td>
</tr>
<tr>
<td>-l</td>
<td>List options. Supported as described in cfgadm(1M)cfgadm(1M).

The *type* field can be one of cpu/mem, mem, dual-sbus, sbus-upa, dual-pci, soc+sbus, soc+upa, disk or unknown.

The hardware-specific info field is set as follows: [disabled at boot] [non-detachable] [100 MHz capable]

For sbus-upa and soc+upa type boards, the following additional information appears first: [single buffered ffb|double buffered ffb|no ffb installed] For disk type boards, the following additional information appears first: {target: # | no disk} {target: # | no disk}</td>
</tr>
<tr>
<td>-o disable-at-boot | enable-at-boot</td>
<td>Modify the state of the non—volatile disabled-board-list variable. Use this the -o option in conjunction with the -c *function* or -l option.

Use -o enable-at-boot with the -c connect to override a block on connecting a disabled-at-boot board.</td>
</tr>
<tr>
<td>-x insert-test | remove-test</td>
<td>Perform a test.

Specify remove-test to change the driver state for the specified slot from disconnected to empty without the need for physically removing the board during automated test sequences.

Specify insert-test to change the driver state of a slot made to appear empty using the remove-test command to the disconnected state as if it had been inserted.</td>
</tr>
<tr>
<td>-x quiesce-test sysctrl0:slot1</td>
<td>Perform a test.

Allows the quiesce operation required for board connect operations to be exercised. The execution of this test confirms that, with the current software and hardware configuration, it is possible to quiesce the</td>
</tr>
</table>

system. If a device or process cannot be quiesced, its name is printed in an error message. Any valid board attachment point can be used with this command, but since all systems have a slot1 the given form is recommended.

-x set-condition-test=# Perform a test.

Allows the condition of a system board attachment point to be set for testing the policy logic for state change commands. The new setting is given as a number indicating one of the following condition values:

```
0       unknown
1       ok
2       failing
3       failed
4       unusable
```

Operands The following operand is supported:

sysctrl0:slot# The attachment points for boards on EXX00 systems are published by instance 0 of the sysctrl driver (sysctrl0). The names of the attachment points are numbered from slot0 through slot15. Specify # as a number between 0 and 15, indicating the slot number. This form conforms to the logical ap_id specification given in cfgadm(1M). The corresponding physical ap_ids are listed in the FILES section.

Name cfgadm_usb – USB hardware-specific commands for cfgadm

Synopsis /usr/sbin/cfgadm [-f] [-y | -n] [-v] -c *function ap_id*...

/usr/sbin/cfgadm -f [-y | -n] [-v] [-o *hardware_options*]
    -x *hardware_function ap_id*...

/usr/sbin/cfgadm -v [-a] [-s *listing_option*]
    [-l [*ap_id* | *ap_type*...]]

/usr/sbin/cfgadm -v -h [*ap_id*]...

Description The Universal Serial Bus (USB) hardware-specific library /usr/lib/cfgadm/usb.so.1
provides the functionality for administering USB devices via the cfgadm(1M) command.
cfgadm operates on attachment points. For details regarding attachment points, refer to
cfgadm(1M).

For USB administration, the only attachment points supported are the ports of hubs attached
to the USB bus.

Attachment points are named through attachment point IDs (*ap_ids*). The USB bus is
hierarchical, so the *ap_ids* are as well. USB hubs have ports, numbered from 1 to *n*. All USB
ap_ids consist of a string of the following form:

usb*N*/*A*[.*B*[.*C*[...]]]

where

N is the *N*th USB host controller on the system,
A is port #*A* on the root (top) hub.
B is port #*B* of the hub plugged into port #*A* of the hub above it.
C is port #*C* of the hub plugged into port #*B* of the hub above it, and so forth.

For example, the first port on the root hub of USB controller 0 (the only controller), has a
logical *ap_id*:

usb0/1

Similarly, the second port on the first external hub plugged into the first port on the root hub
of the first USB controller has a logical *ap_id*:

usb0/1.2

For example, if the *ap_id* is usb0/1.4.3.4, it represents port 4 of the hub plugged into port 3
of the hub plugged into port 4 of the hub plugged into port 1 of the root hub of the first USB
host controller on the system.

```
example# cfgadm -l
Ap_Id              Type        Receptacle   Occupant      Condition
usb0/1             USB-hub     connected    configured    ok
usb0/2             unknown     empty        unconfigured  ok
```

```
usb0/1.1              USB-storage   connected     configured    ok
usb0/1.2              unknown       empty         unconfigured ok
usb0/1.3              unknown       empty         unconfigured ok
usb0/1.4              USB-device    connected     configured    ok
```

USB2.0 chips have one EHCI host USB2.0 host controller and a number of companion USB 1.x host controllers (either OHCI or UHCI host controllers).

When a USB2.0 device has been plugged in, it shows up on the EHCI logical ports which might not have a 1 to 1 mapping to external physical port numbers on the system. When a USB1.x device is plugged in, the EHCI host controller reroutes the device to a companion host controller and the device shows up on the companion's logical port number.

The mapping of logical port numbers to physical port numbers can get quite complicated. For example:

```
% cfgadm
Ap_Id              Type          Receptacle    Occupant      Condition
c0                 scsi-bus      connected     configured    unknown
usb0/1             usb-mouse     connected     configured    ok
usb0/2             usb-kbd       connected     configured    ok
usb0/3             unknown       empty         unconfigured ok
usb0/4             usb-hub       connected     configured    ok
usb0/4.1           unknown       empty         unconfigured ok
usb0/4.2           unknown       empty         unconfigured ok
usb0/4.3           unknown       empty         unconfigured ok
usb0/4.4           usb-storage   connected     configured    ok
usb1/1             unknown       empty         unconfigured ok
usb1/2             unknown       empty         unconfigured ok
usb1/3             unknown       empty         unconfigured ok
usb2/1             unknown       empty         unconfigured ok
usb2/2             usb-device    connected     configured    ok
usb3/1             unknown       empty         unconfigured ok
usb3/2             unknown       empty         unconfigured ok
usb3/3             unknown       empty         unconfigured ok
usb3/4             unknown       empty         unconfigured ok
usb3/5             unknown       empty         unconfigured ok
```

In this example usb0 is the onboard USB 1.x host controller. usb1 and usb2 are companion OHCI USB1.x host controllers and usb3 is an EHCI USB2.0 host controller.

The following table shows the somewhat confusing routing for this USB2.0 chip:

```
logical port number        physical port number
------------------         --------------------
    usb1/1           internal port 1
    usb1/2           external port 1
    usb1/3           external port 3
```

```
            usb2/1          internal port 2
            usb2/2          external port 2

            usb3/1          internal port 1
            usb3/2          internal port 2
            usb3/3          external port 1
            usb3/4          external port 2
            usb3/5          external port 3
```

Unfortunately, the exact routing can often only be determined by experimentation.

The receptacle states for attachment points at the USB port have the following meanings:

connected

USB port is powered on and enabled. A USB device is plugged in to the port. The device is logically connected to the USB bus.

disconnected

USB port is powered on and enabled. A USB device is plugged into the port. The device has been logically disconnected from the USB bus (using the cfgadm -c disconnect command).

empty

USB port is powered on, but no device is plugged in to it.

The occupant states for devices at USB port attachment points at the USB port have the following meanings:

configured

The USB device at the USB port is configured and usable by Solaris.

unconfigured

The USB device at the USB port was explicitly off-lined using cfgadm -c unconfigure, or was not successfully configured for use with Solaris, for example, having no driver or a device problem.

The attachment point conditions are:

ok

Normal state - ready for use.

failing

Not used.

failed

Not used.

unusable

The user has physically removed a device while an application had the device open (there might be outstanding I/O). Users need to reinsert the same physical device and close the application properly before removing the device again. The port cannot configure other inserted devices until this is done.

If the original device cannot be reinserted into the port, see the *Oracle Solaris Administration: Common Tasks* for instructions for clearing this attachment point condition.

unknown

Not used.

A USB device can be hotplugged or hotunplugged at any time, and the system detects the event and takes the appropriate action.

It is not necessary to transition a receptacle to the disconnected state before removing its device from the USB. However, it is not recommended to hot-remove devices currently in use (such as removable disks currently opened by a volume manager or some other application).

Options cfgadm defines several types of operations. These operations include invoking configuration state changes (-c), invoking hardware-specific functions (-x), and obtaining configuration administration help messages (-h).

If any of these operations fail, the device and attachment point might not be in the expected state. Use the cfgadm -l command to display the device's current status.

All other options have the same meaning as defined in cfgadm(1M).

The following options are supported:

-c *function*

The following generic commands are defined for the USB hardware specific library. The following configuration state change operations are supported:

configure

If there is a USB device plugged into the port, this command attempts to configure it and set everything up so that it is usable by Solaris. This command does an implied connect (reverse of disconnect) if necessary. This command accomplishes nothing, and returns an error message, if the device at that port is already configured. After successful execution of this command, the device is ready for use under Solaris.

disconnect

Performs an unconfigure on the *ap_id* (if it is not already unconfigured), and then transitions the receptacle to the disconnected state, even though a device is still be plugged into the port. Issuing a cfgadm -c configure, or physically hotplugging the device, brings the device back to the connected receptacle state, and to the configured occupant state, assuming a driver can be found and there are no problems enumerating and configuring the device.

unconfigure

Makes the device plugged into the port unusable by Solaris (offline it). If successful,
cfgadm reports this *ap_id*'s occupant state as *unconfigured*. Issuing a configure to the
ap_id (if successful) brings its occupant back to the configured (online) condition, as it
physically hotplugging the device on the port.

-f

Not supported.

-h *ap_id*

USB specific help can be obtained by using the help option with any USB attachment point.

-l[v]

The -l option works as described in cfgadm(1M). When paired with the -v option, the
Information field contains the following USB-specific information:

- Mfg: manufacturer string (iManufacturer)

- Product: product string (iProduct)

- NConfigs: total number of configurations the device supports (bNumConfigurations).

- Config: current configuration setting in decimal (configuration index, not
  configuration value).

- The configuration string descriptor for the current configuration (iConfiguration)

See the Universal Serial Bus specification for a description of these fields.

-o *hardware_options*

Hardware options are only supported for the hardware-specific command, -x usb_config.
See the description of that command below for an explanation of the options available.

-s *listing_options*

Attachment points of class USB can be listed by using the select sub-option. See
cfgadm(1M).

-x *hardware_function*

The following hardware-specific functions are defined:

usb_config -o config=*n*

This command requires the mandatory config value to be specified using the -o option.

Sets the USB configuration of a multi-configuration USB device at *ap_id* to
configuration index *n*. The device is set to this configuration henceforth and this setting
persists across reboots, hot-removes, and unconfigure/configure of the device.

Valid values of *n* range from 0 to (Nconfigs -1). The device is reset by a disconnect
followed by a configure. The configure causes the device to be configured to the new
configuration setting.

If any of these steps fail, the configuration file and the device are restored to their
previous state and an error message is issued.

usb_reset

Performs a software reset (re-enumeration) of the device. This is the equivalent of removing the device and inserting it back again. The port on the hub is power cycled if the hub supports power cycling of individual ports.

If the connected device is a hub, this function has the effect of resetting that hub and any devices down the tree of which it is the root.

If any of these steps fail, the device is restored to its previous state and an error message is issued.

State table: attachment points state versus commands:

```
Valid states:
    empty/unconfigured          → no device connected

    disconnected/unconfigured   → logically disconnected,
                                    unavailable,
                                    devinfo node removed,
                                    device physically connected

    connected/unconfigured      → logically connected,
                                    unavailable,
                                    devinfo node present

    connected/configured        → connected, available
```

The table below clarifies the state transitions resulting from actions or commands:

```
current state       operation            new state
-------------       ---------            ---------
empty/
unconfigured:
            device plugged in:   connected/configured or
                                 connected/unconfigured
                                 (if enumeration failed)
            device removed:      n/a
            cfgadm -c unconfigure: empty/unconfigured
            cfgadm -c configure:   empty/unconfigured
            cfgadm -c disconnect:  empty/unconfigured
                                 (no-op and error)

disconnected/
unconfigured:
            device plugged in:   n/a
            device removed:      empty/unconfigured
            cfgadm -c unconfigure: disconnected/unconfigured
            cfgadm -c configure:   connected/configured, or
                                 connected/unconfigured
```

```
                                           (if reenumeration failed)
                    cfgadm -c disconnect:  disconnected/unconfigured

connected/unconfigured:
                    device plugged in:     n/a
                    device removed:        empty/unconfigured
                    cfgadm -c unconfigure: connected/unconfigured
                    cfgadm -c configure:   connected/configured, or
                                           connected/unconfigured
                                           (if reenumeration failed)
                    cfgadm -c disconnect:  disconnected/unconfigured

connected/configured:
                    device plugged in:     n/a
                    device removed:        empty/unconfigured or
                                           connected/configured,
                                           but with ap condition
                                           'unusable' if device
                                           was open when removed
                    cfgadm -c unconfigure: connected/unconfigured
                    cfgadm -c configure:   connected/configured
                    cfgadm -c disconnect:  disconnected/unconfigured
```

Examples   EXAMPLE 1   Listing the Status of All USB Devices

The following command lists the status of all USB devices on the system:

```
# cfgadm
Ap_Id           Type          Receptacle   Occupant      Condition
usb0/1          USB-hub       connected    configured    ok
usb0/2          unknown       empty        unconfigured ok
usb0/1.1        USB-storage   connected    configured    ok
usb0/1.2        unknown       empty        unconfigured ok
usb0/1.3        unknown       empty        unconfigured ok
usb0/1.4        USB-device connected       configured    ok
```

Notice that cfgadm treats the USB-device device at ap_id usb0/1.4 as a single unit, since it cannot currently control individual interfaces.

EXAMPLE 2   Listing the Status of a Port with No Device Plugged In

The following command lists the status of a port with no device plugged in:

```
example# cfgadm -l usb0/1.3
Ap_Id           Type          Receptacle   Occupant      Condition
usb0/1.3        unknown       empty        unconfigured ok
```

EXAMPLE 3   Listing the Status of the Same Port with a Device Plugged In

The following command lists the status of the same port after physically plugging in a device that configures without problems:

EXAMPLE 3 Listing the Status of the Same Port with a Device Plugged In   *(Continued)*

```
example# cfgadm -l usb0/1.3
Ap_Id          Type        Receptacle   Occupant    Condition
usb0/1.3       USB-hub     connected    configured  ok
```

EXAMPLE 4 Unconfiguring an Existing USB Device

The following command unconfigures the USB device attached to usb0/1.3, then displays the status of the ap_id:

```
example# cfgadm -c unconfigure usb0/1.3
Unconfigure the device: /devices/pci@0,0/pci8086,7112@7,2/hub@2:2.3
This operation suspends activity on the USB device
Continue (yes/no)?

Enter:

y

example# cfgadm -l usb0/1.3
Ap_Id          Type        Receptacle   Occupant    Condition
usb0/1.3       unknown     connected    unconfigured ok
```

EXAMPLE 5 Unconfiguring and Logically Disconnecting an Existing USB Device

The following command unconfigures and logically disconnects a USB device attached to usb0/1.3:

```
example# cfgadm -c disconnect usb0/1.3
Disconnect the device: /devices/pci@0,0/pci8086,7112@7,2/hub@2:2.3
This operation suspends activity on the USB device
Continue (yes/no)?

Enter:

y

example# cfgadm -l usb0/1.3
Ap_Id          Type        Receptacle    Occupant     Condition
usb0/1.3       unknown     disconnected  unconfigured  ok
```

A disconnect implies that cfgadm does an unconfigure first. The receptacle status now shows disconnected, even though the device is still physically connected. In this case, a physical hotplug or using the cfgadm -c configure on the ap_id brings it back on-line.

EXAMPLE 6 Configuring a Previously Unconfigured USB Device

The following command configures a USB device that was previously attached to usb0/1.3:

EXAMPLE 6 Configuring a Previously Unconfigured USB Device   *(Continued)*

```
example # cfgadm -yc configure usb0/1.3
example# cfgadm -l usb0/1.3
Ap_Id          Type          Receptacle   Occupant     Condition
usb0/1.3       unknown       connected    configured   ok
```

EXAMPLE 7 Resetting a USB Device

The following command resets a USB device:

```
example# cfgadm -x usb_reset usb0/1.3
Reset the device: /devices/pci@0,0/pci8086,7112@7,2/hub@2:2.3
This operation suspends activity on the USB device
Continue (yes/no)?

Enter:

y
```

EXAMPLE 8 Displaying Detailed Information About a USB Device

The following command displays detailed information about a USB device. This device shows the following USB-specific information in the 'Information' field:

- Manufacturer string: Iomega
- Product string: USB Zip 250
- Number of configurations supported: 1
- Configuration currently active: 0
- Configuration string descriptor for configuration 0: Default

```
example# cfgadm -lv  usb0/1.5
Ap_Id                 Receptacle   Occupant     Condition  Information
When        Type         Busy        Phys_Id
usb0/1.5    connected    configured   ok         Mfg:"Io
mega" Product:"USB Zip 250" NConfigs:1 Config:0 : Default

example# cfgadm -l -s "cols=ap_id:info" usb0/1.5
Ap_Id                      Information
usb0/1.5                   Mfg:"Iomega"  Product:"USB Zip 250"
NConfigs:1  Config:0 : Default
```

EXAMPLE 9 Displaying Detailed Information About All USB Devices

The following command displays detailed information about all USB devices on the system:

```
example# cfgadm -l -s "select=class(usb),cols=ap_id:info"
Ap_Id                      Information
usb0/1                     Mfg:<undefined>  Product:<undefined>
NConfigs:1  Config:0 <no cfg str descr>
usb0/2
```

EXAMPLE 9   Displaying Detailed Information About All USB Devices   *(Continued)*

```
usb0/1.1                        Mfg:<undefined>  Product:<undefined>
NConfigs:1  Config:0 <no cfg str descr>
usb0/1.2
usb0/1.3
usb0/1.4                        Mfg:"Wizard"  Product:"Modem/ISDN"
NConfigs:3  Config:1 : V.90 Analog Modem
usb0/1.5                        Mfg:"Iomega"  Product:"USB Zip 250"
NConfigs:1  Config:0 : Default
usb0/1.6                        Mfg:"SOLID YEAR"  Product:"SOLID YEAR
USB"NConfigs:1  Config:0 <no cfg str descr>
usb0/1.7
```

Lines containing only an `ap_id` are empty ports. These can be filtered out. This example only lists USB ap_ids with connected devices, and information about those devices.

```
example# cfgadm -l -s "select=class(usb),cols=ap_id:info" | grep Mfg
usb0/1                          Mfg:<undefined>  Product:<undefined>
NConfigs:1  Config:0 <no cfg str descr>
usb0/1.1                        Mfg:<undefined>  Product:<undefined>
NConfigs:1  Config:0 <no cfg str descr>
usb0/1.4                        Mfg:"Wizard"  Product:"Modem/ISDN"
NConfigs:3  Config:1 : V.90 Analog Modem
usb0/1.5                        Mfg:"Iomega"  Product:"USB Zip 250"
NConfigs:1  Config:0 : Default
usb0/1.6                        Mfg:"SOLID YEAR"  Product:"SOLID YEAR USB"
Config:0 <no cfg str descr>
```

EXAMPLE 10   Listing Information About a Multi-configuration USB Device

The following example lists information about a multi-configuration USB device.

Notice the NConfigs field: the configurations available for this device are 0, 1, and 2 (0 to (*N*Configs-1)).

```
example# cfgadm -l -s "cols=ap_id:info" usb0/1.4
Ap_Id                     Information
usb0/1.4                  Mfg:"Wizard"  Product:"Modem/ISDN"
NConfigs:3  Config:1 V.90 Analog Modem"
```

EXAMPLE 11   Setting the Current Configuration of a Multi-configuration USB Device

The following example sets the current configuration of a multi-configuration USB device:

```
example# cfgadm -o config=2 -x usb_config usb0/1.4
Setting the device: /devices/pci@1f,2000/usb@1/device@3
to USB configuration 2
This operation suspends activity on the USB device
Continue (yes/no)?
```

EXAMPLE 11 Setting the Current Configuration of a Multi-configuration USB Device   *(Continued)*

Enter:

y

USB configuration changed successfully.

The device path should be checked to ensure that the right instance of a device is being referred to, in the case where multiple devices of the exact same type are on the same bus. This information is available in the 'Information' field.

Files /usr/lib/cfgadm/usb.so.1
Hardware specific library for generic USB device administration

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library

See Also cfgadm(1M), config_admin(3CFGADM), attributes(5), scsa2usb(7D), usba(7D)

Universal Serial Bus 1.1 Specification (www.usb.org)

Oracle Solaris Administration: Common Tasks

Notes cfgadm(1M) can not unconfigure, disconnect, reset, or change the configuration of any USB device currently opened by any application. These operations also fail on a hub if a device in its hierarchy is opened by an application. See scsa2usb(7D) for unconfiguring a USB mass-storage device that is currently in use.

Only super-users can execute any functions on an attachment point. However, one need not be a super-user to list the attachment points.

Name chat – automated conversational exchange tool

Synopsis chat [*options*] *script*

Description The chat program implements a conversational text-based exchange between the computer and any serial device, including (but not limited to) a modem, an ISDN TA, and the remote peer itself, establishing a connection between the Point-To-Point Protocol daemon (pppd) and the remote pppd process.

Options The chat command supports the following options:

-f <*chat file*>	Read the chat script from the chat file. This option is mutually exclusive with the chat script parameters. You must have read access to use the file. Multiple lines are permitted in the file. Use the space or horizontal tab characters to separate the strings.
-t <*timeout*>	Set the timeout for the expected string to be received. If the string is not received within the time limit, the reply string is not sent. If specified, a 'subexpect' (alternate reply) string can be sent. Otherwise, if no alternate reply strings remain, the chat script fails.. A failed script will cause the chat program to terminate with a non-zero error code.
-r <*report file*>	Set the file for output of the report strings. If you use the keyword REPORT, the resulting strings are written to this file. If the -r option is not used and you use the REPORT keyword, the stderr file is used for the report strings.
-e	Start with the echo option turned on. You turn echo on or off at specific points in the chat script using the ECHO keyword. When echoing is enabled, all output from the modem is echoed to stderr.
-E	Enables environment variable substitution within chat scripts using the standard *$xxx* syntax.
-v	Request that the chat script execute in a verbose mode. The chat program logs the execution state of the chat script as well as all text received from the modem and output strings sent to the modem. The default is to log through syslog(3C) with facility local2; the logging method is alterable using the -S and -s options.
-V	Request that the chat script be executed in a stderr verbose mode. The chat program logs all text received from the modem and output strings sent to the modem to stderr. stderr is usually the local console at the station running the chat or pppd program.
-s	Use stderr. Log messages from -v and error messages are sent to stderr.

-S	Do not use syslog. By default, error messages are set to syslog. This option prevents log messages from -v and error messages from being sent to syslog.
-T <*phone number*>	Pass in an arbitrary string (usually a telephone number) that will be substituted for the \T substitution metacharacter in a send string.
-U <*phone number 2*>	Pass in a second string (usually a telephone number) that will be substituted for the \U substitution metacharacter in a send string. This is useful when dialing an ISDN terminal adapter that requires two numbers.
script	If the script is not specified in a file with the -f option, the script is included as parameters to the chat program.

Extended Description

Chat Script The chat script defines communications. A script consists of one or more "expect-send" pairs of strings separated by spaces, with an optional "subexpect-subsend" string pair, separated by a dash (as in the following example:)

ogin:-BREAK-ogin: ppp ssword: hello2u2

The example indicates that the chat program should expect the string "ogin:". If it fails to receive a login prompt within the time interval allotted, it sends a break sequence to the remote and then expects the string "ogin:". If the first "ogin:" is received, the break sequence is not generated.

Upon receiving the login prompt, the chat program sends the string "ppp" and then expects the prompt "ssword:". When the password prompt is received, it sends the password hello2u2.

A carriage return is normally sent following the reply string. It is not expected in the "expect" string unless it is specifically requested by using the \r character sequence.

The expect sequence should contain only what is needed to identify the received data. Because it's stored on a disk file, it should not contain variable information. Generally it is not acceptable to look for time strings, network identification strings, or other variable pieces of data as an expect string.

To correct for characters that are corrupted during the initial sequence, look for the string "ogin:" rather than "login:". The leading "l" character may be received in error, creating problems in finding the string. For this reason, scripts look for "ogin:" rather than "login:" and "ssword:" rather than "password:".

An example of a simple script follows:

ogin: ppp ssword: hello2u2

The example can be intrepreted as: expect ogin:, send ppp, expect ...ssword:, send hello2u2.

When login to a remote peer is necessary, simple scripts are rare. At minimum, you should include sub-expect sequences in case the original string is not received. For example, consider the following script:

```
ogin:--ogin: ppp ssword: hello2u2
```

This script is more effective than the simple one used earlier. The string looks for the same login prompt; however, if one is not received, a single return sequence is sent and then the script looks for login: again. If line noise obscures the first login prompt, send the empty line to generate a login prompt again.

Comments   Comments can be embedded in the chat script. Comment lines are ignored by the chat program. A comment starts with the hash ("#") character in column one. If a # character is expected as the first character of the expect sequence, quote the expect string. If you want to wait for a prompt that starts with a # character, write something like this:

```
# Now wait for the prompt and send logout string
'# ' logout
```

Sending Data From A   If the string to send begins with an at sign ("@"), the remainder of the string is interpreted as
File   the name of the file that contains the string. If the last character of the data read is a newline, it is removed. The file can be a named pipe (or fifo) instead of a regular file. This enables chat to communicate with another program, for example, a program to prompt the user and receive a password typed in.

Abort   Many modems report the status of a call as a string. These status strings are often "CONNECTED" or "NO CARRIER" or "BUSY." If the modem fails to connect to the remote, you can terminate the script. Abort strings may be specified in the script using the ABORT sequence. For example:

```
ABORT BUSY ABORT 'NO CARRIER' '' ATZ OK ATDT5551212 CONNECT
```

This sequence expects nothing and sends the string ATZ. The expected response is the string OK. When OK is received, the string ATDT5551212 dials the telephone. The expected string is CONNECT. If CONNECT is received, the remainder of the script is executed. When the modem finds a busy telephone, it sends the string BUSY, causing the string to match the abort character sequence. The script fails because it found a match to the abort string. If the NO CARRIER string is received, it aborts for the same reason.

Clr_Abort   The CLR_ABORT sequence clears previously set ABORT strings. ABORT strings are kept in an array of a pre-determined size; CLR_ABORT reclaims the space for cleared entries, enabling new strings to use that space.

Say   The SAY string enables the script to send strings to a user at a terminal via standard error. If
       chat is being run by pppd and pppd is running as a daemon (detached from its controlling
       terminal), standard error is normally redirected to the /etc/ppp/connect-errors file.

       SAY strings must be enclosed in single or double quotes. If carriage return and line feed are
       required for the output, you must explicitly add them to your string.

       The SAY string can provide progress messages to users even with "ECHO OFF." For example,
       add a line similar to the following to the script:

```
ABORT BUSY
ECHO OFF
SAY "Dialing your ISP...\n"
'' ATDT5551212
TIMEOUT 120
SAY "Waiting up to 2 minutes for connection ..."
CONNECT ''
SAY "Connected, now logging in ...\n"
ogin: account
ssword: pass
$ \c
SAY "Logged in OK ... \n"
```

       This sequence hides script detail while presenting the SAY string to the user. In this case, you
       will see:

```
Dialing your ISP...
Waiting up to 2 minutes for connection...Connected, now logging in...
Logged in OK ...
```

Report   REPORT is similar to the ABORT string. With REPORT, however, strings and all characters
          to the next control character (such as a carriage return), are written to the report file.

          REPORT strings can be used to isolate a modem's transmission rate from its CONNECT
          string and return the value to the chat user. Analysis of the REPORT string logic occurs in
          conjunction with other string processing, such as looking for the expect string. It's possible to
          use the same string for a REPORT and ABORT sequence, but probably not useful.

          Report strings may be specified in the script using the REPORT sequence. For example:

```
REPORT CONNECT
ABORT BUSY
ATDT5551212 CONNECT
ogin: account
```

          The above sequence expects nothing, then sends the string ATDT5551212 to dial the
          telephone. The expected string is CONNECT. If CONNECT is received, the remainder of the

script is executed. In addition, the program writes the string CONNECT to the report file (specified by -r) in addition to any characters that follow.

Clr_Report CLR_REPORT clears previously set REPORT strings. REPORT strings are kept in an array of a pre-determined size; CLR_REPORT reclaims the space for cleared entries so that new strings can use that space.

Echo ECHO determines if modem output is echoed to stderr. This option may be set with the -e option, but can also be controlled by the ECHO keyword. The "expect-send" pair ECHO ON enables echoing, and ECHO OFF disables it. With ECHO, you can select which parts of the conversation should be visible. In the following script:

```
ABORT    'BUSY'
ABORT    'NO CARRIER'
""       AT&F
OK\r\n   ATD1234567
\r\n     \c
ECHO     ON
CONNECT \c
ogin:    account
```

All output resulting from modem configuration and dialing is not visible, but output is echoed beginning with the CONNECT (or BUSY) message.

Hangup The HANGUP option determines if a modem hangup is considered as an error. HANGUP is useful for dialing systems that hang up and call your system back. HANGUP can be ON or OFF. When HANGUP is set to OFF and the modem hangs up (for example, following the first stage of logging in to a callback system), chat continues running the script (for example, waiting for the incoming call and second stage login prompt). When the incoming call is connected, use the HANGUP ON string to reinstall normal hang up signal behavior. An example of a simple script follows:

```
ABORT    'BUSY'
 ""  AT&F
 OK\r\n  ATD1234567
 \r\n     \c
 CONNECT \c
 'Callback login:' call_back_ID
 HANGUP OFF
 ABORT "Bad Login"
 'Callback Password:' Call_back_password
 TIMEOUT 120
 CONNECT \c
 HANGUP ON
 ABORT "NO CARRIER"
 ogin:--BREAK--ogin: real_account
```

Timeout   The initial timeout value is 45 seconds. Use the -t parameter to change the intial timeout value.

To change the timeout value for the next expect string, the following example can be used:

```
'' "AT&F
 OK ATDT5551212
 CONNECT \c
 TIMEOUT 10
 ogin:--ogin: username
 TIMEOUT 5
 assword: hello2u2
```

The example changes the timeout to ten seconds when it expects the login: prompt. The timeout is changed to five seconds when it looks for the password prompt.

Once changed, the timeout value remains in effect until it is changed again.

EOT   The EOT special reply string instructs the chat program to send an EOT character to the remote. This is equivalent to using ^D\c as the reply string. The EOT string normally indicates the end-of-file character sequence. A return character is not sent following the EOT. The EOT sequence can embedded into the send string using the sequence ^D.

BREAK   The BREAK special reply string sends a break condition. The break is a special transmitter signal. Many UNIX systems handle break by cycling through available bit rates, and sending break is often needed when the remote system does not support autobaud. BREAK is equivalent to using \K\c as the reply string. You embed the break sequence into the send string using the \K sequence.

Escape Sequences   Expect and reply strings can contain escape sequences. Reply strings accept all escape sequences, while expect strings accept most sequences. A list of escape sequences is presented below. Sequences that are not accepted by expect strings are indicated.

''   Expects or sends a null string. If you send a null string, chat sends the return character. If you expect a null string, chat proceeds to the reply string without waiting. This sequence can be a pair of apostrophes or quote mark characters.

\b   Represents a backspace character.

\c   Suppresses the newline at the end of the reply string. This is the only method to send a string without a trailing return character. This sequence must be at the end of the send string. For example, the sequence hello\c will simply send the characters h, e, l, l, o. (Not valid in expect.)

\d   Delay for one second. The program uses sleep(1) which delays to a maximum of one second. (Not valid in expect.)

\K   Insert a BREAK. (Not valid in expect.)

\n	Send a newline or linefeed character.
\N	Send a null character. The same sequence may be represented by \0. (Not valid in expect.)
\p	Pause for 1/10th of a second. (Not valid in expect.)
\q	Suppress writing the string to syslog. The string ?????? is written to the log in its place. (Not valid in expect.)
\r	Send or expect a carriage return.
\s	Represents a space character in the string. Can be used when it is not desirable to quote the strings which contains spaces. The sequence 'HI TIM' and HI\sTIM are the same.
\t	Send or expect a tab character.
\T	Send the phone number string as specified with the -T option. (Not valid in expect.)
\U	Send the phone number 2 string as specified with the -U option. (Not valid in expect.)
\\	Send or expect a backslash character.
\ddd	Collapse the octal digits (ddd) into a single ASCII character and send that character. (\000 is not valid in an expect string.)
^C	Substitute the sequence with the control character represented by C. For example, the character DC1 (17) is shown as ^Q. (Some characters are not valid in expect.)

Environment Variables Environment variables are available within chat scripts if the -E option is specified on the command line. The metacharacter $ introduces the name of the environment variable to substitute. If the substition fails because the requested environment variable is not set, nothing is replaced for the variable.

Exit Status The chat program terminates with the following completion codes:

0	Normal program termination. Indicates that the script was executed without error to normal conclusion.
1	One or more of the parameters are invalid or an expect string was too large for the internal buffers. Indicates that the program was not properly executed.
2	An error occurred during the execution of the program. This may be due to a read or write operation failing or chat receiving a signal such as SIGINT.
3	A timeout event occurred when there was an expect string without having a "-subsend" string. This indicates that you may not have programmed the script correctly for the condition or that an unexpected event occurred and the expected string could not be found.

4	The first string marked as an ABORT condition occurred.
5	The second string marked as an ABORT condition occurred.
6	The third string marked as an ABORT condition occurred.
7	The fourth string marked as an ABORT condition occurred.
. . .	The other termination codes are also strings marked as an ABORT condition.

To determine which event terminated the script, use the termination code. It is possible to decide if the string "BUSY" was received from the modem versus "NO DIALTONE." While the first event may be retried, the second probably will not succeed during a retry.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/ppp
Interface Stability	Committed

See Also   sleep(1), uucp(1C), pppd(1M), uucico(1M), syslog(3C), attributes(5)

Additional information on chat scripts are available with UUCP documentation. The chat script format was taken from scripts used by the uucico program.

Name check-hostname – check if sendmail can determine the system's fully-qualified host name

Synopsis `/usr/sbin/check-hostname`

Description The check-hostname script is a migration aid for sendmail(1M). This script tries to determine the local host's fully-qualified host name (FQHN) in a manner similar to sendmail(1M). If check-hostname is able to determine the FQHN of the local host, it reports success. Otherwise, check-hostname reports how to reconfigure the system so that the FQHN can be properly determined.

Files /etc/hosts   Host name database

/etc/nsswitch.conf   Name service switch configuration file

/etc/resolv.conf   Configuration file for name server routines

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/smtp/sendmail
Interface Stability	Committed

See Also domainname(1M), sendmail(1M), hosts(4), attributes(5)

Name check-permissions – check permissions on mail rerouting files

Synopsis /usr/sbin/check-permissions [*login*]

Description The check-permissions script is intended as a migration aid for sendmail(1M). It checks the /etc/mail/sendmail.cf file for all configured alias files, and checks the alias files for :include: files. It also checks for certain .forward files. For each file that check-permissions checks, it verifies that none of the parent directories are group- or world-writable. If any directories are overly permissive, it is reported. Otherwise it reports that no unsafe directories were found.

As to which .forward files are checked, it depends on the arguments included on the command line. If no argument is given, the current user's home directory is checked for the presence of a .forward file. If any arguments are given, they are assumed to be valid logins, and the home directory of each one is checked.

If the special argument ALL is given, the passwd entry in the /etc/nsswitch.conf file is checked, and all password entries that can be obtained through the switch file are checked. In large domains, this can be time-consuming.

Operands The following operands are supported:

login Where *login* is a valid user name, checks the home directory for *login*.

ALL Checks the home directory of *all* users.

Files /etc/mail/sendmail.cf Defines environment for sendmail

/etc/mail/aliases Ascii mail aliases file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/smtp/sendmail
Interface Stability	Committed

See Also getent(1M), sendmail(1M), aliases(4), attributes(5)

Name chk_encodings – check the label encodings file syntax

Synopsis `/usr/sbin/chk_encodings [-a] [-c maxclass] [pathname]`

Description chk_encodings checks the syntax of the label-encodings file that is specified by *pathname*. With the -a option, chk_encodings also prints a semantic analysis of the label-encodings file that is specified by *pathname*. If *pathname* is not specified, chk_encodings checks and analyzes the /etc/security/tsol/label_encodings file.

If label-encodings file analysis was requested, whatever analysis can be provided is written to the standard output file even if errors were found.

Options

-a   Provide a semantic analysis of the label encodings file.

-c *maxclass*   Accept a maximum classification value of *maxclass* (default 255) in the label encodings file CLASSIFICATIONS section.

Exit Status When successful, chk_encodings returns an exit status of 0 (true) and writes to the standard output file a confirmation that no errors were found in *pathname*. Otherwise, chk_encodings returns an exit status of nonzero (false) and writes an error diagnostic to the standard output file.

Files /etc/security/tsol/label_encodings
The label encodings file contains the classification names, words, constraints, and values for the defined labels of this system.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/trusted
Interface Stability	See below.
Standard	DDS-2600-6216-93, *Compartmented Mode Workstation Labeling: Encodings Format*, September 1993

The command output is Not-an-Interface. The command invocation is Committed for systems that implement the DIA MAC policy.

See Also label_encodings(4), attributes(5), labels(5)

"How to Analyze and Verify the label_encodings File" in *Oracle Solaris Trusted Extensions Label Administration*

Notes   The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

This file is part of the Defense Intelligence Agency (DIA) Mandatory Access Control (MAC) policy. This file might not be applicable to other MAC policies that might be developed for future releases of Solaris Trusted Extensions software.

Name chroot – change root directory for a command

Synopsis /usr/sbin/chroot *newroot command*

Description The chroot utility causes *command* to be executed relative to *newroot*. The meaning of any initial slashes (/) in the path names is changed to *newroot* for *command* and any of its child processes. Upon execution, the initial working directory is *newroot*.

Notice that redirecting the output of *command* to a file,

chroot *newroot command* >x

will create the file x relative to the original root of *command*, not the new one.

The new root path name is always relative to the current root. Even if a chroot is currently in effect, the *newroot* argument is relative to the current root of the running process.

This command can be run only by the super-user.

Return Values The exit status of chroot is the return value of *command*.

Examples EXAMPLE 1 Using the chroot Utility

The chroot utility provides an easy way to extract tar files (see tar(1)) written with absolute filenames to a different location. It is necessary to copy the shared libraries used by tar (see ldd(1)) to the *newroot* filesystem.

```
example# mkdir /tmp/lib; cd /lib
example# cp ld.so.1 libc.so.1 libcmd.so.1 libdl.so.1 \
        libsec.so.1 /tmp/lib
example# cp /usr/bin/tar /tmp
example# dd if=/dev/rmt/0 | chroot /tmp tar xvf -
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also cd(1), tar(1), chroot(2), ttyname(3C), attributes(5)

Notes Exercise extreme caution when referencing device files in the new root file system.

References by routines such as ttyname(3C) to stdin, stdout, and stderr will find that the device associated with the file descriptor is unknown after chroot is run.

Name cimworkshop – start the Sun WBEM CIM WorkShop application

Synopsis `/usr/sadm/bin/cimworkshop`

Description The `cimworkshop` command starts Sun WBEM CIM WorkShop, a graphical user interface that enables you to create, modify, and view the classes and instances that describe the managed resources on your system.

Managed resources are described using a standard information model called Common Information Model (CIM). A CIM class is a computer representation, or model, of a type of managed resource, such as a printer, disk drive, or CPU. A CIM instance is a particular managed resource that belongs to a particular class. Instances contain actual data. Objects can be shared by any WBEM-enabled system, device, or application. CIM objects are grouped into meaningful collections called schema. One or more schemas can be stored in directory-like structures called namespaces.

The CIM WorkShop application displays a Login dialog box. Context help is displayed on the left side of the CIM WorkShop dialog boxes. When you click on a field, the help content changes to describe the selected field.

By default, CIM WorkShop uses the RMI protocol to connect to the CIM Object Manager on the local host, in the default namespace, `root\cimv2`. You can select HTTP if you want to communicate to a CIM Object Manager using the standard XML/HTTP protocol from the Desktop Management Task Force. When a connection is established, all classes contained in the default namespace are displayed in the left side of the CIM WorkShop window.

The name of the current namespace is listed in the tool bar. All programming operations are performed within a namespace. Four namespaces are created in a `root` namespace during installation:

cimv2   Contains the default CIM classes that represent managed resources on your system.

security   Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.

system   Contains properties for configuring the CIM Object Manager.

snmp   Contains pre-defined SNMP-related classes and all SNMP MOF files that are compiled.

The `cimworkshop` application allows you to perform the following tasks:

Create, view, and change namespaces.   Use the CIM WorkShop application to view all namespaces. A namespace is a directory-like structure that can store CIM classes and instances.

Create, delete, and view CIM classes. You cannot modify the unique attributes of the classes that make up the CIM and Solaris Schema. You can create a new instance or subclass of the class and modify the desired attributes in that instance or subclass.

Create, modify, delete, and view CIM instances. You can add instances to a class and modify its inherited properties or create new properties. You can also change the property values of a CIM instance.

Invoke methods. You can set input values for a parameter of a method and invoke the method.

When CIM WorkShop connects to the CIM Object Manager in a particular namespace, all subsequent operations occur within that namespace. When you connect to a namespace, you can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace.

When you use CIM WorkShop to view CIM data, the WBEM system validates your login information on the current host. By default, a validated WBEM user is granted read access to the CIM Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.

Read Only   Allows read-only access to CIM Schema objects. Users with this privilege can retrieve instances and classes, but cannot create, delete, or modify CIM objects.

Read/Write   Allows full read, write, and delete access to all CIM classes and instances.

Write   Allows write and delete, but not read access to all CIM classes and instances.

None   Allows no access to CIM classes and instances.

Usage   The `cimworkshop` command is not a tool for a distributed environment. Rather, this command is used for local administration on the machine on which the CIM Object Manager is running.

Exit Status   The `cimworkshop` utility terminates with exit status 0.

Attributes   See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbdev

See Also   mofcomp(1M), wbemlogviewer(1M), init.wbem(1M), attributes(5)

Name clear_locks – clear locks held on behalf of an NFS client

Synopsis /usr/sbin/clear_locks [-s] *hostname*

Description The clear_locks command removes all file, record, and share locks created by the *hostname* and held on the current host, regardless of which process created or owns the locks.

This command can be run only by the super-user.

This command should only be used to repair the rare case of a client crashing and failing to clear held locks. Clearing locks held by an active client may cause applications to fail in an unexpected manner.

Options -s Remove all locks created by the current machine and held by the server *hostname*.

Operands The following operands are supported:

hostname   name of host server

Exit Status 0 Successful operation.

1 If not root.

2 Usage error.

3 If unable to contact server (RPC).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also fcntl(2), attributes(5)

Name clinfo – display cluster information

Synopsis `clinfo [-nh]`

Description The `clinfo` command displays cluster configuration information about the node from which the command is executed.

Without arguments, `clinfo` returns an exit status of `0` if the node is configured and booted as part of a cluster. Otherwise, `clinfo` returns an exit status of `1`.

Options The following options are supported:

-h Displays the highest node number allowed to be configured. This is different from the maximum number of nodes supported in a given cluster. The current highest configured node number can change immediately after the command returns since new nodes can be dynamically added to a running cluster.

For example, `clinfo -h` might return 64, meaning that the highest number you can use to identify a node is 64. See the *Sun Cluster 3.0 System Administration Guide* for a description of utilities you can use to determine the number of nodes in a cluster.

-n Prints the number of the node from which `clinfo` is executed.

Exit Status The following exit values are returned:

0 Successful completion.

1 An error occurred.

This is usually because the node is not configured or booted as part of a cluster.

Attributes See `attributes`(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also `attributes`(5)

Name clri, dcopy – clear inode

Synopsis clri [-F *FSType*] [-V] *special i-number*

dcopy [-F *FSType*] [-V] *special i-number*

Description clri writes zeros on the inodes with the decimal *i-number* on the file system stored on *special*. After clri, any blocks in the affected file show up as missing in an fsck(1M) of *special*.

Read and write permission is required on the specified file system device. The inode becomes allocatable.

The primary purpose of this routine is to remove a file that for some reason appears in no directory. If it is used to zap an inode that does appear in a directory, care should be taken to track down the entry and remove it. Otherwise, when the inode is reallocated to some new file, the old entry will still point to that file. At that point, removing the old entry will destroy the new file. The new entry will again point to an unallocated inode, so the whole cycle is likely to be repeated again and again.

dcopy is a symbolic link to clri.

Options -F *FSType*   Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from /etc/vfstab by matching *special* with an entry in the table, or by consulting /etc/default/fs.

     -V   Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option should be used to verify and validate the command line.

Usage See largefile(5) for the description of the behavior of clri and dcopy when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files /etc/default/fs   Default local file system type

/etc/vfstab   List of default parameters for each file system

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also fsck(1M), vfstab(4), attributes(5), largefile(5)

Notes This command might not be supported for all *FSTypes*.

Name consadm – select or display devices used as auxiliary console devices

Synopsis /usr/sbin/consadm

/usr/sbin/consadm [-a *device*. . .] [-p]

/usr/sbin/consadm [-d *device*. . .] [-p]

/usr/sbin/consadm [-p]

Description consadm selects the hardware *device* or devices to be used as auxiliary console devices, or displays the current device. Only superusers are allowed to make or display auxiliary console device selections.

Auxiliary console devices receive copies of console messages, and can be used as the console during single user mode. In particular, they receive kernel messages and messages directed to /dev/sysmsg. On Solaris x86 based systems they can also be used for interaction with the bootstrap.

By default, selecting a display device to be used as an auxiliary console device selects that device for the duration the system remains up. If the administrator needs the selection to persist across reboots the -p option can be specified.

consadm runs a daemon in the background, monitoring auxiliary console devices. Any devices that are disconnected (hang up, lose carrier) are removed from the auxiliary console device list, though not from the persistent list. While auxiliary console devices may have been removed from the device list receiving copies of console messages, those messages will always continue to be displayed by the default console device.

The daemon will not run if it finds there are not any auxiliary devices configured to monitor. Likewise, after the last auxiliary console is removed, the daemon will shut itself down. Therefore the daemon persists for only as long as auxiliary console devices remain active.

See eeprom(1M) for instructions on assigning an auxiliary console device as the system console.

Options The following options are supported:

-a *device* Adds *device* to the list of auxiliary console devices. Specify *device* as the path name to the device or devices to be added to the auxiliary console device list.

-d *device* Removes *device* from the list of auxiliary console devices. Specify *device* as the path name to the device or devices to be removed from the auxiliary console device list.

-p Prints the list of auxiliary consoles that will be auxiliary across reboots.

When invoked with the -a or -d options , tells the application to make the change persist across reboot.

Examples   EXAMPLE 1   Adding to the list of devices that will receive console messages

The following command adds /dev/term/a to the list of devices that will receive console messages.

```
example# consadm -a /dev/term/a
```

EXAMPLE 2   Removing from the list of devices that will receive console messages

The following command removes /dev/term/a from the list of devices that will receive console messages. This includes removal from the persistent list.

```
example# consadm -d -p /dev/term/a
```

EXAMPLE 3   Printing the list of devices selected as auxiliary console devices

The following command prints the name or names of the device or devices currently selected as auxiliary console devices.

```
example# consadm
```

Environment Variables   See environ(5) for descriptions of the following environment variables that affect the execution of consadm: LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also   kmdb(1), svcs(1), eeprom(1M), svcadm(1M), syslogd(1M), environ(5), attributes(5), smf(5), sysmsg(7D), console(7D)

Notes   Auxiliary console devices are not usable for kmdb or firmware I/O, do not receive panic messages, and do not receive output directed to /dev/console.

The consadm service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/consadm
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name console-reset – force console login to display

Synopsis svc:/system/console-reset

Description The console-reset service runs if X is not running on console and the console is ready for interactive use. Under these conditions, console-reset turns off the boot-time graphics, forcing the console login prompt to display.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Uncommitted

See Also svcs(1), svcadm(1M), vbiosd(1M), attributes(5), smf(5)

Notes The console-reset service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/console-reset:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name conv_lp – convert LP configuration

Synopsis conv_lp [-d *dir*] [-f *file*]

Description conv_lp reads LP printer configuration information from a directory and converts it to an output file for use with print client software.

Options The following options are supported:

-d*dir*   The root (/) directory from which LP configuration information is read. The default is root (/).

-f*file*   The output file to which conv_lp writes the converted LP configuration information.

Exit Status The following exit values are returned:

0   Successful completion.

non-zero   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	print/lp/print-client-commands

See Also attributes(5)

Name conv_lpd – convert LPD configuration

Synopsis conv_lpd [-c printcap] [-n] *file*

Description conv_lpd converts LPD printer configuration information from *file* to a printcap file. *file* specifies the name of the input file, and is in printcap format.

Options The following options are supported:

-c printcap   Specifies the type of output file produced by the conversion. -c printcap converts to a printcap file.

-n   Preserves the namelist during the conversion.

Operands The following operands are supported:

file   The file to be converted.

Exit Status The following exit values are returned:

0   Successful completion.

non-zero   An error occurred.

Files /etc/printcap   SunOS 4.*x* printer capability database.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	print/lp/print-client-commands

See Also lpset(1M), attributes(5)

Name coreadm – core file administration

Synopsis coreadm [-g *pattern*] [-G *content*] [-i *pattern*] [-I *content*]
          [-d *option*]... [-e *option*]...

coreadm [-p *pattern*] [-P *content*] [*pid*]...

Description coreadm specifies the name and location of core files produced by abnormally-terminating processes. See core(4).

Only users and roles that belong to the "Maintenance and Repair" RBAC profile can execute the first form of the SYNOPSIS. This form configures system-wide core file options, including a global core file name pattern and a core file name pattern for the init(1M) process. All settings are saved persistently and will be applied at boot.

Non-privileged users can execute the second form of the SYNOPSIS. This form specifies the file name pattern and core file content that the operating system uses to generate a per-process core file.

A core file name pattern is a normal file system path name with embedded variables, specified with a leading % character. The variables are expanded from values that are effective when a core file is generated by the operating system. The possible embedded variables are as follows:

%d

Executable file directory name, up to a maximum of MAXPATHLEN characters

%f

Executable file name, up to a maximum of MAXCOMLEN characters

%g

Effective group-ID

%m

Machine name (uname -m)

%n

System node name (uname -n)

%p

Process-ID

%t

Decimal value of time(2)

%u

Effective user-ID

%z

Name of the zone in which process executed (zonename)

%%

Literal %

For example, the core file name pattern /var/cores/core.%f.%p would result, for command foo with process-ID 1234, in the core file name /var/cores/core.foo.1234.

A core file content description is specified using a series of tokens to identify parts of a process's binary image:

anon
   Anonymous private mappings, including thread stacks that are not main thread stacks

ctf
   CTF type information sections for loaded object files

data
   Writable private file mappings

dism
   DISM mappings

heap
   Process heap

ism
   ISM mappings

rodata
   Read-only private file mappings

shanon
   Anonymous shared mappings

shfile
   Shared mappings that are backed by files

shm
   System V shared memory

stack
   Process stack

symtab
   Symbol table sections for loaded object files

text
   Readable and executable private file mappings

In addition, you can use the token all to indicate that core files should include all of these parts of the process's binary image. You can use the token none to indicate that no mappings are to be included. The default token indicates inclusion of the system default content (stack+heap+shm+ism+dism+text+data+rodata+anon+shanon+ctf+symtab). The /proc file system data structures are always present in core files regardless of the mapping content.

You can use + and - to concatenate tokens. For example, the core file content `default-ism` would produce a core file with the default set of mappings without any intimate shared memory mappings.

The `coreadm` command with no arguments reports the current system configuration, for example:

```
$ coreadm
    global core file pattern: /var/cores/core.%f.%p
    global core file content: all
      init core file pattern: core
      init core file content: default
            global core dumps: enabled
      per-process core dumps: enabled
     global setid core dumps: enabled
per-process setid core dumps: disabled
    global core dump logging: disabled
```

The `coreadm` command with only a list of process-IDs reports each process's per-process core file name pattern, for example:

```
$ coreadm 278 5678
  278:    core.%f.%p default
  5678:  /home/george/cores/%f.%p.%t all-ism
```

Only the owner of a process or a user with the `proc_owner` privilege can interrogate a process in this manner.

When a process is dumping core, up to three core files can be produced: one in the per-process location, one in the system-wide global location, and, if the process was running in a local (non-global) zone, one in the global location for the zone in which that process was running. Each core file is generated according to the effective options for the corresponding location.

When generated, a global core file is created in mode `600` and owned by the superuser. Nonprivileged users cannot examine such files.

Ordinary per-process core files are created in mode `600` under the credentials of the process. The owner of the process can examine such files.

A process that is or ever has been setuid or setgid since its last exec(2) presents security issues that relate to dumping core. Similarly, a process that initially had superuser privileges and lost those privileges through setuid(2) also presents security issues that are related to dumping core. A process of either type can contain sensitive information in its address space to which the current nonprivileged owner of the process should not have access. If setid core files are enabled, they are created mode `600` and owned by the superuser.

Options   The following options are supported:

-d *option...*
    Disable the specified core file option. See the -e *option* for descriptions of possible options.

    Multiple -e and -d options can be specified on the command line. Only users and roles belonging to the "Maintenance and Repair" RBAC profile can use this option.

-e *option...*
    Enable the specified core file option. Specify *option* as one of the following:

    global
        Allow core dumps that use global core pattern.

    global-setid
        Allow set-id core dumps that use global core pattern.

    log
        Generate a syslog(3C) message when generation of a global core file is attempted.

    process
        Allow core dumps that use per-process core pattern.

    proc-setid
        Allow set-id core dumps that use per-process core pattern.

        Multiple -e and -d options can be specified on the command line. Only users and roles belonging to the "Maintenance and Repair" RBAC profile can use this option.

-g *pattern*
    Set the global core file name pattern to *pattern*. The pattern must start with a / and can contain any of the special % variables that are described in the DESCRIPTION.

    Only users and roles belonging to the "Maintenance and Repair" RBAC profile can use this option.

-G *content*
    Set the global core file content to content. You must specify content by using the tokens that are described in the DESCRIPTION.

    Only users and roles belonging to the "Maintenance and Repair" RBAC profile can use this option.

-i *pattern*
    Set the default per-process core file name to *pattern*. This changes the per-process pattern for any process whose per-process pattern is still set to the default. Processes that have had their per-process pattern set or are descended from a process that had its per-process pattern set (using the -p option) are unaffected. This default persists across reboot.

    Only users and roles belonging to the "Maintenance and Repair" RBAC profile can use this option.

-I *content*

Set the default per-process core file content to *content*. This changes the per-process content for any process whose per-process content is still set to the default. Processes that have had their per-process content set or are descended from a process that had its per-process content set (using the -P option) are unaffected. This default persists across reboot.

Only users and roles belonging to the "Maintenance and Repair" RBAC profile can use this option.

-p *pattern*

Set the per-process core file name pattern to *pattern* for each of the specified process-IDs. The pattern can contain any of the special % variables described in the DESCRIPTION and need not begin with /. If the pattern does not begin with /, it is evaluated relative to the directory that is current when the process generates a core file.

A nonprivileged user can apply the -p option only to processes that are owned by that user. A user with the proc_owner privilege can apply the option to any process. The per-process core file name pattern is inherited by future child processes of the affected processes. See fork(2).

If no process-IDs are specified, the -p option sets the per-process core file name pattern to *pattern* on the parent process (usually the shell that ran coreadm).

-P *content*

Set the per-process core file content to *content* for each of the specified process-IDs. The content must be specified by using the tokens that are described in the DESCRIPTION.

A nonprivileged user can apply the -p option only to processes that are owned by that user. A user with the proc_owner privilege can apply the option to any process. The per-process core file name pattern is inherited by future child processes of the affected processes. See fork(2).

If no process-IDs are specified, the -P option sets the per-process file content to *content* on the parent process (usually the shell that ran coreadm).

Operands   The following operands are supported:

pid

   process-ID

Examples   EXAMPLE 1   Setting the Core File Name Pattern

When executed from a user's $HOME/.profile or $HOME/.login, the following command sets the core file name pattern for all processes that are run during the login session:

```
example$  coreadm -p core.%f.%p
```

Note that since the process-ID is omitted, the per-process core file name pattern will be set in the shell that is currently running and is inherited by all child processes.

EXAMPLE 2 Dumping a User's Files Into a Subdirectory

The following command dumps all of a user's core dumps into the `corefiles` subdirectory of the home directory, discriminated by the system node name. This command is useful for users who use many different machines but have a shared home directory.

```
example$  coreadm -p $HOME/corefiles/%n.%f.%p 1234
```

EXAMPLE 3 Culling the Global Core File Repository

The following commands set up the system to produce core files in the global repository only if the executables were run from `/usr/bin` or `/usr/sbin`.

```
example# mkdir -p /var/cores/usr/bin
example# mkdir -p /var/cores/usr/sbin
example# coreadm -G all -g /var/cores/%d/%f.%p.%n
```

Files /var/cores
Directory provided for global core file storage.

Exit Status The following exit values are returned:

0

Successful completion.

1

A fatal error occurred while either obtaining or modifying the system core file configuration.

2

Invalid command-line options were specified.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also gcore(1), pfexec(1), svcs(1), init(1M), svcadm(1M), exec(2), fork(2), setuid(2), time(2), syslog(3C), core(4), prof_attr(4), user_attr(4), attributes(5), smf(5)

Notes In a local (non-global) zone, the global settings apply to processes running in that zone. In addition, the global zone's apply to processes run in any zone.

The term *global settings* refers to settings which are applied to the system or zone as a whole, and does not necessarily imply that the settings are to take effect in the global zone.

The coreadm service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/coreadm:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

The -g, -G, -i, -I, -e, and -d options can be also used by a user, role, or profile that has been granted both the solaris.smf.manage.coreadm and solaris.smf.value.coreadm authorizations.

Name cpustat – monitor system behavior using CPU performance counters

Synopsis cpustat -c *eventspec* [-c *eventspec*]... [-p *period*] [-T u | d]
         [-sntD] [*interval* [*count*]]

cpustat -h

Description The cpustat utility allows CPU performance counters to be used to monitor the overall
behavior of the CPUs in the system.

If *interval* is specified, cpustat samples activity every *interval* seconds, repeating forever. If a
count is specified, the statistics are repeated *count* times. If neither are specified, an interval of
five seconds is used, and there is no limit to the number of samples that are taken.

Options The following options are supported:

-c *eventspec*
   Specifies a set of events for the CPU performance counters to monitor. The syntax of these
   event specifications is:

   [picn=]*eventn*[,attr[*n*][=*val*]][,[picn=]*eventn*
       [,attr[n][=*val*]],...,]

   You can use the -h option to obtain a list of available events and attributes. This causes
   generation of the usage message. You can omit an explicit counter assignment, in which
   case cpustat attempts to choose a capable counter automatically.

   Attribute values can be expressed in hexadecimal, octal, or decimal notation, in a format
   suitable for strtoll(3C). An attribute present in the event specification without an explicit
   value receives a default value of 1. An attribute without a corresponding counter number is
   applied to all counters in the specification.

   The semantics of these event specifications can be determined by reading the CPU
   manufacturer's documentation for the events.

   Multiple -c options can be specified, in which case the command cycles between the
   different event settings on each sample.

-D
   Enables debug mode.

-h
   Prints an extensive help message on how to use the utility and how to program the
   processor-dependent counters.

-n
   Omits all header output (useful if cpustat is the beginning of a pipeline).

-p *period*
   Causes cpustat to cycle through the list of *eventspec*s every *period* seconds. The tool sleeps
   after each cycle until *period* seconds have elapsed since the first *eventspec* was measured.

When this option is present, the optional *count* parameter specifies the number of total cycles to make (instead of the number of total samples to take). If *period* is less than the number of *eventspec*s times *interval*, the tool acts as it period is 0.

-s

Creates an idle soaker thread to spin while system-only *eventspec*s are bound. One idle soaker thread is bound to each CPU in the current processor set. System-only *eventspec*s contain both the nouser and the sys tokens and measure events that occur while the CPU is operating in privileged mode. This option prevents the kernel's idle loop from running and triggering system-mode events.

-T u | d

Display a time stamp.

Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See date(1).

-t

Prints an additional column of processor cycle counts, if available on the current architecture.

Usage A closely related utility, cputrack(1), can be used to monitor the behavior of individual applications with little or no interference from other activities on the system.

The cpustat utility must be run by the super-user, as there is an intrinsic conflict between the use of the CPU performance counters system-wide by cpustat and the use of the CPU performance counters to monitor an individual process (for example, by cputrack.)

Once any instance of this utility has started, no further per-process or per-LWP use of the counters is allowed until the last instance of the utility terminates.

The times printed by the command correspond to the wallclock time when the hardware counters were actually sampled, instead of when the program told the kernel to sample them. The time is derived from the same timebase as gethrtime(3C).

The processor cycle counts enabled by the -t option always apply to both user and system modes, regardless of the settings applied to the performance counter registers.

On some hardware platforms running in system mode using the "sys" token, the counters are implemented using 32-bit registers. While the kernel attempts to catch all overflows to synthesize 64-bit counters, because of hardware implementation restrictions, overflows can be lost unless the sampling interval is kept short enough. The events most prone to wrap are those that count processor clock cycles. If such an event is of interest, sampling should occur frequently so that less than 4 billion clock cycles can occur between samples.

The output of cpustat is designed to be readily parsable by nawk(1) and perl(1), thereby allowing performance tools to be composed by embedding cpustat in scripts. Alternatively, tools can be constructed directly using the same APIs that cpustat is built upon using the facilities of libcpc(3LIB). See cpc(3CPC).

The cpustat utility only monitors the CPUs that are accessible to it in the current processor set. Thus, several instances of the utility can be running on the CPUs in different processor sets. See psrset(1M) for more information about processor sets.

Because cpustat uses LWPs bound to CPUs, the utility might have to be terminated before the configuration of the relevant processor can be changed.

Examples

SPARC **EXAMPLE 1** Measuring External Cache References and Misses

The following example measures misses and references in the external cache. These occur while the processor is operating in user mode on an UltraSPARC machine.

```
example% cpustat -c EC_ref,EC_misses 1 3

  time cpu event     pic0      pic1
 1.008   0  tick    69284      1647
 1.008   1  tick    43284      1175
 2.008   0  tick   179576      1834
 2.008   1  tick   202022     12046
 3.008   0  tick    93262       384
 3.008   1  tick    63649      1118
 3.008   2 total   651077     18204
```

x86 **EXAMPLE 2** Measuring Branch Prediction Success on Pentium 4

The following example measures branch mispredictions and total branch instructions in user and system mode on a Pentium 4 machine.

```
 example% cpustat -c \
    pic12=branch_retired,emask12=0x4,pic14=branch_retired,\
    emask14=0xf,sys 1 3

  time cpu event    pic12     pic14
 1.010   1  tick      458       684
 1.010   0  tick      305       511
 2.010   0  tick      181       269
 2.010   1  tick      469       684
 3.010   0  tick      182       269
 3.010   1  tick      468       684
 3.010   2 total     2063      3101
```

EXAMPLE 3 Counting Memory Accesses on Opteron

The following example determines the number of memory accesses made through each memory controller on an Opteron, broken down by internal memory latency:

```
cpustat -c \
   pic0=NB_mem_ctrlr_page_access,umask0=0x01, \
   pic1=NB_mem_ctrlr_page_access,umask1=0x02, \
```

EXAMPLE 3 Counting Memory Accesses on Opteron *(Continued)*

```
pic2=NB_mem_ctrlr_page_access,umask2=0x04,sys \
1

 time cpu event     pic0     pic1     pic2
1.003  0  tick     41976    53519     7720
1.003  1  tick      5589    19402      731
2.003  1  tick      6011    17005      658
2.003  0  tick     43944    45473     7338
3.003  1  tick      7105    20177      762
3.003  0  tick     47045    48025     7119
4.003  0  tick     43224    46296     6694
4.003  1  tick      5366    19114      652
```

Warnings By running the cpustat command, the super-user forcibly invalidates all existing performance counter context. This can in turn cause all invocations of the cputrack command, and other users of performance counter context, to exit prematurely with unspecified errors.

If cpustat is invoked on a system that has CPU performance counters which are not supported by Solaris, the following message appears:

```
cpustat: cannot access performance counters - Operation not applicable
```

This error message implies that cpc_open() has failed and is documented in cpc_open(3CPC). Review this documentation for more information about the problem and possible solutions.

If a short interval is requested, cpustat might not be able to keep up with the desired sample rate. In this case, some samples might be dropped.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	diagnostic/cpu-counters
Interface Stability	Committed

See Also cputrack(1), nawk(1), perl(1), iostat(1M), prstat(1M), psrset(1M), vmstat(1M), cpc(3CPC), cpc_open(3CPC), cpc_bind_cpu(3CPC), gethrtime(3C), strtoll(3C), libcpc(3LIB), attributes(5)

Notes When cpustat is run on a Pentium 4 with HyperThreading enabled, a CPC set is bound to only one logical CPU of each physical CPU. See cpc_bind_cpu(3CPC).

Name croinfo, diskinfo – query and display information about 1) chassis, receptacle, and occupants or 2) disk occupants of bay receptacles

Synopsis
```
croinfo [-h] [-v] [-I cro_db] [-o fields] [-O fields]
        [-P product-id] [-C chassis-id] [-A alias-id]
        [-R receptacle-name] [-T receptacle-type] [-t occupant-type]
        [-D devchassis-path] [-d occupant-devices] [-p occupant-paths]
        [-c occupant-compdev] [-i occupant-devid] [-m occupant-mfg]
        [-e occupant-model] [-n occupant-part] [-s occupant-serial]
        [-f occupant-firm] [-1 occupant-misc-1] [-2 occupant-misc-2]
        [-3 occupant-misc-3]

diskinfo [-h] [-v] [-I cro_db] [-o fields] [-O fields]
        [-P product-id] [-C chassis-id] [-A alias-id]
        [-R receptacle-name] [-T receptacle-type] [-t occupant-type]
        [-D devchassis-path] [-d occupant-devices] [-p occupant-paths]
        [-c occupant-compdev] [-i occupant-devid] [-m occupant-mfg]
        [-e occupant-model] [-n occupant-part] [-s occupant-serial]
        [-f occupant-firm] [-1 occupant-misc-1] [-2 occupant-misc-2]
        [-3 occupant-misc-3]

croinfo -?

diskinfo -?
```

Description The `diskinfo` and `croinfo` utility share the same binary executable. At runtime, the utility checks to see how it was invoked, and adjusts defaults.

The `croinfo` utility allows users to query and display specific aspects of a system's configuration. Queries are performed against a record-oriented dataset that captures the relationship between physical location and various aspects of the device currently at that physical location. This relationship is expressed in terms of Chassis, Receptacle, and Occupant (thus the `cro` prefix).

Records in a CRO dataset are composed of multiple, named fields with each record having a potentially unique field value. An angle-bracket reference, such as *product-id*, is referring to a specific *field-name*. For a given record, a field value is either undefined (empty) or defined with a set of indexed string values. Some defined field values have just one string value, while others can have multiple string values.

Each *field-name* defined is associated with a separate *field-char* character. By convention, uppercase *field-char* characters are associated for chassis and receptacle information fields, and lowercase *field-char* characters are associated with occupant information fields. For each *field-char* character, a separate `-field-char field-name-RE` flag regular expression filter option is provided. This allows the user to customize queries to display information about specific aspects of the configuration. Records that match all regular expressions are selected, in dataset order, for display. For multiple string values, only one index value needs to match for the field to match.

By default, only a minimal number of default output fields are displayed. You can override the default with either -o *fields* for human-readable output or with -O *fields* for parseable output. In both cases, output fields can be specified using either the short-hand *field-char*[...] notation or in the more descriptive *field-name*[,...] notation.

For human-readable use, by using the -o *fields* option, the user can override the default fields, and output any fields, in the specified order, in a column-aligned whitespace separated format. In general, output will be one line of output per matching record with undefined (empty) *field-name* values displayed as a hyphen (–). If, however, a displayed record has a multiple string *value* field, then multiple lines of output are produced with any secondary non-multiple string values fields showing a colon (:).

For scripting, by using the -O *fields* option, the user can override the default output fields and output any fields, in the specified order, in a parseable colon-separated format with whitespace removed and column headers suppressed. Output will be one line of output per matching record with undefined (empty) field-name values displayed with no value. If a displayed record *field-name* has a multiple string *value* field, then all the values are concatenated, separated by a comma. Any occurrence of a colon or a comma in a value is escaped with a leading backslash (\\). To make scripts more legible, use of the -O *field-name*[,...]' notation is encouraged.

The -o and -O options are mutually exclusive.

If the -h option is used, or scripting output format is requested by using -o, the column headers for output fields are suppressed.

A Chassis is identified by a specific *product-id* and *chassis-id*. The *product-id* relates to a specific chassis-level product, like a system chassis Sun-Fire-X4200-M2 or a storage chassis SUN-Storage-J4410. For a given *product-id* value, the *chassis-id* defines a unique serial number.

A specific *product-id.chassis-id* combination can have an "managed" location-oriented *alias-id* defined by the administrator, using fmadm(1M) that provides installation-specific location information about where a chassis is physically located. This might include such information as building, room, rack, and U-number range within a rack.

In addition to the managed location-oriented *alias-id* defined using fmadm(1M), system chassis always have one well-known alias called SYS that can be used to identify receptacles that are internal to the system chassis.

Within a chassis, each receptacle has a unique *receptacle-name* that should match the physical silk-screen label designation for the receptacle. Each receptacle also has a *receptacle-type*, which helps define acceptable *occupant-types*.

When a receptacle is occupied, use the -f flag definitions for available *occupant-information*. Of particular interest is the -c *occupant-compdev* occupant information: it describes the common component of the public /dev name associated with the occupant device. For disks, this is the whole-disk c#t#d# name.

The CRO dataset order is associated with the *devchassis-path* of the record, which corresponds to the /dev/chassis name space maintained by devchassisd(1M). That ordering places records associated with the well-known SYS internal alias first, and records with BOOT receptacle-name first in SYS. This is done to ensure that, when applicable, information about the typical boot device is provided first.

For croinfo, the default output is in -o *Dtc* format, and all CRO records are shown.

For diskinfo, the default output is in -o *Dc* format, and a -T *bay receptacle-type* filter is applied. The meanings of the *occupant-misc-#* fields also take on a disk-specific interpretation: *misc-1* is capacity, and *misc-2* is target-port information. These defaults allow the diskinfo command to query the relationship between chassis, *bay* receptacles, and their *disk* occupants, while ignoring other CRO information.

Options For each record *field-name* defined, a separate *-field-char field-name-RE* flag regular expression filter can be specified. For a given *field-name*, if no specific *-field-char field-name-RE* filter is defined, all CRO records match.

This allows the user to customize queries to display information about specific aspects of the configuration. CRO records that match all of the specified *field-name* regular expressions (as in regex(3C)) will be selected for display, with specific fields output controlled by means of -o, -O, or the default.

-P *product-id*
  The *product-id* specifies the product identifier of an enumerated chassis. The *product-id* might be exposed in the /dev/chassis name space. For storage products that do not have an established fmadm(1M) managed *alias-id*, the *product-id* is visible in the devchassis(7FS) /dev/chassis name space.

  Example system *product-id* value: Sun-Fire-X4200-M2

  Example storage *product-id* value: SUN-Storage-J4410

-C *chassis-id*
  The *chassis-id* specifies the serial number of a product chassis. The *chassis-id* might be exposed in the /dev/chassis name space. For storage products that do not have an established fmadm(1M) managed *alias-id*, the *product-id* is visible in the devchassis(7FS) /dev/chassis name space.

  Example *chassis-id* value: 0818QAJ002

-A *alias-id*
  An *alias-id* value can be the well-known alias value of SYS, for system internal devices. In addition, an *alias-id* value can be a managed alias, defined by the administrator using fmadm(1M). The intended use of a managed alias is to define the physical location of the *product-id.chassis-id*. The *alias-id* is exposed in the /dev/chassis name space.

  Example well-known *alias-id* value: SYS

Example managed *alias-id* value: `RACK29.U01-04`

-R *receptacle-name*

For a specific *product-id*, the unique *receptacle-name* defines location of a specific receptacle in a chassis. The *receptacle-name* should be identical to a silk-screen label on the physical chassis, and should also match product documentation. The *receptacle-name* can have multiple path components, such as `SYS/HD0`. The receptacle-name is exposed in the `/dev/chassis` name space.

Example *receptacle-name* value: `SYS/HD0`

-T *receptacle-type*

Example *receptacle-type* value: `bay`

-t *occupant-type*

A receptacle without an occupant has an undefined (empty) *occupant-type* value, shown as a hyphen (–).

Example *occupant-type* value: `disk`

-D *devchassis-path*

Example *devchassis-path* value: `/dev/chassis/SYS/HD0/disk`

-d *occupant-devices*

A receptacle without an occupant has an undefined (empty) *occupant-devices* value, shown as a hyphen (–).

Example *occupant-devices* value:

`/devices/scsi_vhci/disk@g5000c500101ba0a3`

-p *occupant-paths*

A receptacle without an occupant has an undefined (empty) *occupant-paths* value, shown as a hyphen (–).

Example occupant-paths value:

`devices/pci@0,0/pci10de,5d@d/pci11f8,8001@0/iport@f/disk@w5000c500101ba0a1,0`

-c *occupant-compdev*

A receptacle without an occupant has an undefined (empty) *occupant-compdev* value, shown as a hyphen (–).

Example *occupant-compdev* value: `c0t5000C500101BA0A3d0`

-i *occupant-devid*

A receptacle without an occupant has an undefined (empty) *occupant-devid* value, shown as a hyphen (–).

Example *occupant-devid* value: `id1,sd@n5000c500101ba0a3`

-m *occupant-mfg*
A receptacle without an occupant has an undefined (empty) *occupant-mfg* value, shown as a hyphen (–).

Example *occupant-mfg* value: SEAGATE

-e *occupant-model*
A receptacle without an occupant has an undefined (empty) *occupant-model*, shown as a hyphen (–).

Example *occupant-model* value: ST32000SSSUN2.0T

-n *occupant-part*
A receptacle without an occupant has an undefined (empty) *occupant-part* value, shown as a hyphen (–).

Example *occupant-part* value: SEAGATE-ST32000SSSUN2.0T

-s *occupant-serial*
A receptacle without an occupant has an undefined (empty) *occupant-serial* value, shown as a hyphen (–).

Example *occupant-serial* value: 000949L09C8L_____9WM09C8L

-f *occupant-firm*
A receptacle without an occupant has an undefined (empty) *occupant-firm* value, shown as a hyphen (–).

Example *occupant-firm* value: 0313

-1 *occupant-misc-1*
A receptacle without an occupant has an undefined (empty) *occupant-misc-1* value, shown as a hyphen (–).

-2 *occupant-misc-2*
A receptacle without an occupant has an undefined (empty) *occupant-misc-2* value, shown as a hyphen (–).

-3 *occupant-misc-3*
A receptacle without an occupant has an undefined (empty) *occupant-misc-3* value, shown as a hyphen (–).

-?
Display usage information.

Output *field-name* Control Options
-o *fields*
Output specified fields, in order, in human-readable format.

For croinfo, default output is in -o *Dtc* format. For diskinfo, default output is in -O *Dc* format.

-O *fields*
>   Output specified fields, in order, in parseable format.

-h
>   Do not output *field-name* column headers

-v
>   Display verbose header that includes various information about when the CRO dataset was created. This option is of particular use with -I and is used to specify a non-standard source for the CRO dataset.

Dataset Selection Option
-I *cro_db*
>   Data file from which to obtain CRO dataset information.

Examples   In some of the following examples, example output wraps in an 80–character-wide display.

EXAMPLE 1   Determining Where a Disk is Located

The following command determines where a disk is located:

```
# croinfo -c c0t5000C500101BA0A3d0
D:devchassis-path                       t:occupant-type
--------------------------------------- ---------------
/dev/chassis/RACK29.U01-04/DISK_00/disk  disk

c:occupant-compdev
------------------
c0t5000C500101BA0A3d0
```

EXAMPLE 2   Reporting Internal Disks

The following command reports the *receptacle-name* and the *occupant-compdev* of internal disks, that is, disks that are associated with the well-known SYS alias.

```
# diskinfo -A SYS -o Rc
R:receptacle-name c:occupant-compdev
----------------- ------------------
SYS/HD0           c8t0d0
SYS/HD1           c8t1d0
SYS/HD2           -
SYS/HD3           -
```

Note that the SYS/HD2 and SYS/HD3 receptacles are empty.

The same command, in scripting output mode, would produce:

```
# diskinfo -A SYS -O receptacle-name,occupant-compdev
SYS/HD0:c8t0d0
SYS/HD1:c8t1d0
SYS/HD2:
SYS/HD3:
```

EXAMPLE 3 Reporting Disks in a Specific Enclosure

The following command reports all the disks within a chassis with a specific *product-id* and *chassis-id* value.

```
# diskinfo -P SUN-Storage-J4410 -C SUN-Storage-J4410 -o Rc
R:receptacle-name  c:occupant-compdev
-----------------  --------------------
DISK_00            c0t5000C500101BA0A3d0
DISK_01            c0t5000C500101B95BBd0
DISK_02            -
```

EXAMPLE 4 Reporting Physical Path Information

The following command reports physical path information for a specific disk.

```
# croinfo -c c0t5000C500101BA0A3d0 -o cp
c:occupant-compdev
------------------
c0t5000C500101BA0A3d0

p:occupant-paths
-------------------------------------------------
/devices/pci@0,0/pci10de,5d@d/pci11f8,8001@0/iport@f/disk@w5000c500101ba0a1,0
/devices/pci@7b,0/pci10de,5d@d/pci11f8,8001@0/iport@f/disk@w5000c500101ba0a2,0
```

Note that *occupant-paths* has multiple string values.

EXAMPLE 5 Making Inventory of Disks

The following example reports how many of a specific type of disk are available using *occupant-part*.

```
# for i in ‘croinfo -h -o n  | sort -u‘
> do
> echo $i "\\t\\c";croinfo -h -n $i | wc -l
> done
SEAGATE-ST330055SSUN300G            3
SEAGATE-ST330056SSUN300G           19
SEAGATE-ST345056SSUN450G            5
```

EXAMPLE 6 Locating a Specific Type of Disk

The following command reports where disks of a specific type are located, what their ctd name is (by means of *occupant-compdev*), and what firmware level they are at.

```
# croinfo -n SEAGATE-ST330055SSUN300G -o Dcf
D:Devchassis                                     c:component
----------------------------------------------- --------------------
/dev/chassis/RACK29.U29-32/SCSI_Device__11/disk  c0t5000C50007DD49F7d0
/dev/chassis/RACK29.U33-36/SCSI_Device__18/disk  c0t5000C50008F7FB4Fd0
/dev/chassis/RACK29.U33-36/SCSI_Device__19/disk  c0t5000C50007DD412Fd0
```

EXAMPLE 6 Locating a Specific Type of Disk *(Continued)*

```
f:firm
------
0892
0892
0892
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below

The interface stability of croinfo and diskinfo is Committed. The interface stability of command output is Not-an-Interface.

See Also devchassisd(1M), fmadm(1M), fmd(1M), attributes(5), devchassis(7FS)

The SCSI Storage Interfaces committee website, http://www.t10.org

SCSI Primary Commands-4, SPC4; *SCSI Enclosure Services-2*; *SES2, Serial Attached SCSI-2, SAS2*

Notes croinfo representation depends on the ability of fmd(1M) to enumerate system topology and accurately represent associated chassis, receptacles, and occupants. These dependencies might extend through fmd(1M) and require that connected hardware, and its associated firmware, comply with specific standards. For disk bays, this requires that storage chassis behave in a T10 standards-compliant (SPC4 and SES2) fashion. Storage chassis that do not respond appropriately might not report chassis, bays, or disk nodes correctly. Specifically, diskinfo requires that chassis support SES diagnostic page 0xa (Additional Element Status) and set the Element Index Present (EIP) bit to 1. Enclosures that do not meet this criterion will not be fully enumerated, and thus will not be properly represented.

Name   cron – clock daemon

Synopsis   `/usr/sbin/cron`

Description   cron starts a process that executes commands at specified dates and times.

You can specify regularly scheduled commands to cron according to instructions found in crontab files in the directory /var/spool/cron/crontabs. Users can submit their own crontab file using the crontab(1) command. Commands which are to be executed only once can be submitted using the at(1) command.

cron only examines crontab or at command files during its own process initialization phase and when the crontab or at command is run. This reduces the overhead of checking for new or changed files at regularly scheduled intervals.

As cron never exits, it should be executed only once. This is done routinely by way of the svc:/system/cron:default service. The file /etc/cron.d/FIFO file is used as a lock file to prevent the execution of more than one instance of cron.

cron captures the output of the job's stdout and stderr streams, and, if it is not empty, mails the output to the user. If the job does not produce output, no mail is sent to the user. An exception is if the job is an at(1) job and the -m option was specified when the job was submitted.

cron and at jobs are not executed if your account is locked. Jobs and processses execute. The shadow(4) file defines which accounts are not locked and will have their jobs and processes executed.

Setting cron Jobs Across Timezones   The timezone of the cron daemon sets the system-wide timezone for cron entries. This, in turn, is by set by default system-wide using /etc/default/init. The timezone for cron entries can be overridden in a user's crontab file; see crontab(1).

If some form of *daylight savings* or *summer/winter time* is in effect, then jobs scheduled during the switchover period could be executed once, twice, or not at all.

Setting cron Defaults   To keep a log of all actions taken by cron, you must specify CRONLOG=YES in the /etc/default/cron file. If you specify CRONLOG=NO, no logging is done. Keeping the log is a user configurable option since cron usually creates huge log files.

You can specify the PATH for user cron jobs by using PATH= in /etc/default/cron. You can set the PATH for root cron jobs using SUPATH= in /etc/default/cron. Carefully consider the security implications of setting PATH and SUPATH.

Example /etc/default/cron file:

```
CRONLOG=YES
PATH=/usr/bin:/usr/ucb:
```

This example enables logging and sets the default PATH used by non-root jobs to /usr/bin:/usr/ucb:. Root jobs continue to use /usr/sbin:/usr/bin.

The cron log file is periodically rotated by logadm(1M).

Files

/etc/cron.d	Main cron directory
/etc/cron.d/FIFO	Lock file
/etc/default/cron	cron default settings file
/var/cron/log	cron history information
/var/spool/cron	Spool area
/etc/cron.d/queuedefs	Queue description file for at, batch, and cron
/etc/logadm.conf	Configuration file for logadm

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also svcs(1), at(1), crontab(1), sh(1), logadm(1M), svcadm(1M), queuedefs(4), shadow(4), attributes(5), rbac(5), smf(5), smf_security(5)

Notes The cron service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/cron:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command. Most administrative actions may be delegated to users with the solaris.smf.manage.cron authorization (see rbac(5) and smf_security(5)).

Diagnostics A history of all actions taken by cron is stored in /var/cron/log and possibly in /var/cron/olog.

Name cryptoadm – cryptographic framework administration

Synopsis cryptoadm list [-mpv] [provider=*provider-name*]
      [mechanism=*mechanism-list*]

cryptoadm disable
    provider=*provider-name* mechanism=*mechanism-list* | random | all

cryptoadm enable
    provider=*provider-name* mechanism=*mechanism-list* | random | all

cryptoadm install provider=*provider-name*

cryptoadm install provider=*provider-name*
    [mechanism=*mechanism-list*]

cryptoadm uninstall provider=*provider-name*

cryptoadm unload provider=*provider-name*

cryptoadm disable fips-140

cryptoadm enable fips-140

cryptoadm list fips-140

cryptoadm refresh

cryptoadm start

cryptoadm stop

cryptoadm --help

Description The cryptoadm utility displays cryptographic provider information for a system, configures the mechanism policy for each provider, and installs or uninstalls a cryptographic provider. The cryptographic framework supports three types of providers: a user-level provider (a PKCS11 shared library), a kernel software provider (a loadable kernel software module), and a kernel hardware provider (a cryptographic hardware device).

For kernel software providers, the cryptoadm utility provides the unload subcommand. This subcommand instructs the kernel to unload a kernel software providers.

For the cryptographic framework's metaslot, the cryptoadm utility provides subcommands to enable and disable the metaslot's features, list metaslot's configuration, specify alternate persistent object storage, and configure the metaslot's mechanism policy.

The cryptoadm utility provides subcommands to enable and disable FIPS-140 mode in the Cryptographic Framework. It also provides a list subcommand to display the current status of FIPS-140 mode.

Administrators will find it useful to use syslog facilities (see syslogd(1M) and logadm(1M)) to maintain the cryptographic subsystem. Logging can be especially useful under the following circumstances:

- If kernel-level daemon is dead, all applications fail. You can learn this from syslog and use svcadm(1M) to restart the svc:/system/cryptosvc service.

- If there are bad providers plugged into the framework, you can learn this from syslog and remove the bad providers from the framework.

With the exception of the subcommands or options listed below, the cryptoadm command needs to be run by a privileged user.

- subcommand list, any options
- subcommand --help

Options   The cryptoadm utility has the various combinations of subcommands and options shown below.

cryptoadm list
   Display the list of installed providers.

cryptoadm list metaslot
   Display the system-wide configuration for metaslot.

cryptoadm list -m [provider=*provider-name* | metaslot]
   Display a list of mechanisms that can be used with the installed providers or metaslot. If a provider is specified, display the name of the specified provider and the mechanism list that can be used with that provider. If the metaslot keyword is specified, display the list of mechanisms that can be used with metaslot.

cryptoadm list -p [provider=*provider-name* | metaslot]
   Display the mechanism policy (that is, which mechanisms are available and which are not) for the installed providers. Also display the provider feature policy or metaslot. If a provider is specified, display the name of the provider with the mechanism policy enforced on it only. If the metaslot keyword is specified, display the mechanism policy enforced on the metaslot.

cryptoadm list -v provider=*provider-name* | metaslot
   Display details about the specified provider if a provider is specified. If the metaslot keyword is specified, display details about the metaslot.

-v
   For the various list subcommands described above (except for list -p), the -v (verbose) option provides details about providers, mechanisms and slots.

cryptoadm disable provider=*provider-name*
[mechanism=*mechanism-list* | *provider-feature* ... | all]
   Disable the mechanisms or provider features specified for the provider. See OPERANDS for a description of *mechanism*, *provider-feature*, and the all keyword.

cryptoadm [mechanism=*mechanism-list*] [auto-key-migrate]
   Disable the metaslot feature in the cryptographic framework or disable some of metaslot's features. If no operand is specified, this command disables the metaslot feature in the

cryptographic framework. If a list of mechanisms is specified, disable mechanisms specified for metaslot. If all mechanisms are disabled for metaslot, the metaslot will be disabled. See OPERANDS for a description of mechanism. If the auto-key-migrate keyword is specified, it disables the migration of sensitive token objects to other slots even if it is necessary for performing crypto operations. See OPERANDS for a description of auto-key-migrate.

cryptoadm enable provider=*provider-name*
[mechanism=*mechanism-list* | *provider-feature* ... | all]

Enable the mechanisms or provider features specified for the provider. See OPERANDS for a description of *mechanism*, *provider-feature*, and the all keyword.

cryptoadm enable metaslot [mechanism=*mechanism-list*] |
[[token=*token-label*] [slot=*slot-description*] |
default-keystore] | [auto-key-migrate]

If no operand is specified, this command enables the metaslot feature in the cryptographic framework. If a list of mechanisms is specified, it enables only the list of specified mechanisms for metaslot. If *token-label* is specified, the specified token will be used as the persistent object store. If the *slot-description* is specified, the specified slot will be used as the persistent object store. If both the *token-label* and the *slot-description* are specified, the provider with the matching token label and slot description is used as the persistent object store. If the default-keystore keyword is specified, metaslot will use the default persistent object store. If the auto-key-migrate keyword is specified, sensitive token objects will automatically migrate to other slots as needed to complete certain crypto operations. See OPERANDS for a description of mechanism, token, slot, default-keystore, and auto-key-migrate.

cryptoadm install provider=*provider-name*

Install a user-level provider into the system. The *provider* operand must be an absolute pathname of the corresponding shared library. If there are both 32–bit and 64–bit versions for a library, this command should be run once only with the path name containing $ISA. Note that $ISA is not a reference to an environment variable. Note also that $ISA must be quoted (with single quotes [for example, '$ISA']) or the $ must be escaped to keep it from being incorrectly expanded by the shell. The user-level framework expands $ISA to an empty string or an architecture-specific directory, for example, sparcv9.

The preferred way of installing a user-level provider is to build a package for the provider. For more information, see the *Solaris Security for Developer's Guide*.

cryptoadm install provider=*provider-name*
mechanism=*mechanism-list*

Install a kernel software provider into the system. The provider should contain the base name only. The *mechanism-list* operand specifies the complete list of mechanisms to be supported by this provider.

The preferred way of installing a kernel software provider is to build a package for providers. For more information, see the *Solaris Security for Developer's Guide*.

cryptoadm uninstall provider=*provider-name*
> Uninstall the specified *provider* and the associated mechanism policy from the system. This subcommand applies only to a user-level provider or a kernel software provider.

cryptoadm unload provider=*provider-name*
> Unload the kernel software module specified by *provider*.

cryptoadm disable fips-140
> Disable FIPS-140 mode in the Cryptographic Framework and for hardware providers.

cryptoadm enable fips-140
> Enable FIPS-140 mode in the Cryptographic Framework and for hardware providers. This subcommand does not disable the non-FIPS approved algorithms from the user-level pkcs11_softtoken library and the kernel software providers. It is the consumers of the framework that are responsible for using only FIPS-approved algorithms.
>
> Upon completion of this subcommand, a message is issued to inform the administrator that any plugins added that are not within the boundary might invalidate FIPS compliance and to check the Security Policies for those plugins.
>
> The system will require a reboot to perform Power-Up Self Tests that include a cryptographic algorithm test and a software integrity test.

cryptoadm list fips-140
> Display the current setting of FIPS-140 mode in the Cryptographic Framework and for hardware providers. The status of FIPS-140 mode is enabled or disabled. The default FIPS-140 mode is disabled.

cryptoadm refresh
cryptoadm start
cryptoadm stop
> Private interfaces for use by smf(5), these must not be used directly.

cryptoadm -help
> Display the command usage.

Operands provider=*provider-name*
> A user-level provider (a PKCS11 shared library), a kernel software provider (a loadable kernel software module), or a kernel hardware provider (a cryptographic hardware device).
>
> A valid value of the *provider* operand is one entry from the output of a command of the form: cryptoadm *list*. A *provider* operand for a user-level provider is an absolute pathname of the corresponding shared library. A *provider* operand for a kernel software provider contains a base name only. A *provider* operand for a kernel hardware provider is in a "*name*/*number*" form.

mechanism=*mechanism-list*

    A comma separated list of one or more PKCS #11 mechanisms. A process for implementing a cryptographic operation as defined in PKCS #11 specification. You can substitute all for *mechanism-list*, to specify all mechanisms on a provider. See the discussion of the all keyword, below.

provider-feature

    A cryptographic framework feature for the given provider. Currently only random is accepted as a feature. For a user-level provider, disabling the random feature makes the PKCS #11 routines C_GenerateRandom and C_SeedRandom unavailable from the provider. For a kernel provider, disabling the random feature prevents /dev/random from gathering random numbers from the provider.

all

    The keyword all can be used with with the disable and enable subcommands to operate on all provider features.

token=*token-label*

    The label of a token in one of the providers in the cryptographic framework.

    A valid value of the token operand is an item displayed under "Token Label" from the output of the command cryptoadm list -v.

slot=*slot-description*

    The description of a slot in one of the providers in the cryptographic framework.

    A valid value of the slot operand is an item displayed under "Description" from the output of the command cryptoadm list -v.

default-keystore

    The keyword default-keystore is valid only for metaslot. Specify this keyword to set the persistent object store for metaslot back to using the default store.

auto-key-migrate

    The keyword auto-key-migrate is valid only for metaslot. Specify this keyword to configure whether metaslot is allowed to move sensitive token objects from the token object slot to other slots for performing cryptographic operations.

The keyword all can be used in two ways with the disable and enable subcommands:

- You can substitute all for mechanism=*mechanism-list* and any other provider-features, as in:

  # **cryptoadm enable provider=dca/0 all**

  This command enables the mechanisms on the provider *and* any other provider-features, such as random.

- You can also use all as an argument to mechanism, as in:

  # **cryptoadm enable provider=des mechanism=all**

...which enables all mechanisms on the provider, but enables no other provider–features, such as random.

Examples **EXAMPLE 1** Display List of Providers Installed in System

The following command displays a list of all installed providers:

```
example% cryptoadm list
user-level providers:
/usr/lib/security/$ISA/pkcs11_kernel.so
/usr/lib/security/$ISA/pkcs11_softtoken.so
/opt/lib/libcryptoki.so.1
/opt/system/core-osonn/lib/$ISA/libpkcs11.so.1

kernel software providers:
    des
    aes
    bfish
    sha1
    md5

kernel hardware providers:
    dca/0
```

EXAMPLE 2 Display Mechanism List for md5 Provider

The following command is a variation of the list subcommand:

```
example% cryptoadm list -m provider=md5
md5: CKM_MD5,CKM_MD5_HMAC,CKM_MD5_HMAC_GENERAL
```

EXAMPLE 3 Disable Specific Mechanisms for Kernel Software Provider

The following command disables mechanisms CKM_DES3_ECB and CKM_DES3_CBC for the kernel software provider des:

```
example# cryptoadm disable provider=des
```

EXAMPLE 4 Display Mechanism Policy for a Provider

The following command displays the mechanism policy for the des provider:

```
example% cryptoadm list -p provider=des
des: All mechanisms are enabled, except CKM_DES3_ECB, CKM_DES3_CBC
```

EXAMPLE 5 Enable Specific Mechanism for a Provider

The following command enables the CKM_DES3_ECB mechanism for the kernel software provider des:

```
example# cryptoadm enable provider=des mechanism=CKM_DES3_ECB
```

EXAMPLE 6 Install User-Level Provider

The following command installs a user-level provider:

```
example# cryptoadm install provider=/opt/lib/libcryptoki.so.1
```

EXAMPLE 7 Install User-Level Provider That Contains 32– and 64–bit Versions

The following command installs a user-level provider that contains both 32–bit and 64–bit versions:

```
example# cryptoadm install \
provider=/opt/system/core-osonn/lib/'$ISA'/libpkcs11.so.1
```

EXAMPLE 8 Uninstall a Provider

The following command uninstalls the md5 provider:

```
example# cryptoadm uninstall provider=md5
```

EXAMPLE 9 Disable metaslot

The following command disables the metaslot feature in the cryptographic framework.

```
example# cryptoadm disable metaslot
```

EXAMPLE 10 Specify metaslot to Use Specified Token as Persistent Object Store

The following command specifies that metaslot use the Venus token as the persistent object store.

```
example# cryptoadm enable metaslot token="SUNW,venus"
```

Exit Status The following exit values are returned:

0
  Successful completion.

>0
  An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

The start, stop, and refresh options are Private interfaces. All other options and the utility name are Committed.

See Also logadm(1M), svcadm(1M), syslogd(1M), libpkcs11(3LIB), exec_attr(4), prof_attr(4), attributes(5), smf(5), random(7D)

Oracle Solaris Administration: Security Services

Solaris Security for Developer's Guide

Notes If a hardware provider's policy was made explicitly (that is, some of its mechanisms were disabled) and the hardware provider has been detached, the policy of this hardware provider is still listed.

cryptoadm assumes that, minimally, a 32–bit shared object is delivered for each user-level provider. If both a 32–bit and 64–bit shared object are delivered, the two versions must provide the same functionality. The same mechanism policy applies to both.

Name cvcd – virtual console daemon

Synopsis /platform/*platform_name*/cvcd [-a *auth*] [-e *encr*]
         [-u *esp_auth*]

Description The virtual console daemon, cvcd, is a server process that supports the network console provided on some platforms. The cvcd daemon accepts network console connections from a remote host (only one host at any given time). Console input is read from this connection and forwarded to cvc(7D) by way of cvcredir(7D).

Similarly, console output is read from cvcredir(7D) and forwarded across the network console connection. If cvcd dies, console traffic is automatically rerouted through an internal hardware interface.

The cvcd daemon normally starts at system boot time. Each domain supports only one cvcd process at a time.

Caution – On Sun Enterprise 10000 domains, cvcd uses a configuration file (/etc/ssphostname) to determine the name of the host from which network console connections are allowed. If the remote console host is renamed, you must edit the configuration file to reflect that change.

The cvcd daemon supports per-socket IP Security Architecture (IPsec) through the options described below. See ipsec(7P).

Options The cvcd daemon supports the options listed below.

-a *auth*   Controls the IPsec Authentication Header (AH) algorithm. *auth* can be one of none, md5, or sha1.

-e *encr*   Controls the IPsec Encapsulating Security Payload (ESP) encryption algorithm. *encr* can be one of none, des, or 3des.

-u *esp_auth*   Controls the IPsec Encapsulating Security Payload (ESP) authentication algorithm. *esp_auth* can be one of none, md5, or sha1.

Operands The following operands are supported:

platform_name   The official Sun platform name used in packaging and code. For example, for Sun Fire 15K servers, the *platform_name* would be SUNW,Sun-Fire-15000.

Examples EXAMPLE 1 Setting an IPSec Option

The command below sets the value of the IPsec Authentication Header algorithm to md5. As a result of this command, cvcd will use the HMAC-MD5 authentication algorithm.

```
# svccfg -s svc:/system/cvc setprop cvc/ah_auth = "md5"
# svccfg -s svc:/system/cvc setprop cvc/esp_encr = "none"
# svccfg -s svc:/system/cvc setprop cvc/esp_auth = "none"
```

EXAMPLE 1 Setting an IPSec Option *(Continued)*

```
# svcadm refresh svc:/system/cvc
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	Sun Enterprise 10000 servers, Sun Fire High-End Systems
Availability	system/network-console

See Also svcs(1), svcadm(1M), svccfg(1M), services(4), attributes(5), smf(5), cvc(7D), cvcredir(7D), ipsec(7P)

Sun Enterprise 10000 SSP Reference Manual

System Management Services (SMS) Reference Manual

Notes The cvcd service is managed by the service management facility, smf(5), under the fault management resource identifier (FMRI):

```
svc:/system/cvc
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M) or svccfg(1M). The service's status can be queried using the svcs(1) command.

Name datadm – maintain DAT static registry file

Synopsis /usr/bin/datadm [-v] [-u] [-a service_provider.conf]
       [-r service_provider.conf]

Description The datadm utility maintains the DAT static registry file, dat.conf(4).

This administrative configuration program allows uDAPL service providers to add and remove themselves to the dat.conf file.

You can add or remove interface adapters that a service provider supports from a system after its installation. You can use datadm to update the dat.conf file to reflect the current state of the system. A new set of interface adapters for all the service providers currently installed is regenerated.

Options The following options are supported:

-a service_provider.conf

    Enumerate each device entry in the service_provider.conf(4) file into a list of interface adapters, that is, interfaces to external network that are available to uDAPL consumers.

-r service_provider.conf

    Remove the list of interface adapters that corresponds to the device entry in the service_provider.conf(4) file.

-u

    Update the dat.conf to reflect the current state of the system with an up to date set of interface adapters for the service providers that are currently listed in the DAT static registry.

-v

    Display the DAT static registry file, dat.conf.

Examples **EXAMPLE 1** Enumerating a Device Entry

The following example enumerates a device entry in the service_provider.conf(4) file into interface adapters in the dat.conf(4) file.

Assume that SUNW has a service provider library that supports the device tavor. It has a service_provider.conf(4) file installed in the directory /usr/share/dat/SUNWudaplt.conf with a single entry as follows:

```
driver_name=tavor u1.2 nonthreadsafe default\
    udapl_tavor.so.1 SUNW.1.0 ""
```

tavor is an Infiniband Host Channel Adapter with two ports. Both IB ports exist in a single IB partition, 0x8001. If an IB partition is created and plumbed to each port (with the names p8001.ibd0 and p8001.ibd1), there will be two IB partition instances. See dladm(1M) for more information on creating IB partition data links.

EXAMPLE 1 Enumerating a Device Entry   *(Continued)*

```
# dladm show-part
```

```
LINK          PKEY    OVER      STATE      FLAGS
p8001.ibd0    8001    ibd0      unknown    ----
p8001.ibd1    8001    ibd1      unknown    ----
```

Running the command:

```
# datadm -a /usr/share/dat/SUNWudaplt.conf
```

...appends two new entries (if they do not already exist) in the /etc/dat/dat.conf file:

```
p8001.ibd0 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 ""
"driver_name=tavor"
p8001.ibd1 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 ""
"driver_name=tavor"
```

EXAMPLE 2 Updating the dat.conf to Reflect the Current State of the System

A new IB partition, 0x8002, is added to the above example covering port 1 of the Host Channel Adapter. If a new IB partition is created on the port 1/partition 0x8002 with the partition link name specified as p8002.ibd0, there will be a third IB partition instance: p8002.ibd0.

```
# dladm show-part
LINK          PKEY    OVER      STATE      FLAGS
p8001.ibd0    8001    ibd0      unknown    ----
p8001.ibd1    8001    ibd1      unknown    ----
p8002.ibd0    8000    ibd0      unknown    ----
```

Running datadm -u command, updates the /etc/dat/dat.conf file with a new entry added reflecting the current state of the system.

datadm -v shows that there are now three entries in the /etc/dat/dat.conf file:

```
p8001.ibd0 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 ""
"driver_name=tavor"
p8001.ibd1 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 ""
"driver_name=tavor"
p8002.ibd0 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 ""
"driver_name=tavor"
```

Name dcs – domain configuration server

Synopsis /usr/lib/dcs [-s *sessions*]
        [[-a *auth*] [-e *encr*] [-u *esp_auth*]] [-l]

Description The Domain Configuration Server (DCS) is a daemon process that runs on Sun servers that support remote Dynamic Reconfiguration (DR) clients. It is started by the Service Management Facility (see smf(5)) when the first DR request is received from a client connecting to the network service sun-dr. After the DCS accepts a DR request, it uses the libcfgadm(3LIB) interface to execute the DR operation. After the operation is performed, the results are returned to the client.

The DCS listens on the network service labeled sun-dr. Its underlying protocol is TCP. It is invoked as a server program by the SMF using the TCP transport. The fault management resource identifier (FMRI) for DCS is:

svc:/platform/sun4u/dcs:default

If you disable this service, DR operations initiated from a remote host fail. There is no negative impact on the server.

Security for the DCS connection is provided differently based upon the architecture of the system. The SMF specifies the correct options when invoking the DCS daemon, based upon the current architecture. For all architectures, security is provided on a per-connection basis.

The DCS daemon has no security options that are applicable when used on a Sun Enterprise 10000 system. So there are no options applicable to that architecture.

The security options for Sun Fire high-end systems are based on IPsec options defined as SMF properties. These options include the -a *auth*, -e *encr*, and -u *esp_auth* options, and can be set using the svccfg(1M) command. These options must match the IPsec policies defined for DCS on the system controller. Refer to the kmd(1M) man page in the *System Management Services (SMS) Reference Manual*. The kmd(1M) man page is not part of the SunOS man page collection.

Security on SPARC Enterprise Servers is not configurable. The DCS daemon uses a platform-specific library to configure its security options when running on such systems. The -l option is provided by the SMF when invoking the DCS daemon on SPARC Enterprise Servers. No other security options to the DCS daemon should be used on SPARC Enterprise Servers.

Options The following options are supported:

    -a *auth*   Controls the IPsec Authentication Header (AH) algorithm. *auth* can be one of none, md5, or sha1.

    -e *encr*   Controls the IPsec Encapsulating Security Payload (ESP) encryption algorithm. *encr* can be one of none, des, or 3des.

-l   Enables the use of platform-specific security options on SPARC Enterprise Servers.

-s *sessions*   Sets the number of active sessions that the DCS allows at any one time. When the limit is reached, the DCS stops accepting connections until active sessions complete the execution of their DR operation. If this option is not specified, a default value of 128 is used.

-u *esp_auth*   Controls the IPsec Encapsulating Security Payload (ESP) authentication algorithm. *esp_auth* can be one of none, md5, or sha1.

Examples   EXAMPLE 1   Setting an IPSec Option

The following command sets the Authentication Header algorithm for the DCS daemon to use the HMAC-MD5 authentication algorithm. These settings are only applicable for using the DCS daemon on a Sun Fire high-end system.

```
# svccfg -s svc:/platform/sun4u/dcs setprop dcs/ah_auth = "md5"
# svccfg -s svc:/platform/sun4u/dcs setprop dcs/esp_encr = "none"
# svccfg -s svc:/platform/sun4u/dcs setprop dcs/esp_auth = "none"
# svcadm refresh svc:/platform/sun4u/dcs
```

Errors   The DCS uses syslog(3C) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_INFO priority. The default entries in the /etc/syslog.conf file log all of the DCS error messages to the /var/adm/messages log.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/domain-configuration/sparc-enterprise, SUNWdcsr
Interface Stability	Committed

See Also   svcs(1), cfgadm_sbd(1M), svcadm(1M), svccfg(1M), syslog(3C), config_admin(3CFGADM), libcfgadm(3LIB), syslog.conf(4), attributes(5), smf(5), dr(7d)

Notes   The dcs service is managed by the service management facility, smf(5), under the fault management resource identifier (FMRI):

svc:/platform/sun4u/dcs:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name dd – convert and copy a file

Synopsis /usr/bin/dd [*operand=value*]...

Description The dd utility copies the specified input file to the specified output with possible conversions. The standard input and output are used by default. The input and output block sizes may be specified to take advantage of raw physical I/O. Sizes are specified in bytes; a number may end with k, b, or w to specify multiplication by 1024, 512, or 2, respectively. Numbers may also be separated by x to indicate multiplication.

The dd utility reads the input one block at a time, using the specified input block size. dd then processes the block of data actually returned, which could be smaller than the requested block size. dd applies any conversions that have been specified and writes the resulting data to the output in blocks of the specified output block size.

cbs is used only if ascii, asciib, unblock, ebcdic, ebcdicb, ibm, ibmb, or block conversion is specified. In the first two cases, cbs characters are copied into the conversion buffer, any specified character mapping is done, trailing blanks are trimmed, and a NEWLINE is added before sending the line to output. In the last three cases, characters up to NEWLINE are read into the conversion buffer and blanks are added to make up an output record of size cbs. ASCII files are presumed to contain NEWLINE characters. If cbs is unspecified or 0, the ascii, asciib, ebcdic, ebcdicb, ibm, and ibmb options convert the character set without changing the input file's block structure. The unblock and block options become a simple file copy.

After completion, dd reports the number of whole and partial input and output blocks.

Operands The following operands are supported:

if=*file*	Specifies the input path. Standard input is the default.
of=*file*	Specifies the output path. Standard output is the default. If the seek=expr conversion is not also specified, the output file will be truncated before the copy begins, unless conv=notrunc is specified. If seek=expr is specified, but conv=notrunc is not, the effect of the copy will be to preserve the blocks in the output file over which dd seeks, but no other portion of the output file will be preserved. (If the size of the seek plus the size of the input file is less than the previous size of the output file, the output file is shortened by the copy.)
ibs=*n*	Specifies the input block size in *n* bytes (default is 512).
obs=*n*	Specifies the output block size in *n* bytes (default is 512).
bs=*n*	Sets both input and output block sizes to *n* bytes, superseding ibs= and obs=. If no conversion other than sync, noerror, and notrunc is specified, each input block is copied to the output as a single block without aggregating short blocks.

cbs=*n*	Specifies the conversion block size for block and unblock in bytes by *n* (default is 0). If cbs= is omitted or given a value of 0, using block or unblock produces unspecified results.
	This option is used only if ASCII or EBCDIC conversion is specified. For the ascii and asciib operands, the input is handled as described for the unblock operand except that characters are converted to ASCII before the trailing SPACE characters are deleted. For the ebcdic, ebcdicb, ibm, and ibmb operands, the input is handled as described for the block operand except that the characters are converted to EBCDIC or IBM EBCDIC after the trailing SPACE characters are added.
files=*n*	Copies and concatenates *n* input files before terminating (makes sense only where input is a magnetic tape or similar device).
skip=*n*	Skips *n* input blocks (using the specified input block size) before starting to copy. On seekable files, the implementation reads the blocks or seeks past them. On non-seekable files, the blocks are read and the data is discarded.
iseek=*n*	Seeks *n* blocks from beginning of input file before copying (appropriate for disk files, where skip can be incredibly slow).
oseek=*n*	Seeks *n* blocks from beginning of output file before copying.
seek=*n*	Skips *n* blocks (using the specified output block size) from beginning of output file before copying. On non-seekable files, existing blocks are read and space from the current end-of-file to the specified offset, if any, is filled with null bytes. On seekable files, the implementation seeks to the specified offset or reads the blocks as described for non-seekable files.
count=*n*	Copies only *n* input blocks.
conv=*value*[, *value*. . .]	Where *value*s are comma-separated symbols from the following list:

	ascii	Converts EBCDIC to ASCII.
	asciib	Converts EBCDIC to ASCII using BSD-compatible character translations.
	ebcdic	Converts ASCII to EBCDIC. If converting fixed-length ASCII records without NEWLINEs, sets up a pipeline with dd conv=unblock beforehand.
	ebcdicb	Converts ASCII to EBCDIC using BSD-compatible character translations. If converting fixed-length

ASCII records without NEWLINEs, sets up a pipeline
with dd conv=unblock beforehand.

ibm   Slightly different map of ASCII to EBCDIC. If
               converting fixed-length ASCII records without
               NEWLINEs, sets up a pipeline with dd conv=unblock
               beforehand.

ibmb   Slightly different map of ASCII to EBCDIC using
               BSD-compatible character translations. If converting
               fixed-length ASCII records without NEWLINEs, sets up
               a pipeline with dd conv=unblock beforehand.

The ascii (or asciib), ebcdic (or ebcdicb), and ibm (or ibmb)
values are mutually exclusive.

block   Treats the input as a sequence of
               NEWLINE-terminated or EOF-terminated
               variable-length records independent of the input
               block boundaries. Each record is converted to a
               record with a fixed length specified by the conversion
               block size. Any NEWLINE character is removed from
               the input line. SPACE characters are appended to lines
               that are shorter than their conversion block size to fill
               the block. Lines that are longer than the conversion
               block size are truncated to the largest number of
               characters that will fit into that size. The number of
               truncated lines is reported.

unblock   Converts fixed-length records to variable length.
               Reads a number of bytes equal to the conversion
               block size (or the number of bytes remaining in the
               input, if less than the conversion block size), delete
               all trailing SPACE characters, and append a NEWLINE
               character.

The block and unblock values are mutually exclusive.

lcase   Maps upper-case characters specified by the LC_CTYPE
               keyword tolower to the corresponding lower-case
               character. Characters for which no mapping is specified
               are not modified by this conversion.

ucase   Maps lower-case characters specified by the LC_CTYPE
               keyword toupper to the corresponding upper-case
               character. Characters for which no mapping is specified
               are not modified by this conversion.

The lcase and ucase symbols are mutually exclusive.

swab   Swaps every pair of input bytes. If the current input record is an odd number of bytes, the last byte in the input record is ignored.

noerror   Does not stop processing on an input error. When an input error occurs, a diagnostic message is written on standard error, followed by the current input and output block counts in the same format as used at completion. If the sync conversion is specified, the missing input is replaced with null bytes and processed normally. Otherwise, the input block will be omitted from the output.

notrunc   Does not truncate the output file. Preserves blocks in the output file not explicitly written by this invocation of dd. (See also the preceding of=*file* operand.)

sync   Pads every input block to the size of the ibs= buffer, appending null bytes. (If either block or unblock is also specified, appends SPACE characters, rather than null bytes.)

If operands other than conv= are specified more than once, the last specified operand=*value* is used.

For the bs=, cbs=, ibs=, and obs= operands, the application must supply an expression specifying a size in bytes. The expression, expr, can be:

1. a positive decimal number
2. a positive decimal number followed by k, specifying multiplication by 1024
3. a positive decimal number followed by b, specifying multiplication by 512
4. two or more positive decimal numbers (with or without k or b) separated by x, specifying the product of the indicated values.

All of the operands will be processed before any input is read.

Usage   See largefile(5) for the description of the behavior of dd when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples   EXAMPLE 1   Copying from one tape drive to another

The following example copies from tape drive 0 to tape drive 1, using a common historical device naming convention.

EXAMPLE 1 Copying from one tape drive to another   *(Continued)*

```
example% dd if=/dev/rmt/0h  of=/dev/rmt/1h
```

EXAMPLE 2 Stripping the first 10 bytes from standard input

The following example strips the first 10 bytes from standard input:

```
example% dd ibs=10  skip=1
```

EXAMPLE 3 Reading a tape into an ASCII file

This example reads an EBCDIC tape blocked ten 80-byte EBCDIC card images per block into the ASCII file x:

```
example% dd if=/dev/tape of=x ibs=800 cbs=80 conv=ascii,lcase
```

EXAMPLE 4 Using conv=sync to write to tape

The following example uses conv=sync when writing to a tape:

```
example% tar cvf - . | compress | dd obs=1024k of=/dev/rmt/0 conv=sync
```

Environment Variables See environ(5) for descriptions of the following environment variables that affect the execution of dd: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

0   The input file was copied successfully.

>0   An error occurred.

If an input error is detected and the noerror conversion has not been specified, any partial output block will be written to the output file, a diagnostic message will be written, and the copy operation will be discontinued. If some other error is detected, a diagnostic message will be written and the copy operation will be discontinued.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed
Standard	See standards(5).

See Also cp(1), sed(1), tr(1), attributes(5), environ(5), largefile(5), standards(5)

Diagnostics   `f+p records in(out)`   numbers of full and partial blocks read(written)

Notes   Do not use dd to copy files between file systems having different block sizes.

Using a blocked device to copy a file will result in extra nulls being added to the file to pad the final block to the block boundary.

When dd reads from a pipe, using the ibs=X and obs=Y operands, the output will always be blocked in chunks of size Y. When bs=Z is used, the output blocks will be whatever was available to be read from the pipe at the time.

When using dd to copy files to a tape device, the file size must be a multiple of the device sector size (for example, 512 Kbyte). To copy files of arbitrary size to a tape device, use tar(1) or cpio(1).

For SIGINT, dd writes status information to standard error before exiting. It takes the standard action for all other signals.

Name ddu – GUI-based device driver utility

Synopsis /usr/bin/ddu [--silent]

Description The GUI-based device driver utility, ddu, provides information about devices on a system running the Oracle Solaris operating system. ddu enables a user to connect to the Image Packaging System (IPS) and search device drivers for the devices that do not have drivers attached to them. By doing this, ddu gives the user an opportunity to install missing drivers.

ddu is a GUI, with an easy-to-use interface. It has a text-based counterpart, ddu-text(1M), which is described in its own man page.

Options The following options is supported:

--silent
ddu runs silently. If it finds devices that are missing drivers a notification is posted. Clicking on the notification displays the DDU GUI.

Examples EXAMPLE 1 Launching the ddu GUI

The following command launches the ddu GUI.

% **ddu**

EXAMPLE 2 Launching ddu in Silent Mode

The following command launches ddu in silent mode.

% **ddu --silent**

Exit Status 0
Application exited successfully.

>0
Application exited with a failure.

Files /usr/bin/ddu
Executable for ddu.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	diagnostic/ddu
Interface Stability	External

Additional availability attribute values are: diagnostic/ddu/data, diagnostic/ddu/library, and diagnostic/ddu/locale.

See Also ddu-text(1M), attributes(5)

Name   ddu-text – text-based device driver utility

Synopsis   ddu-text

Description   The text-based device driver utility, ddu-text, provides information about devices on a system running the Oracle Solaris operating system. ddu-text enables a user to connect to the Image Packaging System (IPS) and search device drivers for the devices that do not have drivers attached to them. By doing this, ddu-text gives the user an opportunity to install missing drivers.

ddu-text is text-based. It has a GUI counterpart, ddu(1M), which is described in its own man page.

ddu-text has no command-line options.

Examples   EXAMPLE 1   Invoking the ddu-text

The following command invokes ddu-text.

    % **ddu-text**

Exit Status   0
    Application exited successfully.

>0
    Application exited with a failure.

Files   /usr/bin/ddu-text
    Executable for ddu-text.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	diagnostic/ddu
Interface Stability	External

Additional availability attribute values are: diagnostic/ddu/data, diagnostic/ddu/library, and diagnostic/ddu/locale.

See Also   ddu(1M), attributes(5)

Name devchassisd – devchassis daemon

Synopsis `/usr/lib/devchassis/devchassisd [-d]`

Description The devchassis daemon, devchassisd, provides user-level services for the management of the /dev/chassis name space. It is a system daemon started by the Service Management Facility (see smf(5)). Its fault management resource identifier (FMRI) is:

`svc:/system/devchassis:daemon`

Note that devchassisd is a Consolidation Private interface. See attributes(5).

Options The following option is supported:

-d, --debug
Run the daemon in standalone debug mode. Messages will be displayed on the controlling terminal instead of to syslog. And increased verbosity will be enabled to display more details about the internal operations of the daemon.

Examples EXAMPLE 1 Enabling the devchassis Service

The following command enables the devchassis service:

`# svcadm enable svc:/system/devchassis`

EXAMPLE 2 Disabling the devchassis Service

The following command disables the devchassis service:

`# svcadm disable svc:/system/devchassis`

Errors The devchassisd daemon uses syslog(3C) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_INFO priority. The default entries in the /etc/syslog.conf file log all of the devchassisd daemon error messages to the /var/adm/messages log.

Files /usr/lib/devchassis/devchassisd
devchassisd daemon binary.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Consolidation Private

See Also svcs(1), svcadm(1M), syslog(3C), syslog.conf(4), attributes(5), smf(5), devchassis(7FS)

Notes The devchassis service is managed by the service management facility, smf(5), under the fault management resource identifier (FMRI):

svc:/system/devchassis

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

The devchassis service is enabled by default.

Name devfsadm, devfsadmd – administration command for /dev

Synopsis /usr/sbin/devfsadm [-C] [-c *device_class*] [-i *driver_name*]
        [-n] [-r *root_dir*] [-s] [-t *table_file*] [-u] [-v]

/usr/lib/devfsadm/devfsadmd

Description devfsadm maintains the /dev namespace. It replaces the previous suite of devfs
administration tools including drvconfig(1M), disks(1M), tapes(1M), ports(1M),
audlinks(1M), and devlinks(1M).

The default operation is to attempt to load every driver in the system and attach to all possible
device instances. Next, devfsadm creates logical links to device nodes in /dev and /devices
and loads the device policy.

devfsadmd(1M) is the daemon version of devfsadm(1M). The daemon is started during
system startup and is responsible for handling both reconfiguration boot processing and
updating /dev and /devices in response to dynamic reconfiguration event notifications from
the kernel.

For compatibility purposes, drvconfig(1M), disks(1M), tapes(1M), ports(1M),
audlinks(1M), and devlinks(1M) are implemented as links to devfsadm.

In addition to managing /dev, devfsadm also maintains the path_to_inst(4) database.

Options The following options are supported:

-C

  Cleanup mode. Prompt devfsadm to cleanup dangling /dev links that are not normally
  removed. If the -c option is also used, devfsadm only cleans up for the listed devices'
  classes.

-c *device_class*

  Restrict operations to devices of class *device_class*. Solaris defines the following values for
  device_class: disk, tape, port, audio, and pseudo. This option might be specified more
  than once to specify multiple device classes.

-i *driver_name*

  Configure only the devices for the named driver, *driver_name*.

-n

  Do not attempt to load drivers or add new nodes to the kernel device tree.

-s

  Suppress any changes to /dev. This is useful with the -v option for debugging.

-t *table_file*

  Read an alternate devlink.tab file. devfsadm normally reads /etc/devlink.tab.

-u

    Activate and attach devices for drivers added with add_drv(1M) -u. Cannot be used together with -n or -r.

-r *root_dir*

    Presume that the /dev directory trees are found under *root_dir*, not directly under root (/). No other use or assumptions are made about *root_dir*.

-v

    Print changes to /dev in verbose mode.

Exit Status The following exit values are returned:

0

    Successful completion.

1

    An error occurred.

Files /devices

    device nodes directory

/dev

    logical symbolic links to /devices

/usr/lib/devfsadm/devfsadmd

    devfsadm daemon

/dev/.devfsadm_dev.lock

    update lock file

/dev/.devfsadm_daemon.lock

    daemon lock file

/etc/security/device_policy

    device policy file

/etc/security/extra_privs

    additional device privileges

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also svcs(1), add_drv(1M), modinfo(1M), modload(1M), modunload(1M), rem_drv(1M), svcadm(1M), tapes(1M), path_to_inst(4), attributes(5), privileges(5), smf(5), devfs(7FS)

Notes This document does not constitute an API. The /devices directory might not exist or might have different contents or interpretations in a future release. The existence of this notice does not imply that any other documentation that lacks this notice constitutes an API.

devfsadm no longer manages the /devices name space. See devfs(7FS).

As a daemon to support hot-plug and synchronous device naming, devfsadm is managed by the service management facility, smf(5), under the service identifier:

svc:/system/devfsadm:default

The status of the service can be queried using the svcs(1) command.

Name device_allocate – enable and disable device allocation

Synopsis svc:/system/device/allocate:default

Description The device_allocate service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/device/allocate:default

An administrator with the Devices Security Rights Profile can enable or disable this service to provide for or remove the device allocation functionality as described in allocate(1).

Examples EXAMPLE 1 Enabling Device Allocation

The following command enables device allocation.

svcadm enable svc:/system/device/allocate:default

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Volatile

See Also allocate(1), deallocate(1), list_devices(1), devfsadm(1M), svcadm(1M), attributes(5), smf(5)

Name device_remap – administer the Solaris I/O remapping feature

Synopsis /usr/platform/sun4v/sbin/device_remap [-v | -R *dir*]

Description Certain multi-node sun4v platforms, such as T5440 and T5240 servers, have an integrated PCI topology that cause the I/O device paths to change in a CPU node failover condition. The device remapping script, device_remap, remaps the device paths in /etc/path_to_inst file and the symlinks under /dev to match the hardware.

Options The following options are supported:

-v

   Displays the /etc/path_to_inst and /dev symlink changes.

-R *dir*

   Perform remapping on the /etc/path_to_inst and /etc/path_to_inst files in the root image at *dir*.

Usage The primary function of device_remap is to remap the device paths in the /etc/path_to_inst file and the symlinks under /dev in a CPU node failover condition to match the hardware.

After adding CPU node(s) or removing CPU node(s), boot the system to the OBP prompt and use the following procedure:

1. Boot either the failsafe miniroot using: boot -F failsafe, or an install miniroot using boot net -s or similar command.

2. Mount the root disk as /mnt.

3. Change directory to the mounted root disk:

   # **cd /mnt**

4. Run device_remap script:

   # **/mnt/usr/platform/sun4v/sbin/device_remap**

5. Boot the system from disk.

All the error messages are self-explanatory, except for the error message "missing ioaliases node" which means the firmware on the system does not support device remapping.

Examples EXAMPLE 1 Displaying Changes Following Failover

The following command displays the path_to_inst and /dev changes following a CPU node failover.

   # **device_remap -v**

EXAMPLE 2 Changing Directory Prior to Any Changes

The following command changes the directory on which the boot image is mounted prior to making any changes.

```
# device_remap -R /newroot
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library/platform
Interface Stability	Uncommitted

See Also boot(1M), attributes(5)

Name   devinfo – print device specific information

Synopsis /usr/sbin/devinfo -i *device*

/usr/sbin/devinfo -p *device*

Description The devinfo command is used to print device specific information about disk devices on standard out. The command can only be used by the superuser.

Options -i   Prints the following device information:

- Device name
- Software version (not supported and prints as 0)
- Drive id number (not supported and prints as 0)
- Device blocks per cylinder
- Device bytes per block
- Number of device partitions with a block size greater than zero

-p   Prints the following device partition information:

- Device name
- Device major and minor numbers (in hexadecimal)
- Partition start block
- Number of blocks allocated to the partition
- Partition flag
- Partition tag

This command is used by various other commands to obtain device specific information for the making of file systems and determining partition information. If the device cannot be opened, an error message is reported.

Operands *device*   Device name.

Exit Status 0   Successful operation.

2   Operation failed.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also prtvtoc(1M), attributes(5)

Name devlinks – adds /dev entries for miscellaneous devices and pseudo-devices

Synopsis /usr/sbin/devlinks [-d] [-r *rootdir*] [-t *table-file*]

Description devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of devlinks.

devlinks creates symbolic links from the /dev directory tree to the actual block- and character-special device nodes under the /devices directory tree. The links are created according to specifications found in the *table-file* (by default /etc/devlink.tab).

devlinks is called each time the system is reconfiguration-booted, and can only be run after drvconfig(1M) is run.

The *table-file* (normally /etc/devlink.tab) is an ASCII file, with one line per record. Comment lines, which must contain a hash character ('#') as their first character, are allowed. Each entry must contain at least two fields, but may contain three fields. Fields are separated by single TAB characters.

The fields are:

devfs-spec   Specification of devinfo nodes that will have links created for them. This specification consists of one or more keyword-value pairs, where the keyword is separated from the value by an equal-sign ('='), and keyword-value pairs are separated from one another by semicolons.

The possible keywords are:

type   The devinfo device type. Possible values are specified in ddi_create_minor_node(9F)

name   The name of the node. This is the portion of the /devices tree entry name that occurs before the first '@' or ':' character.

addr[*n*]   The address portion of a node name. This is the portion of a node name that occurs between the '@' and the ':' characters. It is possible that a node may have a name without an address part, which is the case for many of the pseudo-device nodes. If a number is given after the *addr* it specifies a match of a particular comma-separated subfield of the address field: *addr1* matches the first subfield, *addr2* matches the second, and so on. *addr0* is the same as *addr* and matches the whole field.

minor[*n*]   The minor portion of a node name – the portion of the name after the ':'. As with *addr* above, a number after the *minor* keyword specifies a subfield to match.

Of these four specifications, only the *type* specification must always be present.

name   Specification of the /dev links that correspond to the devinfo nodes. This field allows devlinks to determine matching /dev names for the /devices nodes it has found. The specification of this field uses escape-sequences to allow portions of the /devices name to be included in the /dev name, *or* to allow a counter to be used in creating node names. If a counter is used to create a name, the portion of the name before the counter must be specified absolutely, and all names in the /dev/-subdirectory that match (up to and including the counter) are considered to be subdevices of the same device. This means that they should all point to the same directory, name and address under the /devices/-tree

The possible escape-sequences are:

\D   Substitute the device-name (name) portion of the corresponding devinfo node-name.

\A*n*   Substitute the *n*th component of the address component of the corresponding devinfo node name. Sub-components are separated by commas, and sub-component 0 is the whole address component.

\M*n*   Substitute the *n*th sub-component of the minor component of the corresponding devinfo node name. Sub-components are separated by commas, and sub-component 0 is the whole minor component.

\N*n*   Substitute the value of a 'counter' starting at *n*. There can be only one counter for each dev-spec, and counter-values will be selected so they are as low as possible while not colliding with already-existing link names.

In a dev-spec the counter sequence should not be followed by a digit, either explicitly or as a result of another escape-sequence expansion. If this occurs, it would not be possible to correctly match already-existing links to their counter entries, since it would not be possible to unambiguously parse the already-existing /dev-name.

extra-dev-link   Optional specification of an extra /dev link that points to the initial /dev link (specified in field 2). This field may contain a counter escape-sequence (as described for the *dev-spec* field) but may not contain any of the other escape-sequences. It provides a way to specify an alias of a particular /dev name.

Options   The following options are supported:

-d   Debugging mode – print out all devinfo nodes found, and indicate what links
             would be created, but do not do anything.

-r *rootdir*   Use *rootdir* as the root of the /dev and /devices directories under which the
             device nodes and links are created. Changing the root directory does not
             change the location of the /etc/devlink.tab default table, nor is the root
             directory applied to the filename supplied to the -t option.

-t *table-file*   Set the table file used by devlinks to specify the links that must be created. If
             this option is not given, /etc/devlink.tab is used. This option gives a way to
             instruct devlinks just to perform a particular piece of work, since just the
             links-types that devlinks is supposed to create can be specified in a
             command-file and fed to devlinks.

Errors   If devlinks finds an error in a line of the *table-file* it prints a warning message on its standard
output and goes on to the next line in the *table-file* without performing any of the actions
specified by the erroneous rule.

If it cannot create a link for some filesystem-related reason it prints an error-message and
continues with the current rule.

If it cannot read necessary data it prints an error message and continues with the next *table-file*
line.

Examples   **EXAMPLE 1**   Using the /etc/devlink.tab Fields

The following are examples of the /etc/devlink.tab fields:

```
type=pseudo;name=win    win\M0
type=ddi_display    framebuffer/\M0    fb\N0
```

The first example states that all devices of type pseudo with a name component of win will be
linked to /dev/win*x,* where *x* is the minor-component of the *devinfo-name* (this is always a
single-digit number for the win driver).

The second example states that all devinfo nodes of type ddi_display will be linked to entries
under the /dev/framebuffer directory, with names identical to the entire minor component
of the /devices name. In addition an extra link will be created pointing from /dev/fb*n* to the
entry under /dev/framebuffer. This entry will use a counter to end the name.

Files   /dev   entries for the miscellaneous devices for general use

/devices   device nodes

/etc/devlink.tab   the default rule-file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also devfsadm(1M), attributes(5), devfs(7FS), ddi_create_minor_node(9F)

Bugs It is very easy to construct mutually-contradictory link specifications, or specifications that can never be matched. The program does not check for these conditions.

Name devnm – device name

Synopsis /usr/sbin/devnm *name* [*name*]...

Description The devnm command identifies the special file associated with the mounted file system where the argument *name* resides. One or more *name* can be specified.

Examples EXAMPLE 1 Using the devnm Command

Assuming that /usr is mounted on /dev/dsk/c0t3d0s6, the following command :

/usr/sbin/devnm /usr

produces:

/dev/dsk/c0t3d0s6 /usr

Files /dev/dsk/*

/etc/mnttab

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also mnttab(4), attributes(5)

Name devprop – display device properties

Synopsis /usr/sbin/devprop [-n *device-path*] [-vq] [-{b|i|l|s}] [*property*[...]]

Description The devprop command displays named device properties from the device tree.

If a device path is specified on the command line, devprop displays device properties for that device node.

The output formats, while Volatile, are patterned after those of prtconf(1M).

Options The following options are supported:

-b
> The properties to be output are sequences of bytes (DI_PROP_TYPE_BYTES). -b, -i, -l, and -s are mutually exclusive of one another.

-i
> The properties to be output are integers (DI_PROP_TYPE_INT).

-l
> The properties to be output are 64–bit integers (DI_PROP_TYPE_INT64).

-s
> The properties to be output are strings (DI_PROP_TYPE_STRING) (the default).

-n *device-path*
> The path to a target device node for which properties are displayed. The default path is that of the root node (equivalent to specifying -n /).

-q
> Specifies quoted output mode, in which string properties are output surrounded by double quotation marks (").

-v
> Specifies verbose mode, in which the name of the property is output before its value.

Operands The following operand is supported:

property...
> Name of the property to be displayed.

Exit Status 0
> No error occurred.

non-zero
> An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

The command invocation and output are both Volatile. The location of the utility is Committed.

See Also prtconf(1M), libdevinfo(3LIB), attributes(5)

Name df – displays number of free disk blocks and free files

Synopsis df [-F *FSType*] [-abeghklntPVvZ]
        [-o *FSType-specific_options*]
        [*block_device* | *directory* | *file* | *resource* ...]

Description The df utility displays the amount of disk space occupied by mounted or unmounted file systems, the amount of used and available space, and how much of the file system's total capacity has been used. The file system is specified by device, or by referring to a file or directory on the specified file system.

Used without operands or options, df reports on all mounted file systems.

df may not be supported for all *FSTypes*.

If df is run on a networked mount point that the automounter has not yet mounted, the file system size will be reported as zero. As soon as the automounter mounts the file system, the sizes will be reported correctly.

Options The following options are supported:

-a

  Reports on all file systems including ones whose entries in /etc/mnttab (see mnttab(4)) have the ignore option set.

-b

  Prints the total number of kilobytes free.

-e

  Prints only the number of files free.

-F *FSType*

  Specifies the *FSType* on which to operate. The -F option is intended for use with unmounted file systems. The *FSType* should be specified here or be determinable from /etc/vfstab (see vfstab(4)) by matching the *directory*, *block_device*, or *resource* with an entry in the table, or by consulting /etc/default/fs. See default_fs(4).

-g

  Prints the entire statvfs(2) structure. This option is used only for mounted file systems. It can not be used with the -o option. This option overrides the -b, -e, -k, -n, -P, and -t options.

-h

  Like -k, except that sizes are in a more human readable format. The output consists of one line of information for each specified file system. This information includes the file system name, the total space allocated in the file system, the amount of space allocated to existing files, the total amount of space available for the creation of new files by unprivileged users, and the percentage of normally available space that is currently allocated to all files on the file system. All sizes are scaled to a human readable format, for example, 14K, 234M, 2.7G, or 3.0T. Scaling is done by repetitively dividing by 1024.

This option overrides the -b, -e, -g, -k, -n, -t, and -V options. This option only works on mounted filesystems and can not be used together with -o option.

-k

Prints the allocation in kbytes. The output consists of one line of information for each specified file system. This information includes the file system name, the total space allocated in the file system, the amount of space allocated to existing files, the total amount of space available for the creation of new files by unprivileged users, and the percentage of normally available space that is currently allocated to all files on the file system. This option overrides the -b, -e, -n, and -t options and may not be used together with the -v option.

-l

Reports on local file systems only. This option is used only for mounted file systems. It can not be used with the -o option.

-n

Prints only the *FSType* name. Invoked with no operands, this option prints a list of mounted file system types. This option is used only for mounted file systems. It can not be used with the -o option.

-o *FSType-specific_options*
Specifies *FSType-specific* options. These options are comma-separated, with no intervening spaces. See the manual page for the *FSType-specific* command for details.

-t

Prints full listings with totals. This option overrides the -b, -e, and -n options.

-P

Same as -h except in 512-byte units.

-V

Echoes the complete set of file system specific command lines, but does not execute them. The command line is generated by using the options and operands provided by the user and adding to them information derived from /etc/mnttab, /etc/vfstab, or /etc/default/fs. This option may be used to verify and validate the command line.

-v

Like -k, except that sizes are displayed in multiples of the smallest block size supported by each specified file system.

This option may not be used with the -k option.

The output consists of one line of information for each file system. This one line of information includes the following:

- the file system's mount point
- the file system's name
- the total number of blocks allocated to the file system
- the number of blocks allocated to existing files

■   the number of blocks available for the creation of new files by unprivileged users

■   the percentage of blocks in use by files

-Z

Displays mounts in all visible zones. By default, df displays mounts located only within the current zone. This option has no effect in a non-global zone.

Operands   The df utility interprets operands according to the following precedence: *block_device*, *directory*, *file*, *resource*. The following operands are supported:

block_device

Represents a block special device (for example, /dev/dsk/c1d0s7).

directory

Represents a valid directory name. df reports on the file system that contains *directory*.

file

Represents a valid file name. df reports on the file system that contains *file*.

resource

Represents an NFS resource name.

Usage   See largefile(5) for the description of the behavior of df when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples   EXAMPLE 1   Executing the df command

The following example shows the df command and its output:

```
example% /usr/bin/df

/                 (/dev/dsk/c0t0d0s0 ):  287530 blocks    92028 files
/system/contract  (ctfs              ):       0 blocks 2147483572 files
/system/object    (objfs             ):       0 blocks 2147483511 files
/usr              (/dev/dsk/c0t0d0s6 ): 1020214 blocks   268550 files
/proc             (/proc             ):       0 blocks      878 files
/dev/fd           (fd                ):       0 blocks        0 files
/etc/mnttab       (mnttab            ):       0 blocks        0 files
/var/run          (swap              ):  396016 blocks     9375 files
/tmp              (swap              ):  396016 blocks     9375 files
/opt              (/dev/dsk/c0t0d0s5 ):  381552 blocks    96649 files
/export/home      (/dev/dsk/c0t0d0s7 ):  434364 blocks   108220 files
```

where the columns represent the mount point, device (or "filesystem", according to df -k), free blocks, and free files, respectively. For contract file systems, /system/contract is the mount point, ctfs is the contract file system (used by SMF) with 0 free blocks and 2147483582(INTMAX-1) free files. For object file systems, /system/object is the mount point, objfs is the object file system (see objfs(7FS)) with 0 free blocks and 2147483511 free files.

EXAMPLE 2 Writing Portable Information About the /usr File System

The following example writes portable information about the /usr file system:

```
example% /usr/bin/df -P /usr
```

EXAMPLE 3 Writing Portable Information About the /usr/src file System

Assuming that /usr/src is part of the /usr file system, the following example writes portable information :

```
example% /usr/bin/df -P /usr/src
```

EXAMPLE 4 Using df to Display Inode Usage

The following example displays inode usage on all ufs file systems:

```
example%/usr/bin/df -F ufs -o i
```

Environment Variables
When set, any header which normally displays files will now display nodes. See environ(5) for descriptions of the following environment variables that affect the execution of df: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status
The following exit values are returned:

0
  Successful completion.

>0
  An error occurred.

Files
/dev/dsk/*
  Disk devices

/etc/default/fs
  Default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs, where LOCAL is the default partition for a command if no FSType is specified.

/etc/mnttab
  Mount table

/etc/vfstab
  List of default parameters for each file system

Attributes
See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Standard	See standards(5).

See Also find(1), df_ufs(1M), mount(1M), statvfs(2), default_fs(4), mnttab(4), vfstab(4), attributes(5), environ(5), largefile(5), standards(5), objfs(7FS)

Notes If UFS logging is enabled on a file system, the disk space used for the log is reflected in the df report. The log is allocated from free blocks on the file system, and it is sized approximately 1 Mbyte per 1 Gbyte of file system, up to 256 Mbytes. The log size may be larger (up to a maximum of 512 Mbytes) depending on the number of cylinder groups present in the file system.

Name dfmounts – display mounted resource information

Synopsis dfmounts [-F *FSType*] [-h] [-o *specific_options*]
[*restriction*]...

Description dfmounts shows the local resources shared through a distributed file system *FSType* along
with a list of clients that have the resource mounted. If *restriction* is not specified, dfmounts
shows file systems that are currently shared on any NFS server. *specific_options* as well as the
availability and semantics of *restriction* are specific to particular distributed file system types.

If dfmounts is entered without arguments, remote resources currently mounted on the local
system are displayed, regardless of file system type. However, the dfmounts command does
not display the names of NFS Version 4 clients.

dfmounts Output The output of dfmounts consists of an optional header line (suppressed with the -h flag)
followed by a list of lines containing whitespace-separated fields. For each resource, the fields
are:

resource server pathname clients ...

where:

resource Specifies the resource name that must be given to the mount(1M) command.

server Specifies the system from which the resource was mounted.

pathname Specifies the pathname that must be given to the share(1M) command.

clients Is a comma-separated list of systems that have mounted the resource. Clients are
listed in the form *domain.*, *domain.system*, or *system*, depending on the file
system type.

A field can be null. Each null field is indicated by a hyphen (−) unless the remainder of the
fields on the line are also null, in which case the hyphen can be omitted.

Fields with whitespace are enclosed in quotation marks (" ").

Options -F *FSType* Specify filesystem type. Defaults to the first entry in
/etc/dfs/fstypes. Note: currently the only valid *FSType* is nfs.

-h Suppress header line in output.

-o *specific_options* Specify options specific to the filesystem provided by the -F option.
Note: currently no options are supported.

Files /etc/dfs/fstypes file system types

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   dfshares(1M), mount(1M), share(1M), unshare(1M), attributes(5)

Name   dfmounts_nfs – display mounted NFS resource information

Synopsis   `dfmounts [-F nfs] [-h] [`*server*`]...`

Description   `dfmounts` shows the local resources shared through NFS, along with the list of clients that have mounted the resource. The `-F` flag may be omitted if NFS is the only file system type listed in the file `/etc/dfs/fstypes`.

`dfmounts` without options, displays all remote resources mounted on the local system, regardless of file system type.

The output of `dfmounts` consists of an optional header line (suppressed with the `-h` flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

resource server pathname clients ...

where

resource	Does not apply to NFS. Printed as a hyphen (-).
server	Specifies the system from which the resource was mounted.
pathname	Specifies the pathname that must be given to the share(1M) command.
clients	Is a comma-separated list of systems that have mounted the resource.

Options
`-F nfs`	Specifies the nfs-FSType.
`-h`	Suppress header line in output.
server	Displays information about the resources mounted from each server, where *server* can be any system on the network. If no server is specified, the *server* is assumed to be the local system.

Files   `/etc/dfs/fstypes`

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/nfs

See Also   mount(1M), share(1M), unshare(1M), attributes(5)

Name dfshares – list available resources from remote or local systems

Synopsis dfshares [-F *FSType*] [-h] [-o *specific_options*] [*server*]...

Description dfshares provides information about resources available to the host through a distributed file system of type *FSType*. *specific_options* as well as the semantics of *server* are specific to particular distributed file systems.

If dfshares is entered without arguments, all resources currently shared on the local system are displayed, regardless of file system type.

The output of dfshares consists of an optional header line (suppressed with the -h flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

resource server access transport

where

resource   Specifies the resource name that must be given to the mount(1M) command.

server   Specifies the name of the system that is making the resource available.

access   Specifies the access permissions granted to the client systems, either ro (for read-only) or rw (for read/write). If dfshares cannot determine access permissions, a hyphen (−) is displayed.

transport   Specifies the transport provider over which the resource is shared.

A field may be null. Each null field is indicated by a hyphen (−) unless the remainder of the fields on the line are also null; in which case, the hyphen may be omitted.

Options -F *FSType*   Specify filesystem type. Defaults to the first entry in /etc/dfs/fstypes.

-h   Suppress header line in output.

-o *specific_options*   Specify options specific to the filesystem provided by the -F option.

Files /etc/dfs/fstypes

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also dfmounts(1M), mount(1M), share(1M), unshare(1M), attributes(5)

Name   dfshares_nfs – list available NFS resources from remote systems

Synopsis   dfshares [-F nfs] [-h] [*server*]...

Description   dfshares provides information about resources available to the host through NFS. The -F flag may be omitted if NFS is the first file system type listed in the file /etc/dfs/fstypes.

The query may be restricted to the output of resources available from one or more servers.

dfshares without arguments displays all resources shared on the local system, regardless of file system type.

Specifying *server* displays information about the resources shared by each server. *Server* can be any system on the network. If no server is specified, then *server* is assumed to be the local system.

The output of dfshares consists of an optional header line (suppressed with the -h flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

resource server access transport

where

resource	Specifies the resource name that must be given to the mount(1M) command.
server	Specifies the system that is making the resource available.
access	Specifies the access permissions granted to the client systems; however, dfshares cannot determine this information for an NFS resource and populates the field with a hyphen (-).
transport	Specifies the transport provider over which the *resource* is shared; however, dfshares cannot determine this information for an NFS resource and populates the field with a hyphen (-).

A field may be null. Each null field is indicated by a hyphen (-) unless the remainder of the fields on the line are also null; in which case, the hyphen may be omitted.

Options   -F nfs   Specify the NFS file system type

   -h   Suppress header line in output.

Files   /etc/dfs/fstypes

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/nfs

See Also   mount(1M), share(1M), unshare(1M), attributes(5)

Name df_ufs – report free disk space on ufs file systems

Synopsis df -F ufs [*generic_options*] [-o i] [*directory | special*]

Description df displays the amount of disk space occupied by ufs file systems, the amount of used and available space, and how much of the file system's total capacity has been used. The amount of space reported as used and available is less than the amount of space in the file system; this is because the system reserves a fraction of the space in the file system to allow its file system allocation routines to work well. The amount reserved is typically about 10%; this can be adjusted using tunefs(1M). When all the space on the file system except for this reserve is in use, only the superuser can allocate new files and data blocks to existing files. When the file system is overallocated in this way, df might report that the file system is more than 100% utilized. If neither *directory* nor *special* is specified, df displays information for all mounted ufs file systems.

Options The following options are supported:

generic_options   Options supported by the generic df command. See df(1M) for a description of these options.

-o   Specify ufs file system specific options. The available option is:

i   Report the number of used and free inodes. This option can not be used with *generic_options*.

Files /etc/mnttab   list of file systems currently mounted

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os, system/xopen/xcu4

See Also df(1M), fsck(1M), fstyp(1M), tunefs(1M), mnttab(4), attributes(5), ufs(7FS),

Notes df calculates its results differently for mounted and unmounted file systems. For unmounted systems, the numbers reflect the 10% reservation. This reservation is not reflected in df output for mounted file systems. For this reason, the available space reported by the generic command can differ from the available space reported by this module.

df might report remaining capacity even though syslog warns filesystem full. This issue can occur because df only uses the available fragment count to calculate available space, but the file system requires contiguous sets of fragments for most allocations.

If you suspect that you have exhausted contiguous fragments on your file system, you can use the fstyp(1M) utility with the -v option. In the fstyp output, look at the nbfree (number of blocks free) and nffree (number of fragments free) fields. On unmounted filesystems, you can use fsck(1M) and observe the last line of output, which reports, among other items, the number of fragments and the degree of fragmentation. See fsck(1M).

Name dhcpagent – Dynamic Host Configuration Protocol (DHCP) client daemon

Synopsis dhcpagent [-a] [-d *n*] [-f] [-v]

Description dhcpagent implements the client half of the Dynamic Host Configuration Protocol (DHCP) for machines running Solaris software.

The dhcpagent daemon obtains configuration parameters for the client (local) machine's network interfaces from a DHCP server. These parameters may include a lease on an IP address, which gives the client machine use of the address for the period of the lease, which may be infinite. If the client wishes to use the IP address for a period longer than the lease, it must negotiate an extension using DHCP. For this reason, dhcpagent must run as a daemon, terminating only when the client machine powers down.

For IPv4, the dhcpagent daemon is controlled through ifconfig(1M).

dhcpagent can be invoked as a user process, albeit one requiring root privileges, but this is not necessary, as ifconfig(1M) will start it automatically.

For IPv6, the dhcpagent daemon is invoked automatically by in.ndpd(1M). It can also be controlled through ifconfig(1M), if necessary.

When invoked, dhcpagent enters a passive state while it awaits instructions from ifconfig(1M) or in.ndpd(1M). When it receives a command to configure an interface, it brings up the interface (if necessary) and starts DHCP. Once DHCP is complete, dhcpagent can be queried for the values of the various network parameters. In addition, if DHCP was used to obtain a lease on an address for an interface, it configures the address for use. When a lease is obtained, it is automatically renewed as necessary. If the lease cannot be renewed, dhcpagent will unconfigure the address, but the interface will be left up and dhcpagent will attempt to acquire a new address lease. dhcpagent monitors system suspend/resume events and will validate any non-permanent leases with the DHCP server upon resume. Similarly, dhcpagent monitors link up/down events and will validate any non-permanent leases with the DHCP server when the downed link is brought back up. The lease validation mechanism will restart DHCP if the server indicates that the existing lease is no longer valid. If the server cannot be contacted, then the existing lease will continue. This behavior can be modified with the VERIFIED_LEASE_ONLY parameter in the /etc/default/dhcpagent file. See the description of this parameter below.

For IPv4, if the configured interface is found to be unplumbed, or to have a different IP address, subnet mask, or broadcast address from those obtained from DHCP, the interface is abandoned from DHCP control.

For IPv6, dhcpagent automatically plumbs and unplumbs logical interfaces as necessary for the IPv6 addresses supplied by the server. The IPv6 prefix length (netmask) is not set by the DHCPv6 protocol, but is instead set by in.ndpd(1M) using prefix information obtained by Router Advertisements. If any of the logical interfaces created by dhcpagent is unplumbed, or

configured with a different IP address, it will be abandoned from DHCP control. If the link-local interface is unplumbed, then all addresses configured by DHCP on that physical interface will be removed.

In addition to DHCP, dhcpagent also supports BOOTP (IPv4 only). See *RFC 951, Bootstrap Protocol*. Configuration parameters obtained from a BOOTP server are treated identically to those received from a DHCP server, except that the IP address received from a BOOTP server always has an infinite lease.

DHCP also acts as a mechanism to configure other information needed by the client, for example, the domain name and addresses of routers. Aside from the IP address, and for IPv4 alone, the netmask, broadcast address, and default router, the agent does not directly configure the workstation, but instead acts as a database which may be interrogated by other programs, and in particular by dhcpinfo(1).

On clients with a single interface, this is quite straightforward. Clients with multiple interfaces may present difficulties, as it is possible that some information arriving on different interfaces may need to be merged, or may be inconsistent. Furthermore, the configuration of the interfaces is asynchronous, so requests may arrive while some or all of the interfaces are still unconfigured. To handle these cases, one interface may be designated as primary, which makes it the authoritative source for the values of DHCP parameters in the case where no specific interface is requested. See dhcpinfo(1) and ifconfig(1M) for details.

All DHCP packets sent by dhcpagent include a vendor class identifier (RFC 2132, option code 60; RFC 3315, option code 16). This identifier is the same as the platform name returned by the uname -i command, except:

- Any commas in the platform name are changed to periods.
- If the name does not start with a stock symbol and a comma, it is automatically prefixed with SUNW.

Messages   The dhcpagent daemon writes information and error messages in five categories:

critical
    Critical messages indicate severe conditions that prevent proper operation.

errors
    Error messages are important, sometimes unrecoverable events due to resource exhaustion and other unexpected failure of system calls; ignoring errors may lead to degraded functionality.

warnings
    Warnings indicate less severe problems, and in most cases, describe unusual or incorrect datagrams received from servers, or requests for service that cannot be provided.

informational

Informational messages provide key pieces of information that can be useful to debugging a DHCP configuration at a site. Informational messages are generally controlled by the -v option. However, certain critical pieces of information, such as the IP address obtained, are always provided.

debug

Debugging messages, which may be generated at two different levels of verbosity, are chiefly of benefit to persons having access to source code, but may be useful as well in debugging difficult DHCP configuration problems. Debugging messages are only generated when using the -d option.

When dhcpagent is run without the -f option, all messages are sent to the system logger syslog(3C) at the appropriate matching priority and with a facility identifier LOG_DAEMON. When dhcpagent is run with the -f option, all messages are directed to standard error.

DHCP Events and User-Defined Actions

If an executable (binary or script) is placed at /etc/dhcp/eventhook, the dhcpagent daemon will automatically run that program when any of the following events occur:

BOUND and BOUND6

These events occur during interface configuration. The event program is invoked when dhcpagent receives the DHCPv4 ACK or DHCPv6 Reply message from the DHCP server for the lease request of an address, indicating successful initial configuration of the interface. (See also the INFORM and INFORM6 events, which occur when configuration parameters are obtained without address leases.)

EXTEND and EXTEND6

These events occur during lease extension. The event program is invoked just after dhcpagent receives the DHCPv4 ACK or DHCPv6 Reply from the DHCP server for the DHCPv4 REQUEST (renew) message or the DHCPv6 Renew or Rebind message.

Note that with DHCPv6, the server might choose to remove some addresses, add new address leases, and ignore (allow to expire) still other addresses in a given Reply message. The EXTEND6 event occurs when a Reply is received that leaves one or more address leases still valid, even if the Reply message does not extend the lease for any address. The event program is invoked just before any addresses are removed, but just after any new addresses are added. Those to be removed will be marked with the IFF_DEPRECATED flag.

EXPIRE and EXPIRE6

These events occur during lease expiration. For DHCPv4, the event program is invoked just before the leased address is removed from an interface. For DHCPv6, the event program is invoked just before the last remaining leased addresses are removed from the interface.

DROP and DROP6

These events occur during the period when an interface is dropped. The event program is invoked just before the interface is removed from DHCP control. If the interface has been

abandoned due the user unplumbing the interface, then this event will occur after the user's action has taken place. The interface might not be present.

INFORM and INFORM6

These events occur when an interface acquires new or updated configuration information from a DHCP server by means of the DHCPv4 INFORM or the DHCPv6 Information-Request message. These messages are sent using an ifconfig(1M) dhcp inform command or when the DHCPv6 Router Advertisement O (letter O) bit is set and the M bit is not set. Thus, these events occur when the DHCP client does not obtain an IP address lease from the server, and instead obtains only configuration parameters.

LOSS6

This event occurs during lease expiration when one or more valid leases still remain. The event program is invoked just before expired addresses are removed. Those being removed will be marked with the IFF_DEPRECATED flag.

Note that this event is not associated with the receipt of the Reply message, which occurs only when one or more valid leases remain, and occurs only with DHCPv6. If all leases have expired, then the EXPIRE6 event occurs instead.

RELEASE and RELEASE6

This event occurs during the period when a leased address is released. The event program is invoked just before dhcpagent relinquishes the address on an interface and sends the DHCPv4 RELEASE or DHCPv6 Release packet to the DHCP server.

The system does not provide a default event program. The file /etc/dhcp/eventhook is expected to be owned by root and have a mode of 755.

The event program will be passed two arguments, the interface name and the event name, respectively. For DHCPv6, the interface name is the name of the physical interface.

The event program can use the dhcpinfo(1) utility to fetch additional information about the interface. While the event program is invoked on every event defined above, it can ignore those events in which it is not interested. The event program runs with the same privileges and environment as dhcpagent itself, except that stdin, stdout, and stderr are redirected to /dev/null. Note that this means that the event program runs with root privileges.

If an invocation of the event program does not exit after 55 seconds, it is sent a SIGTERM signal. If does not exit within the next three seconds, it is terminated by a SIGKILL signal.

See EXAMPLES for an example event program.

Options   The following options are supported:

-a

Adopt a configured IPv4 interface. This option is for use with diskless DHCP clients. In the case of diskless DHCP, DHCP has already been performed on the network interface

providing the operating system image prior to running dhcpagent. This option instructs the agent to take over control of the interface. It is intended primarily for use in boot scripts.

The effect of this option depends on whether the interface is being adopted.

If the interface is being adopted, the following conditions apply:

dhcpagent uses the client id specified in /chosen:<*client_id*>, as published by the PROM or as specified on a boot(1M) command line. If this value is not present, the client id is undefined. The DHCP server then determines what to use as a client id. It is an error condition if the interface is an Infiniband interface and the PROM value is not present.

If the interface is not being adopted:

dhcpagent uses the value stored in /etc/default/dhcpagent. If this value is not present, the client id is undefined. If the interface is Infiniband and there is no value in /etc/default/dhcpagent, a client id is generated as described by the draft document on DHCP over Infiniband, available at:

```
http://www.ietf.org
```

-d *n*
Set debug level to *n*. Two levels of debugging are currently available, 1 and 2; the latter is more verbose.

-f
Run in the foreground instead of as a daemon process. When this option is used, messages are sent to standard error instead of to syslog(3C).

-v
Provide verbose output useful for debugging site configuration problems.

Examples EXAMPLE 1 Example Event Program

The following script is stored in the file /etc/dhcp/eventhook, owned by root with a mode of 755. It is invoked upon the occurrence of the events listed in the file.

```
#!/bin/sh

(
echo "Interface name: " $1
echo "Event: " $2

case $2 in
"BOUND")
    echo "Address acquired from server "\
        '/usr/sbin/dhcpinfo -i $1 ServerID'
    ;;
"BOUND6")
```

EXAMPLE 1 Example Event Program *(Continued)*

```
     echo "Addresses acquired from server " \
         `/usr/sbin/dhcpinfo -v6 -i $1 ServerID`
     ;;
"EXTEND")
    echo "Lease extended for " \
        `/usr/sbin/dhcpinfo -i $1 LeaseTime`" seconds"
    ;;
"EXTEND6")
    echo "New lease information obtained on $i"
    ;;
"EXPIRE" | "DROP" | "RELEASE")
    ;;

esac
) >/var/run/dhcp_eventhook_output 2>&1
```

Note the redirection of stdout and stderr to a file.

Files /etc/dhcp/*if*.dhc
/etc/dhcp/*if*.dh6

Contains the configuration for interface. The mere existence of this file does not imply that the configuration is correct, since the lease might have expired. On start-up, dhcpagent confirms the validity of the address using REQUEST (for DHCPv4) or Confirm (DHCPv6).

/etc/dhcp/duid
/etc/dhcp/iaid

Contains persistent storage for DUID (DHCP Unique Identifier) and IAID (Identity Association Identifier) values. The format of these files is undocumented, and applications should not read from or write to them.

/etc/default/dhcpagent

Contains default values for tunable parameters. All values may be qualified with the interface they apply to by prepending the interface name and a period (".") to the interface parameter name. The parameters include: the interface parameter name.

To configure IPv6 parameters, place the string .v6 between the interface name (if any) and the parameter name. For example, to set the global IPv6 parameter request list, use .v6.PARAM_REQUEST_LIST. To set the CLIENT_ID (DUID) on hme0, use hme0.v6.CLIENT_ID.

The parameters include:

VERIFIED_LEASE_ONLY

Indicates that a RELEASE rather than a DROP should be performed on managed interfaces when the agent terminates. Release causes the client to discard the lease, and the server to make the address available again. Drop causes the client to record the lease in

/etc/dhcp/*interface*.dhc or /etc/dhcp/*interface*.dh6 for later use. In addition, when the link status changes to up or when the system is resumed after a suspend, the client will verify the lease with the server. If the server is unreachable for verification, then the old lease will be discarded (even if it has time remaining) and a new one obtained.

Enabling this option is often desirable on mobile systems, such as laptops, to allow the system to recover quickly from moves.

OFFER_WAIT

Indicates how long to wait between checking for valid OFFERs after sending a DISCOVER. For DHCPv6, sets the time to wait between checking for valid Advertisements after sending a Solicit.

CLIENT_ID

Indicates the value that should be used to uniquely identify the client to the server. This value can take one of three basic forms:

decimal,*data*...
0xHHHHH...
"*string*...."

The first form is an RFC 3315 DUID. This is legal for both IPv4 DHCP and DHCPv6. For IPv4, an RFC 4361 Client ID is constructed from this value. In this first form, the format of *data*... depends on the decimal value. The following formats are defined for this first form:

1,*hwtype*,*time*,*lla*

Type 1, DUID-LLT. The *hwtype* value is an integer in the range 0-65535, and indicates the type of hardware. The *time* value is the number of seconds since midnight, January 1st, 2000 UTC, and can be omitted to use the current system time. The *lla* value is either a colon-separated MAC address or the name of a physical interface. If the name of an interface is used, the *hwtype* value can be omitted. For example: 1,,,hme0

2,*enterprise*,*hex*...

Type 2, DUID-EN. The *enterprise* value is an integer in the range 0-4294967295 and represents the SMI Enterprise number for an organization. The *hex* string is an even-length sequence of hexadecimal digits.

3,*hwtype*,*lla*

Type 3, DUID-LL. This is the same as DUID-LLT (type 1), except that a time stamp is not used.

*,*hex*

Any other type value (0 or 4-65535) can be used with an even-length hexadecimal string.

The second and third forms of CLIENT_ID are legal for IPv4 only. These both represent raw Client ID (without RFC 4361), in hex, or NVT ASCII string format. Thus, "Sun" and 0x53756E are equivalent.

PARAM_REQUEST_LIST

Specifies a list of comma-separated integer values of options for which the client would like values, or symbolic Site or Option option names. Symbolic option names for IPv4 are resolved through /etc/dhcp/inittab. Option names for IPv6 are resolved by means of /etc/dhcp/inittab6.

PARAM_IGNORE_LIST

Specifies a list of options (constructed in the same manner as PARAM_REQUEST_LIST) that the DHCP client will ignore. Ignored options are treated as though the server did not return the options specified. Ignored options are not visible using dhcpinfo(1) or acted on by the client. This parameter can be used, for example, to disable an unwanted client name or default router.

/etc/dhcp/eventhook

Location of a DHCP event program.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

Oracle Solaris Administration: IP Services

Croft, B. and Gilmore, J.,*Bootstrap Protocol (BOOTP)*RFC 951, Network Working Group, September 1985.

Droms, R., *Dynamic Host Configuration Protocol*, RFC 2131, Network Working Group, March 1997.

Lemon, T. and B. Sommerfeld. *RFC 4361, Node-specific Client Identifiers for Dynamic Host Configuration Protocol Version Four (DHCPv4)*. Nominum and Sun Microsystems. February 2006.

Droms, R. *RFC 3315, Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*. Cisco Systems. July 2003.

Notes The dhcpagent daemon can be used on IPv4 logical interfaces, just as with physical interfaces. When used on a logical interface, the daemon automatically constructs a Client ID value based on the DUID and IAID values, according to RFC 4361. The /etc/default/dhcpagent CLIENT_ID value, if any, overrides this automatic identifier.

Unlike physical IPv4 interfaces, dhcpagent does not add or remove default routes associated with logical interfaces.

DHCP can be performed on IPMP IP interfaces to acquire and maintain IPMP data addresses. Because an IPMP IP interface has no hardware address, the daemon automatically constructs a Client ID using the same approach described above for IPv4 logical interfaces. In addition, the lack of a hardware address means the daemon must set the "broadcast" flag in all DISCOVER and REQUEST messages on IPMP IP interfaces. Some DHCP servers may refuse such requests.

DHCP can be performed on IP interfaces that are part of an IPMP group (to acquire and maintain test addresses). The daemon will automatically set the NOFAILOVER and DEPRECATED flags on each test address. Additionally, the daemon will not add or remove default routes in this case. Note that the actual DHCP packet exchange may be performed over any active IP interface in the IPMP group. It is strongly recommended that test addresses have infinite leases. Otherwise, an extended network outage detectable only by probes may cause test address leases to expire, causing in.mpathd(1M) to revert to link-based failure detection and trigger an erroneous repair.

Name dhcpconfig – DHCP service configuration utility

Synopsis dhcpconfig -D -r *resource* -p *path* [-u *uninterpreted*]
      [-l *lease_length*] [-n] [-d *DNS_domain*]
      [-a *DNS_server_addresses*] [-h *hosts_resource*]
      [-y *hosts_domain*]

dhcpconfig -R *server_addresses*

dhcpconfig -U [-f] [-x] [-h]

dhcpconfig -N *network_address* [-m *subnet_mask*] [-b]
      [-t *router_addresses*] [-y *NIS-domain*]
      [-a *NIS_server_addresses*] [-g]

dhcpconfig -C -r *resource* -p *path* [-f] [-k]
      [-u *uninterpreted*]

dhcpconfig -X *filename* [-m *macro_list*] [-o *option_list*]
      [-a *network_addresses*] [-f] [-x] [-g]

dhcpconfig -I *filename* [-f] [-g]

dhcpconfig -P [*parameter*[=*value*],]...

dhcpconfig -S [-f] [-e | -d | -r | -q]

Description The dhcpconfig command is used to configure and manage the Dynamic Host Configuration
Protocol (DHCP) service or BOOTP relay services. It is intended for use by experienced
Solaris system administrators and is designed for ease of use in scripts. The dhcpmgr utility is
recommended for less experienced administrators or those preferring a graphical utility to
configure and manage the DHCP service or BOOTP relay service.

The dhcpconfig command can be run by root, or by other users assigned to the DHCP
Management profile. See rbac(5) and user_attr(4).

dhcpconfig requires one of the following function flags: -D, -R, -U, -N, -C, -X, -I, -P or -S.

The dhcpconfig menu driven mode is supported in Solaris 8 and previous versions of Solaris.

Where dhcpconfig Obtains Configuration Information dhcpconfig scans various configuration files on your Solaris machine for information it can
use to assign values to options contained in macros it adds to the dhcptab configuration table.
The following table lists information dhcpconfig needs, the source used, and how the
information is used:

Information	*Source*	*Where Used*
Timezone	System date, timezone settings	Locale macro
DNS parameters	nsswitch.conf, /etc/resolv.conf	Server macro

| NIS parameters | System domainname, nsswitch.conf, NIS | Network macros |
| Subnetmask | Network interface, netmasks table in nameservice | Network macros |

If you have not set these parameters on your server machine, you should do so before configuring the DHCP server with dhcpconfig. Note that if you specify options with the dhcpconfig -D command line, the values you supply override the values obtained from the system files.

The dhcpconfig utility is obsolete and is subject to removal in a future release of Oracle Solaris.

Options The following options are supported:

-C

Convert to using a new data store, recreating the DHCP data tables in a format appropriate to the new data store, and setting up the DHCP server to use the new data store.

The following sub-options are required:

-p *path_to_data*

The paths for SUNWfiles and SUNWbinfiles must be absolute UNIX pathnames. See dhcp_modules(5).

-r *data_resource*

New data store resource. One of the following must be specified: SUNWfiles or SUNWbinfiles. See dhcp_modules(5).

The following sub-options are optional:

-f

Do not prompt for confirmation. If -f is not used, a warning and confirmation prompt are issued before the conversion starts.

-k

Keep the old DHCP data tables after successful conversion. If any problem occurs during conversion, tables are not deleted even if -k sub-option is not specified.

-u *uninterpreted*

Data which is ignored by dhcpconfig, but passed on to the datastore for interpretation. The private layer provides for module-specific configuration information through the use of the RESOURCE_CONFIG keyword. Uninterpreted data is stored within RESOURCE_CONFIG keyword of dhcpsvc.conf(4). The -u sub-option is not used with the SUNWfiles and SUNWbinfiles data stores. See dhcp_modules(5).

-D

Configure the DHCP service.

The following sub-options are required:

-r *data_resource*

    One of the following must be specified: `SUNWfiles` or `SUNWbinfiles`. Other data stores may be available. See dhcp_modules(5).

-p *path*

    The paths for `SUNWfiles` and `SUNWbinfiles` must be absolute UNIX pathnames. See dhcp_modules(5).

The following sub-options are optional:

-a *DNS_servers*

    IP addresses of DNS servers, separated with commas.

-d *DNS_domain*

    DNS domain name.

-h *hosts_resource*

    Resource in which to place hosts data. Usually, the name service in use on the server. Valid values are `files` or `dns`.

-l *seconds*

    Lease length used for addresses not having a specified lease length, in seconds.

-n

    Non-negotiable leases

-y *hosts_domain*

    DNS domain name to be used for hosts data. Valid only if `dns` is specified for `-h` sub-option.

-u *uninterpreted*

    Data which is ignored by dhcpconfig, but passed on to the datastore for interpretation. The private layer provides for module-specific configuration information through the use of the `RESOURCE_CONFIG` keyword. Uninterpreted data is stored within `RESOURCE_CONFIG` keyword of dhcpsvc.conf(4). The `-u` sub-option is not used with the `SUNWfiles` and `SUNWbinfiles` data stores. See dhcp_modules(5).

-I *filename*

    Import data from *filename*, containing data previously exported from a Solaris DHCP server. Note that after importing, you may have to edit macros to specify the correct domain names, and edit network tables to change the owning server of addresses in imported networks. Use dhtadm and pntadm to do this.

The following sub-options are supported:

-f

    Replace any conflicting data with the data being imported.

-g
  Signal the daemon to reload the dhcptab once the import has been completed.

-N *net_address*
  Configure an additional network for DHCP service.

  The following sub-options are supported:

  -a *NIS_server_addresses*
    List of IP addresses of NIS servers.

  -b
    Network is a point-to-point (PPP) network, therefore no broadcast address should be configured. If -b is not used, the network is assumed to be a LAN, and the broadcast address is determined using the network address and subnet mask.

  -g
    Signal the daemon to reload the dhcptab.

  -m *xxx.xxx.xxx.xxx*
    Subnet mask for the network; if -m is not used, subnet mask is obtained from netmasks.

  -t *router_addresses*
    List of router IP addresses; if not specified, router discovery flag is set.

  -y *NIS_domain_name*
    If NIS is used on this network, specify the NIS domain name.

-P
  Configure the DHCP service parameters. Each parameter and value are specified by the following pattern:

  parameter[=*value*],...

  Where parameter and value are:

  parameter
    One of the DHCP service parameters listed in dhcpsvc.conf(4). If the corresponding *value* is not specified, the current parameter value is displayed. If *parameter* is not specified, all parameters and current values are displayed.

  value
    Optional string to set the servers parameter to if the value is acceptable. If the value is missing or is empty (""), the parameter and its current value are deleted.

  After a parameter has changed the DHCP server requires re-starting before you can use new parameter values.

-R *server_addresses*
  Configure the BOOTP relay service. BOOTP or DHCP requests are forwarded to the list of servers specified.

server_addresses is a comma separated list of hostnames and/or IP addresses.

-S

Control the DHCP service.

The following sub-options are supported:

-d

Disable and stop the DHCP service.

-e

Enable and start the DHCP service.

-q

Display the state of the DHCP service. The state is encoded into the exit status.

```
0    DHCP service disabled and stopped
1    DHCP service enabled and stopped
2    DHCP service disabled and running
3    DHCP service enabled and running
```

-r

Enable and restart the DHCP service.

-U

Unconfigure the DHCP service or BOOTP relay service.

The following sub-options are supported:

-f

Do not prompt for confirmation. If -f is not used, a warning and confirmation prompt is issued.

-h

Delete hosts entries from name service.

-x

Delete the dhcptab and network tables.

-X *filename*

Export data from the DHCP data tables, saving to *filename*, to move the data to another Solaris DHCP server.

The following sub-options are optional:

-a *networks_to_export*

List of networks whose addresses should be exported, or the keyword ALL to specify all networks. If -a is not specified, no networks are exported.

-g

Signal the daemon to reload the dhcptab after the export has been completed.

-m *macros_to_export*

List of macros to export, or the keyword ALL to specify all macros. If -m is not specified, no macros are exported.

-o *options_to_export*

List of options to export, or the keyword ALL to specify all options. If -o is not specified, no options are exported.

-x

Delete the data from this server after it is exported. If -x is not specified you are in effect copying the data.

Examples   **EXAMPLE 1**   Configuring DHCP Service with Binary Files Data Store

The following command configures DHCP service, using the binary files data store, in the DNS domain acme.eng, with a lease time of 28800 seconds (8 hours),

```
example# dhcpconfig -D -r SUNWbinfiles -p /var/dhcp -l 28800\
            -d acme.eng -a 120.30.33.4 -h dns -y acme.eng
```

EXAMPLE 2   Configuring BOOTP Relay Agent

The following command configures the DHCP daemon as a BOOTP relay agent, which forwards BOOTP and DHCP requests to the servers having the IP addresses 120.30.33.7 and 120.30.42.132:

```
example# dhcpconfig -R 120.30.33.7,120.30.42.132
```

EXAMPLE 3   Unconfiguring DHCP Service

The following command unconfigures the DHCP service, with confirmation, and deletes the DHCP data tables and host table entries:

```
example# dhcpconfig -U -x -h
```

EXAMPLE 4   Configuring a Network for DHCP Service

The following command configures an additional LAN network for DHCP service, specifying that clients should use router discovery and providing the NIS domain name and NIS server address:

```
example# dhcpconfig -N 120.30.171.0 -y east.acme.eng.com\
            -a 120.30.33.4
```

EXAMPLE 5   Exporting a Network, Macros, and Options from a DHCP Server

The following command exports one network (120.30.171.0) and its addresses, the macro 120.30.171.0, and the options motd and PSptr from a DHCP server, saves the exported data in file /export/var/120301710_data, and deletes the exported data from the server.

```
example# dhcpconfig -X /var/dhcp/120301710_export
    -a 120.30.171.0 -m 120.30.171.0 -o motd,PSptr
```

EXAMPLE 6 Importing Data on a DHCP Server

The following command imports DHCP data from a file,
/net/golduck/export/var/120301710_data, containing data previously exported from a
Solaris DHCP server, overwrites any conflicting data on the importing server, and signals the
daemon to reload the dhcptab once the import is completed:

```
example# dhcpconfig -I /net/golduck/export/var/120301710_data -f -g
```

EXAMPLE 7 Setting DHCP Server Parameters

The following command sets the number of minutes that the DHCP server waits before
timing out when updating DNS information on DHCP clients to five minutes.

```
example# example# dhcpconfig -P UPDATE_TIMEOUT=5
```

EXAMPLE 8 Re-starting the DHCP server

The following command stops and re-starts the DHCP server.

```
example#  example# dhcpconfig -S -r
DHCP server stopped
DHCP server started
```

Oracle Solaris Administration: IP Services

Name   dhcpmgr – graphical interface for managing DHCP service

Synopsis   `/usr/sadm/admin/bin/dhcpmgr`

Description   dhcpmgr is a graphical user interface which enables you to manage the Dynamic Host Configuration Protocol (DHCP) service on the local system. It performs the functions of the dhcpconfig, dhtadm, and pntadm command line utilities. You must be root to use dhcpmgr. The dhcpmgr Help, available from the Help menu, contains detailed information about using the tool.

The dhcpmgr utility is obsolete and is subject to removal in a future release of Oracle Solaris.

Usage   You can perform the following tasks using dhcpmgr:

Configure DHCP service   Use dhcpmgr to configure the DHCP daemon as a DHCP server, and select the data store to use for storing network configuration tables..

Configure BOOTP relay service   Use dhcpmgr to configure the DHCP daemon as a BOOTP relay.

Manage DHCP or BOOTP relay service   Use dhcpmgr to start, stop, enable, disable or unconfigure the DHCP service or BOOTP relay service, or change DHCP server parameters.

Manage DHCP addresses   Use dhcpmgr to add, modify, or delete IP addresses leased by the DHCP service.

Manage DHCP macros   Use dhcpmgr to add, modify or delete macros used to supply configuration parameters to DHCP clients.

Manage DHCP options   Use dhcpmgr to add, modify or delete options used to define parameters deliverable through DHCP.

Convert to a new DHCP data store   Use dhcpmgr to configure the DHCP server to use a different data store, and convert the DHCP data to the format used by the new data store.

Move DHCP data to another server   Use dhcpmgr to export data from one Solaris DHCP server and import data onto another Solaris DHCP server.

Exit Status   The following exit values are returned:

0   Successful completion.

non-zero   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/dhcp/dhcpmgr
Interface Stability	Obsolete

See Also dhcpconfig(1M), dhtadm(1M), pntadm(1M), in.dhcpd(1M), dhcpsvc.conf(4), dhcp_network(4), dhcptab(4), attributes(5), dhcp(5), dhcp_modules(5)

Oracle Solaris DHCP Service Developer's Guide

Oracle Solaris Administration: IP Services

Name   dhtadm – DHCP configuration table management utility

Synopsis   dhtadm -C [-r *resource*] [-p *path*] [-u *uninterpreted*] [-g]

dhtadm -A -s *symbol_name* -d *definition* [-r *resource*]
      [-p *path*] [-u *uninterpreted*] [-g]

dhtadm -A -m *macro_name* -d *definition* [-r *resource*]
      [-p *path*] [-u *uninterpreted*] [-g]

dhtadm -M -s *symbol_name* -d *definition* [-r *resource*]
      [-p *path*] [-u *uninterpreted*] [-g]

dhtadm -M -s *symbol_name* -n *new_name* [-r *resource*]
      [-p *path*] [-u *uninterpreted*] [-g]

dhtadm -M -m *macro_name* -n *new_name* [-r *resource*] [-p *path*]
      [-u *uninterpreted*] [-g]

dhtadm -M -m *macro_name* -d *definition* [-r *resource*]
      [-p *path*] [-u *uninterpreted*] [-g]

dhtadm -M -m *macro_name* -e *symbol=value* [-r *resource*]
      [-p *path*] [-u *uninterpreted*] [-g]

dhtadm -D -s *symbol_name* [-r *resource*] [-p *path*]
      [-u *uninterpreted*] [-g]

dhtadm -D -m *macro_name* [-r *resource*] [-p *path*]
      [-u *uninterpreted*] [-g]

dhtadm -P [-r *resource*] [-p *path*] [-u *uninterpreted*] [-g]

dhtadm -R [-r *resource*] [-p *path*] [-u *uninterpreted*] [-g]

dhtadm -B [-v] [*batchfile*] [-g]

Description   dhtadm manages the Dynamic Host Configuration Protocol (DHCP) service configuration
table, dhcptab. You can use it to add, delete, or modify DHCP configuration macros or
options or view the table. For a description of the table format, see dhcptab(4).)

The dhtadm command can be run by root, or by other users assigned to the DHCP
Management profile. See rbac(5) and user_attr(4).

After you make changes with dhtadm, you should issue a SIGHUP to the DHCP server, causing
it to read the dhcptab and pick up the changes. Do this using the -g option.

The dhtadm utility is obsolete and is subject to removal in a future release of Oracle Solaris.

Options   One of the following function flags must be specified with the dhtadm command: -A, -B, -C, -D,
-M, -P or -R.

The following options are supported:

-A

Add a symbol or macro definition to the dhcptab table.

The following sub-options are required:

-d *definition*

Specify a macro or symbol definition.

definition must be enclosed in single quotation marks. For macros, use the form -d
'*:symbol=value:symbol=value:*'. Enclose a *value* that contains colons in double
quotation marks. For symbols, the definition is a series of fields that define a symbol's
characteristics. The fields are separated by commas. Use the form -d
'*context,code,type,granularity,maximum*'. See dhcptab(4) for information about
these fields.

-m *macro_name*

Specify the name of the macro to be added.

The -d option must be used with the -m option. The -s option cannot be used with the
-m option.

-s *symbol_name*

Specify the name of the symbol to be added.

The -d option must be used with the -s option. The -m option cannot be used with the
-s option.

-B

Batch process dhtadm commands. dhtadm reads from the specified file or from standard
input a series of dhtadm commands and execute them within the same process. Processing
many dhtadm commands using this method is much faster than running an executable
batchfile itself. Batch mode is recommended for using dhtadm in scripts.

The following sub-option is optional:

-v

Display commands to standard output as they are processed.

-C

Create the DHCP service configuration table, dhcptab.

-D

Delete a symbol or macro definition.

The following sub-options are required:

-m *macro_name*
Delete the specified macro.

-s *symbol_name*
Delete the specified symbol.

-g

Signal the DHCP daemon to reload the dhcptab after successful completion of the operation.

-M

Modify an existing symbol or macro definition.

The following sub-options are required:

-d *definition*

Specify a macro or symbol definition to modify.

The definition must be enclosed in single quotation marks. For macros, use the form -d *':symbol=value:symbol=value:'*. Enclose a *value* that contains colons in double quotation marks. For symbols, the definition is a series of fields that define a symbol's characteristics. The fields are separated by commas. Use the form -d *'context,code,type,granularity,maximum'*. See dhcptab(4) for information about these fields.

-e

This sub-option uses the *symbol* =*value* argument. Use it to edit a *symbol/value* pair within a macro. To add a symbol which does not have an associate value, enter:

symbol=_NULL_VALUE_

To delete a symbol definition from a macro, enter:

symbol=

-m

This sub-option uses the *macro_name* argument. The -n, -d, or -e sub-options are legal companions for this sub-option..

-n

This sub-option uses the *new_name* argument and modifies the name of the object specified by the -m or -s sub-option. It is not limited to macros. . Use it to specify a new macro name or symbol name.

-s

This sub-option uses the *symbol_name* argument. Use it to specify a symbol. The -d sub-option is a legal companion.

-p *path*

Override the dhcpsvc.conf(4) configuration value for PATH= with *path*. See dhcpsvc.conf(4) for more details regarding *path*. See dhcp_modules(5) for information regarding data storage modules for the DHCP service.

-P

Print (display) the dhcptab table.

-r *data_store_resource*

Override the dhcpsvc.conf(4) configuration value for RESOURCE= with the
data_store_resource specified. See dhcpsvc.conf(4) for more details on resource type.
See *Oracle Solaris DHCP Service Developer's Guide* for more information about adding
support for other data stores. See dhcp_modules(5) for information regarding data storage
modules for the DHCP service.

-R

Remove the dhcptab table.

-u *uninterpreted*

Data which is ignored by dhtadm, but passed to currently configured public module, to be
interpreted by the data store. The private layer provides for module-specific configuration
information through the use of the RESOURCE_CONFIG keyword. Uninterpreted data is
stored within RESOURCE_CONFIG keyword of dhcpsvc.conf(4). See dhcp_modules(5) for
information regarding data storage modules for the DHCP service.

Examples **EXAMPLE 1** Creating the DHCP Service Configuration Table

The following command creates the DHCP service configuration table, dhcptab:

```
# dhtadm -C
```

EXAMPLE 2 Adding a Symbol Definition

The following command adds a Vendor option symbol definition for a new symbol called
MySym to the dhcptab table in the SUNWfiles resource in the /var/mydhcp directory:

```
# dhtadm -A -s MySym
  -d 'Vendor=SUNW.PCW.LAN,20,IP,1,0'
  -r SUNWfiles -p /var/mydhcp
```

EXAMPLE 3 Adding a Macro Definition

The following command adds the aruba macro definition to the dhcptab table. Note that
symbol/value pairs are bracketed with colons (:).

```
# dhtadm -A -m aruba \
    -d ':Timeserv=10.0.0.10 10.0.0.11:DNSserv=10.0.0.1:'
```

EXAMPLE 4 Modifying a Macro Definition

The following command modifies the Locale macro definition, setting the value of the
UTCOffst symbol to 18000 seconds. Note that any macro definition which includes the
definition of the Locale macro inherits this change.

```
# dhtadm -M -m Locale -e 'UTCOffst=18000'
```

EXAMPLE 5 Deleting a Symbol

The following command deletes the `Timeserv` symbol from the `aruba` macro. Any macro definition which includes the definition of the `aruba` macro inherits this change.

```
# dhtadm -M -m aruba -e 'Timeserv='
```

EXAMPLE 6 Adding a Symbol to a Macro

The following command adds the `Hostname` symbol to the `aruba` macro. Note that the `Hostname` symbol takes no value, and thus requires the special value `_NULL_VALUE_`. Note also that any macro definition which includes the definition of the `aruba` macro inherits this change.

```
# dhtadm -M -m aruba -e 'Hostname=_NULL_VALUE_'
```

EXAMPLE 7 Renaming a Macro

The following command renames the `Locale` macro to `MyLocale`. Note that any `Include` statements in macro definitions which include the `Locale` macro also need to be changed.

```
# dhtadm -M -m Locale -n MyLocale
```

EXAMPLE 8 Deleting a Symbol Definition

The following command deletes the `MySym` symbol definition. Note that any macro definitions which use `MySym` needs to be modified.

```
# dhtadm -D -s MySym
```

EXAMPLE 9 Printing a dhcptab

The following command prints to standard output the contents of the `dhcptab` that is located in the data store and path indicated in the `dhcpsvc.conf` file:.

```
# dhtadm -P
```

EXAMPLE 10 Executing dhtadm in Batch Mode

The following command runs a series of `dhtadm` commands contained in a batch file and signals the daemon to reload the `dhcptab` once the commands have been executed: :

```
# dhtadm -B addmacros -g
```

Exit Status   0

Successful completion.

1

Object already exists.

2

Object does not exist.

3
   Non-critical error.

4
   Critical error.

Files /etc/inet/dhcpsvc.conf
   contains service configuration parameters for the DHCP service

Name dig – DNS lookup utility

Synopsis dig [@server] [-b *address*] [-c *class*] [-f *filename*]
        [-k *filename*] [-m] [-p *port#*] [-q *name*] [-t *type*] [-x *addr*]
        [-y [*hmac*:]*name:key*] [-4] [-6] [*name*] [*type*] [*class*] [*queryopt*]...

dig [-h]

dig [*global-queryopt*...] [*query*...]

Description The dig utility (domain information groper) is a flexible tool for interrogating DNS name servers. It performs DNS lookups and displays the answers that are returned from the name server(s) that were queried. Most DNS administrators use dig to troubleshoot DNS problems because of its flexibility, ease of use and clarity of output. Other lookup tools tend to have less functionality than dig.

Although dig is normally used with command-line arguments, it also has a batch mode of operation for reading lookup requests from a file. A brief summary of its command-line arguments and options is printed when the -h option is specified. Unlike earlier versions, the BIND 9 implementation of dig allows multiple lookups to be issued from the command line.

Unless it is told to query a specific name server, dig tries each of the servers listed in /etc/resolv.conf.

When no command line arguments or options are given, dig performs an NS query for "." (the root).

It is possible to set per-user defaults for dig with ${HOME}/.digrc. This file is read and any options in it are applied before the command line arguments.

The IN and CH class names overlap with the IN and CH top level domains names. Either use the -t and -c options to specify the type and class, or use "IN." and "CH." when looking up these top level domains.

Simple Usage The following is a typical invocation of dig:

dig @server name type

where:

server
   The name or IP address of the name server to query. This can be an IPv4 address in dotted-decimal notation or an IPv6 address in colon-delimited notation. When the supplied *server* argument is a hostname, dig resolves that name before querying that name server. If no *server* argument is provided, dig consults /etc/resolv.conf and queries the name servers listed there. The reply from the name server that responds is displayed.

name
   The name of the resource record that is to be looked up.

type

Indicates what type of query is required (ANY, A, MX, SIG, among others.) *type* can be any valid query type. If no *type* argument is supplied, dig performs a lookup for an A record.

Options The following options are supported:

-4

Use only IPv4 transport. By default both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

-6

Use only IPv6 transport. By default both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

-b *address*

Set the source IP address of the query to *address*. This must be a valid address on one of the host's network interfaces or 0.0.0.0 or ::. An optional port may be specified by appending: #<*port*>

-c *class*

Override the default query class (IN for internet). The *class* argument is any valid class, such as HS for Hesiod records or CH for CHAOSNET records.

-f *filename*

Operate in batch mode by reading a list of lookup requests to process from the file *filename*. The file contains a number of queries, one per line. Each entry in the file should be organized in the same way they would be presented as queries to dig using the command-line interface.

-h

Print a brief summary of command-line arguments and options.

-k *filename*

Specify a transaction signature (TSIG) key file to sign the DNS queries sent by dig and their responses using TSIGs.

-m

Enable memory usage debugging.

-p *port#*

Query a non-standard port number. The *port#* argument is the port number that dig sends its queries instead of the standard DNS port number 53. This option tests a name server that has been configured to listen for queries on a non-standard port number.

-q *name*

Sets the query name to *name*. This can be useful in that the query name can be easily distinguished from other arguments.

-t *type*

Set the query type to *type*, which can be any valid query type supported in BIND9. The default query type "A", unless the -x option is supplied to indicate a reverse lookup. A zone transfer can be requested by specifying a type of AXFR. When an incremental zone transfer (IXFR) is required, *type* is set to ixfr=*N*. The incremental zone transfer will contain the changes made to the zone since the serial number in the zone's SOA record was *N*.

-x *addr*

Simplify reverse lookups (mapping addresses to names). The *addr* argument is an IPv4 address in dotted-decimal notation, or a colon-delimited IPv6 address. When this option is used, there is no need to provide the *name*, *class* and *type* arguments. The dig utility automatically performs a lookup for a name like 11.12.13.10.in-addr.arpa and sets the query type and class to PTR and IN, respectively. By default, IPv6 addresses are looked up using nibble format under the IP6.ARPA domain. To use the older RFC1886 method using the IP6.INT domain, specify the -i option. Bit string labels (RFC 2874) are now experimental and are not attempted.

-y [*hmac*:]*name*:*key*

Specify a transaction signature (TSIG) key on the command line. This is done to sign the DNS queries sent by dig, as well as their responses. You can also specify the TSIG key itself on the command line using the -y option. The optional *hmac* is the type of TSIG; the default is HMAC-MD5. The *name* argument is the name of the TSIG key and the *key* argument is the actual key. The key is a base-64 encoded string, typically generated by dnssec-keygen(1M).

Caution should be taken when using the -y option on multi-user systems, since the key can be visible in the output from ps(1) or in the shell's history file. When using TSIG authentication with dig, the name server that is queried needs to know the key and algorithm that is being used. In BIND, this is done by providing appropriate key and server statements in named.conf.

Query Options The dig utility provides a number of query options which affect the way in which lookups are made and the results displayed. Some of these set or reset flag bits in the query header, some determine which sections of the answer get printed, and others determine the timeout and retry strategies.

Each query option is identified by a keyword preceded by a plus sign (+). Some keywords set or reset an option. These may be preceded by the string no to negate the meaning of that keyword. Other keywords assign values to options like the timeout interval. They have the form +keyword=*value*. The query options are:

+[no]tcp

Use [do not use] TCP when querying name servers. The default behaviour is to use UDP unless an AXFR or IXFR query is requested, in which case a TCP connection is used.

+[no]vc

Use [do not use] TCP when querying name servers. This alternate syntax to +[no]tcp is provided for backwards compatibility. The "vc" stands for "virtual circuit".

+[no]ignore

Ignore truncation in UDP responses instead of retrying with TCP. By default, TCP retries are performed.

+domain=*somename*

Set the search list to contain the single domain *somename*, as if specified in a domain directive in /etc/resolv.conf, and enable search list processing as if the +search option were given.

+[no]search

Use [do not use] the search list defined by the searchlist or domain directive in resolv.conf (if any). The search list is not used by default.

+[no]showsearch

Perform [do not perform] a search showing intermediate results.

+[no]defname

Deprecated, treated as a synonym for +[no]search.

+[no]aaonly

Sets the aa flag in the query.

+[no]aaflag

A synonym for +[no]aaonly.

+[no]adflag

Set [do not set] the AD (authentic data) bit in the query. This requests that the server return, regardless of whether all of the answer and authority sections have all been validated as secure according to the security policy of the server. A setting of AD=1 indicates that all records have been validated as secure and the answer is not from an OPT-OUT range. AD=0 indicates that some part of the answer is insecure or not validated.

+[no]cdflag

Set [do not set] the CD (checking disabled) bit in the query. This requests the server to not perform DNSSEC validation of responses.

+[no]cl

Display [do not display] the CLASS when printing the record.

+[no]ttlid

Display [do not display] the TTL when printing the record.

+[no]recurse

Toggle the setting of the RD (recursion desired) bit in the query. This bit is set by default, which means dig normally sends recursive queries. Recursion is automatically disabled when the +nssearch or +trace query options are used.

+[no]nssearch

When this option is set, dig attempts to find the authoritative name servers for the zone containing the name being looked up and display the SOA record that each name server has for the zone.

+[no]trace

Toggle tracing of the delegation path from the root name servers for the name being looked up. Tracing is disabled by default. When tracing is enabled, dig makes iterative queries to resolve the name being looked up. It will follow referrals from the root servers, showing the answer from each server that was used to resolve the lookup.

+[no]cmd

Toggle the printing of the initial comment in the output identifying the version of dig and the query options that have been applied. This comment is printed by default.

+[no]short

Provide a terse answer. The default is to print the answer in a verbose form.

+[no]identify

Show [or do not show] the IP address and port number that supplied the answer when the +*short* option is enabled. If short form answers are requested, the default is not to show the source address and port number of the server that provided the answer.

+[no]comments

Toggle the display of comment lines in the output. The default is to print comments.

+[no]stats

Toggle the printing of statistics: when the query was made, the size of the reply and so on. The default behaviour is to print the query statistics.

+[no]qr

Print [do not print] the query as it is sent. By default, the query is not printed.

+[no]question

Print [do not print] the question section of a query when an answer is returned. The default is to print the question section as a comment.

+[no]answer

Display [do not display] the answer section of a reply. The default is to display it.

+[no]authority

Display [do not display] the authority section of a reply. The default is to display it.

+[no]additional

Display [do not display] the additional section of a reply. The default is to display it.

+[no]all

Set or clear all display flags.

+time=*T*

Sets the timeout for a query to *T* seconds. The default time out is 5 seconds. An attempt to set *T* to less than 1 will result in a query timeout of 1 second being applied.

+tries=*T*

Sets the maximum number of UDP attempts to *T*. The default number is 3 (1 initial attempt followed by 2 retries). If T is less than or equal to zero, the number of retries is silently rounded up to 1.

+retry=*T*

Sets the number of UDP retries to *T*. The default is 2.

+ndots=*D*

Set the number of dots that have to appear in *name* to *D* for it to be considered absolute. The default value is that defined using the ndots statement in /etc/resolv.conf, or 1 if no ndots statement is present. Names with fewer dots are interpreted as relative names and will be searched for in the domains listed in the search or domain directive in /etc/resolv.conf.

+bufsize=*B*

Set the UDP message buffer size advertised using EDNS0 to *B* bytes. The maximum and minimum sizes of this buffer are 65535 and 0 respectively. Values outside this range are rounded up or down appropriately.

+edns=#

Specify the EDNS version with which to query. Valid values are 0 to 255. Setting the EDNS version causes a EDNS query to be sent. +noedns clears the remembered EDNS version.

+[no]multiline

Print records like the SOA records in a verbose multi-line format with human-readable comments. The default is to print each record on a single line, to facilitate machine parsing of the dig output.

+[no]fail

Do not try the next server if you receive a SERVFAIL. The default is to not try the next server which is the reverse of normal stub resolver behavior.

+[no]besteffort

Attempt to display the contents of messages which are malformed. The default is to not display malformed answers.

+[no]dnssec

Request DNSSEC records be sent by setting the DNSSEC OK bit (DO) in the OPT record in the additional section of the query.

+[no]sigchase

Chase DNSSEC signature chains. Requires dig be compiled with -DDIG_SIGCHASE.

+trusted-key=####
> Specifies a file containing trusted keys to be used with +sigchase. Each DNSKEY record must be on its own line.
>
> If not specified dig will look for /etc/trusted-key.key then trusted-key.key in the current directory.
>
> Requires dig be compiled with -DDIG_SIGCHASE.

+[no]topdown
> When chasing DNSSEC signature chains, perform a top-down validation. Requires dig be compiled with -DDIG_SIGCHASE.

+[no]nsid
> Include an EDNS name server ID request when sending a query.

Multiple Queries The BIND 9 implementation of dig supports specifying multiple queries on the command line (in addition to supporting the -f batch file option). Each of those queries can be supplied with its own set of flags, options and query options.

In this case, each *query* argument represent an individual query in the command-line syntax described above. Each consists of any of the standard options and flags, the name to be looked up, an optional query type, and class and any query options that should be applied to that query.

A global set of query options, which should be applied to all queries, can also be supplied. These global query options must precede the first tuple of name, class, type, options, flags, and query options supplied on the command line. Any global query options (except the +[no]cmd option) can be overridden by a query-specific set of query options. For example:

```
dig +qr www.isc.org any -x 127.0.0.1 isc.org ns +noqr
```

...shows how dig could be used from the command line to make three lookups: an ANY query for www.isc.org, a reverse lookup of 127.0.0.1 and a query for the NS records of isc.org. A global query option of +qr is applied, so that dig shows the initial query it made for each lookup. The final query has a local query option of +noqr which means that dig will not print the initial query when it looks up the NS records for isc.org.

/usr/sbin/directoryserver help [*subcommand*]

Description The directoryserver command is a comprehensive, front end to the utility programs provided by the Solaris Directory Server (DS).

Options for the directoryserver command itself must appear before the subcommand. Arguments for a subcommand must appear after the subcommand. Subcommands have specific arguments. See SUBCOMMANDS.

Subcommands The following subcommands are supported:

account-inactivate *args*   Inactivates and locks an entry or group of entries.

The account-inactivate subcommand supports the following arguments:

[-D *rootdn*]   Directory Server *userDN* with root permissions, such as Directory Manager.

[-h *host*]   Host name of Directory Server. The default value is the full hostname of the machine where Directory Server is installed.

-I *DN*   Entry DN or role DN to activate.

	-j *file*	Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting.
		This is considered insecure. Use with extreme caution.
	[-p *port*]	Directory Server port. The default value is the LDAP port of Directory Server specified at installation time.
	-w *password*	Password associated with the user DN. Supplying the password on the command line is visible using the /bin/ps command. This is considered insecure. Use with extreme caution.
		The value - can be used in place the password. The program prompts the user for a password to be entered from the terminal.
account-activate *args*		Activates an entry or group of entries.
		The account-activate subcommand supports the following arguments
	-D *rootdn*	Directory Server userDN with root permissions, such as Directory Manager.
	-h *host*	Host name of Directory Server. The default value is the full hostname of the machine where Directory Server is installed.
	-I DN	Entry DN or role DN to activate.
	-j *file*	Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting.
		This is considered insecure. Use with extreme caution.

	-p *port*	Directory Server port. The default value is the LDAP port of Directory Server specified at installation time.
	-w *password*	Password associated with the user DN. Supplying the password on the command line is visible using the `/bin/ps` command. This is considered insecure. Use with extreme caution.
		The value - can be used in place the password. The program prompts the user for a password to be entered from the terminal.

account-status *args* Provides account status information to establish whether an entry or group of entries is inactivated or not.

The `account-status` subcommand supports the following arguments:

-D *rootdn*

	-h *host*	Host name of Directory Server. The default value is the full hostname of the machine where Directory Server is installed.
	-I *DN*	Entry DN or role DN whose status is required.
	-j *file*	Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting.
		This is considered insecure. Use with extreme caution.
	-p *port*	Directory Server port. The default value is the LDAP port of Directory Server specified at installation time.
	-w *password*	Password associated with the rootDN. Supplying the password on the command line is visible using the

| | /bin/ps command. This is considered insecure. Use with extreme caution. |
| | The value -can be used in place of the password. The program prompts the user for a password to be entered from the terminal. |

| admin_ip *args* | Change the IP address of the administrative server in the configuration. |
| | The admin_ip subcommand supports the following arguments: |

dir_mgr_DN	Directory Manager's DN.
dir_mgr_password	Directory Manager's password.
old_ip	Old IP.
new_ip	New IP.
port_#	Port number.

| bak2db *backup_directory* | Restore the database from the most recent archived backup. |
| | Specify *backup_directory* as the backup directory. |

| bak2db-task *args* | Restore the data to the database. |
| | The bak2db-task subcommand supports the following arguments: |

| [-a *directory*] | Directory where the backup files are stored. By default it is under /var/ds5/slapd-serverID/bak |
| -D *rootDN* | User DN with root permissions, such as Directory Manager. The default is the DN of the directory manager which is read from the nsslapd-root attribute under cn=config. |

-j *file*	Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting.
	This is considered insecure. Use with extreme caution.
[-t *database_type*]	Database type. The only possible database type is ldbm.
[-v]	Verbose mode.
-w *password*	Password associated with the user DN. Supplying the password on the command line is visible using the /bin/ps command. This is considered insecure. Use with extreme caution.
	The value - can be used in place the password. The program prompts the user for a password to be entered from the terminal.

db2bak-task *args*

Back up the contents of the database. It creates an entry in the directory that launches this dynamic task. An entry is generated based upon the values provided for each option.

The db2bak-task subcommand supports the following arguments:

[-a *directory*]	Directory where the backup files are stored. By default it is under /var/ds5/slapd-serverID/bak. The backup file is named according to the year-month-day-hour format (*YYYY_MM_DD_hhmmss*).
-D *rootDN*	User DN with root permissions, such as Directory

	Manager. The default is the DN of the directory manager which is read from the nsslapd-root attribute under cn=config.
-j *file*	Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting.
	This is considered insecure. Use with extreme caution.
-t *database_type*	Database type. The only possible database type is ldbm.
[-v]	Verbose mode.
-w *password*	Password associated with the user DN. Supplying the password on the command line is visible using the /bin/ps command. This is considered insecure. Use with extreme caution.
	The value - can be used in place the password. The program prompts the user for a password to be entered from the terminal.
db2bak [*backup_directory*]	Create a backup of the current database contents. The server must be stopped to run this subcommand.
	The default is /var/ds5/slapd-serverID/bak. The backup file is named according to the year-month-day-hour format (*YYYY_MM_DD_hhmmss*).
db2index-text *args*	Create and generate the new set of indexes to be maintained following the modification of indexing entries in the cn=config configuration file.
	The db2index-text subcommand supports the following arguments:

-D *rootdn*	User DN with root permissions, such as Directory Manager.
-j *file*	Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting. This is considered insecure. Use with extreme caution.
-n *backend_instance*	Instance to be indexed.
[-t *attributeName*]	Name of the attribute to be indexed. If omitted, all indexes defined for that instance are generated.
[-v]	Verbose mode.
-w *password*	Password associated with the user DN. Supplying the password on the command line is visible using the /bin/ps command. This is considered insecure. Use with extreme caution.
	The value - can be used in place the password. The program prompts the user for a password to be entered from the terminal.

db2ldif-task *args*	Exports the contents of the database to LDIF. It creates an entry in the directory that launches this dynamic task. The entry is generated based upon the values you provide for each option. To run this subcommand the server must be running and either -n *backend_instance* or -s *include* suffix is required.

The db2ldif-task subcommand supports the following arguments:

[-a *outputfile*]	File name of the output LDIF file.

-C	Only the main db file is used.
-D *rootDN*	User DN with root permissions, such as Directory Manager.
-j *file*	Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting. This is considered insecure.Use with extreme caution.
[-M]	Output LDIF is stored in multiple files.
[-m]	Minimal base 64 encoding.
{-n *backend_instance*}*	Instance to be exported.
[-N]	Minimal base 64 encoding.
[-o]	Output LDIF to be stored in one file by default with each instance stored in *instance_file* name.
[-r]	Export replica.
[-s]*includesuffix*}*	Suffix(es) to be included or to specify the subtrees to be included if -n has been used.
[-u]	Request that the unique ID is not exported.
[-U]	Request that the output LDIF is not folded.
-w *password*	Password associated with the user DN. Supplying the password on the command line is visible

	using the /bin/ps command. This is considered insecure. Use with extreme caution.
	The value - can be used in place the password. The program prompts the user for a password to be entered from the terminal.
{-x *excludesuffix*}*	Suffixes to be excluded.
[-1]	Delete, for reasons of backward compatibility the first line of the LDIF file that gives the version of the LDIF standard.

db2ldif *args* Export the contents of the database to LDIF. You must specify either the -n or the -s option or both.

The db2ldif subcommand supports the following options:

[-a *outputfile*]	File name of the output LDIF file.
[-C]	Only use the main db file.
[-m]	Minimal base64 encoding.
[-M]	Use of several files for storing the output LDIF with each instance stored in *instance_file name* (where file name is the file name specified for -a option).
{-n *baclemd_instance*}*	Instance to be exported.
[-N]	Specify that the entry IDs are not to be included in the LDIF output. The entry IDs are necessary

		only if the db2ldif output is to be used as input to db2index-text.
	[-r]	Export replica.
	{-s *includesuffix*}*	Suffixes to be included or to specify the subtrees to be included if -n has been used.
	[{-x *excludesuffix*}]*	Suffixes to be excluded.
	[-u]	Request that the unique id is not exported.
	[-U]	Request that the output LDIF is not folded.
	[-1]	Delete, for reasons of backward compatibility, the first line of the LDIF file which gives the version of the LDIF standard.

help [*subcommand*]   Display directoryserver usage message or subcommand specific usage message.

idsktune *args*   Provide an easy and reliable way of checking the patch levels and kernel parameter settings for your system. You must install the Directory Server before you can run idsktune. It gathers information about the operating system, kernel, and TCP stack to make tuning recommendations.

The idsktune subcommand supports the following arguments:

[-c]	Client-specific tuning: the output only includes tuning recommendations for running a directory client application.
[-D]	Debug mode: the output includes the commands it runs internally, preceded by DEBUG heading.
[-i *installdir*]	The install directory.

| | | [-q] | Quiet mode. Output only includes tuning recommendations. OS version statements are omitted. |
| | | [-v] | Version. Gives the build date identifying the version of the toll. |

keyupg *args*

Upgrade the key from Lite to normal (only one way).

The keyupg subcommand supports the following arguments:

| -k*key* | The key to be upgraded. |
| -f *key_file_path* | The key file path. |

ldif2db-task args

Import data to the directory. It create an entry in the directory that launches this dynamic task. The entry is generated based upon the values you provide for each option. The server must be running when you run this subcommand.

The ldif2sb-task subcommand supports the following arguments:

[-c]	Request that only the core db is created without attribute indexes.
-D rootDN	User DN with root permissions, such as Directory Manager.
[-g *string*]	Generation of a unique ID. Enter none for no unique ID to be generated and deterministic for the generated unique ID to be name-based. Generates a time based unique ID by default.
	If you use the deterministic generation to have a name-based unique ID, you can also

specify the namespace you want the server to use as follows:

`-g deterministic` *namespace_id*

where namespace_id is a string of characters in the following format

`00-xxxxxxxx-xxxxxxxx-xxxxxxxx-xxxxxxxx`

Use this option if you want to import the same LDIF file into two different directory servers, and you want the contents of both directories to have the same set of unique IDs. If unique IDs already exist in the LDIF file you are importing, then the existing IDs are imported to the server regardless of the options you have specified.

[`-G` *namespace_id*]	Generate a namespace ID as a name-based unique ID. This is the same as specifying `-g deterministic`.
{ `-i` *filename*}*	File name of the input LDIF files. When you import multiple files, they are imported in the order in which you specify them on the command line.
`-j` *file*	Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting. This is considered insecure. Use with extreme caution.
`-n` backend_instance	Instance to be imported.

	[-O]	Request that only the core db is created without attribute indexes.
	{-s *includesuffix* }*	Suffixes to be included. This argument can also be used to specify the subtrees to be included with -n.
	-w *password*	Password associated with the user DN. Supplying the password on the command line is visible using the /bin/ps command. This is considered insecure. Use with extreme caution.
		The value - can be used in place the password. The program prompts the user for a password to be entered from the terminal.
	[{-x *excludesuffix* }*]	
	[-v]	Verbose mode.

ldif *args*   Format LDIF files, and create base 64 encoded attribute values. With Base 64 Encoding you can represent binary data, such as a JPEG image, in LDIF by using base 64 encoding. You identify base 64 encoded data by using the : : symbol. The ldifsubcommand takes any input and formats it with the correct line continuation and appropriate attribute information. The subcommand also senses whether the input requires base 64 encoding.

The ldif subcommand supports the following arguments

[-b]   Interpret the entire input as a single binary value. If -b is not present, each line is considered to be a separate input value.

[*attrtype*] If -b is specified, the output is attrtype:: <base 64 encoded

value.

ldif2db *args* Import the data to the directory. To run this subcommand the server must be stopped. Note that ldif2db supports LDIF version 1 specifications. You can load an attribute using the URL specifier notation, for example:
jpegphoto:file:///tmp/myphoto.jpg

[-c] Merge chunk size.

[-g *string*] Generation of a unique ID. Type none for no unique ID to be generated and deterministic for the generated unique ID to be name-based. By default a time based unique ID is generated.

If you use the deterministic generation to have a name-based unique ID, you can also specify the namespace you want the server to use as follows:

-g deterministic *namespace_id*

where *namespace_id* is a string of characters in the following format:

00-xxxxxxxx-xxxxxxxx-xxxxxxxx-xxxxxxxx

Use this option if you want to import the same LDIF file into two different directory servers, and you want the contents of both directories to have the same set of unique IDs. If unique IDs already exist in the LDIF file you are importing, then the existing IDs are imported to the server regardless of the options you have specified.

[-G *naemspace_id*]	Generate a namespace ID as a name-based unique ID. This is the same as specifying the -g deterministic option.
{- *filename*}*	File name of the input LDIF file(s). When you import multiple files, they are imported in the order in which you specify them on the command line.
-n *backend_instance*	Instance to be imported.
[-O]	Request that only the core db is created without attribute indexes.
{-s *includesuffix*}*	Suffixes to be included or to specify the subtrees to be included if -n has been used.
[{-x *excludesuffix*}*]	Suffixes to be excluded

ldif2ldap *rootDN password filename*
Perform an import operation over LDAP to the Directory Server. To run this subcommand the server must be running.

The ldif2ldap subcommand supports the following arguments:

rootdn	User DN with root permissions, such as Directory Manager.
password	Password associated with the user DN.
filename	File name of the file to be imported. When you import multiple files, they are imported in the order in which you specify them on the command line.

magt CONFIG INIT
Start SNMP master agent. The Config and INIT files are in /usr/iplanet/ds5/plugins/snmp/magt. For more information, see the *iPlanet Directory Server 5.1 Administrator's Guide*.

The magt subcommand supports the following options:

CONFIG   The CONFIG file defines the community and the manager that master agent works with. Specify the manager value as a valid system name or an IP address.

INIT   The INIT file is a nonvolatile file that contains information from the MIB-II system group, including system location and contact information. If INIT doesn't already exist, starting the master agent for the first time creates it. An invalid manager name in the CONFIG file causes the master agent start-up to fail.

monitor   Retrieves performance monitoring information using the ldapsearch command-line utility.

mmldif *args*   Combine multiple LDIF files into a single authoritative set of entries. Typically each LDIF file is from a master server cooperating in a multi master replication agreement.[e.g. masters that refuse to sync up for whatever reason]. Optionally, it can generate LDIF change files that could be applied to original to bring it up to date with authoritative. At least two input files must be specified.

The mmldif subcommand supports the following arguments:

[-c *inputfile* ...]   Write a change file (.delta) for each input file. Specify *inputfile* as the input LDIF files.

[-D]   Print debugging information.

[-o *out.ldif*]   Write authoritative data to this file.

nativetoascii *args*   Convert one language encoding to another. For example, convert a native language to UTF-8 format.

The nativetoascii subcommand supports the following options:

-d *Encodings Directory*   Path to the

		directory which contains the conv directory
	[-i *input_filename* -o *output_filename*]	The input file name and output file name.
	-l	List supported encodings
	-r	Replace existing files.
	-s *suffix*	Suffix to be mapped to the backend.
	-s *SourceEncoding*	Source Encoding of input stream.
	-t *TargetEncoding*	Target Encoding of output stream.
	-v	Verbose output.
pwdhash *args*		Print the encrypted form of a password using one of the server's encryption algorithms. If a user cannot log in, you can use this script to compare the user's password to the password stored in the directory.
		The pwdhash subcommand supports the following arguments:

-c *comparepwd* | -s *scheme*	The available schemes are SSHA, SHA, CRYPT and CLEARE. It generates the encrypted passwords according to scheme's algorithm. The -c specifies the encrypted password to be compared with. The result of comparison is either OK or doesn't match.
-D *instance-dir*	The instance directory.
[-H]	The passwords are hex-encoded.
password ...	The clear passwords to generate encrypted form from or to be compared with.

restart   Restarts the directory server.

When the -s option is not specified, restarts all instances of servers. When the -s option is specified, restarts the server specified by -s.

restart-admin

Restarts the administration server.

restoreconfig   Restores the most recently saved Administration Server configuration information to the NetscapeRoot partition under /var/ds5/slapd-serverID/confbak.

sagt -c CONFIG   Start proxy SNMP agent. For more information, see the *iPlanet Directory Server 5.1 Administrator's Guide*.

The sagt subcommand supports the following options:

	-c *configfile*	The CONFIG file includes the port that the SNMP daemon listens to. It also needs to include the MIB trees and traps that the proxy SNMP agent forwards. Edit the CONFIG file located in /usr/iplanet/ds5/plugins/snmp/sagt.
saveconfig		Saves the administration server configuration information to the /var/ds5/slapd-serverID/confbak directory.
setup [-f *configuration_file*]		Configures an instance of the directory server or administration server. Creates a basic configuration for the directory server and the administrative server that is used to manage the directory.

The setup subcommand has two modes of operation. You can invoke it with a curses-based interaction to gather input. Alternatively, you can provide input in a configuration file using the -f option.

The setup subcommand supports the following option:

-f *configuration_file*

Specifies the configuration file for silent installation.

start	Starts the directory server. When the -s option is not specified, starts servers of all instances. When the -s option is specified, starts the server instance specified by -s.
start-admin	Starts the directory server.

When the -s option is not specified, restarts all instances of servers. When the -s option is specified, restarts the server specified by -s.

startconsole	Starts the directory console..
stop	Stops the directory server.

When the -s option is not specified, restarts all instances of servers. When the -s option is specified, restarts the server specified by -s.

stop-admin	Stop the administration server.

suffix2instance { -s *suffix*}	Map a suffix to a backend name.
	Specify -s *suffix* as the suffix to be mapped to the backend.
uninstall	Uninstalls the directory server and the administration server.
	This subcommand stops servers of all instances and removes all the changes created by setup.
vlvindex *args*	Create virtual list view (VLV) indexes, known in the Directory Server Console as Browsing Indexes. The server must be stopped beforehand.
	The vlvindex subcommand supports the following arguments:

	-d *debug_level*	Specify the debug level to use during index creation. Debug levels are defined in nsslapd-errorlog-level (error Log Level). See the *iPlanet Directory Server 5.1 Configuration, Command, and File Reference*.
	-n *backend_instance*	Name of the database containing the entries to index.
	-s *suffix*	Name of the suffix containing the entries to index.
	-T *VLVTag*	Name of the database containing the entries to index.

Options Options for the directoryserver command itself must appear before the subcommand argument.

The following options are supported:

-s *server-instance*
-server *server-instance*   The server instance name. Specify the directory server instance to process the command against. For some of the listed subcommands the server instance is optional and for other sub

commands it is a required option.

Examples   **EXAMPLE 1**   Starting All Instances of the Directory Servers

The following command starts all the instances of the directory servers:

```
example% directoryserver start
```

EXAMPLE 2   Starting the Instances of myhost of the Directory Server

The following command starts the instances myhost of the directory server.

```
example% directoryserver -s myhost start
```

EXAMPLE 3   Running the Monitor Tool and Outputting the Current Status

The following command runs the monitor tool and output the current status of the ephesus directory instance.

```
example% directoryserver -s ephesus monitor
```

EXAMPLE 4   Running the idsktune Tool and Outputting Performance Tuning Information

The following command runs the idsktune tool and outputs performance tuning information:

```
example% directoryserver idsktune
```

Exit Status   The following exit values are returned:

0   Successful completion.

non-zero   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

iPlanet Directory Server 5.1 Configuration, Command, and File Reference

Name disks – creates /dev entries for hard disks attached to the system

Synopsis /usr/sbin/disks [-C] [-r *rootdir*]

Description [devfsadm(1M)](devfsadm) is now the preferred command for /dev and should be used instead of disks.

disks creates symbolic links in the /dev/dsk and /dev/rdsk directories pointing to the actual disk device special files under the /devices directory tree. It performs the following steps:

1. disks searches the kernel device tree to see what hard disks are attached to the system. It notes the /devices pathnames for the slices on the drive and determines the physical component of the corresponding /dev/dsk or /dev/rdsk name.

2. The /dev/dsk and /dev/rdsk directories are checked for disk entries – that is, symbolic links with names of the form cN[tN]dNsN, or cN[tN]dNpN, where N represents a decimal number. cN is the logical controller number, an arbitrary number assigned by this program to designate a particular disk controller. The first controller found on the first occasion this program is run on a system, is assigned number 0. tN is the bus-address number of a subsidiary controller attached to a peripheral bus such as SCSI or IPI (the target number for SCSI, and the facility number for IPI controllers). dN is the number of the disk attached to the controller. sN is the *slice* number on the disk. pN is the FDISK partition number used by [fdisk(1M)](fdisk). (x86 Only)

3. If only some of the disk entries are found in /dev/dsk for a disk that has been found under the /devices directory tree, disks creates the missing symbolic links. If none of the entries for a particular disk are found in /dev/dsk, disks checks to see if any entries exist for other disks attached to the same controller, and if so, creates new entries using the same controller number as used for other disks on the same controller. If no other /dev/dsk entries are found for slices of disks belonging to the same physical controller as the current disk, disks assigns the lowest-unused controller number and creates entries for the disk slices using this newly-assigned controller number.

disks is run automatically each time a reconfiguration-boot is performed or when [add_drv(1M)](add_drv) is executed. When invoking disks manually, first run [drvconfig(1M)](drvconfig) to ensure /devices is consistent with the current device configuration.

Notice to Driver Writers disks considers all devices with a node type of DDI_NT_BLOCK, DDI_NT_BLOCK_CHAN, DDI_NT_CD, DDI_NT_BLOCK_WWN or DDI_NT_CD_CHAN to be disk devices. disks requires the minor name of disk devices obey the following format conventions.

The minor name for block interfaces consists of a single lowercase ASCII character, a through u, representing the slices and the primary partitions. The minor name for logical drive block interfaces consists of the strings p5 through p36. The minor name for character (raw) interfaces consists of a single lowercase ASCII character, a through a, followed by the string ,raw, representing the slices and the primary partitions. The minor name for logical drive character (raw) interfaces consists of the string p5 through p36 followed by ,raw.

disks performs the following translations:

- a through p to s0 through s15
- q through u to p0 through p4
- p5 through p36 to p5 through p36

SPARC drivers should only use the first eight slices: a through h, while x86 drivers can use a through u, with q through u corresponding to fdisk(1M) primary partitions. q represents the entire disk, while r, s, t, and u represent up to four additional primary partitions. For logical drives, p5 to p36 correspond to the 32 logical drives that are supported. The device nodes for logical drives change dynamically as and when they are created or deleted.

To prevent disks from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using a node type: DDI_NT_BLOCK, DDI_NT_BLOCK_CHAN, DDI_NT_CD, or DDI_NT_CD_CHAN when calling ddi_create_minor_node(9F).

Options The following options are supported:

-C   Causes disks to remove any invalid links after adding any new entries to /dev/dsk and /dev/rdsk. Invalid links are links which refer to non-existent disk nodes that have been removed, powered off, or are otherwise inaccessible.

-r *rootdir*   Causes disks to presume that the /dev/dsk, /dev/rdsk and /devices directory trees are found under *rootdir*, not directly under /.

Errors If disks finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the /dev directory, since it cannot determine which of the two alternative logical-to-physical mappings is correct. The links should be manually corrected or removed before another reconfiguration-boot is performed.

Examples EXAMPLE 1   Creating Block and Character Minor Devices

The following example demonstrates creating the block and character minor devices from within the xkdisk driver's attach(9E) function.

```
#include    <sys/dkio.h>
/*
 * Create the minor number by combining the instance number
 * with the slice number.
 */
#define MINOR_NUM(i, s)   ((i) << 4 | (s))

int
xkdiskattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance, slice;
    char name[8];
```

EXAMPLE 1 Creating Block and Character Minor Devices   *(Continued)*

```
        /* other stuff in attach... */

    instance = ddi_get_instance(dip);
    for (slice = 0; slice < V_NUMPAR; slice++) {
        /*
         * create block device interface
         */
        sprintf(name, "%c", slice + 'a');
        ddi_create_minor_node(dip, name, S_IFBLK,
            MINOR_NUM(instance, slice), DDI_NT_BLOCK_CHAN, 0);

        /*
         * create the raw (character) device interface
         */
        sprintf(name,"%c,raw", slice + 'a');
        ddi_create_minor_node(dip, name, S_IFCHR,
            MINOR_NUM(instance, slice), DDI_NT_BLOCK_CHAN, 0);
    }
}
```

Installing the xkdisk disk driver on a Sun Fire 4800, with the driver controlling a SCSI disk (target 3 attached to an isp(7D) SCSI HBA) and performing a reconfiguration-boot (causing disks to be run) creates the following special files in /devices.

```
# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/SUNW,isptwo@4/
brw-r-----  1 root sys  32, 16 Aug 29 00:02 xkdisk@3,0:a
crw-r-----  1 root sys  32, 16 Aug 29 00:02 xkdisk@3,0:a,raw
brw-r-----  1 root sys  32, 17 Aug 29 00:02 xkdisk@3,0:b
crw-r-----  1 root sys  32, 17 Aug 29 00:02 xkdisk@3,0:b,raw
brw-r-----  1 root sys  32, 18 Aug 29 00:02 xkdisk@3,0:c
crw-r-----  1 root sys  32, 18 Aug 29 00:02 xkdisk@3,0:c,raw
brw-r-----  1 root sys  32, 19 Aug 29 00:02 xkdisk@3,0:d
crw-r-----  1 root sys  32, 19 Aug 29 00:02 xkdisk@3,0:d,raw

Writing Device Drivers

Bugs disks silently ignores malformed minor device names.

Name diskscan – perform surface analysis

Synopsis diskscan [-W] [-n] [-y] *raw_device*

Description diskscan is used by the system administrator to perform surface analysis on a portion of a hard disk. The disk portion may be a raw partition or slice; it is identified using its raw device name. By default, the specified portion of the disk is read (non-destructive) and errors reported on standard error. In addition, a progress report is printed on standard out. The list of bad blocks should be saved in a file and later fed into addbadsec(1M), which will remap them.

Options The following options are supported:

-n   Causes diskscan to suppress linefeeds when printing progress information on standard out.

-W   Causes diskscan to perform write and read surface analysis. This type of surface analysis is destructive and should be invoked with caution.

-y   Causes diskscan to suppress the warning regarding destruction of existing data that is issued when -W is used.

Operands The following operands are supported:

raw_device   The address of the disk drive (see FILES).

Files The raw device should be /dev/rdsk/c?[t?]d?[ps]?. See disks(1M) for an explanation of SCSI and IDE device naming conventions.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	x86
Availability	system/core-os

See Also addbadsec(1M), disks(1M), fdisk(1M), fmthard(1M), format(1M), attributes(5)

Notes The format(1M) utility is available to format, label, analyze, and repair SCSI disks. This utility is included with the diskscan, addbadsec(1M), fdisk(1M), and fmthard(1M) commands available for x86. To format an IDE disk, use the DOS format utility; however, to label, analyze, or repair IDE disks on x86 systems, use the Solaris format(1M) utility.

Name dispadmin – process scheduler administration

Synopsis dispadmin -l

dispadmin -c *class* {-g [-r *res*] | -s *file*}

dispadmin -d [*class*]

Description The dispadmin command displays or changes process scheduler parameters while the system is running.

dispadmin does limited checking on the values supplied in *file* to verify that they are within their required bounds. The checking, however, does not attempt to analyze the effect that the new values have on the performance of the system. Inappropriate values can have a negative effect on system performance. (See *Oracle Solaris Administration: Common Tasks*.)

Options The following options are supported:

-c *class*

Specifies the class whose parameters are to be displayed or changed. Valid *class* values are: RT for the real-time class, TS for the time-sharing class, IA for the inter-active class, FSS for the fair-share class, and FX for the fixed-priority class. The time-sharing and inter-active classes share the same scheduler, so changes to the scheduling parameters of one will change those of the other.

-d [*class*]

Sets or displays the name of the default scheduling class to be used on reboot when starting svc:/system/scheduler:default. If class name is not specified, the name and description of the current default scheduling class is displayed. If class name is specified and is a valid scheduling class name, then it is saved in dispadmin's private configuration file /etc/dispadmin.conf. Only super-users can set the default scheduling class.

-g

Gets the parameters for the specified class and writes them to the standard output. Parameters for the real-time class are described in rt_dptbl(4). Parameters for the time-sharing and inter-active classes are described in ts_dptbl(4). Parameters for the fair-share class are described in FSS(7). Parameters for the fixed-priority class are described in fx_dptbl(4).

The -g and -s options are mutually exclusive: you may not retrieve the table at the same time you are overwriting it.

-l

Lists the scheduler classes currently configured in the system.

-r *res*

When using the -g option you may also use the -r option to specify a resolution to be used for outputting the time quantum values. If no resolution is specified, time quantum values are in milliseconds. If *res* is specified it must be a positive integer between 1 and 1000000000 inclusive, and the resolution used is the reciprocal of *res* in seconds. For

example, a *res* value of 10 yields time quantum values expressed in tenths of a second; a *res* value of 1000000 yields time quantum values expressed in microseconds. If the time quantum cannot be expressed as an integer in the specified resolution, it is rounded up to the next integral multiple of the specified resolution.

-s *file*

Sets scheduler parameters for the specified class using the values in *file*. These values overwrite the current values in memory—they become the parameters that control scheduling of processes in the specified class. The values in *file* must be in the format output by the -g option. Moreover, the values must describe a table that is the same size (has same number of priority levels) as the table being overwritten. Super-user privileges are required in order to use the -s option.

Specify time quantum values for scheduling classes in system clock ticks, and not in constant-time units. Time quantum values are based on the value of the kernel's hz variable. If kernel variable hires_tick is set to 1 to get higher resolution clock behavior, the actual time quanta will be reduced by the order of 10.

The -g and -s options are mutually exclusive: you may not retrieve the table at the same time you are overwriting it.

Examples   **EXAMPLE 1**   Retrieving the Current Scheduler Parameters for the real-time class

The following command retrieves the current scheduler parameters for the real-time class from kernel memory and writes them to the standard output. Time quantum values are in microseconds.

```
dispadmin -c RT -g -r 1000000
```

EXAMPLE 2   Overwriting the Current Scheduler Parameters for the Real-time Class

The following command overwrites the current scheduler parameters for the real-time class with the values specified in rt.config.

```
dispadmin -c RT -s rt.config
```

EXAMPLE 3   Retrieving the Current Scheduler Parameters for the Time-sharing Class

The following command retrieves the current scheduler parameters for the time-sharing class from kernel memory and writes them to the standard output. Time quantum values are in nanoseconds.

```
dispadmin -c TS -g -r 1000000000
```

EXAMPLE 4   Overwriting the Current Scheduler Parameters for the Time-sharing Class

The following command overwrites the current scheduler parameters for the time-sharing class with the values specified in ts.config.

```
dispadmin -c TS -s ts.config
```

Files /etc/dispadmin.conf

Possible location for argument to -s option.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also priocntl(1), svcs(1), svcadm(1M), priocntl(2), fx_dptbl(4), rt_dptbl(4), ts_dptbl(4), attributes(5), smf(5), FSS(7)

Oracle Solaris Administration: Common Tasks Programming Interfaces Guide

Diagnostics dispadmin prints an appropriate diagnostic message if it fails to overwrite the current scheduler parameters due to lack of required permissions or a problem with the specified input file.

Notes The default scheduling class setting facility is managed by the service management facility, smf(5), under the service identifier:

svc:/system/scheduler:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Note that disabling the service while it is running will not change anything. The service's status can be queried using the svcs(1) command.

Name   dladm – administer data links

Synopsis   dladm show-link [-PZ] [-s [-i *interval*]] [[-p] -o *field*[,...]]

dladm show-usage [-a] -f filename [-p plotfile -F format] [-s time]
    [-e time] [link]
```

Description   The dladm command is used to administer data-links. A data-link is represented in the system as a STREAMS DLPI (v2) interface which can be plumbed under protocol stacks such as TCP/IP. Each data-link relies on either a single network device or an aggregation of devices to send packets to or receive packets from a network.

Each dladm subcommand operates on one of the following objects:

link

A datalink, identified by a name. In general, the name can use any alphanumeric characters (or the underscore, _, or the period, .), but must start with an alphabetic character and end with a number. A datalink name can be at most 31 characters, and the ending number must be between 0 and 4294967294 (inclusive). The ending number must not begin with a zero. Datalink names between 3 and 8 characters are recommended.

Some subcommands operate only on certain types or classes of datalinks. For those cases, the following object names are used:

aggr-link
  An aggregation datalink (or a key; see NOTES).

ether-link
  A physical Ethernet datalink.

iptun-link
  An IP tunnel link.

part-link
  An InfiniBand (IB) partition data link.

phys-link
  A physical datalink.

vlan-link
  A VLAN datalink.

vnic-link
  A virtual network interface created on a link or an etherstub. It is a pseudo device that
  can be treated as if it were an network interface card on a machine.

wifi-link
  A WiFi datalink.

bridge
  A bridge instance, identified by an administratively-chosen name. The name may use any
  alphanumeric characters or the underscore, _, but must start and end with an alphabetic
  character. A bridge name can be at most 31 characters. The name default is reserved, as
  are all names starting with SUNW.

  Note that appending a zero (0) to a bridge name produces a valid link name, used for
  observability.

  Also note that the bridge-related subcommands, described with dladm subcommands
  below, require installation of the pkg://solaris/network/bridging package.

dev
  A network device, identified by concatenation of a driver name and an instance number.

etherstub
  An Ethernet stub can be used instead of a physical NIC to create VNICs. VNICs created on
  an etherstub will appear to be connected through a virtual switch, allowing complete
  virtual networks to be built without physical hardware.

part
  An IB partition link created on a IB physical link.

secobj
  A secure object, identified by an administratively-chosen name. The name can use any
  alphanumeric characters, as well as underscore (_), period (.), and hyphen (-). A secure
  object name can be at most 32 characters.

Options   Each dladm subcommand has its own set of options. However, many of the subcommands have the following as a common option:

-R *root-dir*, --root-dir=*root-dir*
Specifies an alternate root directory where the operation-such as creation, deletion, or renaming-should apply.

SUBCOMMANDS   The following subcommands are supported:

dladm show-link [-PZ] [-s [-i *interval*]] [[-p] -o *field*[,...]] [-z *zone*[,...]] [*link*]
Show link configuration information either for all datalinks or for the specified link. By default, the system is configured with one datalink for each known network device. The option to print link statistics is moved to dlstat(1M).

-o *field*[,...], --output=*field*[,...]
A case-insensitive, comma-separated list of output fields to display. When not modified by the -s option (described below), the field name must be one of the fields listed below, or the special value all to display all fields. By default (without -o), show-link displays all fields.

LINK
The name of the datalink.

ZONE
The current zone of the datalink.

CLASS
The class of the datalink. dladm distinguishes between the following classes:

aggr
An IEEE 802.3ad link aggregation. The show-aggr subcommand displays more detail for this class of datalink.

bridge
A bridge instance, identified by an administratively-chosen name.

etherstub
Instance of an etherstub. An Ethernet stub can be used instead of a physical NIC to create VNICs. VNICs created on an etherstub will appear to be connected through a virtual switch, allowing complete virtual networks to be built without physical hardware.

iptun
An instance of an IP tunnel link.

part
An IP-over-IB interface. The show-part subcommand displays more detail for this class of datalink.

phys
>   A physical datalink. The show-phys subcommand displays more detail for this class
>   of datalink.

vlan
>   A VLAN datalink. The show-vlan subcommand displays more detail for this class of
>   datalink.

vnic
>   A virtual network interface. The show-vnic subcommand displays more detail for
>   this class of datalink.

MTU
>   The maximum transmission unit size for the datalink being displayed.

STATE
>   The link state of the datalink. The state can be up, down, or unknown.

BRIDGE
>   The name of the bridge to which this link is assigned, if any.

OVER
>   The physical datalink(s) over which the datalink is operating. This applies to aggr,
>   bridge, and vlan and part partition classes of datalinks. A VLAN or IB partition is
>   created over a single physical datalink, a bridge has multiple attached links, and an
>   aggregation is comprised of one or more physical datalinks.

When the -o option is used in conjunction with the -s option, used to display link
statistics, the field name must be one of the fields listed below, or the special value all to
display all fields

LINK
>   The name of the datalink.

IPACKETS
>   Number of packets received on this link.

RBYTES
>   Number of bytes received on this link.

IERRORS
>   Number of input errors.

OPACKETS
>   Number of packets sent on this link.

OBYTES
>   Number of bytes sent on this link.

OERRORS
>   Number of output errors.

-p, --parseable

Display using a stable machine-parseable format. The -o option is required with -p. See "Parseable Output Format", below.

-P, --persistent

Display the persistent link configuration.

-s, --statistics

Display link statistics. This option is made obsolete by dlstat(1M).

-i *interval*, --interval=*interval*

Used with the -s option to specify an interval, in seconds, at which statistics should be displayed. This option is made obsolete by dlstat(1M).

-Z

Display ZONE column in the output.

-z *zone*[,...]

Display links from the specified zones. By default, dladm displays links in all the zones when it is run from the global zone. The links in other zones are displayed with the corresponding zonename as its prefix, followed by the slash (/) separator. For example, zone1/net0

When run from a non-global zone, this subcommand displays only links from that zone. A non-global zone cannot see links in other zones.

dladm rename-link [-R *root-dir*] *link new-link*

Rename *link* to *new-link*. This is used to give a link a meaningful name, or to associate existing link configuration such as link properties of a removed device with a new device. See the EXAMPLES section for specific examples of how this subcommand is used.

-R *root-dir*, --root-dir=*root-dir*

See "Options," above.

dladm delete-phys *phys-link*

This command is used to delete the persistent configuration of a link associated with physical hardware which has been removed from the system. See the EXAMPLES section.

dladm show-phys [-PZ] [-Lm] [[-p] -o *field*[,...]] [-H] [-z *zone*[,...]] [*phys-link*]

Show the physical device and attributes of all physical links, or of the named physical link. Without -P, only physical links that are available on the running system are displayed.

-H

Show hardware resource usage, as returned by the NIC driver. Output from -H displays the following elements:

LINK

A physical device corresponding to a NIC driver.

RINGTYPE

The type of the ring, either RX or TX.

RINGS

> The ring index. A ring is an hardware resource, which typically maps to a DMA channel, that can be programmed for specific use. For example, an RX ring can be programmed to receive only packets belonging to a specific MAC address.

CLIENTS

> MAC clients that are using the rings.

-L

> Display location information for the physical devices/links. Output is in location order—that is, onboard devices before expansion slots—and location information (for example, PCIexp Slot 2, MB) is supplied where available. Output from -L supports the following elements:

LINK

> A physical device corresponding to a NIC driver.

DEVICE

> The name of the physical device under this link.

LOC

> Physical location description string (where available).

-m

> Display the list of factory MAC addresses, their slot identifiers, and their availability.

-o *field*, --output=*field*

> A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all, to display all fields. For each link, the following fields can be displayed:

LINK

> The name of the datalink.

MEDIA

> The media type provided by the physical datalink.

STATE

> The state of the link. This can be up, down, or unknown.

SPEED

> The current speed of the link, in megabits per second.

DUPLEX

> For Ethernet links, the full/half duplex status of the link is displayed if the link state is up. The duplex is displayed as unknown in all other cases.

DEVICE

> The name of the physical device under this link.

-p, --parseable

Display using a stable machine-parseable format. The -o option is required with -p. See "Parseable Output Format", below.

-P, --persistent

This option displays persistent configuration for all links, including those that have been removed from the system. The output provides a FLAGS column in which the r flag indicates that the physical device associated with a physical link has been removed. For such links, delete-phys can be used to purge the link's configuration from the system.

-Z

Display ZONE column in the output.

-z *zone*[,...]

See description of -z option under dladm show-link, above.

dladm create-aggr [-t] [-R *root-dir*] [-P *policy*] [-L *mode*] [-T *time*] [-u *address*] -l *ether-link1* [-l *ether-link2*...] *aggr-link*

Combine a set of links into a single IEEE 802.3ad link aggregation named *aggr-link*. The use of an integer *key* to generate a link name for the aggregation is also supported for backward compatibility. Many of the *-aggr subcommands below also support the use of a *key* to refer to a given aggregation, but use of the aggregation link name is preferred. See the NOTES section for more information on keys.

dladm supports a number of port selection policies for an aggregation of ports. (See the description of the -P option, below.) If you do not specify a policy, create-aggr uses the default, the L4 policy, described under the -P option.

-l *ether-link*, --link=*ether-link*

Each Ethernet link (or port) in the aggregation is specified using an -l option followed by the name of the link to be included in the aggregation. Multiple links are included in the aggregation by specifying multiple -l options. For backward compatibility with previous versions of Solaris, the dladm command also supports the using the -d option (or --dev) with a device name to specify links by their underlying device name. The other *-aggr subcommands that take -l options also accept -d.

-t, --temporary

Specifies that the aggregation is temporary. Temporary aggregations last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*

See "Options," above.

-P *policy*, --policy=*policy*

Specifies the port selection policy to use for load spreading of outbound traffic. The policy specifies which *dev* object is used to send packets. A policy is a list of one or more layers specifiers separated by commas. A layer specifier is one of the following:

L2

Select outbound device according to source and destination MAC addresses of the packet.

L3

Select outbound device according to source and destination IP addresses of the packet.

L4

Select outbound device according to the upper layer protocol information contained in the packet. For TCP and UDP, this includes source and destination ports. For IPsec, this includes the SPI (Security Parameters Index).

For example, to use upper layer protocol information, the following policy can be used:

-P L4

Note that policy L4 is the default.

To use the source and destination MAC addresses as well as the source and destination IP addresses, the following policy can be used:

-P L2,L3

-L *mode*, --lacp-mode=*mode*
Specifies whether LACP should be used and, if used, the mode in which it should operate. Supported values are off, active or passive.

-T *time*, --lacp-timer=*time*
Specifies the LACP timer value. The supported values are short or long.

-u *address*, --unicast=*address*
Specifies a fixed unicast hardware address to be used for the aggregation. If this option is not specified, then an address is automatically chosen from the set of addresses of the component devices.

dladm modify-aggr [-t] [-R *root-dir*] [-P *policy*] [-L *mode*] [-T *time*] [-u *address*] *aggr-link*
Modify the parameters of the specified aggregation.

-t, --temporary
Specifies that the modification is temporary. Temporary aggregations last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*
See "Options," above.

-P *policy*, --policy=*policy*
Specifies the port selection policy to use for load spreading of outbound traffic. See dladm create-aggr for a description of valid policy values.

-L *mode*, --lacp-mode=*mode*
    Specifies whether LACP should be used and, if used, the mode in which it should operate. Supported values are off, active, or passive.

-T *time*, --lacp-timer=*time*
    Specifies the LACP timer value. The supported values are short or long.

-u *address*, --unicast=*address*
    Specifies a fixed unicast hardware address to be used for the aggregation. If this option is not specified, then an address is automatically chosen from the set of addresses of the component devices.

    (Note that modification of the fixed unicast hardware address will override any previously defined mac-address link property defined for the aggregation. See "General Link Properties".)

dladm delete-aggr [-t] [-R *root-dir*] *aggr-link*
    Deletes the specified aggregation.

-t, --temporary
    Specifies that the deletion is temporary. Temporary deletions last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*
    See "Options," above.

dladm add-aggr [-t] [-R *root-dir*] -l *ether-link1* [--link=*ether-link2*...] *aggr-link*
    Adds links to the specified aggregation.

-l *ether-link*, --link=*ether-link*
    Specifies an Ethernet link to add to the aggregation. Multiple links can be added by supplying multiple -l options.

-t, --temporary
    Specifies that the additions are temporary. Temporary additions last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*
    See "Options," above.

dladm remove-aggr [-t] [-R *root-dir*] -l *ether-link1* [--l=*ether-link2*...] *aggr-link*
    Removes links from the specified aggregation.

-l *ether-link*, --link=*ether-link*
    Specifies an Ethernet link to remove from the aggregation. Multiple links can be added by supplying multiple -l options.

-t, --temporary
    Specifies that the removals are temporary. Temporary removal last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*
    See "Options," above.

dladm show-aggr [-PLxZ] [-s [-i *interval*]] [[-p] -o *field*[,...]] [-z *zone*[,...]] [*aggr-link*]

Show aggregation configuration (the default) or LACP information either for all aggregations or for the specified aggregation.

By default (with no options), the following fields can be displayed:

LINK

The name of the aggregation link.

POLICY

The LACP policy of the aggregation. See the create-aggr -P option for a description of the possible values.

ADDRPOLICY

Either auto, if the aggregation is configured to automatically configure its unicast MAC address (the default if the -u option was not used to create or modify the aggregation), or fixed, if -u was used to set a fixed MAC address.

LACPACTIVITY

The LACP mode of the aggregation. Possible values are off, active, or passive, as set by the -l option to create-aggr or modify-aggr.

LACPTIMER

The LACP timer value of the aggregation as set by the -T option of create-aggr or modify-aggr.

FLAGS

A set of state flags associated with the aggregation. The only possible flag is f, which is displayed if the administrator forced the creation the aggregation using the -f option to create-aggr. Other flags might be defined in the future.

The show-aggr command accepts the following options:

-L, --lacp

Displays detailed LACP information for the aggregation link and each underlying port. Most of the state information displayed by this option is defined by IEEE 802.3. With this option, the following fields can be displayed:

LINK

The name of the aggregation link.

PORT

The name of one of the underlying aggregation ports.

AGGREGATABLE

Whether the port can be added to the aggregation.

SYNC

If yes, the system considers the port to be synchronized and part of the aggregation.

COLL

If yes, collection of incoming frames is enabled on the associated port.

DIST

If yes, distribution of outgoing frames is enabled on the associated port.

DEFAULTED

If yes, the port is using defaulted partner information (that is, has not received LACP data from the LACP partner).

EXPIRED

If yes, the receive state of the port is in the EXPIRED state.

-x, --extended

Display additional aggregation information including detailed information on each underlying port. With -x, the following fields can be displayed:

LINK

The name of the aggregation link.

PORT

The name of one of the underlying aggregation ports.

SPEED

The speed of the link or port in megabits per second.

DUPLEX

The full/half duplex status of the link or port is displayed if the link state is up. The duplex status is displayed as unknown in all other cases.

STATE

The link state. This can be up, down, or unknown.

ADDRESS

The MAC address of the link or port.

PORTSTATE

This indicates whether the individual aggregation port is in the standby or attached state.

-o *field*[,...], --output=*field*[,...]

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed above, or the special value all, to display all fields. The fields applicable to the -o option are limited to those listed under each output mode. For example, if using -L, only the fields listed under -L, above, can be used with -o.

-p, --parseable

Display using a stable machine-parseable format. The -o option is required with -p. See "Parseable Output Format", below.

-P, --persistent
> Display the persistent aggregation configuration rather than the state of the running system.

-s, --statistics
> Displays aggregation statistics. This option is made obsolete by dlstat(1M).

-i *interval*, --interval=*interval*
> Used with the -s option to specify an interval, in seconds, at which statistics should be displayed. This option is made obsolete by dlstat(1M).

-Z
> Display ZONE column in the output.

-z *zone*[,...]
> See description of -z option under dladm show-link, above.

dladm create-bridge [-P *protect*] [-R *root-dir*] [-p *priority*] [-m *max-age*] [-h *hello-time*] [-d *forward-delay*] [-f *force-protocol*] [-l *link*...] *bridge-name*
> Create an 802.1D bridge instance and optionally assign one or more network links to the new bridge. By default, no bridge instances are present on the system.
>
> In order to bridge between links, you must create at least one bridge instance. Each bridge instance is separate, and there is no forwarding connection between bridges.
>
> Note that the bridge-related subcommands, create-bridge among them, require installation of the pkg://solaris/network/bridging package.

-P *protect*, --protect=*protect*
> Specifies a protection method. The defined protection methods are stp for the Spanning Tree Protocol and trill for TRILL, which is used on RBridges. The default value is stp.

-R *root-dir*, --root-dir=*root-dir*
> See "Options," above.

-p *priority*, --priority=*priority*
> Specifies the Bridge Priority. This sets the IEEE STP priority value for determining the root bridge node in the network. The default value is 32768. Valid values are 0 (highest priority) to 61440 (lowest priority), in increments of 4096.
>
> If a value not evenly divisible by 4096 is used, the system silently rounds downward to the next lower value that is divisible by 4096.

-m *max-age*, --max-age=*max-age*
> Specifies the maximum age for configuration information in seconds. This sets the STP Bridge Max Age parameter. This value is used for all nodes in the network if this node is the root bridge. Bridge link information older than this time is discarded. It defaults to 20 seconds. Valid values are from 6 to 40 seconds. See the -d *forward-delay* parameter for additional constraints.

-h *hello-time*, --hello-time=*hello-time*
Specifies the STP Bridge Hello Time parameter. When this node is the root node, it sends Configuration BPDUs at this interval throughout the network. The default value is 2 seconds. Valid values are from 1 to 10 seconds. See the -d *forward-delay* parameter for additional constraints.

-d *forward-delay*, --forward-delay=*forward-delay*
Specifies the STP Bridge Forward Delay parameter. When this node is the root node, then all bridges in the network use this timer to sequence the link states when a port is enabled. The default value is 15 seconds. Valid values are from 4 to 30 seconds.

Bridges must obey the following two constraints:

2 * (*forward-delay* - 1.0) >= *max-age*

max-age >= 2 * (*hello-time* + 1.0)

Any parameter setting that would violate those constraints is treated as an error and causes the command to fail with a diagnostic message. The message provides valid alternatives to the supplied values.

-f *force-protocol*, --force-protocol=*force-protocol*
Specifies the MSTP forced maximum supported protocol. The default value is 3. Valid values are non-negative integers. The current implementation does not support RSTP or MSTP, so this currently has no effect. However, to prevent MSTP from being used in the future, the parameter may be set to 0 for STP only or 2 for STP and RSTP.

-l *link*, --link=*link*
Specifies one or more links to add to the newly-created bridge. This is similar to creating the bridge and then adding one or more links, as with the add-bridge subcommand. However, if any of the links cannot be added, the entire command fails, and the new bridge itself is not created. To add multiple links on the same command line, repeat this option for each link. You are permitted to create bridges without links. For more information about link assignments, see the add-bridge subcommand.

Bridge creation and link assignment require the PRIV_SYS_DL_CONFIG privilege. Bridge creation might fail if the optional bridging feature is not installed on the system.

dladm modify-bridge [-P *protect*] [-R *root-dir*] [-p *priority*] [-m *max-age*] [-h *hello-time*] [-d *forward-delay*] [-f *force-protocol*] [-l *link*...] *bridge-name*
Modify the operational parameters of an existing bridge. The options are the same as for the create-bridge subcommand, except that the -l option is not permitted. To add links to an existing bridge, use the add-bridge subcommand.

Bridge parameter modification requires the PRIV_SYS_DL_CONFIG privilege.

dladm delete-bridge [-R *root-dir*] *bridge-name*
Delete a bridge instance. The bridge being deleted must not have any attached links. Use the remove-bridge subcommand to deactivate links before deleting a bridge.

Bridge deletion requires the PRIV_SYS_DL_CONFIG privilege.

The -R (--root-dir) option is the same as for the create-bridge subcommand.

dladm add-bridge [-R *root-dir*] -l *link* [-l *link*...] *bridge-name*
Add one or more links to an existing bridge. If multiple links are specified, and adding any one of them results in an error, the command fails and no changes are made to the system.

Link addition to a bridge requires the PRIV_SYS_DL_CONFIG privilege.

A link may be a member of at most one bridge. An error occurs when you attempt to add a link that already belongs to another bridge. To move a link from one bridge instance to another, remove it from the current bridge before adding it to a new one.

The links assigned to a bridge must not also be VLANs, VNICs, or tunnels. Only physical Ethernet datalinks, aggregation datalinks, and Ethernet stubs are permitted to be assigned to a bridge.

Links assigned to a bridge must all have the same MTU. This is checked when the link is assigned. The link is added to the bridge in a deactivated form if it is not the first link on the bridge and it has a differing MTU.

Note that systems using bridging should not set the eeprom(1M) local-mac-address? variable to false.

The options are the same as for the create-bridge subcommand.

dladm remove-bridge [-R *root-dir*] -l *link* [-l *link*...] *bridge-name*
Remove one or more links from a bridge instance. If multiple links are specified, and removing any one of them would result in an error, the command fails and none are removed.

Link removal from a bridge requires the PRIV_SYS_DL_CONFIG privilege.

The options are the same as for the create-bridge subcommand.

dladm show-bridge [-flt] [-s [-i *interval*]] [[-p] -o *field*,...] [*bridge-name*]
Show the running status and configuration of bridges, their attached links, learned forwarding entries, and TRILL nickname databases. When showing overall bridge status and configuration, the bridge name can be omitted to show all bridges. The other forms require a specified bridge.

The show-bridge subcommand accepts the following options:

-i *interval*, --interval=*interval*
Used with the -s option to specify an interval, in seconds, at which statistics should be displayed. If this option is not specified, statistics will be displayed only once.

-s, --statistics
Display statistics for the specified bridges or for a given bridge's attached links. This option cannot be used with the -f and -t options.

-p, --parseable

Display using a stable machine-parsable format. See "Parsable Output Format," below.

-o *field*[,...], --output=*field*[,...]

A case-insensitive, comma-separated list of output fields to display. The field names are described below. The special value all displays all fields. Each set of fields has its own default set to display when -o is not specified.

By default, the show-bridge subcommand shows bridge configuration. The following fields can be shown:

BRIDGE

The name of the bridge.

ADDRESS

The Bridge Unique Identifier value (MAC address).

PRIORITY

Configured priority value; set by -p with create-bridge and modify-bridge.

BMAXAGE

Configured bridge maximum age; set by -m with create-bridge and modify-bridge.

BHELLOTIME

Configured bridge hello time; set by -h with create-bridge and modify-bridge.

BFWDDELAY

Configured forwarding delay; set by -d with create-bridge and modify-bridge.

FORCEPROTO

Configured forced maximum protocol; set by -f with create-bridge and modify-bridge.

TCTIME

Time, in seconds, since last topology change.

TCCOUNT

Count of the number of topology changes.

TCHANGE

This indicates that a topology change was detected.

DESROOT

Bridge Identifier of the root node.

ROOTCOST

Cost of the path to the root node.

ROOTPORT

Port number used to reach the root node.

MAXAGE

Maximum age value from the root node.

HELLOTIME

Hello time value from the root node.

FWDDELAY

Forward delay value from the root node.

HOLDTIME

Minimum BPDU interval.

By default, when the -o option is not specified, only the BRIDGE, ADDRESS, PRIORITY, and DESROOT fields are shown.

When the -s option is specified, the show-bridge subcommand shows bridge statistics. The following fields can be shown:

BRIDGE

Bridge name.

DROPS

Number of packets dropped due to resource problems.

FORWARDS

Number of packets forwarded from one link to another.

MBCAST

Number of multicast and broadcast packets handled by the bridge.

RECV

Number of packets received on all attached links.

SENT

Number of packets sent on all attached links.

UNKNOWN

Number of packets handled that have an unknown destination. Such packets are sent to all links.

By default, when the -o option is not specified, only the BRIDGE, DROPS, and FORWARDS fields are shown.

The show-bridge subcommand also accepts the following options:

-l, --link

Displays link-related status and statistics information for all links attached to a single bridge instance. By using this option and without the -s option, the following fields can be displayed for each link:

LINK

The link name.

INDEX
Port (link) index number on the bridge.

STATE
State of the link. The state can be disabled, discarding, learning, forwarding, non-stp, or bad-mtu.

UPTIME
Number of seconds since the last reset or initialization.

OPERCOST
Actual cost in use (1-65535).

OPERP2P
This indicates whether point-to-point (P2P) mode been detected.

OPEREDGE
This indicates whether edge mode has been detected.

DESROOT
The Root Bridge Identifier that has been seen on this port.

DESCOST
Path cost to the network root node through the designated port.

DESBRIDGE
Bridge Identifier for this port.

DESPORT
The ID and priority of the port used to transmit configuration messages for this port.

TCACK
This indicates whether Topology Change Acknowledge has been seen.

When the -l option is specified without the -o option, only the LINK, STATE, UPTIME, and DESROOT fields are shown.

When the -l option is specified, the -s option can be used to display the following fields for each link:

LINK
Link name.

CFGBPDU
Number of configuration BPDUs received.

TCNBPDU
Number of topology change BPDUs received.

RSTPBPDU
Number of Rapid Spanning Tree BPDUs received.

TXBPDU

Number of BPDUs transmitted.

DROPS

Number of packets dropped due to resource problems.

RECV

Number of packets received by the bridge.

XMIT

Number of packets sent by the bridge.

When the -o option is not specified, only the LINK, DROPS, RECV, and XMIT fields are shown.

-f, --forwarding

Displays forwarding entries for a single bridge instance. With this option, the following fields can be shown for each forwarding entry:

DEST

Destination MAC address.

AGE

Age of entry in seconds and milliseconds. Omitted for local entries.

FLAGS

The L (local) flag is shown if the MAC address belongs to an attached link or to a VNIC on one of the attached links.

OUTPUT

For local entries, this is the name of the attached link that has the MAC address. Otherwise, for bridges that use Spanning Tree Protocol, this is the output interface name. For RBridges, this is the output TRILL nickname.

When the -o option is not specified, the DEST, AGE, FLAGS, and OUTPUT fields are shown.

-t, --trill

Displays TRILL nickname entries for a single bridge instance. With this option, the following fields can be shown for each TRILL nickname entry:

NICK

TRILL nickname for this RBridge, which is a number from 1 to 65535.

FLAGS

The L flag is shown if the nickname identifies the local system.

LINK

Link name for output when sending messages to this RBridge.

NEXTHOP

MAC address of the next hop RBridge that is used to reach the RBridge with this nickname.

When the `-o` option is not specified, the NICK, FLAGS, LINK, and NEXTHOP fields are shown.

dladm create-vlan [-ft] [-R *root-dir*] -l *ether-link* -v *vid* [*vlan-link*]
Create a tagged VLAN link with an ID of *vid* over Ethernet link *ether-link*. The name of the VLAN link can be specified as *vlan-link*. If the name is not specified, a name will be automatically generated (assuming that *ether-link* is *namePPA*) as:

*<name><1000 * vlan-tag + PPA>*

For example, if *ether-link* is bge1 and *vid* is 2, the name generated is bge2001.

-f, --force
Force the creation of the VLAN link. Some devices do not allow frame sizes large enough to include a VLAN header. When creating a VLAN link over such a device, the -f option is needed, and the MTU of the IP interfaces on the resulting VLAN must be set to 1496 instead of 1500.

-l *ether-link*
Specifies Ethernet link over which VLAN is created.

-t, --temporary
Specifies that the VLAN link is temporary. Temporary VLAN links last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*
See "Options," above.

dladm delete-vlan [-t] [-R *root-dir*] *vlan-link*
Delete the VLAN link specified.

The delete-vlansubcommand accepts the following options:

-t, --temporary
Specifies that the deletion is temporary. Temporary deletions last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*
See "Options," above.

dladm show-vlan [-PZ] [[-p] -o *field*[,...]] [-z *zone*[,...]] [*vlan-link*]
Display VLAN configuration for all VLAN links or for the specified VLAN link.

The show-vlan subcommand accepts the following options:

-o *field*[,...], --output=*field*[,...]
A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all, to display all fields. For each VLAN link, the following fields can be displayed:

LINK
The name of the VLAN link.

VID
    The ID associated with the VLAN.

OVER
    The name of the physical link over which this VLAN is configured.

FLAGS
    A set of flags associated with the VLAN link. Possible flags are:

f
    The VLAN was created using the -f option to create-vlan.

i
    The VLAN was implicitly created when the DLPI link was opened. These VLAN
    links are automatically deleted on last close of the DLPI link (for example, when the
    IP interface associated with the VLAN link is unplumbed).

Additional flags might be defined in the future.

-p, --parseable
    Display using a stable machine-parseable format. The -o option is required with -p. See
    "Parseable Output Format", below.

-P, --persistent
    Display the persistent VLAN configuration rather than the state of the running system.

-Z
    Display ZONE column in the output.

-z *zone*[,...]
    See description of -z option under dladm show-link, above.

dladm scan-wifi [[-p] -o *field*[,...]] [*wifi-link*]
    Scans for WiFi networks, either on all WiFi links, or just on the specified *wifi-link*.

    By default, currently all fields but BSSTYPE are displayed.

    -o *field*[,...], --output=*field*[,...]
        A case-insensitive, comma-separated list of output fields to display. The field name must
        be one of the fields listed below, or the special value all to display all fields. For each
        WiFi network found, the following fields can be displayed:

        LINK
            The name of the link the WiFi network is on.

        ESSID
            The ESSID (name) of the WiFi network.

        BSSID
            Either the hardware address of the WiFi network's Access Point (for BSS networks),
            or the WiFi network's randomly generated unique token (for IBSS networks).

SEC

    Either none for a WiFi network that uses no security, wep for a WiFi network that requires WEP (Wired Equivalent Privacy), or wpa for a WiFi network that requires WPA (Wi-Fi Protected Access).

MODE

    The supported connection modes: one or more of a, b, g, or n.

STRENGTH

    The strength of the signal: one of excellent, very good, good, weak, or very weak.

SPEED

    The maximum speed of the WiFi network, in megabits per second.

BSSTYPE

    Either bss for BSS (infrastructure) networks, or ibss for IBSS (ad-hoc) networks.

-p, --parseable

    Display using a stable machine-parseable format. The -o option is required with -p. See "Parseable Output Format", below.

dladm connect-wifi [-e *essid*] [-i *bssid*] [-k *key*,...] [-s none | wep | wpa] [-a open|shared] [-b bss|ibss] [-c] [-m a|b|g|n] [-T *time*] [*wifi-link*]

    Connects to a WiFi network. This consists of four steps: *discovery*, *filtration*, *prioritization*, and *association*. However, to enable connections to non-broadcast WiFi networks and to improve performance, if a BSSID or ESSID is specified using the -e or -i options, then the first three steps are skipped and connect-wifi immediately attempts to associate with a BSSID or ESSID that matches the rest of the provided parameters. If this association fails, but there is a possibility that other networks matching the specified criteria exist, then the traditional discovery process begins as specified below.

    The discovery step finds all available WiFi networks on the specified WiFi link, which must not yet be connected. For administrative convenience, if there is only one WiFi link on the system, *wifi-link* can be omitted.

    Once discovery is complete, the list of networks is filtered according to the value of the following options:

-e *essid*, --essid=*essid*

    Networks that do not have the same *essid* are filtered out.

-b bss|ibss, --bsstype=bss|ibss

    Networks that do not have the same bsstype are filtered out.

-m a|b|g, --mode=a|b|g|n

    Networks not appropriate for the specified 802.11 mode are filtered out.

-k *key*,..., --key=*key*, ...

    Use the specified secobj named by the key to connect to the network. Networks not appropriate for the specified keys are filtered out.

-s none|wep|wpa, --sec=none|wep|wpa
    Networks not appropriate for the specified security mode are filtered out.

Next, the remaining networks are prioritized, first by signal strength, and then by
maximum speed. Finally, an attempt is made to associate with each network in the list, in
order, until one succeeds or no networks remain.

In addition to the options described above, the following options also control the behavior
of connect-wifi:

-a open|shared, --auth=open|shared
    Connect using the specified authentication mode. By default, open and shared are tried
    in order.

-c, --create-ibss
    Used with -b ibss to create a new ad-hoc network if one matching the specified ESSID
    cannot be found. If no ESSID is specified, then -c -b ibss always triggers the creation
    of a new ad-hoc network.

-T *time*, --timeout=*time*
    Specifies the number of seconds to wait for association to succeed. If *time* is forever,
    then the associate will wait indefinitely. The current default is ten seconds, but this
    might change in the future. Timeouts shorter than the default might not succeed
    reliably.

-k *key*,..., --key=*key*,...
    In addition to the filtering previously described, the specified keys will be used to secure
    the association. The security mode to use will be based on the key class; if a security
    mode was explicitly specified, it must be compatible with the key class. All keys must be
    of the same class.

    For security modes that support multiple key slots, the slot to place the key will be
    specified by a colon followed by an index. Therefore, -k mykey:3 places mykey in slot 3.
    By default, slot 1 is assumed. For security modes that support multiple keys, a
    comma-separated list can be specified, with the first key being the active key.

dladm disconnect-wifi [-a] [*wifi-link*]
    Disconnect from one or more WiFi networks. If *wifi-link* specifies a connected WiFi link,
    then it is disconnected. For administrative convenience, if only one WiFi link is connected,
    wifi-link can be omitted.

    -a, --all-links
        Disconnects from all connected links. This is primarily intended for use by scripts.

dladm show-wifi [-Z] [[-p] -o *field*,...] [-z *zone*[,...]] [*wifi-link*]
    Shows WiFi configuration information either for all WiFi links or for the specified link
    wifi-link.

-o *field*,..., --output=*field*

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all, to display all fields. For each WiFi link, the following fields can be displayed:

LINK

The name of the link being displayed.

STATUS

Either connected if the link is connected, or disconnected if it is not connected. If the link is disconnected, all remaining fields have the value --.

ESSID

The ESSID (name) of the connected WiFi network.

BSSID

Either the hardware address of the WiFi network's Access Point (for BSS networks), or the WiFi network's randomly generated unique token (for IBSS networks).

SEC

Either none for a WiFi network that uses no security, wep for a WiFi network that requires WEP, or wpa for a WiFi network that requires WPA.

MODE

The supported connection modes: one or more of a, b, g, or n.

STRENGTH

The connection strength: one of excellent, very good, good, weak, or very weak.

SPEED

The connection speed, in megabits per second.

AUTH

Either open or shared (see connect-wifi).

BSSTYPE

Either bss for BSS (infrastructure) networks, or ibss for IBSS (ad-hoc) networks.

By default, currently all fields but AUTH, BSSID, BSSTYPE are displayed.

-p, --parseable

Displays using a stable machine-parseable format. The -o option is required with -p. See "Parseable Output Format", below.

-Z

Display ZONE column in the output.

-z *zone*[,...]

See description of -z option under dladm show-link, above.

dladm show-ether [-xZ] [[-p] -o *field*,...] [-z *zone*[,...]] [*ether-link*]
Shows state information either for all physical Ethernet links or for a specified physical
Ethernet link.

The show-ether subcommand accepts the following options:

-o *field*,..., --output=*field*
A case-insensitive, comma-separated list of output fields to display. The field name must
be one of the fields listed below, or the special value all to display all fields. For each
link, the following fields can be displayed:

LINK
The name of the link being displayed.

PTYPE
Parameter type, where current indicates the negotiated state of the link, capable
indicates capabilities supported by the device, adv indicates the advertised
capabilities, and peeradv indicates the capabilities advertised by the link-partner.

STATE
The state of the link.

AUTO
A yes/no value indicating whether auto-negotiation is advertised.

SPEED-DUPLEX
Combinations of speed and duplex values available. The units of speed are encoded
with a trailing suffix of G (Gigabits/s) or M (Mb/s). Duplex values are encoded as f
(full-duplex) or h (half-duplex).

PAUSE
Flow control information. Can be no, indicating no flow control is available; tx,
indicating that the end-point can transmit pause frames, but ignores any received
pause frames; rx, indicating that the end-point receives and acts upon received pause
frames; or bi, indicating bi-directional flow-control.

REM_FAULT
Fault detection information. Valid values are none or fault.

By default, all fields except REM_FAULT are displayed for the "current" PTYPE.

-p, --parseable
Displays using a stable machine-parseable format. The -o option is required with -p. See
"Parseable Output Format", below.

-x, --extended
Extended output is displayed for PTYPE values of current, capable, adv and peeradv.

-Z
Display ZONE column in the output.

-z *zone*[,...]
　　See description of -z option under dladm show-link, above.

dladm set-linkprop [-t] [-R *root-dir*] -p *prop*=*value*[,...] *link*
　　Sets the values of one or more properties on the link specified. The list of properties and their possible values depend on the link type, the network device driver, and networking hardware. These properties can be retrieved using show-linkprop.

　　-t, --temporary
　　　　Specifies that the changes are temporary. Temporary changes last until the next reboot.

　　-R *root-dir*, --root-dir=*root-dir*
　　　　See "Options," above.

　　-p *prop*=*value*[,...], --prop *prop*=*value*[,...]
　　　　A comma-separated list of properties to set to the specified values.

　　Note that when the persistent value is set, the temporary value changes to the same value.

dladm reset-linkprop [-t] [-R *root-dir*] [-p *prop*,...] *link*
　　Resets one or more properties to their values on the link specified. Properties are reset to the values they had at startup. If no properties are specified, all properties are reset. See show-linkprop for a description of properties.

　　-t, --temporary
　　　　Specifies that the resets are temporary. Values are reset to default values. Temporary resets last until the next reboot.

　　-R *root-dir*, --root-dir=*root-dir*
　　　　See "Options," above.

　　-p *prop, ...*, --prop=*prop, ...*
　　　　A comma-separated list of properties to reset.

　　Note that when the persistent value is reset, the temporary value changes to the same value.

dladm show-linkprop [-PZ] [[-c] -o *field*[,...]] [-p *prop*[,...]] [-z *zone*[,...]] [*link*]
　　Show the current or persistent values of one or more properties, either for all datalinks or for the specified link. By default, current values are shown. If no properties are specified, all available link properties are displayed. For each property, the following fields are displayed:

　　-o *field*[,...], --output=*field*
　　　　A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. For each link, the following fields can be displayed:

　　　　LINK
　　　　　　The name of the datalink.

　　　　PROPERTY
　　　　　　The name of the property.

PERM

The read/write permissions of the property. The value shown is one of ro or rw.

VALUE

The current (or persistent) property value. If the value is not set, it is shown as --. If it is unknown, the value is shown as ?. Persistent values that are not set or have been reset will be shown as -- and will use the system DEFAULT value (if any).

DEFAULT

The default value of the property. If the property has no default value, -- is shown.

POSSIBLE

A comma-separated list of the values the property can have. If the values span a numeric range, *min - max* might be shown as shorthand. If the possible values are unknown or unbounded, -- is shown.

The list of properties depends on the link type and network device driver, and the available values for a given property further depends on the underlying network hardware and its state. General link properties are documented in the "General Link Properties" section. However, link properties that begin with "_" (underbar) are specific to a given link or its underlying network device and subject to change or removal. See the appropriate network device driver man page for details.

-c, --parseable

Display using a stable machine-parseable format. The -o option is required with this option. See "Parseable Output Format", below.

-P, --persistent

Display persistent link property information

-p *prop*, ..., --prop=*prop*, ...

A comma-separated list of properties to show. See the sections on link properties following subcommand descriptions.

-Z

Display ZONE column in the output.

-z *zone*[,...]

See description of -z option under dladm show-link, above.

dladm create-secobj [-t] [-R *root-dir*] [-f *file*] -c *class secobj*

Create a secure object named *secobj* in the specified *class* to be later used as a WEP or WPA key in connecting to an encrypted network. The value of the secure object can either be provided interactively or read from a file. The sequence of interactive prompts and the file format depends on the class of the secure object.

Currently, the classes wep and wpa are supported. The WEP (Wired Equivalent Privacy) key can be either 5 or 13 bytes long. It can be provided either as an ASCII or hexadecimal string -- thus, 12345 and 0x3132333435 are equivalent 5-byte keys (the 0x prefix can be omitted).

A file containing a WEP key must consist of a single line using either WEP key format. The WPA (Wi-Fi Protected Access) key must be provided as an ASCII string with a length between 8 and 63 bytes.

This subcommand is only usable by users or roles that belong to the "Network Link Security" RBAC profile.

-c *class*, --class=*class*
    class can be wep or wpa. See preceding discussion.

-t, --temporary
    Specifies that the creation is temporary. Temporary creation last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*
    See "Options," above.

-f *file*, --file=*file*
    Specifies a file that should be used to obtain the secure object's value. The format of this file depends on the secure object class. See the EXAMPLES section for an example of using this option to set a WEP key.

dladm delete-secobj [-t] [-R *root-dir*] *secobj*[,...]
    Delete one or more specified secure objects. This subcommand is only usable by users or roles that belong to the "Network Link Security" RBAC profile.

    -t, --temporary
        Specifies that the deletions are temporary. Temporary deletions last until the next reboot.

    -R *root-dir*, --root-dir=*root-dir*
        See "Options," above.

dladm show-secobj [-P] [[-p] -o *field*[,...]] [*secobj*,...]
    Show current or persistent secure object information. If one or more secure objects are specified, then information for each is displayed. Otherwise, all current or persistent secure objects are displayed.

    By default, current secure objects are displayed, which are all secure objects that have either been persistently created and not temporarily deleted, or temporarily created.

    For security reasons, it is not possible to show the value of a secure object.

    -o *field*[,...] , --output=*field*[,...]
        A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below. For displayed secure object, the following fields can be shown:

        OBJECT
            The name of the secure object.

CLASS
   The class of the secure object.

-p, --parseable
   Display using a stable machine-parseable format. The -o option is required with -p. See
   "Parseable Output Format", below.

-P, --persistent
   Display persistent secure object information

dladm create-vnic [-t] -l *link* [-R *root-dir*] [-m *value* | auto | {factory [-n *slot-identifier*]} |
{vrrp -A {inet | inet6} -V *vrid*} | {random [-r *prefix*]}] [-v *vlan-id*] [-p *prop=value*[,...]]]
vnic-link
   Create a VNIC with name *vnic-link* over the specified link.

-t, --temporary
   Specifies that the VNIC is temporary. Temporary VNICs last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*
   See "Options," above.

-l *link*, --link=*link*
   link can be a physical link or an etherstub.

-m *value* | *keyword*, --mac-address=*value* | *keyword*
   Sets the VNIC's MAC address based on the specified value or keyword. If *value* is not a
   keyword, it is interpreted as a unicast MAC address, which must be valid for the
   underlying NIC. A user-specified MAC address must be drawn from the ranges
   specified by the Globally Unique and Locally Administered types of MAC addresses.

   The following special keywords can be used:

   factory [-n *slot-identifier*],
   factory [--slot=*slot-identifier*]
      Assign a factory MAC address to the VNIC. When a factory MAC address is
      requested, -m can be combined with the -n option to specify a MAC address slot to be
      used. If -n is not specified, the system will choose the next available factory MAC
      address. The -m option of the show-phys subcommand can be used to display the list
      of factory MAC addresses, their slot identifiers, and their availability.
   random [-r *prefix*],
   random [--mac-prefix=*prefix*]
      Assign a random MAC address to the VNIC. A default prefix consisting of a valid
      IEEE OUI with the local bit set will be used. That prefix can be overridden with the -r
      option.

   vrrp -A {inet | inet6} -V *vrid*
      Assign a VRRP virtual MAC address to the VNIC base on the specified address
      family and *vrid*.

Try and use a factory MAC address first. If none is available, assign a random MAC address. auto is the default action if the -m option is not specified.

-v *vlan-id*

Enable VLAN tagging for this VNIC. The VLAN tag will have id *vlan-id*.

-p *prop=value*,..., -–prop *prop=value*,...

A comma-separated list of properties to set to the specified values.

dladm delete-vnic [-t] [-R *root-dir*] *vnic-link*

Deletes the specified VNIC.

-t, -–temporary

Specifies that the deletion is temporary. Temporary deletions last until the next reboot.

-R *root-dir*, -–root-dir=*root-dir*

See "Options," above.

dladm show-vnic [-pPZ] [-s [-i *interval*]] [-o *field*[,...]] [-l *link*] [-z *zone*[,...]] [*vnic-link*]

Show VNIC configuration information for all VNICs, all VNICs on a link, or only the specified *vnic-link*.

-o *field*[,...] , --output=*field*[,...]

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. By default (without -o), show-vnic displays all fields.

LINK

The name of the VNIC.

OVER

The name of the physical link over which this VNIC is configured.

SPEED

The maximum speed of the VNIC, in megabits per second.

MACADDRESS

MAC address of the VNIC.

MACADDRTYPE

MAC address type of the VNIC. dladm distinguishes among the following MAC address types:

random

A random address assigned to the VNIC.

factory

A factory MAC address used by the VNIC.

-p, --parseable

Display using a stable machine-parseable format. The -o option is required with -p. See "Parseable Output Format", below.

-P, --persistent

Display the persistent VNIC configuration.

-s, --statistics

Displays VNIC statistics. This option is made obsolete by dlstat(1M).

-i *interval*, --interval=*interval*

Used with the -s option to specify an interval, in seconds, at which statistics should be displayed. This option is made obsolete by dlstat(1M).

-l *link*, --link=*link*

Display information for all VNICs on the named link.

-Z

Display ZONE column in the output.

-z *zone*[,...]

See description of -z option under dladm show-link, above.

dladm create-part [-t] [-f] [-R *root-dir*] -l *ib-link* [-p *prop=value*[,..]] -P *pkey part-link*

Create an IP-over-IB link with the name *part-link* over the specified link. This subcommand is supported only on InfiniBand physical links.

-f, --force

Forces the creation of the partition link even if *pkey* is absent on the port, the multicast group is absent, or the port is down.

-l *ib-link*, --link=*ib-link*

IP-over-IB physical link name.

-P, --pkey=*pkey*

Partition key to be used for creating the partition link. *pkey* specified is always treated as hexadecimal, whether it has the 0x prefix or not.

-p *prop=value*[,..]
--prop *prop=value*[,..]

A comma-separated list of properties to set to the specified values. Supported properties are given "General Link Properties" section below.

-R *root-dir*, --root-dir=*root-dir*

See "Options," above.

-t, --temporary

Specifies that the partition link creation is temporary. Temporary partition links last until the next reboot.

dladm delete-part [-R *root-dir*] *part-link*

Delete the specified partition link.

-R *root-dir*, --root-dir=*root-dir*
  See "Options," above.

-t, --temporary
  Specifies that the partition link deletion is temporary. Temporary deletion last until the next reboot.

dladm show-part [-pP] [-l *ib-link*] [-o *field*[,...]] [*part-link*]
  Displays IB partition link information for all partition links, for all partitions on *ib-link*, or for only the specified *part-link*.

-l *ib-link*, --link=*ib-link*
  Display information for all the partitions on the named link.

-o *field*[,...]
  A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. By default (without -o), show-part displays all fields.

  LINK
    The name of the partition link.

  PKEY
    Pkey associated with the partition link.

  OVER
    The name of the physical link over which this partition link is created.

  STATE
    Current state of the partition link. Possible values are up, down, or unknown.

  FLAGS
    A set of state flags used for creating the partition link. Possible values are:

  f
    Partition was created forcibly (without checking whether creating a partition were possible).

  t
    Partition link is temporary, lasting only until the next reboot.

-P, --persistent
  Display the persistent IB partition link configuration.

-p, --parseable
  Display using a stable machine-parseable format. The -o option is required with -p. See "Parseable Output Format", below.

dladm show-ib [-pP] [-o *field*[,...]] [*ib-link*]
  Display IB physical link information on all or the specified IB links.

-o *field*[,...]

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. By default (without -o), show-ib displays all fields.

LINK

The name of the physical link.

HCAGUID

Globally unique identifier of the HCA.

PORTGUID

Globally unique identifier of the port.

PORT

Port number.

STATE

Current state of the physical link. Possible values are up, down, or unknown.

PKEYS

Pkeys available on the port associated with the IP-over-IB link specified in the LINK field.

-P, --persistent

Display the persistent IB physical link configuration.

-p, --parseable

Display using a stable machine-parseable format. The -o option is required with -p. See "Parseable Output Format", below.

dladm create-etherstub [-t] [-R *root-dir*] *etherstub*

Create an etherstub with the specified name.

-t, --temporary

Specifies that the etherstub is temporary. Temporary etherstubs do not persist across reboots.

-R *root-dir*, --root-dir=*root-dir*

See "Options," above.

VNICs can be created on top of etherstubs instead of physical NICs. As with physical NICs, such a creation causes the stack to implicitly create a virtual switch between the VNICs created on top of the same etherstub.

dladm delete-etherstub [-t] [-R *root-dir*] *etherstub*

Delete the specified etherstub.

-t, --temporary

Specifies that the deletion is temporary. Temporary deletions last until the next reboot.

-R *root-dir*, -—root-dir=*root-dir*
    See "Options," above.

dladm show-etherstub [-Z] [-z *zone*[,...]] [*etherstub*]
    Show all configured etherstubs by default, or the specified etherstub if *etherstub* is specified.

  -Z

    Display ZONE column in the output.

  -z *zone*[,...]

    See description of -z option under dladm show-link, above.

dladm create-iptun [-t] [-R *root-dir*] -T *type* [-a {local|remote}=*addr*,...] *iptun-link*
    Create an IP tunnel link named *iptun-link*. Such links can additionally be protected with
    IPsec using ipsecconf(1M).

    An IP tunnel is conceptually comprised of two parts: a virtual link between two or more IP
    nodes, and an IP interface above this link that allows the system to transmit and receive IP
    packets encapsulated by the underlying link. This subcommand creates a virtual link. The
    ipadm(1M) command is used to configure IP interfaces above the link.

  -t, --temporary

    Specifies that the IP tunnel link is temporary. Temporary tunnels last until the next
    reboot.

  -R *root-dir*, --root-dir=*root-dir*

    See "Options," above.

  -T *type*, --tunnel-type=*type*

    Specifies the type of tunnel to be created. The type must be one of the following:

    ipv4

       A point-to-point, IP-over-IP tunnel between two IPv4 nodes. This type of tunnel
       requires IPv4 source and destination addresses to function. IPv4 and IPv6 interfaces
       can be plumbed above such a tunnel to create IPv4-over-IPv4 and IPv6-over-IPv4
       tunneling configurations.

    ipv6

       A point-to-point, IP-over-IP tunnel between two IPv6 nodes as defined in IETF RFC
       2473. This type of tunnel requires IPv6 source and destination addresses to function.
       IPv4 and IPv6 interfaces can be plumbed above such a tunnel to create
       IPv4-over-IPv6 and IPv6-over-IPv6 tunneling configurations.

    6to4

       A 6to4, point-to-multipoint tunnel as defined in IETF RFC 3056. This type of tunnel
       requires an IPv4 source address to function. An IPv6 interface is plumbed on such a
       tunnel link to configure a 6to4 router.

  -a {local|remote}=*addr*,...
  --address {local|remote}=*addr*,...

Literal IP addresses or hostnames corresponding to the local or remote tunnel addresses. Either local or remote can be specified individually, or both can be specified separated by a comma (for example, -a local=*laddr*, remote=*raddr*).

`dladm modify-iptun` [`-t`] [`-R` *root-dir*] `-a` {`local`|`remote`}=*addr*,... *iptun-link*
Modify the parameters of the specified IP tunnel.

`-t, --temporary`
Specifies that the modification is temporary. Temporary modifications last until the next reboot.

`-R` *root-dir*, `--root-dir`=*root-dir*
See "Options," above.

`-a` {`local`|`remote`}=*addr*,...
`--address` {`local`|`remote`}=*addr*,...
Specify new local or remote addresses for the tunnel link. See `create-iptun` for a description.

`dladm delete-iptun` [`-t`] [`-R` *root-dir*] *iptun-link*
Delete the specified IP tunnel link.

`-t, --temporary`
Specifies that the deletion is temporary. Temporary deletions last until the next reboot.

`-R` *root-dir*, `--root-dir`=*root-dir*
See "Options," above.

`dladm show-iptun` [`-PZ`] [[`-p`] `-o` *field*[,...]] [`-z` *zone*[,...]] [*iptun-link*]
Show IP tunnel link configuration for a single IP tunnel or all IP tunnels.

`-P, --persistent`
Display the persistent IP tunnel configuration.

`-p, --parseable`
Display using a stable machine-parseable format. The -o option is required with -p. See "Parseable Output Format", below.

`-o` *field*[,...], `--output`=*field*[,...]
A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all`, to display all fields. By default (without `-o`), `show-iptun` displays all fields.

LINK
The name of the IP tunnel link.

TYPE
Type of tunnel as specified by the `-T` option of `create-iptun`.

FLAGS
A set of flags associated with the IP tunnel link. Possible flags are:

s

The IP tunnel link is protected by IPsec policy. To display the IPsec policy associated with the tunnel link, enter:

ipsecconf -ln -i *tunnel-link*

See ipsecconf(1M) for more details on how to configure IPsec policy.

i

The IP tunnel link was implicitly created with ipadm(1M), and will be automatically deleted when it is no longer referenced (that is, when the last IP interface over the tunnel is removed). See ipadm(1M) for details on implicit tunnel creation.

LOCAL
The local tunnel address.

REMOTE
The remote tunnel address.

-Z
Display ZONE column in the output.

-z *zone*[,...]
See description of -z option under dladm show-link, above.

dladm show-usage [-a] -f *filename* [-p *plotfile* -F *format*] [-s *time*] [-e *time*] [*link*]
This subcommand is made obsolete by the dlstat(1M) show-link -h command.

Parseable Output Format

Many dladm subcommands have an option that displays output in a machine-parseable format. The output format is one or more lines of colon (:) delimited fields. The fields displayed are specific to the subcommand used and are listed under the entry for the -o option for a given subcommand. Output includes only those fields requested by means of the -o option, in the order requested.

When you request multiple fields, any literal colon characters are escaped by a backslash (\) before being output. Similarly, literal backslash characters will also be escaped (\\). This escape format is parseable by using shell read(1) functions with the environment variable IFS=: (see EXAMPLES, below). Note that escaping is not done when you request only a single field.

General Link Properties

The following general link properties are supported:

autopush
Specifies the set of STREAMS modules to push on the stream associated with a link when its DLPI device is opened. It is a space-delimited list of modules.

The optional special character sequence [anchor] indicates that a STREAMS anchor should be placed on the stream at the module previously specified in the list. It is an error to specify more than one anchor or to have an anchor first in the list.

The autopush property is preferred over the more general autopush(1M) command.

cpus

> Bind the processing of packets for a given data link to a processor or a set of processors. The value can be a comma-separated list of one or more processor ids or a range of ids. If the list consists of more than one processor, the processing will spread out to all the processors. Connection to processor affinity and packet ordering for any individual connection will be maintained.
>
> The processor or set of processors are not exclusively reserved for the link. Only the kernel threads and interrupts associated with processing of the link are bound to the processor or the set of processors specified. In case it is desired that processors be dedicated to the link, psrset(1M) can be used to create a processor set and then specifying the processors from the processor set to bind the link to.
>
> If the link was already bound to processor or set of processors due to a previous operation, the binding will be removed and the new set of processors will be used instead.
>
> The default is no CPU binding, which is to say that the processing of packets is not bound to any specific processor or processor set.
>
> Specification of the cpus property is not allowed on links with a pool link property.

cpus-effective

> This read-only property displays the list of CPUs used for packet processing on the named data link.
>
> If the cpus property has been set, cpus-effective will be the same.
>
> If the pool property has been set, the cpus-effective will be selected from the pool designated by the administrator.
>
> If neither the pool nor cpus property is set, the system will select the appropriate value for cpus-effective.

rxfanout

> Allows you to specify the number of receive-side fanout threads.
>
> Traffic received on a receive ring can be fanned out across multiple threads and processed in parallel. This is particularly useful when the system has large number of CPUs. This property is a count for the number of receive-side fanout threads for a particular datalink. Note that this property lets an administrator specify the desired rxfanout. However, based on the number of available CPUs and hardware RX rings, the system might choose a different (smaller or even higher) value for fanout.

rxfanout-effective

> The number of CPUs is the upper bound on the receive side fanout while the number of rxrings is the lower bound. Thus, the actual receive-side fanout count can have a value different from the one set by the user.

learn_limit
> Limits the number of new or changed MAC sources to be learned over a bridge link. When the number exceeds this value, learning on that link is temporarily disabled. Only non-VLAN, non-VNIC type links have this property.
>
> The default value is 1000. Valid values are greater or equal to 0.

learn_decay
> Specifies the decay rate for source changes limited by learn_limit. This number is subtracted from the counter for a bridge link every 5 seconds. Only non-VLAN, non-VNIC type links have this property.
>
> The default value is 200. Valid values are greater or equal to 0.

mac-address
> Sets the primary MAC address for the data link. When set, changes the primary MAC address used by all current and future MAC clients of the underlying data link.

maxbw
> Sets the full duplex bandwidth for the link. The bandwidth is specified as an integer with one of the scale suffixes (K, M, or G for Kbps, Mbps, and Gbps). If no units are specified, the input value will be read as Mbps. The default is no bandwidth limit.

pool
> Bind the processing of packets for a given data link to a pool of processors defined and administered by poolcfg(1M) and pooladm(1M). The binding of processes is similar to what occurs with the cpus link property, except that the list of CPUs is not explicit and is instead maintained by the pools facility.
>
> If pools are enabled, and no pool is specified for the link, pool_default will be used for packet processing.
>
> For zones with ip-type=exclusive, if a pool is specified through a pool zone property or dedicated-cpus allocation, that pool will also be used for all data links associated with the zone.
>
> Specification of the pool property is not allowed on links with a cpus link property.

pool-effective
> If the pools facility has been enabled, this read-only property displays the pool that is being used for packet processing. If the administrator has not assigned a pool to a data link, the pool will be pool_default.
>
> If the pools facility is disabled, there is no effective pool and the value will be empty.

priority
> Sets the relative priority for the link. The value can be given as one of the tokens high, medium, or low. The default is high. This priority is not reflected in any protocol priority fields on the wire, but used for packet processing scheduling within the system.

rxringsavail

    A read-only property that specifies the number of rings available on the receive side.

rxrings

    Specifies the number of receive rings side for the MAC client. A value of sw means this MAC client should not be assigned any RX ring and will be software-based. A value of hw means this MAC client can get one RX ring, if available, or will be software-based. A non-zero value means reserve that many rings for this MAC client, if available, and fail if not. If this property is not specified, the MAC client can get one RX ring, if available, or will be software-based.

rxhwclntavail

    A read-only property that specifies the number of additional RX hardware-based MAC clients that can be created.

txringsavail

    A read-only property that specifies the number of rings available on the transmit side.

txrings

    Specifies the number of transmit rings for the MAC client. A value of sw means this MAC client should not be assigned any TX ring. A value of hw means this MAC client can get one TX ring, if available, or will be software-based. A non-zero value means reserve that many rings for this MAC client, if available, and fail if not. If this property is not specified, the MAC client can get one TX ring, if available, or will be software-based.

txhwclntavail

    A read-only property that specifics the number of additional TX hardware-based MAC clients that can be created.

stp

    Enables or disables Spanning Tree Protocol on a bridge link. Setting this value to 0 disables Spanning Tree, and puts the link into forwarding mode with BPDU guarding enabled. This mode is appropriate for point-to-point links connected only to end nodes. Only non-VLAN, non-VNIC type links have this property. The default value is 1, to enable STP.

forward

    Enables or disables forwarding for a VLAN. Setting this value to 0 disables bridge forwarding for a VLAN link. Disabling bridge forwarding removes that VLAN from the "allowed set" for the bridge. The default value is 1, to enable bridge forwarding for configured VLANs.

default_tag

    Sets the default VLAN ID that is assumed for untagged packets sent to and received from this link. Only non-VLAN, non-VNIC type links have this property. Setting this value to 0 disables the bridge forwarding of untagged packets to and from the port. The default value is VLAN ID 1. Valid values values are from 0 to 4094. The default VLAN ID is also referred to as the Port VLAN Identifier (PVID).

You cannot create a tagged VLAN or VLAN-tagged VNIC link with a VLAN ID that matches the default VLAN value of the underlying link. All untagged packets on the link are already associated with the default VLAN (PVID). To successfully create a tagged VLAN or VLAN-tagged VNIC link with VLAN ID equal to the default VLAN value, you must first change the default_tag property of the underlying link to a different VLAN value.

When default_tag=0, all untagged packets on the link are no longer associated with any VLAN. As a result, you can create a VLAN link with any VLAN ID from 1 to 4094. Note that any received packets that are erroneously tagged with the PVID at an end-point might be dropped. This situation occurs if all the end-points on a given link do not agree on the PVID. All end-points on a link must use the same PVID and must not tag traffic with the PVID.

stp_priority

Sets the STP and RSTP Port Priority value, which is used to determine the preferred root port on a bridge. Lower numerical values are higher priority. The default value is 128. Valid values range from 0 to 255.

stp_cost

Sets the STP and RSTP cost for using the link. The default value is auto, which sets the cost based on link speed, using 100 for 10Mbps, 19 for 100Mbps, 4 for 1Gbps, and 2 for 10Gbps. Valid values range from 1 to 65535.

stp_edge

Enables or disables bridge edge port detection. If set to 0 (false), the system assumes that the port is connected to other bridges even if no bridge PDUs of any type are seen. The default value is 1, which detects edge ports automatically.

stp_p2p

Sets bridge point-to-point operation mode. Possible values are true, false, and auto. When set to auto, point-to-point connections are automatically discovered. When set to true, the port mode is forced to use point-to-point. When set to false, the port mode is forced to use normal multipoint mode. The default value is auto.

stp_mcheck

Triggers the system to run the RSTP Force BPDU Migration Check procedure on this link. The procedure is triggered by setting the property value to 1. The property is automatically reset back to 0. This value cannot be set unless the following are true:

- The link is bridged
- The bridge is protected by Spanning Tree
- The bridge force-protocol value is at least 2 (RSTP)

The default value is 0.

protection

Enables one or more types of link protection. Valid values are:

mac-nospoof

MAC address anti-spoof. An outbound packet's source MAC address must match the link's configured MAC address. Non-matching packets will be dropped. If the link belongs to a zone, turning mac-nospoof on will prevent the zone's owner from modifying the link's MAC address.

ip-nospoof

IP address anti-spoof. This protection type works in conjunction with the link property allowed-ips.

allowed-ips is a list containing IP (IPv4 or IPv6) addresses. This list is empty by default. Addresses that are implicitly in this list are: the link local IPv6 address conforming to RFC 2464 (derived from the link's MAC address); IPv4/IPv6 addresses learned from DHCP replies; the unspecified (all-zeros) IPv4/IPv6 address.

An outbound IP packet can pass if its source address is in allowed-ips.

An outbound ARP packet can pass if its sender protocol address is in allowed-ips.

When a datalink has been protected by setting allowed-ips to a set of one or more IP addresses, any attempts to configure IP addresses that are not in this set will fail with an EPERM error being returned to the user. Moreover, the interface may not be used for forwarding IP packets, and attempts to set the [ipadm(1M)] forwarding property on the interface will encounter an EPERM error.

dhcp-nospoof

DHCP client ID (DUID for DHCPv6) and hardware address anti-spoof. This protection type works in conjunction with the link property allowed-dhcp-cids.

Items in the allowed-dhcp-cids list should be formatted in the same way as the CLIENT_ID field in the /etc/default/dhcpagent file. The only difference is that . (period) should be used in place of , (comma) when specifying DUIDs. See [dhcpagent(1M)] for details.

An outbound DHCP (v4/v6) packet can pass only if these conditions are satisfied:

- If allowed-dhcp-cids is not configured and the packet type is:
  - DHCPv4, the client ID field must match the configured MAC address.
  - DHCPv6, the DUID must be of type 1 or 3 and the link layer address part of the DUID must match the configured MAC address.
- If allowed-dhcp-cids is configured and the packet type is:
  - DHCPv4, the client ID field must match one of the IDs on this list or the configured MAC address.
  - DHCPv6, the DUID field must match one of the IDs on this list or, the DUID must be of type 1 or 3 and the link layer address part of the DUID matches the configured MAC address.

restricted

This protection restricts outgoing packet types to just IPv4, IPv6, and ARP.

zone

Specifies the zone to which the link belongs. This property can be modified only temporarily through dladm, and thus the -t option must be specified. To modify the zone assignment such that it persists across reboots, please use zonecfg(1M). Possible values consist of any exclusive-IP zone currently running on the system. By default, the zone binding is as per zonecfg(1M).

Wifi Link Properties The following WiFi link properties are supported. Note that the ability to set a given property to a given value depends on the driver and hardware.

channel

Specifies the channel to use. This property can be modified only by certain WiFi links when in IBSS mode. The default value and allowed range of values varies by regulatory domain.

powermode

Specifies the power management mode of the WiFi link. Possible values are off (disable power management), max (maximum power savings), and fast (performance-sensitive power management). Default is off.

radio

Specifies the radio mode of the WiFi link. Possible values are on or off. Default is on.

speed

Specifies a fixed speed for the WiFi link, in megabits per second. The set of possible values depends on the driver and hardware (but is shown by show-linkprop); common speeds include 1, 2, 11, and 54. By default, there is no fixed speed.

Ethernet Link Properties The following MII Properties, as documented in ieee802.3(5), are supported in read-only mode:

- duplex
- state
- adv_autoneg_cap
- adv_10gfdx_cap
- adv_1000fdx_cap
- adv_1000hdx_cap
- adv_100fdx_cap
- adv_100hdx_cap
- adv_10fdx_cap
- adv_10hdx_cap

Each adv_ property (for example, adv_10fdx_cap) also has a read/write counterpart en_ property (for example, en_10fdx_cap) controlling parameters used at auto-negotiation. In the absence of Power Management, the adv* speed/duplex parameters provide the values that are both negotiated and currently effective in hardware. However, with Power Management

enabled, the speed/duplex capabilities currently exposed in hardware might be a subset of the set of bits that were used in initial link parameter negotiation. Thus the MII adv_* parameters are marked read-only, with an additional set of en_* parameters for configuring speed and duplex properties at initial negotiation.

Note that the adv_autoneg_cap does not have an en_autoneg_cap counterpart: the adv_autoneg_cap is a 0/1 switch that turns off/on autonegotiation itself, and therefore cannot be impacted by Power Management.

In addition, the following Ethernet properties are reported:

flowctrl
> Establishes flow-control modes that will be advertised by the device. Valid input is one of:

> auto
>> Flow control mode on the device is dynamically determined. To see the actual flow control mode set on the device, check the flowctrl-effective link property.

> no
>> No flow control enabled.

> rx
>> Receive, and act upon incoming pause frames.

> tx
>> Transmit pause frames to the peer when congestion occurs, but ignore received pause frames.

> pfc
>> Transmit pause frames including the priority value of the traffic that should be paused. Receive pause frames, and act upon the traffic whose priority values are specified in the frame.

> bi
>> Bidirectional flow control.

> Note that the actual settings for this value are constrained by the capabilities allowed by the device and the link partner.

gvrp-timeout
> Specifies wait period between VID announcement broadcasts, in milliseconds.

flowctrl-effective
> Actual flow-control mode configured on the device. When flowctrl property is set to auto, this indicates the flow control mode that is in effect. This is a read-only property.

mtu
> The maximum client SDU (Send Data Unit) supported by the device. Valid range is 68-65536.

ntcs

The number of Traffic Classes supported on the device. A device supporting extensions for DCB (Data Center Bridging) can support multiple traffic classes. This property can be used to determine if the device supports DCB extensions. This is a read-only property.

pfcmap

This property is used to indicate the 802.1p priority values for which PFC (Priority-based flow control) is enabled. This is an 8-bit mask, in which an individual bit signifies whether PFC is enabled for the corresponding priority. For priorities that have PFC enabled, the device will transmit a pause frame for that priority in the event of congestion. This is relevant only if ntcs is greater than zero and flowctrl-effective is pfc.

speed

(read-only) The operating speed of the device, in Mbps.

tagmode

This link property controls the conditions in which 802.1Q VLAN tags will be inserted in packets being transmitted on the link. Two mode values can be assigned to this property:

normal   Insert a VLAN tag in outgoing packets under the following conditions:
- The packet belongs to a VLAN.
- The user requested priority tagging.

vlanonly   Insert a VLAN tag only when the outgoing packet belongs to a VLAN. If a tag is being inserted in this mode and the user has also requested a non-zero priority, the priority is honored and included in the VLAN tag.

The default value is vlanonly.

vlan-announce

This property controls automatic VLAN ID anouncement. When enabled, it broadcasts the VIDs of any VNICs or VLANs configured on the device. It supports both physical links and aggregations. Possible values are:

off

No VID announcements will be sent.

gvrp

Announcements sent using GVRP protocol, as defined in 802.1D. See gvrp-timeout to configure broadcast frequency.

InfiniBand Link Properties   The following properties are supported only on IB partition object links.

linkmode

Sets the link transport service type on an IB partition datalink. The default value is cm. Valid values are:

cm

  Connected Mode. This mode uses a default MTU of 65520 and supports a maximum
  MTU of 65535 bytes. If Connected Mode is not available for a remote node, Unreliable
  Datagram mode will automatically be used instead.

ud

  Unreliable Datagram Mode. This mode uses a default MTU of 2044 and supports a
  maximum MTU of 4092 bytes.

IP Tunnel Link
Properties
The following IP tunnel link properties are supported.

hoplimit

  Specifies the IPv4 TTL or IPv6 hop limit for the encapsulating outer IP header of a tunnel
  link. This property exists for all tunnel types. The default value is 64.

encaplimit

  Specifies the IPv6 encapsulation limit for an IPv6 tunnel as defined in RFC 2473. This value
  is the tunnel nesting limit for a given tunneled packet. The default value is 4. A value of 0
  disables the encapsulation limit.

Examples   **EXAMPLE 1**   Configuring an Aggregation

To configure a data-link over an aggregation of devices bge0 (linkname net0) and bge1
(linkname net1) with key 1, enter the following command:

```
# dladm create-aggr -d net0 -d net1 1
```

EXAMPLE 2   Connecting to a WiFi Link

To connect to the most optimal available unsecured network on a system with a single WiFi
link (as per the prioritization rules specified for connect-wifi), enter the following
command:

```
# dladm connect-wifi
```

EXAMPLE 3   Creating a WiFi Key

To interactively create the WEP key mykey, enter the following command:

```
# dladm create-secobj -c wep mykey
```

Alternatively, to non-interactively create the WEP key mykey using the contents of a file:

```
# umask 077
 # cat >/tmp/mykey.$$ <<EOF
 12345
 EOF
 # dladm create-secobj -c wep -f /tmp/mykey.$$ mykey
 # rm /tmp/mykey.$$
```

EXAMPLE 4 Connecting to a Specified Encrypted WiFi Link

To use key `mykey` to connect to ESSID `wlan` on link `ath0`, enter the following command:

```
# dladm connect-wifi -k mykey -e wlan ath0
```

EXAMPLE 5 Changing a Link Property

To set `powermode` to the value `fast` on link `pcwl0`, enter the following command:

```
# dladm set-linkprop -p powermode=fast pcwl0
```

EXAMPLE 6 Connecting to a WPA-Protected WiFi Link

Create a WPA key `psk` and enter the following command:

```
# dladm create-secobj -c wpa psk
```

To then use key `psk` to connect to ESSID `wlan` on link `ath0`, enter the following command:

```
# dladm connect-wifi -k psk -e wlan ath0
```

EXAMPLE 7 Renaming a Link

To rename the `bge0` link to `mgmt0`, enter the following command:

```
# dladm rename-link bge0 mgmt0
```

EXAMPLE 8 Replacing a Network Card

Consider that the `bge0` device, whose link was named `mgmt0` as shown in the previous example, needs to be replaced with a `ce0` device because of a hardware failure. The `bge0` NIC is physically removed, and replaced with a new `ce0` NIC. To associate the newly added `ce0` device with the `mgmt0` configuration previously associated with `bge0`, enter the following command:

```
# dladm rename-link ce0 mgmt0
```

EXAMPLE 9 Removing a Network Card

Suppose that in the previous example, the intent is not to replace the `bge0` NIC with another NIC, but rather to remove and not replace the hardware. In that case, the `mgmt0` datalink configuration is not slated to be associated with a different physical device as shown in the previous example, but needs to be deleted. Enter the following command to delete the datalink configuration associated with the `mgmt0` datalink, whose physical hardware (`bge0` in this case) has been removed:

```
# dladm delete-phys mgmt0
```

EXAMPLE 10 Using Parseable Output to Capture a Single Field

The following assignment saves the MTU of link `net0` to a variable named `mtu`.

```
# mtu=`dladm show-link -p -o mtu net0`
```

EXAMPLE 11 Using Parseable Output to Iterate over Links

The following script displays the state of each link on the system.

```
# dladm show-link -p -o link,state | while IFS=: read link state; do
         print "Link $link is in state $state"
     done
```

EXAMPLE 12 Configuring VNICs

Create two VNICs with names hello0 and test1 over a single physical link bge0:

```
# dladm create-vnic -l bge0 hello0
# dladm create-vnic -l bge0 test1
```

EXAMPLE 13 Configuring VNICs and Allocating Bandwidth and Priority

Create two VNICs with names hello0 and test1 over a single physical link bge0 and make hello0 a high priority VNIC with a factory-assigned MAC address with a maximum bandwidth of 50 Mbps. Make test1 a low priority VNIC with a random MAC address and a maximum bandwidth of 100Mbps.

```
# dladm create-vnic -l bge0 -m factory -p maxbw=50,priority=high hello0
# dladm create-vnic -l bge0 -m random -p maxbw=100M,priority=low test1
```

EXAMPLE 14 Configuring a VNIC with a Factory MAC Address

First, list the available factory MAC addresses and choose one of them:

```
# dladm show-phys -m bge0
LINK            SLOT          ADDRESS              INUSE    CLIENT
net0            primary       0:e0:81:27:d4:47     yes      net0
net0            1             8:0:20:fe:4e:a5      no
net0            2             8:0:20:fe:4e:a6      no
net0            3             8:0:20:fe:4e:a7      no
```

Create a VNIC named hello0 and use slot 1's address:

```
# dladm create-vnic -l bge0 -m factory -n 1 hello0
# dladm show-phys -m bge0
LINK            SLOT          ADDRESS              INUSE    CLIENT
net0            primary       0:e0:81:27:d4:47     yes      net0
net0            1             8:0:20:fe:4e:a5      yes      hello0
net0            2             8:0:20:fe:4e:a6      no
net0            3             8:0:20:fe:4e:a7      no
```

EXAMPLE 15 Creating a VNIC with User-Specified MAC Address, Binding it to Set of Processors

Create a VNIC with name hello0, with a user specified MAC address, and a processor binding 0, 2, 4-6.

```
# dladm create-vnic -l bge0 -m 8:0:20:fe:4e:b8 -p cpus=0,2,4-6 hello0
```

EXAMPLE 16 Creating a Virtual Network Without a Physical NIC

First, create an etherstub with name stub1:

```
# dladm create-etherstub stub1
```

Create two VNICs with names hello0 and test1 on the etherstub. This operation implicitly creates a virtual switch connecting hello0 and test1.

```
# dladm create-vnic -l stub1 hello0
# dladm create-vnic -l stub1 test1
```

EXAMPLE 17 Displaying Bridge Information

The following commands use the show-bridge subcommand with no and various options.

```
# dladm show-bridge
BRIDGE       PROTECT ADDRESS            PRIORITY DESROOT
foo          stp     32768/8:0:20:bf:f 32768    8192/0:d0:0:76:14:38
bar          stp     32768/8:0:20:e5:8 32768    8192/0:d0:0:76:14:38

# dladm show-bridge -l foo
LINK         STATE       UPTIME   DESROOT
hme0         forwarding  117      8192/0:d0:0:76:14:38
qfe1         forwarding  117      8192/0:d0:0:76:14:38

# dladm show-bridge -s foo
BRIDGE       DROPS       FORWARDS
foo          0           302

# dladm show-bridge -ls foo
LINK         DROPS     RECV     XMIT
hme0         0         360832   31797
qfe1         0         322311   356852

# dladm show-bridge -f foo
DEST            AGE      FLAGS  OUTPUT
8:0:20:bc:a7:dc  10.860  --     hme0
8:0:20:bf:f9:69  --      L      hme0
8:0:20:c0:20:26  17.420  --     hme0
8:0:20:e5:86:11  --      L      qfe1
```

EXAMPLE 18 Creating an IPv4 Tunnel

The following sequence of commands creates and then displays a persistent IPv4 tunnel link named mytunnel0 between 66.1.2.3 and 192.4.5.6:

```
# dladm create-iptun -T ipv4 -a local=66.1.2.3,remote=192.4.5.6 mytunnel0
# dladm show-iptun mytunnel0
LINK           TYPE  FLAGS  SOURCE            DESTINATION
mytunnel0      ipv4  --     66.1.2.3          192.4.5.6
```

EXAMPLE 18 Creating an IPv4 Tunnel *(Continued)*

A point-to-point IP interface can then be created over this tunnel link:

```
# ipadm create-ip mytunnel0
# ipadm create-addr -T static -a local=10.1.0.1,remote=10.1.0.2 \
mytunnel0/addr
# ipadm show-addr mytunnel0/addr
ADDROBJ         TYPE    STATE       ADDR
mytunnel0/addr  static  ok          10.1.0.1->10.1.0.2
```

EXAMPLE 19 Creating a 6to4 Tunnel

The following command creates a 6to4 tunnel link. The IPv4 address of the 6to4 router is 75.10.11.12.

```
# dladm create-iptun -T 6to4 -a local=75.10.11.12 sitetunnel0
# dladm show-iptun sitetunnel0
LINK           TYPE  FLAGS  SOURCE              DESTINATION
sitetunnel0    6to4  --     75.10.11.12         --
```

The following command creates an IPv6 interface on this tunnel:

```
# ipadm create-ip sitetunnel0
# ipadm show-addr sitetunnel0/_a
ADDROBJ          TYPE    STATE       ADDR
sitetunnel0/_a   static  ok          2002:4b0a:b0c::1/16
```

Note that the system automatically configures the IPv6 address on the 6to4 IP interface. See ipadm(1M) for a description of how IPv6 addresses are configured on 6to4 tunnel links.

EXAMPLE 20 Using Link Protection

To enable link protection:

```
# dladm set-linkprop \
-p protection=mac-nospoof,restricted,ip-nospoof,dhcp-nospoof vnic0
```

To disable link protection:

```
# dladm reset-linkprop -p protection vnic0
```

To modify the allowed-ips list:

```
# dladm set-linkprop -p allowed-ips=10.0.0.1,10.0.0.2 vnic0
```

To modify the allowed-dhcp-cids list:

```
# dladm set-linkprop -p allowed-dhcp-cids=hello vnic0
```

To display the resulting configuration:

EXAMPLE 20   Using Link Protection   *(Continued)*

```
# dladm show-linkprop -p protection,allowed-ips vnic0
```

```
LINK       PROPERTY         PERM   VALUE          DEFAULT    POSSIBLE
vnic0      protection       rw     mac-nospoof,   --         mac-nospoof,
                                   restricted,               restricted,
                                   ip-nospoof,               ip-nospoof,
                                   dhcp-nospoof              dhcp-nospoof

vnic0      allowed-ips      rw     10.0.0.1,      --         --
                                   10.0.0.2

vnic0      allowed-dhcp-cids rw    hello          --         --
```

EXAMPLE 21   Creating an IB Partition

The following command creates a partition ffff.ibp0 with partition key 0xffff on the physical link ibp0.

```
# dladm create-part -P ffff -l ibp0 ffff.ibp0
```

EXAMPLE 22   Displaying IB Partition Information

The following command displays IB partition information.

```
# dladm show-part
LINK           PKEY OVER        STATE    FLAGS
ffff.ibp0      FFFF ibp0        up       ----
```

EXAMPLE 23   Displaying IB Data Links Information

The following command displays IB data links information.

```
# dladm show-ib
LINK       HCAGUID         PORTGUID        PORT STATE  PKEYS
ibp0       3BA000100CD7C   3BA000100CD7D   1    down   FFFF
ibp1       3BA000100CD7C   3BA000100CD7E   2    down   FFFF
ibp3       5AD0000033634   5AD0000033636   2    up     FFFF,8001
ibp2       5AD0000033634   5AD0000033635   1    up     FFFF,8001
```

EXAMPLE 24   Deleting a Partition

The following command deletes the partition ffff.ibp0.

```
# dladm delete-part ffff.ibp0
```

EXAMPLE 25   Using show-link to Display Partition Information

The following command uses the show-link subcommand to display partition information.

EXAMPLE 25 Using show-link to Display Partition Information   *(Continued)*

```
# dladm show-link
LINK         CLASS   MTU     STATE     OVER
e1000g0      phys    1500    up        --
e1000g1      phys    1500    unknown   --
ibp0         phys    65520   down      --
ibp3         phys    65520   up        --
ibp2         phys    65520   up        --
ibp1         phys    65520   down      --
pffff.ibp0   part    2044    down      ibp0
p8001.ibp2   part    65520   unknown   ibp2
```

EXAMPLE 26 Displaying Links in All Zones from the Global Zone

The show-link command shown below displays data links in all zones from the global zone.
Links that are not in the global zone are displayed with the zonename prefix followed by the
slash (/) separator.

In this example, net0 is a VNIC created in the global zone, zone1/net0 is an automatically
created VNIC for zone1, and zone2/net0 is an automatically created VNIC for zone2.

```
# dladm show-link
LINK           CLASS   MTU     STATE     OVER
e1000g0        phys    1500    up        --
e1000g1        phys    8170    unknown   --
e1000g2        phys    1500    unknown   --
e1000g3        phys    1500    unknown   --
net0           vnic    1500    up        e1000g0
zone1/net0     vnic    1500    up        e1000g0
zone2/net0     vnic    1500    up        e1000g0
```

EXAMPLE 27 Displaying Links in the Global Zone

The following show-link command displays data links in the global zone only.

```
# dladm show-link -z global
LINK         CLASS   MTU     STATE     OVER
e1000g0      phys    1500    up        --
e1000g1      phys    8170    unknown   --
e1000g2      phys    1500    unknown   --
e1000g3      phys    1500    unknown   --
net0         vnic    1500    up        e1000g0
```

EXAMPLE 28 Displaying Links for a Specified Zone

The following show-link command displays data links in a specific, non-global zone.

```
# dladm show-link -z zone1
LINK           CLASS   MTU     STATE     OVER
zone1/net0     vnic    1500    up        e1000g0
```

EXAMPLE 29 Displaying Links for a Specified Zone from the Global Zone

The following show-link command displays, from the global zone, data links in a specific, non-global zone.

```
# dladm show-link -z zone1
LINK            CLASS   MTU    STATE   OVER
zone1/net0      vnic    1500   up      e1000g0
```

EXAMPLE 30 Displaying Links in a Non-Global Zone

The following show-link shown below is invoked from zone1 and displays only data links for that zone.

Note that, in show-link output, the zone1/ prefix is not displayed. The prefix is not displayed because the command was invoked from within the zone.

```
# zlogin zone1
# dladm show-link -z zone1
LINK            CLASS   MTU    STATE   OVER
net0            vnic    1500   up      ?
```

EXAMPLE 31 Using -Z Option to Display the Current Zone

The command below presumes the following conditions:

- The link net1 is currently assigned to zoneA. The entries net1 and zoneA/net1 represents the same link. The ZONE column for these two entries is the same and is the name of the zone to which the link is currently assigned.

- The link net2 is not assigned to any non-global zone.

- The link zoneB/net2 is an automatic VNIC created for zoneB.

- The link zoneC/net2 is an automatic VNIC created for zoneC.

- The link zoneD/net2 is an IP tunnel created inside zoneD. Unlike for net1, each entry for net2 represents a different link. The ZONE column for these entries is different.

```
# dladm show-link -Z
LINK        ZONE     CLASS   MTU     STATE   OVER
e1000g0     global   phys    1500    up      --
e1000g1     global   phys    1500    up      --
net1        zoneA    vnic    1500    up      e1000g0
zoneA/net1  zoneA    vnic    1500    up      e1000g0
net2        global   vnic    1500    up      e1000g1
zoneB/net2  zoneB    vnic    1500    up      e1000g1
zoneC/net2  zoneC    vnic    1500    up      e1000g1
zoneD/net2  zoneD    iptun   65515   up      --
```

Attributes See attributes(5) for descriptions of the following attributes:

/usr/sbin

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

/sbin

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

Note that, for both /usr/sbin and /sbin, the -s and -i options to the show-aggr, show-link and show-vnic subcommands are Committed Obsolete.

Note that, for both /usr/sbin and /sbin, show-linkprop's *effective properties have an interface stability of Volatile.

Note that the bridge-related subcommands, described with dladm subcommands above, require installation of the pkg://solaris/network/bridging package.

See Also acctadm(1M), autopush(1M), dhcpagent(1M), dlstat(1M), ifconfig(1M), ipadm(1M), ipsecconf(1M), ndd(1M), pooladm(1M), poolcfg(1M), psrset(1M), vrrpadm(1M), wpad(1M), zonecfg(1M), attributes(5), ieee802.3(5), dlpi(7P)

Notes The preferred method of referring to an aggregation in the aggregation subcommands is by its link name. Referring to an aggregation by its integer *key* is supported for backward compatibility, but is not necessary. When creating an aggregation, if a *key* is specified instead of a link name, the aggregation's link name will be automatically generated by dladm as aggr*key*.

Name dlmgmtd – datalink management daemon

Synopsis /usr/sbin/dlmgmtd

svc:/network/datalink-management:default

Description dlmgmtd is a system daemon that handles administrative events for network datalink interfaces. It is controlled through the service management facility (SMF) service instance:

svc:/network/datalink-management:default

The daemon should not be invoked directly. It does not constitute an administrative nor a programming interface. The administrative interface for managing datalinks is dladm(1M).

Options The daemon has no options.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Private

See Also dladm(1M), attributes(5)

Name dlstat – report data links statistics

Synopsis dlstat [-r | -t] [-Z] [-i *interval*] [-z *zone*[,...]] [*link*]

dlstat [-a | -A] [-Z] [-i *interval*] [-p] [-o *field*[,...]]
        [-u R|K|M|G|T|P] [-z *zone*[,...]] [*link*]

dlstat show-phys [-r | -t] [-Z] [-i *interval*] [-a]
        [-p] [-o *field*[,...]] [-u R|K|M|G|T|P] [-z *zone*[,...]] [*link*]

dlstat show-link [-r | -t] [-Z] [-i *interval*] [-a]
        [-p] [-o *field*[,...]] [-u R|K|M|G|T|P] [-z *zone*[,...]] [*link*]

dlstat show-link -h [-Z] [-a] -f *filename* [-d] [-F *format*] [-s *time*]
            [-e time] [-z *zone*[,...]] [*link*]

dlstat show-aggr [-r | -t] [-Z] [-i *interval*] [-p] [-o *field*[,...]]
        [-u R|K|M|G|T|P] [-z *zone*[,...]] [*link*]

Description The dlstat command reports run time statistics about data links. dladm(1M) show-phys
provides link-name information to dlstat show-phys. dladm(1M) show-link provides
link-name information to dlstat show-link. dladm(1M) show-aggr provides
link-aggregation information to dlstat show-aggr.

dlstat has the six forms of commands shown in the SYNOPSIS, above. The first two forms do
not have subcommands, while the remaining forms do. All six forms are described under
"Subcommands," below.

Options The dlstat command has the following options and operands that are common (unless
explicitly marked otherwise) among a number of command forms shown under
"Subcommands," below.

-a
  Dump all total statistics fields.

-i *interval*
  Specify an interval in seconds at which statistics are refreshed. The default interval is one
  second.

-o *field*[,...]
  Display a case-insensitive, comma-separated list of output fields to display. The field name
  must be one of the fields listed below, or the special value all to display all supported fields.

  List of supported RX fields:

  - link
  - index
  - rbytes
  - ipkts
  - intrs (only applicable without a subcommand or with show-link)
  - polls (only applicable without a subcommand or with show-link)
  - idrops (only applicable without a subcommand or with show-link)

List of TX side fields:

- `link`
- `index`
- `obytes`
- `opkts`
- `odrops` (only applicable without a subcommand or with `show-link`)

For the `show-phys` subcommand, the `index` column identifies individual RX and TX hardware rings within a physical device. For the `show-link` subcommand, the `index` column identifies RX and TX hardware lanes within a data link. See *Oracle Solaris Administration: Network Interfaces and Network Virtualization* for an explanation of the difference between hardware rings and hardware lanes.

-p

Display output in a stable, machine-parseable format.

-r

Display receive-side statistics only. Includes bytes and packets received, hardware and software drops, and so forth. See "Examples" for complete listing.

-t

Display transmit-side statistics only. Includes bytes and packets sent, drops, and so forth. See "Examples" for complete listing.

-u R|K|M|G|T|P

If used, allows choosing the unit in which to display all statistics, for example, R:raw count, K:Kilobits, M:Megabits, T:Terabits, P:Petabits. If not used, then different units, as appropriate, are used to display the statistics, using the format *xy.zU*, where *x*, *y*, and *z* are numbers and *U* is the appropriate unit.

-Z

Display `ZONE` column in the output.

-z *zone*[,...]

Display the statistics only for links in the specified zone. By default, `dlstat` displays the statistics for links in all the zones when it is run from the global zone.

When run from a non-global zone, `dlstat` displays statistics only for links in that zone. A non-global zone cannot see links in other zones.

link

If specified, display the statistics only for the named link, physical device (for `show-phys`), or aggregation (for `show-aggr`). Otherwise, display statistics for all links, devices, or aggregations.

Sub-commands   `dlstat` supports the following command forms.

dlstat [-r | -t] [-Z] [-i *interval*] [-z *zone*[,...]] [*link*]

Iteratively examine all links and report statistics. The output is sorted in descending order of link utilization. If no link is specified, the system displays statistics for all links. The traffic statistics are displayed per link and not per physical device. For example, for a VNIC configured on a physical link, traffic flowing through that VNIC is not reflected in the statistics for the underlying physical link. However, the link statistics will include traffic that matches user-defined flows configured on top of that link.

This command form has one option that is not described under "Options," above:

-A

Dump all statistics fields for this data-link. Output statistics of this command are inclusive of all the statistics reported by all other dlstat commands.

dlstat [-a | -A] [-Z] [-i *interval*] [-p] [-o *field*[,...]] [-u R|K|M|G|T|P] [-z *zone*[,...]] [*link*]

Allows specifying which statistics to display.

The options for this command form are described under "Options," above.

dlstat show-phys [-r | -t] [-Z] [-i *interval*] [-a] [-p] [-o *field*[,...]] [-u R|K|M|G|T|P] [-z *zone*[,...]] [*link*]

Display statistics for a physical device.

The options for this subcommand are described under "Options," above.

dlstat show-link [-r | -t] [-Z] [-i *interval*] [-a] [-p] [-o *field*[,...]] [-u R|K|M|G|T|P] [-z *zone*[,...]] [*link*]

Display statistics for a link.

dlstat show-link -h [-Z] [-a] -f *filename* [-d] [-F *format*] [-s *time*] [-e *time*] [-z *zone*[,...]] [*link*]

Show the network usage history from a stored extended accounting file. Use of this syntax requires that net accounting has been previously configured and enabled by using acctadm(1M). The default output is the summary of network usage of the existing links for the entire period when extended accounting was enabled.

The *link* argument is as described under "Options," above.

-a

Display all historical network usage for the specified period when extended accounting is enabled. This includes usage information about links that have already been deleted.

-f *filename*

Specify the file from which extended accounting records of network usage history are read.

-d

Display the dates for which there is logging information. The date is in the format *mm*/*dd*/*yyyy*.

-F *format*

    Specify the output format of the network usage history information. `gnuplot` is the only supported format.

-s *time*

-e *time*

    Specify start and stop times for data display. Time is in the format *MM*/*DD*/*YYYY*,*hh*:*mm*:*ss*. *hh* uses 24-hour clock notation.

dlstat show-aggr [-r | -t] [-Z] [-i *interval*] [-p] [-o *field*[,...]] [-u R|K|M|G|T|P] [-z *zone*[,...]] [*link*]

    Display per-port statistics for an aggregation.

    The options for this subcommand are described under "Options," above.

Examples

EXAMPLE 1 Displaying Statistics

To display statistics for all the links, enter following command. Statistics are displayed as 3-digits followed by decimal and then 2 digits with the appropriate unit.

```
# dlstat
      LINK    IPKTS   RBYTES    OPKTS   OBYTES
    e1000g0 101.88K   32.86M   40.16K    4.37M
      nxge1   4.50M    6.78G    1.38M   90.90M
      vnic1       8      336        0        0
       net0  73.96K    6.81M        0        0
  zone1/net0 144.47K  13.32M      247   16.29K
  zone2/net0 132.89K  12.25M      236   15.82K
```

EXAMPLE 2 Displaying RX-side Statistics

The following command displays receive-side statistics every one second.

```
# dlstat -r -i 1
    LINK    IPKTS   RBYTES    INTRS    POLLS   IDROPS
  e1000g0 101.91K   32.86M   87.56K   14.35K        0
    nxge1   9.61M   14.47G    5.79M    3.82M        0
    vnic1       8      336        0        0        0
  e1000g0       0        0        0        0        0
    nxge1  82.13K  123.69M   50.00K   32.13K        0
    vnic1       0        0        0        0        0
        .        .        .        .        .        .
        .        .        .        .        .        .
```

EXAMPLE 3 Displaying Statistics per Hardware Ring

The following commands displays statistics on a per receive-side hardware ring basis.

```
# dlstat show-phys -r nxge1
 LINK TYPE   INDEX   IPKTS   RBYTES
 nxge1  rx       0       0        0
```

EXAMPLE 3   Displaying Statistics per Hardware Ring   *(Continued)*

```
nxge1   rx      1       0       0
nxge1   rx      2    1.73M    2.61G
nxge1   rx      3       0       0
nxge1   rx      4    8.44M   12.71G
nxge1   rx      5    5.68M    8.56G
nxge1   rx      6    4.90M    7.38G
nxge1   rx      7       0       0
```

EXAMPLE 4   Displaying Statistics per Lane

The following commands displays statistics on a per receive-side lane basis. First, an interface with dedicated hardware lanes:

```
# dlstat show-link -r nxge1
 LINK TYPE     ID INDEX    IPKTS   RBYTES     INTRS    POLLS  IDROPS
nxge1   rx  local    --       0       0        0       0       0
nxge1   rx     hw     1       0       0        0       0       0
nxge1   rx     hw     2    1.73M    2.61G    1.33M 400.22K      0
nxge1   rx     hw     3       0       0        0       0       0
nxge1   rx     hw     4    8.44M   12.71G    4.35M   4.09M      0
nxge1   rx     hw     5    5.68M    8.56G    3.72M   1.97M      0
nxge1   rx     hw     6    4.90M    7.38G    3.11M   1.80M      0
nxge1   rx     hw     7       0       0        0       0       0
```

Then, an interface without dedicated hardware lanes, that is, a software lane only:

```
# dlstat show-link -r ixgbe0
  LINK TYPE     ID INDEX   IPKTS   RBYTES    INTRS   POLLS IDROPS
ixgbe0   rx  local    --       0       0        0       0       0
ixgbe0   rx     sw    -- 794.28K   1.19G  794.28K       0       0
```

EXAMPLE 5   Displaying Transmit-Side Statistics

The following command displays transmit-side statistics at five-second intervals.

```
# dlstat -t -i 5
  LINK    OPKTS  OBYTES  ODROPS
e1000g0  40.24K    4.37M      0
  nxge1   9.76M  644.14M      0
  vnic1       0       0      0
e1000g0       0       0      0
  nxge1  26.82K    1.77M      0
  vnic1       0       0      0
    .       .       .       .
    .       .       .       .
    .       .       .       .
```

EXAMPLE 6   Displaying Transmit-Side Ring Statistics

The following command displays transmit-side hardware ring statistics.

```
# dlstat show-phys -t nxge1
 LINK TYPE INDEX   OPKTS  OBYTES
nxge1   tx    0      44   3.96K
nxge1   tx    1       0       0
nxge1   tx    2   1.48M 121.68M
nxge1   tx    3   2.45M 201.11M
nxge1   tx    4   1.47M 120.82M
nxge1   tx    5       0       0
nxge1   tx    6   1.97M 161.57M
nxge1   tx    7   4.59M 376.21M
nxge1   tx    8   2.43M 199.24M
nxge1   tx    9       0       0
nxge1   tx   10   3.23M 264.69M
nxge1   tx   11   1.88M 153.96M
```

EXAMPLE 7   Displaying Transmit-Side Lane Statistics

The following command displays transmit-side lane statistics.

```
# dlstat show-link -t nxge1
 LINK TYPE    ID INDEX   OPKTS  OBYTES  ODROPS
nxge1   tx    hw    0      32   1.44K       0
nxge1   tx    hw    1       0       0       0
nxge1   tx    hw    2   1.48M  97.95M       0
nxge1   tx    hw    3   2.45M 161.87M       0
nxge1   tx    hw    4   1.47M  97.25M       0
nxge1   tx    hw    5       3     276       0
nxge1   tx    hw    6   1.97M 130.05M       0
nxge1   tx    hw    7   4.59M 302.80M       0
nxge1   tx    hw    8   2.42M 302.80M       0
nxge1   tx    hw    9       0       0       0
nxge1   tx    hw   10   3.23M 213.05M       0
nxge1   tx    hw   11   1.88M 123.93M       0
```

EXAMPLE 8   Selecting a Particular Set of Statistics

The following command shows how you can select a set of statistics of particular interest.

```
# dlstat show-link -r -o LINK,TYPE,ID,INDEX,INTRS,POLLS nxge1
 LINK TYPE    ID INDEX   INTRS   POLLS
nxge1   rx  local    --      0       0
nxge1   rx  other    --      0       0
nxge1   rx    hw     1      0       0
nxge1   rx    hw     2   2.47M 753.90K
nxge1   rx    hw     3       0       0
nxge1   rx    hw     4   8.24M   7.72M
nxge1   rx    hw     5   6.96M   3.68M
```

EXAMPLE 8   Selecting a Particular Set of Statistics   *(Continued)*

```
nxge1   rx    hw    6   5.82M   3.36M
nxge1   rx    hw    7      0       0
```

EXAMPLE 9   Displaying Historical Network Usage

Network usage history statistics can be stored by using the extended accounting facility,
acctadm(1M), with a command such as the following:

```
# acctadm -e basic -f /var/log/net.log net
acctadm net
Network accounting: active
    Network accounting file: /var/log/net.log
  Tracked Network resources: basic
Untracked Network resources: src_ip,dst_ip,src_port,dst_port,protocol,
                             dsfield
```

The saved historical data can then be retrieved in summary form with a command such as the
following:

```
# dlstat show-link -h -f /var/log/net.log
LINK      DURATION  IPACKETS RBYTES     OPACKETS OBYTES     BANDWIDTH
e1000g0   80        1031     546908     0        0          2.44 Kbps
```

Attributes   See attributes(5) for descriptions of the following attributes:

/usr/sbin

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below

Screen output is Uncommitted. The invocation is Committed.

See Also   acctadm(1M), dladm(1M), ifconfig(1M), kstat(1M), netstat(1M), attributes(5)

Name dmesg – collect system diagnostic messages to form error log

Synopsis /usr/bin/dmesg

/usr/sbin/dmesg

Description dmesg is made obsolete by syslogd(1M) for maintenance of the system error log.

dmesg looks in a system buffer for recently printed diagnostic messages and prints them on the standard output.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also syslogd(1M), attributes(5)

Name dminfo – report information about a device entry in a device maps file

Synopsis dminfo [-v] [-a] [-f *pathname*]

dminfo [-v] [-a] [-f *pathname*] -n *dev -name*...

dminfo [-v] [-a] [-f *pathname*] -d *dev -path*...

dminfo [-v] [-a] [-f *pathname*] -t *dev -type*...

dminfo [-v] [-f *pathname*] -u *dm -entry*

Description dminfo reports and updates information about the device_maps(4) file.

Options The following options are supported

-a   Succeed if any of the requested entries are found. If used with -v, all entries
                  that match the requested case(s) are printed.

-d *dev–path*   Search by *dev–path*. Search device_maps(4) for a device special pathname in
                  the *device_list* field matching the *dev–path* argument. This option cannot be
                  used with -n, -t or -u.

-f *pathname*   Use a device_maps file with *pathname* instead of
                  /etc/security/device_maps.

-n *dev–name*   Search by *dev–name*. Search device_maps(4) for a *device_name* field
                  matching *dev–name*. This option cannot be used with -d, -t or -u.

-t *dev–type*   Search by *dev–type*. Search device_maps(4) for a *device_type* field matching
                  the given *dev–type*. This option cannot be used with -d, -n or -u.

-u *dm–entry*   Update the device_maps(4) file. This option is provided to add entries to the
                  device_maps(4) file. The *dm–entry* must be a complete device_maps(4) file
                  entry. The *dm–entry* has fields, as in the device_maps file. It uses the colon
                  (:) as a field separator, and white space as the *device_list* subfield separators.
                  The *dm–entry* is not made if any fields are missing, or if the *dm–entry* would
                  be a duplicate. The default device maps file can be updated only by the super
                  user.

-v   Verbose. Print the requested entry or entries, one line per entry, on the
                  standard output. If no entries are specified, all are printed.

Exit Status 0   Successful completion.

1   Request failed.

2   Incorrect syntax.

Name dns-sd – Multicast DNS (mDNS) & DNS Service Discovery (DNS-SD) Test Tool

Synopsis dns-sd -R *name type domain port* [*key=value* ...]

dns-sd -B *type domain*

dns-sd -L *name type domain*

dns-sd -Q *FQDN rrtype rrclass*

dns-sd -C *FQDN rrtype rrclass*

dns-sd -P *name type domain port host IP* [*key=value* ...]

dns-sd -E | -F | -A | -U | -N | -T | -M | -I

Description The dns-sd command is a network diagnostic tool, much like ping(1M) or traceroute(1M). However, unlike those tools, most of its functionality is not implemented in the dns-sd executable itself, but in library code that is available to any application. The library API that dns-sd uses is documented in /usr/include/dns_sd.h.

The dns-sd command is primarily intended for interactive use. Because its command-line arguments and output format are subject to change, invoking it from a shell script can be unpredictable. Additionally, the asynchronous nature of DNS Service Discovery does not easily lend itself to script-oriented programming. This style of asynchronous interaction works best with applications that are either multi-threaded, or use a main event-handling loop to receive keystrokes, network data, and other asynchronous event notifications as they happen.

Options The following options are supported:

-R *name type domain port* [*key=value* ...]
　Register (advertise) a service in the specified domain with the given *name* and *type* as listening (on the current machine) on the specified *port*.

　name can be any arbitrary unicode text, containing any legal unicode characters (including dots, spaces, slashes, colons, and so on without any restrictions), up to 63 UTF-8 bytes long.

　type must be of the form "_app-proto._tcp" or "_app-proto._udp", where "app-proto" is an application protocol name registered at http://www.dns-sd.org, under the service types (RFC 2782) link.

　domain is the domain in which to register the service. In current implementations, only the local multicast domain "local" is supported. In the future, registering will be supported in any arbitrary domain that has a working DNS Update server [RFC 2136]. The domain "." is a synonym for "pick a sensible default", which currently means "local".

　port is a number from 0 to 65535, and is the TCP or UDP port number upon which the service is listening. Registering a service on port 0 allows an application to explicitly advertise the non-availability of a service.

Additional attributes of the service may optionally be described by *key/value* pairs, which are stored in the advertised service's DNS TXT record. Allowable keys and values are listed with the service registration at `http://www.dns-sd.org`, under the service types (RFC 2782) link.

-B *type domain*
Browse for instances of service *type* in *domain*.

For valid types, see `http://www.dns-sd.org`, under the service types (RFC 2782) link. Omitting the domain name or using "." means "pick a sensible default."

-L *name type domain*
Look up and display the information necessary to contact and use the named service. This information includes the hostname of the machine where that service is available, the port number on which the service is listening, and (if present) TXT record attributes describing properties of the service.

In a typical application, browsing happens rarely, while lookup (or "resolving") happens every time the service is used. For example, a user does not browse the network to pick a default printer that often, but once a default printer has been picked, that named service is resolved to its current IP address and port number every time the user presses Cmd-P to print.

-Q *FQDN rrtype rrclass*
Generic query for any resource record type and class.

-C *FQDN rrtype rrclass*
Generic query for any resource record type and class. This option also reconfirms each result from the query. Reconfirming the record instructs mdnsd(1M) to verify the validity of the record. If the record is not valid mdnsd(1M) flushes the record from the daemon's cache and also from other mdnsd(1M) caches on the network.

-P *name type domain port host IP* [*key=value* ...]
Register (advertise) a service in the specified domain with the given *name* and *type* listening on the specified port and accessible on another host. This option should be used to advertise by proxy a service accessible on another host. The host name and IPv4 address to access the service must be specified.

-E
Discover recommended registration domains. This option returns the recommended domains to register a service. The recommended registration domains are returned by querying the name servers in resolv.conf(4).

-F
Discover recommended browsing domains. This option returns the recommended domains for browsing services. The recommended browsing domains are returned by querying the name servers in resolv.conf(4).

-A

Test registering service with Multicast DNS and test the add, update and delete operations of DNS records with Multicast DNS.

-U

Test registering service with Multicast DNS and test updating of DNS TXT records for a service registered with Multicast DNS.

-N

Test adding a large NULL record for a service registered with Multicast DNS.

-T

Test adding a large TXT record for a service registered with Multicast DNS.

-M

Test creating a registration with multiple TXT records.

-I

Test registering and then immediately updating a TXT record.

Examples EXAMPLE 1 Advertising a printing service

The following command advertises the existence of LPR printing service on port 515 on this machine, so that it will be available to DNS-SD compatible printing clients:

```
dns-sd -R "My Test" _printer._tcp. . 515 pdl=application/postscript
```

For this registration to be useful, the LPR service should be available on port 515. Advertising a service that does not exist is not very useful.

EXAMPLE 2 Advertising a web page

The following command advertises a web page being served by an HTTP server on port 80 on this machine, so that it will appear on the Bonjour list in Safari and other DNS-SD compatible Web clients:

```
dns-sd -R "My Test" _http._tcp . 80 path=/path-to-page.html
```

EXAMPLE 3 Finding the advertised web pages on the local network

The following command finds the advertised web pages on the local network (the same list that Safari shows):

```
dns-sd -B _http._tcp
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Name dnssec-dsfromkey – DNSSEC DS RR generation tool

Synopsis dnssec-dsfromkey [-v *level*] [-1] [-2] [-a *alg*] *keyfile*

dnssec-dsfromkey -s [-v *level*] [-1] [-2] [-a *alg*] [-c *class*]
    [-d *dir*] *keyfile*

Description dnssec-dsfromkey

Options The following options are supported:

-1
  Use SHA-1 as the digest algorithm. The default is to use both SHA-1 and SHA-256.

-2
  Use SHA-256 as the digest algorithm.

-a *algorithm*
  Select the digest algorithm. The value of *algorithm* must be one of SHA-1 (SHA1) or SHA-256
  (SHA256). These values are case-insensitive.

-v *level*
  Sets the debugging level.

-s
  Keyset mode: in place of the keyfile name, the argument is the DNS domain name of a
  keyset file. The -c and -d options have meaning only in this mode.

-c *class*
  Specifies the DNS class (default is IN); useful only in the keyset mode.

-d *directory*
  Look for keyset files in directory as the directory; ignored when not in the keyset mode.

Examples To build the SHA-256 DS RR from the Kexample.com.+003+26160 keyfile name, use a
command such as the following:

 # dnssec-dsfromkey -2 Kexample.com.+003+26160

This command would produce output similar to the following:

```
example.com. IN DS 26160 5 2
3A1EADA7A74B8D0BA86726B0C227AA85AB8BBD2B2004F41A868A54F0
C5EA0B94
```

Files The keyfile can be designated by the key identification K*nnnn*.+*aaa*+*iiiii*, or the full file name
K*nnnn*.+*aaa*+*iiiii*.key, as generated by dnssec-keygen(1M).

The keyset file name is built from the directory, the string keyset- and the *dnsname*.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/dns/bind
Interface Stability	Volatile

See Also dnssec-keygen(1M), dnssec-signzone(1M), attributes(5)

RFC 3658, *RFC 4509*

Caution A keyfile error can produce a "file not found" message, even if the file exists.

Name   dnssec-keyfromlabel – DNSSEC key generation tool

Synopsis   `dnssec-keyfromlabel -a` *algorithm* `-l` *label* [`-c` *class*] [`-f` *flag*] [`-k`]
          [`-n` *nametype*] [`-p` *protocol*] [`-t` *type*] [`-v` *level*] *name*

Description   `dnssec-keyfromlabel` retrieves keys with a specified label from a crypto hardware device and
          builds key files for DNSSEC (Secure DNS), as defined in RFC 2535 and RFC 4034.

Options   The following options are supported:

   `-a` *algorithm*
      Selects the cryptographic algorithm. The value of *algorithm* must be one of RSAMD5 (RSA)
      or RSASHA1, DSA, NSEC3RSASHA1, NSEC3DSA, or DH (Diffie-Hellman). These values are
      case-insensitive.

      Note that for DNSSEC, RSASHA1 is a mandatory-to-implement algorithm, and DSA is
      recommended. Note also that DH automatically sets the -k flag.

   `-l` *label*
      Specifies the label of keys in the crypto hardware (PKCS#11) device.

   `-n` *nametype*
      Specifies the owner type of the key. The value of *nametype* must either be ZONE (for a
      DNSSEC zone key (KEY/DNSKEY)), HOST or ENTITY (for a key associated with a host (KEY)),
      USER (for a key associated with a user (KEY)), or OTHER (DNSKEY). These values are
      case-insensitive.

   `-c` *class*
      Indicates that the DNS record containing the key should have the specified class. If not
      specified, class IN is used.

   `-f` *flag*
      Set the specified flag in the flag field of the KEY/DNSKEY record. The only recognized flag is
      KSK (Key Signing Key) DNSKEY.

   `-h`
      Displays a short summary of the options and arguments to `dnssec-keyfromlabel`.

   `-k`
      Generate KEY records rather than DNSKEY records.

   `-p` *protocol*
      Sets the protocol value for the generated key. The protocol is a number between 0 and 255.
      The default is 3 (DNSSEC). Other possible values for this argument are listed in RFC 2535
      and its successors.

   `-t` *type*
      Indicates the use of the key. *type* must be one of AUTHCONF, NOAUTHCONF, NOAUTH, or NOCONF.
      The default is AUTHCONF. AUTH refers to the ability to authenticate data, and CONF the ability
      to encrypt data.

-v *level*
    Sets the debugging level.

Generated Key Files When dnssec-keyfromlabel completes successfully, it displays a string of the form K*nnnn*.+*aaa*+*iiiii* to the standard output. This is an identification string for the key files it has generated, which translates as follows.

- *nnnn* is the key name.
- *aaa* is the numeric representation of the algorithm.
- *iiiii* is the key identifier (or footprint).

dnssec-keyfromlabel creates two files, with names based on the displayed string. K*nnnn*.+*aaa*+*iiiii*.key contains the public key, and K*nnnn*.+*aaa*+*iiiii*.private contains the private key.

The first file contains a DNS KEY record that can be inserted into a zone file (directly or with an $INCLUDE statement).

The second file contains algorithm-specific fields. For obvious security reasons, this file does not have general read permission.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/dns/bind
Interface Stability	Volatile

See Also dnssec-keygen(1M), dnssec-signzone(1M), attributes(5)

RFC 2539, *RFC 2845*, *RFC 4033*

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at https://www.isc.org/software/bind/documentation.

Name dnssec-keygen – DNSSEC key generation tool

Synopsis dnssec-keygen -a *algorithm* -b *keysize* -n *nametype* [-ehk]
             [-c *class*] [-f *flag*] [-g *generator*] [-p *protocol*]
             [-r *randomdev*] [-s *strength*] [-t *type*] [-v *level*] *name*

Description The dnssec-keygen utility generates keys for DNSSEC (Secure DNS), as defined in RFC 2535
and RFC 4034. It can also generate keys for use with TSIG (Transaction Signatures), as defined
in RFC 2845.

Options The following options are supported:

-a *algorithm*
    Select the cryptographic algorithm. The value of algorithm must be one of RSAMD5 (RSA)
    or RSASHA1, DSA, NSEC3RSASHA1, NSEC3DSA, DH (Diffie-Hellman), or HMAC-MD5.
    These values are case insensitive.

    For DNSSEC, RSASHA1 is a mandatory-to-implement algorithm and DSA is
    recommended. For TSIG, HMAC-MD5 is mandatory.

    Note – HMAC-MD5 and DH automatically set the -k flag.

-b *keysize*
    Specify the number of bits in the key. The choice of key size depends on the algorithm used.
    RSAMD5 and RSASHA1 keys must be between 512 and 2048 bits. Diffie-Hellman keys
    must be between 128 and 4096 bits. DSA keys must be between 512 and 1024 bits and an
    exact multiple of 64. HMAC-MD5 keys must be between 1 and 512 bits.

-c *class*
    Indicate that the DNS record containing the key should have the specified class. If not
    specified, class IN is used.

-e
    Use a large exponent if generating an RSAMD5 or RSASHA1 key.

-f *flag*
    Set the specified flag in the flag field of the KEY/DNSKEY record. The only recognized flag
    is KSK (Key Signing Key) DNSKEY.

-g *generator*
    Use this *generator* if generating a Diffie Hellman key. Allowed values are 2 and 5. If no
    generator is specified, a known prime from RFC 2539 will be used if possible; otherwise the
    default is 2.

-h
    Print a short summary of the options and arguments to dnssec-keygen.

-k
    Generate KEY records rather than DNSKEY records.

-n *nametype*

Specify the owner type of the key. The value of *nametype* must either be ZONE (for a DNSSEC zone key (KEY/DNSKEY)), HOST or ENTITY (for a key associated with a host (KEY)), USER (for a key associated with a user(KEY)), or OTHER (DNSKEY). These values are case insensitive. Defaults to ZONE for DNSKEY generation.

-p *protocol*

Set the protocol value for the generated key. The *protocol* argument is a number between 0 and 255. The default is 3 (DNSSEC) Other possible values for this argument are listed in RFC 2535 and its successors.

-r *randomdev*

Specify the source of randomness. If the operating system does not provide a /dev/random or equivalent device, the default source of randomness is keyboard input. *randomdev* specifies the name of a character device or file containing random data to be used instead of the default. The special value "keyboard" indicates that keyboard input should be used.

-s *strength*

Specify the strength value of the key. The *strength* argument is a number between 0 and 15, and currently has no defined purpose in DNSSEC.

-t *type*

Indicate the use of the key. type must be one of AUTHCONF, NOAUTHCONF, NOAUTH, or NOCONF. The default is AUTHCONF. AUTH refers to the ability to authenticate data, and CONF the ability to encrypt data.

-v *level*

Set the debugging level.

Generated Keys   When dnssec-keygen completes successfully, it prints a string of the form K*nnnn*.+*aaa*+*iiiii* to the standard output. This is an identification string for the key it has generated.

- *nnnn* is the key name.
- *aaa* is the numeric representation of the algorithm.
- *iiiii* is the key identifier (or footprint).

The dnssec-keygen utility creates two files, with names based on the printed string.

- K*nnnn*.+*aaa*+*iiiii*.key contains the public key.
- K*nnnn*.+*aaa*+*iiiii*.private contains the private key.

The .key file contains a DNS KEY record that can be inserted into a zone file (directly or with a $INCLUDE statement).

The .private file contains algorithm specific fields. For obvious security reasons, this file does not have general read permission.

Both .key and .private files are generated for symmetric encryption algorithm such as HMAC-MD5, even though the public and private key are equivalent.

Examples   EXAMPLE 1   Generating a 768-bit DSA Key

To generate a 768-bit DSA key for the domain example.com, the following command would be issued:

```
dnssec-keygen -a DSA -b 768 -n ZONE example.com
```

The command would print a string of the form:

```
Kexample.com.+003+26160
```

The following files would be created:

```
Kexample.com.+003+26160.key
Kexample.com.+003+26160.private
```

Attributes   See attributes(5) for descriptions of the following attributes:

RFC 2539, *RFC 2845*, *RFC 4033*

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at https://www.isc.org/software/bind/documentation.

Name dnssec-makekeyset – DNSSEC zone signing tool

Synopsis dnssec-makekeyset [-ahp] [-s *start-time*] [-e *end-time*]
        [-r *randomdev*] [-t *ttl*] [-v *level*] *key*...

Description The dnssec-makekeyset utility generates a key set from one or more keys created by
dnssec-keygen(1M). It creates a file containing a KEY record for each key, and self-signs the
key set with each zone key. The output file is of the form *keyset-nnnn.*, where *nnnn* is the zone
name.

Options -a   Verify all generated signatures.

-e *end-time*   Specify the date and time when the generated SIG records expire. As with
              start-time, an absolute time is indicated in YYYYMMDDHHMMSS notation. A time
              relative to the start time is indicated with +*N*, which is *N* seconds from the
              start time. A time relative to the current time is indicated with now+*N*. If no
              end-time is specified, 30 days from the start time is used as a default.

-h   Print a short summary of the options and arguments to
              dnssec-makekeyset().

-p   Use pseudo-random data when signing the zone. This is faster, but less
              secure, than using real random data. This option may be useful when signing
              large zones or when the entropy source is limited.

-r *randomdev*   Specify the source of randomness. If the operating system does not provide a
              /dev/random or equivalent device, the default source of randomness is
              keyboard input. The *randomdev* argument specifies the name of a character
              device or file containing random data to be used instead of the default. The
              special value keyboard indicates that keyboard input should be used.

-s *start-time*   Specify the date and time when the generated SIG records become valid. This
              can be either an absolute or relative time. An absolute start time is indicated
              by a number in YYYYMMDDHHMMSS notation; 20000530144500 denotes
              14:45:00 UTC on May 30th, 2000. A relative start time is indicated by +N,
              which is N seconds from the current time. If no start-time is specified, the
              current time is used.

-t *ttl*   Specify the TTL (time to live) of the KEY and SIG records. The default is 3600
              seconds.

-v *level*   Set the debugging level.

Operands The following operands are supported:

key   The list of keys to be included in the keyset file. These keys are expressed in the form
        K*nnnn.*+*aaa*+*iiiii* as generated by dnssec-keygen.

Examples   EXAMPLE 1   Generates a keyset containing the DSA key for example.com.

The following command generates a keyset containing the DSA key for example.com generated in the dnssec-keygen(1M) manual page.

```
dnssec-makekeyset -t 86400 -s 20000701120000 -e +2592000 \
Kexample.com.+003+26160
```

In this example, dnssec-makekeyset() creates the file keyset-example.com. This file contains the specified key and a self-generated signature.

The DNS administrator for example.com could send keyset-example.com. to the DNS administrator for .com for signing, if the .com zone is DNSSEC-aware and the administrators of the two zones have some mechanism for authenticating each other and exchanging the keys and signatures securely.

Attributes   See attributes(5) for descriptions of the following attributes:

RFC 2535

BIND 9 Administrator Reference Manual

Notes   Source for BIND9 is available in the SUNWbind9S package.

Name   dnssec-signkey – DNSSEC key set signing tool

Synopsis   `dnssec-signkey [-ahp] [-c class] [-e end-time]`
                  `[-r randomdev] [-s start-time] [-v level] keyset key...`

Description   The dnssec-signkey utility signs a keyset. Typically the keyset will be for a child zone and will
have been generated by dnssec-makekeyset(1M). The child zone's keyset is signed with the
zone keys for its parent zone. The output file is of the form signedkey-*nnnn*., where *nnnn* is
the zone name.

Options   The following options are supported:

-a   Verify all generated signatures.

-c *class*   Specify the DNS class of the key sets.

-e *end-time*   Specify the date and time when the generated SIG records expire. As with
                start-time, an absolute time is indicated in YYYYMMDDHHMMSS notation. A time
                relative to the start time is indicated with +*N*, which is *N* seconds from the
                start time. A time relative to the current time is indicated with now+*N*. If no
                end-time is specified, 30 days from the start time is used as a default.

-h   Prints a short summary of the options and arguments to dnssec-signkey().

-p   Use pseudo-random data when signing the zone. This is faster, but less
                secure, than using real random data. This option may be useful when signing
                large zones or when the entropy source is limited.

-r *randomdev* Specify the source of randomness. If the operating system does not provide a
                /dev/random or equivalent device, the default source of randomness is
                keyboard input. *randomdev* specifies the name of a character device or file
                containing random data to be used instead of the default. The special value
                keyboard indicates that keyboard input should be used.

-s *start-time* Specify the date and time when the generated SIG records become valid. This
                can be either an absolute or relative time. An absolute start time is indicated
                by a number in YYYYMMDDHHMMSS notation; 20000530144500 denotes
                14:45:00 UTC on May 30th, 2000. A relative start time is indicated by +*N*,
                which is *N* seconds from the current time. If no *start-time* is specified, the
                current time is used.

-v *level*   Set the debugging level.

Operands   The following operands are supported:

key   The keys used to sign the child's keyset.

keyset   The file containing the child's keyset.

Examples EXAMPLE 1 Sign the *keyset* file for example.com.

The DNS administrator for a DNSSEC-aware .com zone would use the following command to sign the *keyset* file for example.com created by dnssec-makekeyset with a key generated by dnssec-keygen:

dnssec-signkey keyset-example.com. Kcom.+003+51944

In this example, dnssec-signkey creates the file signedkey-example.com, which contains the example.com keys and the signatures by the .com keys.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbind9

Notes Source for BIND9 is available in the SUNWbind9S package.

Name   dnssec-signzone – DNSSEC zone signing tool

Synopsis   dnssec-signzone [-Aaghptz] [-c *class*] [-d *directory*]
         [-e *end-time*] [-f *output-file*] [-H *iterations*] [-I *input_format*]
         [-i *interval*] [-k *key*] [-l *domain*] [-N *soa-serial-format*] [-n *ncpus*]
         [-O *output_format*] [-o *origin*] [-r *randomdev*] [-s *start-time*]
         [-v *level*] [-3 *salt*] *zonefile* [*key*]...

Description   The dnssec-signzone utility signs a zone. It generates NSEC and RRSIG records and produces a
         signed version of the zone. The security status of delegations from the signed zone (that is,
         whether the child zones are secure or not) is determined by the presence or absence of a
         keyset file for each child zone.

Options   The following options are supported:

-A
   When generating an NSEC3 chain, set the OPTOUT flag on all NSEC3 records and do not
   generate NSEC3 records for insecure delegations.

-a
   Verify all generated signatures.

-c *class*
   Specify the DNS class of the zone.

-d *directory*
   Look for keyset files in *directory*.

-e *end-time*
   Specify the date and time when the generated RRSIG records expire. As with start-time,
   an absolute time is indicated in YYYYMMDDHHMMSS notation. A time relative to the start time
   is indicated with +*N*, which is *N* seconds from the start time. A time relative to the current
   time is indicated with now+*N*. If no *end-time* is specified, 30 days from the start time is used
   as a default.

-f *output-file*
   The name of the output file containing the signed zone. The default is to append .signed to
   the input file name.

-g
   Generate DS records for child zones from keyset files. Existing DS records will be
   removed.

-H *iterations*
   When generating a NSEC3 chain use the number of interations specified by *iterations*. The
   default is 100.

-h
   Prints a short summary of the options and arguments to dnssec-signzone().

-I *input-format*

The format of the input zone file. Possible formats are text (default) and raw. This option is primarily intended for dynamic signed zones so that the dumped zone file in a non-text format containing updates can be signed directly. The use of this option serves no purpose for non-dynamic zones.

-i *interval*

Specify the cycle interval as an offset from the current time (in seconds). When a previously signed zone is passed as input, records could be resigned. If an RRSIG record expires after the cycle interval, it is retained. Otherwise, it is considered to be expiring soon and will be replaced.

The default cycle interval is one quarter of the difference between the signature end and start times. If neither *end-time* or *start-time* are specified, dnssec-signzone generates signatures that are valid for 30 days, with a cycle interval of 7.5 days. Any existing RRSIG records due to expire in less than 7.5 days would be replaced.

-j *jitter*

When signing a zone with a fixed signature lifetime, all RRSIG records issued at the time of signing expire simultaneously. If the zone is incrementally signed, that is, a previously-signed zone is passed as input to the signer, all expired signatures have to be regenerated at about the same time. The jitter option specifies a jitter window that will be used to randomize the signature-expire time, thus spreading incremental signature regeneration over time.

Signature lifetime jitter also benefits, to some extent, validators and servers by spreading out cache expiration. That is, if large numbers of RRSIGs from all caches do not expire at the same time, there will be less congestion than if all validators needed to refetch at almost the same time.

-k *key*

Treat specified *key* as a key-signing key, ignoring any key flags. This option can be specified multiple times.

-l *domain*

Generate a DLV set in addition to the key (DNSKEY) and DS sets. The domain is appended to the name of the records.

-N *soa-serial-format*

The SOA serial number format of the signed zone. Possible formats are keep (default), increment and unixtime, described as follows.

keep

Do not modify the SOA serial number.

increment

Increment the SOA serial number using RFC 1982 arithmetic.

unixtime

    Set the SOA serial number to the number of seconds since epoch.

-n *nthreads*

    Specifies the number of threads to use. By default, one thread is started for each detected CPU.

-O *output_format*

    The format of the output file containing the signed zone. Possible formats are text (default) and raw.

-o *origin*

    Specify the zone origin. If not specified, the name of the zone file is assumed to be the origin.

-p

    Use pseudo-random data when signing the zone. This is faster, but less secure, than using real random data. This option may be useful when signing large zones or when the entropy source is limited.

-r *randomdev*

    Specifies the source of randomness. If the operating system does not provide a /dev/random or equivalent device, the default source of randomness is keyboard input. *randomdev* specifies the name of a character device or file containing random data to be used instead of the default /dev/random. The special value keyboard indicates that keyboard input should be used.

-s *start-time*

    Specify the date and time when the generated RRSIG records become valid. This can be either an absolute or relative time. An absolute start time is indicated by a number in *YYYYMMDDHHMMSS* notation; 20000530144500 denotes 14:45:00 UTC on May 30th, 2000. A relative start time is indicated by +*N*, which is *N* seconds from the current time. If no *start-time* is specified, the current time minus one hour (to allow for clock skew) is used.

-t

    Print statistics at completion.

-v *level*

    Set the debugging level.

-z

    Ignore KSK flag on key when determining what to sign.

-3 *salt*

    Generate a NSEC3 chain with the specified hex-encoded *salt*. A dash (-) can be used to indicate that no salt is to be used when generating the NSEC3 chain.

Operands The following operands are supported:

zonefile
> The file containing the zone to be signed.

key
> Specify which keys should be used to sign the zone. If no keys are specified, then the zone
> will be examined for DNSKEY records at the zone apex. If these are found and there are
> matching private keys in the current directory, these will be used for signing.

Examples EXAMPLE 1   Signing a Zone with a DSA Key

The following command signs the example.com zone with the DSA key generated in the
example in the dnssec-keygen(1M) manual page (Kexample.com.+003+17247). The zone's
keys must be in the master file (db.example.com). This invocation looks for keyset files in the
current directory, so that DS records can be generated from them (-g).

```
% dnssec-signzone -g -o example.com db.example.com \
Kexample.com.+003+17247
db.example.com.signed
%
```

In the above example, dnssec-signzone creates the file db.example.com.signed. This file
should be referenced in a zone statement in a named.conf file.

EXAMPLE 2   Re-signing a Previously Signed Zone

The following commands re-sign a previously signed zone with default parameters. The
private keys are assumed to be in the current directory.

```
% cp db.example.com.signed db.example.com
% dnssec-signzone -o example.com db.example.com \
db.example.com.signed
%
```

page, this document is available at https://www.isc.org/software/bind/documentation.

Name   domainname – set or display name of the current domain

Synopsis   domainname [*name-of-domain*]

Description   Without an argument, domainname displays the name of the current domain name used in RPC exchanges, usually referred to as the NIS domain name. This name typically encompasses a group of hosts or passwd entries under the same administration. The domainname command is used by various components of Solaris to resolve names for entries such as are found in passwd, hosts and aliases. By default, naming services such as NIS use domainname to resolve names.

With solaris.smf.manage.domainname rbac(5) privileges, you can set the name of the domain by specifying the domain name as the value of the config/domainname property of the nis/domain service with a sequence of commands such as the following:

```
% svccfg -s nis/domain setprop config/domainname = \
hostname: nisdomain.example.com
% svccfg -s nis/domain:default refresh
% svcadm enable nis/domain
```

In addition to setting the value of config/domainname, the preceding sequence enables the nis/domain service. This service is not enabled by default. The nis/domain service sets up all the shared NIS configuration, of which domainname is the one mandatory configuration parameter.

The domain name for various naming services can also be set by other means. For example, ypinit can be used to specify a different domain for all NIS calls. The domain name of the machine is usually set during boot time through the domainname command by the svc:/system/identity:domain service. If the new domain name is not saved in the /etc/defaultdomain file, the machine reverts to the old domain after it reboots.

The sendmail(1M) daemon, as shipped with Solaris, and the sendmail implementation provided by sendmail.org (formerly referred to as "Berkeley 8.x sendmail") both attempt to determine a local host's fully qualified host name at startup and both pursue follow-up actions if the initial search fails. It is in these follow-up actions that the two implementations differ.

Both implementations use a standard Solaris or Unix system call to determine its fully qualified host name at startup, following the name service priorities specified in nsswitch.conf(4). To this point, the Solaris and sendmail.org versions behave identically.

If the request for a fully qualified host name fails, the sendmail.org sendmail sleeps for 60 seconds, tries again, and, upon continuing failure, resorts to a short name. The Solaris version of sendmail makes the same initial request, but then, following initial failure, calls domainname. If successful, the sleep is avoided.

On a Solaris machine, if you run the sendmail.org version of sendmail, you get the startup behavior (omitting the domainname call) described above. If you run the Solaris sendmail, the domainname call is made if needed.

If the Solaris sendmail cannot determine the fully qualified host name, use check-hostname(1M) as a troubleshooting aid. This script can offer guidance as to appropriate corrective action.

Files ■ /etc/defaultdomain
■ /etc/nsswitch.conf

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also svcs(1), check-hostname(1M), hostconfig(1M), named(1M), sendmail(1M), svcadm(1M), svccfg(1M), ypinit(1M), aliases(4), defaultdomain(4), hosts(4), nsswitch.conf(4), passwd(4), attributes(5), rbac(5), smf(5)

Notes The domainname service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/identity:domain

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name drd – Logical Domain Dynamic Reconfiguration daemon

Synopsis /usr/lib/ldoms/drd

Description The drd daemon is part of the framework that enables the addition and removal of resources from a Logical Domain. This framework is collectively called Dynamic Reconfiguration (DR).

drd is responsible for various aspects of DR on a Logical Domain and must be enabled to ensure proper DR functionality. It is started at boot time and has no configuration options.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/ldoms
Interface Stability	Uncommitted

See Also svcs(1), svcadm(1M), syslog(3C), syslog.conf(4), attributes(5), smf(5)

Errors drd uses syslog(3C) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_INFO priority. The default entries in the /etc/syslog.conf file log all the drd error messages to the /var/adm/messages log.

Notes The drd service is managed by the service management facility, smf(5), under the service identifier:

svc:/platform/sun4v/drd:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name drvconfig – apply permission and ownership changes to devices

Synopsis drvconfig [-bn] [-a *alias_name*] [-c *class_name*]
         [-i *drivername*] [-m *major_num*] [-r *root_dir*]

Description devfsadm(1M) is now the preferred command and should be used instead of drvconfig.

The default operation of drvconfig is to apply permission and ownership changes to devices. Normally, this command is run automatically after a new driver has been installed (with add_drv(1M)) and the system has been rebooted.

Options The following options are supported:

-a*alias_name*   Add the name *alias_name* to the list of aliases that this driver is known by. This option, if used, must be used with the -m *major_num*, the -b and the -i *drivername* options.

-b   Add a new major number to name binding into the kernel's internal name_to_major tables. This option is not normally used directly, but is used by other utilities such as add_drv(1M). Use of the -b option requires that -i and -m be used also. No /devices entries are created.

-c*class_name*   The driver being added to the system exports the class *class_name*. This option is not normally used directly, but is used by other utilities. It is only effective when used with the -b option.

-i*drivername*   Only configure the devices for the named driver. The following options are used by the implementation of add_drv(1M) and rem_drv(1M), and may not be supported in future versions of Solaris:

-m*major_num*   Specify the major number *major_num* for this driver to add to the kernel's name_to_major binding tables.

-n   Do not try to load and attach any drivers, or if the -i option is given, do not try to attach the driver named *drivername*.

-r*root_dir*   Perform operations under *root_dir*, rather than directly under root.

Exit Status 0   Successful completion.

non-zero   An error occurred.

Files /devices   Device nodes directory

/etc/minor_perm   Minor mode permissions

/etc/name_to_major   Major number binding

/etc/driver_classes   Driver class binding file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also sh(1), add_drv(1M), modinfo(1M), modload(1M), modunload(1M), rem_drv(1M), update_drv(1M), path_to_inst(4), attributes(5), devfs(7FS)

Name dsbitmap – size Availability Suite bitmap volumes

Synopsis dsbitmap -h

dsbitmap -p *data_volume* [*bitmap_volume*]

dsbitmap -r *data_volume* [*bitmap_volume*]

Description The dsbitmap command calculates the size of the Availability Suite bitmap volume required for use with the specified data volume.

Options The following options are supported:

-h

  Prints the usage message for the dsbitmap command

-p *data_volume* [*bitmap_volume*]

  For the given *data_volume*, dsbitmap calculates and display the required size for the associated Availability Suite Point in Time bitmap volume. The bitmap volume sizes for all possible Availability Suite Point in Time set configurations are displayed. These configurations include Independent shadow, Full size dependent shadow, and Compact dependent shadow. If the optional *bitmap_volume* argument is supplied, dsbitmap determines if this volume is large enough to be used as the bitmap volume for *data_volume*.

-r *data_volume* [*bitmap_volume*]

  For the given *data_volume*, dsbitmap calculates and displays the required size for the associated Availability Suite Remote Mirror bitmap volume. The bitmap volume sizes for all possible Availability Suite Remote Mirror set configurations are displayed. These configurations include Sync replication, Async replication with memory queue, disk queue and 32 bit refcount. If the optional *bitmap_volume* argument is supplied, dsbitmap determines if this volume is large enough to be used as the bitmap volume for *data_volume*.

Usage dsbitmap is typically used by the system administrator during the initial stages of configuring Sun StorageTek Availability Suite software in order to determine the required bitmap volume sizes, and then to check if the bitmap volumes that have been created are suitable.

Exit Status The following exit values are returned:

0   Successful completion. If the name of a bitmap volume was specified, that volume is sufficiently large for all potential uses.

1   An error occurred.

2   An invalid option was supplied on the command line.

3   The specified bitmap volume is not large enough to be used as an Availability Suite Remote Mirror bitmap for an asynchronous set with a disk queue, but is large enough to be used for all other Remote Mirror set configurations.

4   The specified bitmap volume is not large enough to be used as an Availability Suite Remote Mirror bitmap for any Remote Mirror set configuration.

5	The specified bitmap volume is not large enough to be used as an Availability Suite Remote Mirror bitmap for any Remote Mirror set configuration.
6	The specified bitmap volume is not large enough to be used as an Availability Suite Point in Time bitmap for a compact dependent shadow, but is large enough to be used for all other Point in Time set configurations.

Attributes See attributes(5) for descriptions of the following attributes:

Name dscfg – configuration tool for Sun StorageTek Availability Suite software

Synopsis dscfg

dscfg -L

dscfg -h

dscfg [-C *group*]

dscfg [-C *group*] -i [-p *parser_config_file*]

dscfg [-C *group*] -a *config_file*

dscfg [-C *group*] [-l]

dscfg [-C *group*] [-l] -s *config_location*

dscfg -D *dgname*

Description The dscfg command controls the Availability Suite configuration by providing facilities to initialize, list, format, restore the configuration database.

Options If no options are specified, dscfg displays the current local configuration location. The dscfg command supports the following options:

-L

Displays the status of the lock controlling access to the configuration database. If the configuration database is locked, the type of lock (read or write) is displayed along with the process id of the process that holds the lock.

-h

Displays the usage message for the dscfg command.

-i

Initializes the configuration database. As it deletes previous or current configuration information, this option prompts you to confirm the deletion before proceeding.

-p *parser_config_file*

When used with the -i option, dscfg loads the parser configuration file into the persistent configuration, it reformats the configuration database.

-a *config_file*

Restore the specified *config_file* into the configuration. This option does not do any error checking of the file. Use of this option invalidates the configuration file.

-l

Lists the contents of current configuration database in a format that is suitable for the -a option. When used in combination with the -s option, it displays the contents stored in the location passed to the -s option, but does not set the configuration location.

The options below are for Sun Cluster-configured systems only. *group* can be either Sun Cluster device group or as '-' as local devices.

-C *group*	Display the location of cluster configuration database.
-C *group* -i	Initializes the configuration database entries that only associated with group specified. As it deletes previous or current configuration information, this options prompts you to confirm the deletion before proceeding.
-C *group* -p *parser_config_file*	When used with the -i option, dscfg loads the parser configuration file into the persistent configuration, it reformats the configuration database entries that only associated with group specified.
-C *group* -a *config_file*	Restore the specified *config_file* into the configuration database entries that only associated with group specified. This option does not do any error checking of the file. Use of this option invalidates the configuration file.
-C *group* -l	Lists the contents of current configuration database that is associated with resource group specified.
-C *group* -s *config_file_location*	Specifies where the Sun Cluster configuration database resides, the location has to be DID device.
-D *device_group*	Checks whether the specified *device_group* is known by Sun Cluster and whether it is available on this node. It displays a information that indicates the device group's status and return values are as follows,

(use echo $? to retrieve the return value):

1	Device group is in Sun Cluster and is active on this node;
0	Device group is in Sun Cluster but active on another node;
−1	Device group is not in Sun Cluster.

Usage   The dscfg command is typically run from other scripts, such as package installation scripts, and from dscfgadm(1M). It is not intended for general use. For uses of dscfg not covered by dscfgadm, please refer to the *Availability Suite Troubleshooting Guide*.

Files   /etc/dscfg_format
parser configuration file

/etc/dscfg_local
configuration location for all entries with no cluster tags

/etc/dscfg_cluster
reference file specifying the location of the Sun Cluster configuration database.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/avs/avs-cache-management
Interface Stability	Committed

See Also dscfgadm(1M), iiadm(1M), scmadm(1M), sndradm(1M), svadm(1M), ds.log(4), attributes(5)

Name   dscfgadm – administration command for the Availability Suite configuration location and services

Synopsis   dscfgadm -i

dscfgadm -e [-r] [-p]

dscfgadm -d [-r]

dscfgadm -s

Description   The dscfgadm command controls the Availability Suite configuration location and services by providing facilities to set the configuration location, and to enable and disable the Availability Suite services.

Options   If you do not specify any arguments to a dscfgadm command, the utility interactively steps you through setting the configuration location and starting the services. The configuration location is validated to ensure it meets criteria such as size and file type before it is initialized for use.

The dscfgadm command supports the following options.

-d [-r]

Disables the Availability Suite SMF services. This includes stopping daemons and suspending any Point-in-Time Copy or Remote Mirror sets that are currently enabled under the Availability Suite software. When executed with no additional options, the -d option disables all Availability Suite services. This setting is persistent across system boots.

-r

When passed to the -d or -e option, acts only on the Remote Mirror services.

-e [-r] [-p]

Enables the Availability Suite SMF services. This includes starting daemons and resuming any Point-in-Time Copy or Remote Mirror sets that have been previously configured under the Availability Suite software. When executed with no additional options, the -e option enables all Availability Suite services. This setting is persistent across system boots.

-r

When passed to the -d or -e option, acts only on the Remote Mirror services.

-p

When passed to the -e option, enables only the Point-in-Time Copy service.

-i

Displays information on the Availability Suite SMF services.

-s

Allows you to set the location of the configuration database containing information specific to Sun Cluster configurations.

-x

Displays verbose debugging information as the program is executing.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/avs/avs-cache-management
Interface Stability	Committed

See Also dscfg(1M), iiadm(1M), scmadm(1M), sndradm(1M), svadm(1M), attributes(5)

Name dscfglockd – Availability Suite Services lock daemon

Synopsis `/usr/lib/dscfglockd [-e` *program* `| -f` *file*`]`

Description The `dscfglockd` daemon coordinates StorageTek configuration database lock requests between nodes within a cluster.

Options The `dscfglockd` supports the following options:

-e *program*
Executes the script and arguments in *program*. The executable and any arguments it needs must be supplied with suitable quoting as a single argument to this option. This argument is processed by `sh(1)`.

-f *file*
Reads the list of names for peer hosts from *file*.

If no arguments are specified, `dscfglockd` acts as a local lock daemon, but coordinates lock requests with any other daemons that might contact the local host as part of their own configuration process.

Exit Status 0   Daemon started successfully.

>0   Daemon failed to start.

Files `/lib/svc/method/svc-scm`
Shell script for starting and stopping `dscfglockd`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/avs/avs-cache-management
Interface Stability	Committed

See Also `sh(1)`, `attributes(5)`

Name   dsstat – report Sun StorageTek Availability Suite I/O statistics

Synopsis   dsstat -m *mode* [-r *report–options*] [-d *display-options*]
[-s *volume-sets*] [-f | -F] [-z] [*interval* [*count*]]

Description   The dsstat command collects and reports I/O statistics for the Sun StorageTek Availability Suite products.

Options   The dsstat supports the following options:

-m *mode*
   Specifies the mode(s) of operation. Valid modes are:

   cache
      Cache statistics

   ii
      Point-in-Time Copy statistics

   sndr
      Remote Mirror statistics

   To display statistics for multiple services simultaneously, use the -m switch to specify each of the modes required. For example:

   ```
   % dsstat -m ii -m sndr
   % dsstat -m ii -m sndr -m cache
   ```

   To determine which statistics are being reported from which service, use the *role* field, described below. When cache statistics are requested as one of the multiple services, the rkps and wkps statistics is further divided into crkps, drkps, cwkps, and dwkps. If no -m switch is specified, then dsstat displays default statistics for all of the valid modes as described above. See "Field Descriptions," below for descriptions of these fields.

-r *report–options*
   Specifies the volume components to be displayed. Each item is represented by a single character, and multiple items can be selected. The *report–options* vary based on the mode(s) specified above. This option is not used for cache mode.

   Valid *report-options* for ii mode are:

   m   Master volume statistics.

              ■ For the "report-options for ii mode": m, s, b, o
              ■ For the "report-options for sndr mode": b, n
              ■ For the "display-options for cache mode": r, w, d, c, s, f
              ■ For the "display-options for ii mode": r, w, t, s, p, f

   s   Shadow volume statistics.

   b   Bitmap volume statistics.

o   Overflow volume statistics, if attached.

Valid *report–options* for `sndr` mode are:

b   Bitmap volume statistics.

n   Network volume statistics.

-d *display–options*
Specifies the statistics to be displayed. The types of statistics are represented by a single
character; multiple types can be specified.

For `cache` mode, the valid *display-options* are:

r   Detailed read statistics.

w   Detailed write statistics.

s   Summary statistics.

f   Cache behavior flags.

The following *display–options* are available only for cache mode, they need to be combined
with the mode options (`-m`)

d   Destaged data statistics.

c   Write cancellation statistics.

The default *display-options* for `cache` are `sf`.

For `ii` mode, the valid *display-options* are:

r

Detailed read statistics.

w

Detailed write statistics.

t

Timing statistics.

s

Summary statistics.

p

Percentage of volume requiring sync.

f

Volume type/status flags.

The default *display-options* for `ii` are `spf`. For `sndr` mode, the valid *display-options* are:

r   Detailed read statistics.

w		Detailed write statistics.
t		Timing statistics.
s		Summary statistics.
p		Percentage of volume requiring sync.
f		Volume type/status flags.
q		Asynchronous queue statistics.

The following *display-option* is only available for sndr mode, and needs to be combined with the mode options (-m).

q   Asynchronous queue statistics.

The default *display-options* for sndr are spf.

Specifying the summary *display–option* causes r w t *display–options* to be ignored.

-s *volume–sets*   Filters the output to include only the specified *volume–sets*, where *volume-sets* is a comma-delimited list of volume names. When displaying Remote Mirror statistics, the name specified is compared to the Remote Mirror primary volume to determine if they match. Additionally, an Remote Mirror volume should be specified as *<host>*:*<volume>* where *<host>* is the primary or secondary host and *<volume>* is the volume name by which that host recognizes the volume set. When specifying multiple Remote Mirror volumes sets, be aware that each volume set specified is evaluated individually, using the rules above. When displaying Point-in-Time Copy statistics, the volume name specified is compared to the Point-in-Time Copy shadow volume to determine if they match.

-f   Output field headers at every reporting cycle.

-F   Output field headers once, when reporting begins.

-z   Suppress report lines that have zero values or no activity.

Operands   The dsstat command line supports the following operands:

interval
    Specifies the *interval* for each report, in seconds. If no *interval* is specified, a single report with a one second *interval* is output.

    Due to the varying number of entries in a given set and the varying number of sets, header information might appear in the middle a set being reported. To avoid this, use the -f or -F options to display the header information at the desired time.

count

Specifies the number of reports to generate. If no *count* is specified, output continues until interrupted.

Field Descriptions   Unless otherwise specified, all fields are per-second averages based on the data collected during the specified *interval*.

name	Name of the entity being reported
t	Volume type
s	Volume status
r	Cache read behavior
w	Cache write behavior
pct	Percentage of volume requiring sync
role	Role of the item being reported
tps	Total number of reads + writes
rtps	Number of reads
wtps	Number of writes
kps	Total kilobytes read + written
rkps	Kilobytes read
wkps	Kilobytes written
crkps	Kilobytes read from cache
drkps	Kilobytes read from disk
cwkps	Kilobytes written to cache
dwkps	Kilobytes written to disk
ckps	Kilobytes transferred to or from cache
dkps	Kilobytes transferred to or from disk
svt	Service time per operation
hit	Read hits during *interval*
ds/s	Kilobytes destaged from cache
cn/s	Number of write cancellations
q	Type of asynchronous queuing being used
qi	Number of items currently queued

qk   Kilobytes currently queued

qhwi   High water mark of queued items

qhwk   High water mark of queued kilobytes

The name field displays only the last 16 characters of the name.

Valid cache behaviors for cache are:

C   Cache reads/writes

D   Disk reads/writes

Valid volume types for ii are:

I   Independent shadow volume

D   Dependent shadow volume

Valid volume status for ii is:

C   Copy in progress

-   No copy in progress

Valid volume types for sndr are:

P   This is the primary host of this volume set

S   This is the secondary host of this volume set

Valid volume status for sndr is:

L   Changes to this volume are being logged

Q   Volume are in queuing mode

R   Replicating changes to secondary

SY   Synchronization in progress. Sending data.

RS   Reverse synchronization in progress. Receiving data.

SN   Synchronization needed

RN   Reverse synchronization needed

VF   Volume failed

BF   Bitmap failed

QF   Queue failed

Valid queue types for sndr are:

D	Disk-based queuing enabled	
M	Memory-based queuing enabled	

Volume roles for sndr are:

net	Network volume statistics
bmp	Bitmap volume statistics

Volume roles for ii are:

mst	Master volume statistics
shd	Shadow volume statistics
bmp	Bitmap volume statistics
ovr	Overflow volume statistics

Examples   **EXAMPLE 1**   Report Cache Statistics

The following example shows the display of Report Cache statistics, with detailed breakdowns of read and writes to cache/disk. Reports are generated at five second intervals. Reporting is limited to the set /dev/rdsk/c1t1d0s0.

```
 # dsstat -m cache -d rw -s /dev/rdsk/c1t1d0s0 5
- read -            - write -
name             ckps    dkps    hit   ckps    dkps     hit
dev/rdsk/c1t1d0s0    0       0   0.00      0       0    0.00
dev/rdsk/c1t1d0s0    3    2396   0.13    983     763  100.00
dev/rdsk/c1t1d0s0 2399     799  75.00   2815    2686  100.00
dev/rdsk/c1t1d0s0 3200     800  80.00   2755    2908  100.00
dev/rdsk/c1t1d0s0 3999     799  83.33   2809    2868  100.00
dev/rdsk/c1t1d0s0 4800     800  85.71   2867    2931  100.00
```

EXAMPLE 2   Report Master, Shadow and Bitmap Statistics

Report master, shadow and bitmap statistics for Point-in-Time Copy, using default output. Generate reports at two second intervals.

```
# dsstat -m ii -r msb 2
name            t  s    pct role     kps   tps  svt
dev/rdsk/c0t1d0s5  I  C  96.15  mst  19921    38   22
dev/rdsk/c0t1d0s6               shd   9960    19   20
dev/rdsk/c0t1d0s7               bmp     39    77    2
dev/rdsk/c0t1d0s5  I  C  94.24  mst  19623    38   22
dev/rdsk/c0t1d0s6               shd   9939    19   20
dev/rdsk/c0t1d0s7               bmp     39    77    2
dev/rdsk/c0t1d0s5  I  C  92.34  mst  19969    39   22
dev/rdsk/c0t1d0s6               shd   9984    19   20
```

EXAMPLE 2 Report Master, Shadow and Bitmap Statistics *(Continued)*

```
dev/rdsk/c0t1d0s7                bmp    39   78    2
```

EXAMPLE 3 Report Network Statistics for Remote Mirror

Report network statistics for Remote Mirror, using detailed read, write statistics. Report includes volume type/status flags and percentages. Generate reports at two second intervals. Limit reporting to the set /dev/rdsk/c0t1d0s0.

```
# dsstat -m sndr -r n -d rwpf -s /dev/rdsk/c0t1d0s0 2
name             t  s   pct role   rkps  rtps   wkps  wtps
dev/rdsk/c0t1d0s0 P  L 100.00  sec     0     0      0     0
dev/rdsk/c0t1d0s0 P SY  99.90  sec     0     0    288     9
dev/rdsk/c0t1d0s0 P SY  97.90  sec     0     0   5296   165
dev/rdsk/c0t1d0s0 P SY  95.81  sec     0     0   5184   161
dev/rdsk/c0t1d0s0 P SY  93.81  sec     0     0   5280   164
dev/rdsk/c0t1d0s0 P SY  91.71  sec     0     0   5198   162
```

Exit Status The following exit values are returned:

0　　　　Successful completion.

1　　　　Successful completion, no statistics to report.

2　　　　An invalid argument has been encountered.

3　　　　No memory is available to create kstat statistics.

4　　　　An unknown error has occurred.

Attributes See attributes(5) for descriptions of the following attributes:

Name   dsvclockd – DHCP service lock daemon

Synopsis /usr/lib/inet/dsvclockd [-d 1 | 2] [-f] [-v]

Description The dsvclockd daemon is a lock manager that works in conjunction with the Dynamic Host
Configuration Protocol (DHCP) Data Service Library (libdhcpsvc). It provides shared or
exclusive access to the dhcp_network(4) and dhcptab(4) tables. This service is used by the
SUNWbinfiles and SUNWfiles DHCP data store modules. See dhcp_modules(5).

dsvclockd is started on demand by libdhcpsvc. The dsvclockd daemon should be started
manually only if command line options need to be specified.

Options The following options are supported:

-d 1 | 2   Set debug level. Two levels of debugging are currently available, 1 and 2. Level 2 is
more verbose.

-f   Run in the foreground instead of as a daemon process. When this option is used,
messages are sent to standard error instead of to syslog(3C).

-v   Provide verbose output.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/dhcp
Interface Stability	Uncommitted

Name dtrace – DTrace dynamic tracing compiler and tracing utility

Synopsis dtrace [-32 | -64] [-aACeFGHhlqSvVwZ] [-b *bufsz*] [-c *cmd*]
[-D *name* [=*value*]] [-I *path*] [-L *path*] [-o *output*]
[-s *script*] [-U *name*] [-x *arg* [=*val*]]
[-X a | c | s | t] [-p *pid*]
[-P *provider* [[*predicate*] *action*]]
[-m [*provider:*] *module* [[*predicate*] *action*]]
[-f [[*provider:*] *module:*] *function* [[*predicate*] *action*]]
[-n [[[*provider:*] *module:*] *function:*] *name* [[*predicate*] *action*]]
[-i *probe-id* [[*predicate*] *action*]]

Description DTrace is a comprehensive dynamic tracing framework for the Solaris Operating System.
DTrace provides a powerful infrastructure that permits administrators, developers, and
service personnel to concisely answer arbitrary questions about the behavior of the operating
system and user programs.

The *Solaris Dynamic Tracing Guide* describes how to use DTrace to observe, debug, and tune
system behavior. Refer to this book for a detailed description of DTrace features, including the
bundled DTrace observability tools, instrumentation providers, and the D programming
language.

The dtrace command provides a generic interface to the essential services provided by the
DTrace facility, including:

- Options that list the set of probes and providers currently published by DTrace
- Options that enable probes directly using any of the probe description specifiers (provider,
  module, function, name)
- Options that run the D compiler and compile one or more D program files or programs
  written directly on the command line
- Options that generate anonymous tracing programs
- Options that generate program stability reports
- Options that modify DTrace tracing and buffering behavior and enable additional D
  compiler features

You can use dtrace to create D scripts by using it in a #! declaration to create an interpreter
file. You can also use dtrace to attempt to compile D programs and determine their
properties without actually enabling tracing using the -e option. See OPTIONS. See the *Solaris
Dynamic Tracing Guide* for detailed examples of how to use the dtrace utility to perform
these tasks.

Options The arguments accepted by the -P, -m, -f, -n, and -i options can include an optional D
language *predicate* enclosed in slashes // and optional D language *action* statement list
enclosed in braces {}. D program code specified on the command line must be appropriately
quoted to avoid interpretation of meta-characters by the shell.

The following options are supported:

-32 | -64

The D compiler produces programs using the native data model of the operating system kernel. You can use the isainfo -b command to determine the current operating system data model. If the -32 option is specified, dtrace forces the D compiler to compile a D program using the 32-bit data model. If the -64 option is specified, dtrace forces the D compiler to compile a D program using the 64-bit data model. These options are typically not required as dtrace selects the native data model as the default. The data model affects the sizes of integer types and other language properties. D programs compiled for either data model can be executed on both 32-bit and 64-bit kernels. The -32 and -64 options also determine the ELF file format (ELF32 or ELF64) produced by the -G option.

-a

Claim anonymous tracing state and display the traced data. You can combine the -a option with the -e option to force dtrace to exit immediately after consuming the anonymous tracing state rather than continuing to wait for new data. See the *Solaris Dynamic Tracing Guide* for more information about anonymous tracing.

-A

Generate driver.conf(4) directives for anonymous tracing. This option constructs a set of dtrace(7D) configuration file directives to enable the specified probes for anonymous tracing and then exits. By default, dtrace attempts to store the directives to the file /kernel/drv/dtrace.conf. You can modify this behavior if you use the -o option to specify an alternate output file.

-b *bufsz*

Set principal trace buffer size (*bufsz*). The trace buffer size can include any of the size suffixes k, m, g, or t. If the buffer space cannot be allocated, dtrace attempts to reduce the buffer size or exit depending on the setting of the bufresize property.

-c *cmd*

Run the specified command *cmd* and exit upon its completion. If more than one -c option is present on the command line, dtrace exits when all commands have exited, reporting the exit status for each child process as it terminates. The process-ID of the first command is made available to any D programs specified on the command line or using the -s option through the $target macro variable. Refer to the *Solaris Dynamic Tracing Guide* for more information on macro variables.

-C

Run the C preprocessor cpp(1) over D programs before compiling them. You can pass options to the C preprocessor using the -D, -U, -I, and -H options. You can select the degree of C standard conformance if you use the -X option. For a description of the set of tokens defined by the D compiler when invoking the C preprocessor, see -X.

-D *name* [=*value*]

Define *name* when invoking cpp(1) (enabled using the -C option). If you specify the equals sign (=) and additional *value*, the name is assigned the corresponding value. This option passes the -D option to each cpp invocation.

-e

Exit after compiling any requests and consuming anonymous tracing state (-a option) but prior to enabling any probes. You can combine this option with the -a option to print anonymous tracing data and exit. You can also combine this option with D compiler options. This combination verifies that the programs compile without actually executing them and enabling the corresponding instrumentation.

-f[[*provider*:]*module*:]*function*[[*predicate*]*action*]]

Specify function name to trace or list (-l option). The corresponding argument can include any of the probe description forms *provider:module:function*, *module:function*, or *function*. Unspecified probe description fields are left blank and match any probes regardless of the values in those fields. If no qualifiers other than *function* are specified in the description, all probes with the corresponding *function* are matched. The -f argument can be suffixed with an optional D probe clause. You can specify more than one -f option on the command line at a time.

-F

Coalesce trace output by identifying function entry and return. Function entry probe reports are indented and their output is prefixed with ->. Function return probe reports are unindented and their output is prefixed with <-. System call entry probe reports are indented and their output is prefixed with =>. System call return probe reports are unindented and their output is prefixed with <=.

-G

Generate an ELF file containing an embedded DTrace program. The DTrace probes specified in the program are saved inside of a relocatable ELF object which can be linked into another program. If the -o option is present, the ELF file is saved using the pathname specified as the argument for this operand. If the -o option is not present and the DTrace program is contained with a file whose name is *filename*.d, then the ELF file is saved using the name *filename*.o. Otherwise the ELF file is saved using the name d.out.

-H

Print the pathnames of included files when invoking cpp(1) (enabled using the -C option). This option passes the -H option to each cpp invocation, causing it to display the list of pathnames, one for each line, to stderr.

-h

Generate a header file containing macros that correspond to probes in the specified provider definitions. This option should be used to generate a header file that is included by other source files for later use with the -G option. If the -o option is present, the header file is saved using the pathname specified as the argument for that option. If the -o option is not present and the DTrace program is contained with a file whose name is *filename*.d, then the header file is saved using the name *filename*.h.

-i *probe-id*[[*predicate*] *action*]

Specify probe identifier (*probe-id*) to trace or list (-l option). You can specify probe IDs using decimal integers as shown by dtrace -l. The -i argument can be suffixed with an optional D probe clause. You can specify more than one -i option at a time.

-I *path*

　　Add the specified directory *path* to the search path for #include files when invoking cpp(1) (enabled using the -C option). This option passes the -I option to each cpp invocation. The specified *path* is inserted into the search path ahead of the default directory list.

-L *path*

　　Add the specified directory *path* to the search path for DTrace libraries. DTrace libraries are used to contain common definitions that can be used when writing D programs. The specified *path* is added after the default library search path.

-l

　　List probes instead of enabling them. If the -l option is specified, dtrace produces a report of the probes matching the descriptions given using the -P, -m, -f, -n, -i, and -s options. If none of these options are specified, this option lists all probes.

-m [[*provider:*] *module:* [[*predicate*] *action*]]

　　Specify module name to trace or list (-l option). The corresponding argument can include any of the probe description forms *provider:module* or *module*. Unspecified probe description fields are left blank and match any probes regardless of the values in those fields. If no qualifiers other than *module* are specified in the description, all probes with a corresponding *module* are matched. The -m argument can be suffixed with an optional D probe clause. More than one -m option can be specified on the command line at a time.

-n [[[*provider:*] *module:*] *function:*] *name* [[*predicate*] *action*]

　　Specify probe name to trace or list (-l option). The corresponding argument can include any of the probe description forms *provider:module:function:name*, *module:function:name*, *function:name*, or *name*. Unspecified probe description fields are left blank and match any probes regardless of the values in those fields. If no qualifiers other than *name* are specified in the description, all probes with a corresponding *name* are matched. The -n argument can be suffixed with an optional D probe clause. More than one -n option can be specified on the command line at a time.

-o *output*

　　Specify the *output* file for the -A , -G, -h, and -l options, or for the traced data itself. If the -A option is present and -o is not present, the default output file is /kernel/drv/dtrace.conf. If the -G option is present and the -s option's argument is of the form *filename*.d and -o is not present, the default output file is *filename*.o. Otherwise the default output file is d.out.

　　Note that with successive invocations of dtrace with the -o option, dtrace does not overwrite, but rather appends to the output file.

-p *pid*

　　Grab the specified process-ID *pid*, cache its symbol tables, and exit upon its completion. If more than one -p option is present on the command line, dtrace exits when all commands have exited, reporting the exit status for each process as it terminates. The first process-ID

is made available to any D programs specified on the command line or using the -s option through the $target macro variable. Refer to the *Solaris Dynamic Tracing Guide* for more information on macro variables.

-P *provider* [[*predicate*] *action*]

Specify provider name to trace or list (-l option). The remaining probe description fields module, function, and name are left blank and match any probes regardless of the values in those fields. The -P argument can be suffixed with an optional D probe clause. You can specify more than one -P option on the command line at a time.

-q

Set quiet mode. dtrace suppresses messages such as the number of probes matched by the specified options and D programs and does not print column headers, the CPU ID, the probe ID, or insert newlines into the output. Only data traced and formatted by D program statements such as trace() and printf() is displayed to stdout.

-s

Compile the specified D program source file. If the -e option is present, the program is compiled but instrumentation is not enabled. If the -l option is present, the program is compiled and the set of probes matched by it is listed, but instrumentation is not enabled. If none of -e, -l, -G, or -A are present, the instrumentation specified by the D program is enabled and tracing begins.

-S

Show D compiler intermediate code. The D compiler produces a report of the intermediate code generated for each D program to stderr.

-U *name*

Undefine the specified *name* when invoking cpp(1) (enabled using the -C option). This option passes the -U option to each cpp invocation.

-v

Set verbose mode. If the -v option is specified, dtrace produces a program stability report showing the minimum interface stability and dependency level for the specified D programs. DTrace stability levels are explained in further detail in the *Solaris Dynamic Tracing Guide*.

-V

Report the highest D programming interface version supported by dtrace. The version information is printed to stdout and the dtrace command exits. Refer to the *Solaris Dynamic Tracing Guide* for more information about DTrace versioning features.

-w

Permit destructive actions in D programs specified using the -s, -P, -m, -f, -n, or -i options. If the -w option is not specified, dtrace does not permit the compilation or enabling of a D program that contains destructive actions.

-x *arg* [*=val*]

Enable or modify a DTrace runtime option or D compiler option. The list of options is found in the *Solaris Dynamic Tracing Guide*. Boolean options are enabled by specifying their name. Options with values are set by separating the option name and value with an equals sign (=).

-X a | c | s | t

Specify the degree of conformance to the ISO C standard that should be selected when invoking cpp(1) (enabled using the -C option). The -X option argument affects the value and presence of the __STDC__ macro depending upon the value of the argument letter.

The -X option supports the following arguments:

a   Default. ISO C plus K&R compatibility extensions, with semantic changes required by ISO C. This is the default mode if -X is not specified. The predefined macro __STDC__ has a value of 0 when cpp is invoked in conjunction with the -Xa option.

c   Conformance. Strictly conformant ISO C, without K&R C compatibility extensions. The predefined macro __STDC__ has a value of 1 when cpp is invoked in conjunction with the -Xc option.

s   K&R C only. The macro __STDC__ is not defined when cpp is invoked in conjunction with the -Xs option.

t   Transition. ISO C plus K&R C compatibility extensions, without semantic changes required by ISO C. The predefined macro __STDC__ has a value of 0 when cpp is invoked in conjunction with the -Xt option.

As the -X option only affects how the D compiler invokes the C preprocessor, the -Xa and -Xt options are equivalent from the perspective of D and both are provided only to ease re-use of settings from a C build environment.

Regardless of the -X mode, the following additional C preprocessor definitions are always specified and valid in all modes:

- __sun
- __unix
- __SVR4
- __sparc (on SPARC systems only)
- __sparcv9 (on SPARC systems only when 64-bit programs are compiled)
- __i386 (on x86 systems only when 32-bit programs are compiled)
- __amd64 (on x86 systems only when 64-bit programs are compiled)
- __'*uname -s*'_'*uname -r*' (for example, __SunOS_5_10)
- __SUNW_D=1
- __SUNW_D_VERSION=0x*MMmmmuuu*

Where *MM* is the major release value in hexadecimal, *mmm* is the minor release value in hexadecimal, and *uuu* is the micro release value in hexadecimal. Refer to the *Solaris Dynamic Tracing Guide* for more information about DTrace versioning.

-Z

Permit probe descriptions that match zero probes. If the -Z option is not specified, dtrace reports an error and exits if any probe descriptions specified in D program files (-s option) or on the command line (-P, -m, -f, -n, or -i options) contain descriptions that do not match any known probes.

Operands   You can specify zero or more additional arguments on the dtrace command line to define a set of macro variables ($1, $2, and so forth). The additional arguments can be used in D programs specified using the -s option or on the command line. The use of macro variables is described further in the *Solaris Dynamic Tracing Guide*.

Exit Status   The following exit values are returned:

0   Successful completion.

For D program requests, an exit status of 0 indicates that programs were successfully compiled, probes were successfully enabled, or anonymous state was successfully retrieved. dtrace returns 0 even if the specified tracing requests encountered errors or drops.

1   An error occurred.

For D program requests, an exit status of 1 indicates that program compilation failed or that the specified request could not be satisfied.

2   Invalid command line options or arguments were specified.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/dtrace
Interface Stability	See below.

The command-line syntax is Committed. The human-readable output is Uncommitted.

See Also   cpp(1), isainfo(1), ssh(1), libdtrace(3LIB), driver.conf(4), attributes(5), dtrace(7D)

Solaris Dynamic Tracing Guide

Usage   When using the -p flag, dtrace stops the target processes while it is inspecting them and reporting results. A process can do nothing while it is stopped. This means that, if , for example, the X server is inspected by dtrace running in a window under the X server's

control, the whole window system can become deadlocked, because the proc tool would be attempting to display its results to a window that cannot be refreshed. In such a case, logging in from another system using ssh(1) and killing the offending proc tool clears the deadlock.

Name dumpadm – configure operating system crash dump

Synopsis `/usr/sbin/dumpadm [-nuy] [-c` *content-type*`] [-d` *dump-device*`]`
`        [-m` *min*`k |` *min*`m |` *min*`%] [-s` *savecore-dir*`]`
`        [-r` *root-dir*`] [-z on | off]`

Description The `dumpadm` program is an administrative command that manages the configuration of the operating system crash dump facility. A crash dump is a disk copy of the physical memory of the computer at the time of a fatal system error. When a fatal operating system error occurs, a message describing the error is printed to the console. The operating system then generates a crash dump by writing the contents of physical memory to a predetermined dump device, which is typically a local disk partition. The dump device can be configured by way of `dumpadm`. Once the crash dump has been written to the dump device, the system will reboot.

Fatal operating system errors can be caused by bugs in the operating system, its associated device drivers and loadable modules, or by faulty hardware. Whatever the cause, the crash dump itself provides invaluable information to your support engineer to aid in diagnosing the problem. As such, it is vital that the crash dump be retrieved and given to your support provider. Following an operating system crash, the savecore(1M) utility is executed automatically during boot to retrieve the crash dump from the dump device and write it to your file system in compressed form, to a file name vmdump.*X*, where *X* is an integer identifying the dump. Afterwards, savecore(1M) can be invoked on the same or another system to expand the compressed crash dump to a pair of files named unix.*X* and vmcore.*X*. The directory in which the crash dump is saved on reboot can be configured using `dumpadm`.

For systems with a UFS root file system, the default dump device is configured to be an appropriate swap partition. Swap partitions are disk partitions reserved as virtual memory backing store for the operating system. Thus, no permanent information resides in swap to be overwritten by the dump. See swap(1M). For systems with a ZFS root file system, dedicated ZFS volumes are used for swap and dump areas. For further information about setting up a dump area with ZFS, see the *ZFS Administration Guide*. To view the current dump configuration, use the `dumpadm` command with no arguments:

```
example# dumpadm

      Dump content: kernel pages
       Dump device: /dev/dsk/c0t0d0s1 (swap)
Savecore directory: /var/crash
  Savecore enabled: yes
    Save compressed: yes
```

When no options are specified, `dumpadm` displays the current crash dump configuration. The example above shows the set of default values: the dump content is set to kernel memory pages only, the dump device is a swap disk partition, the directory for savecore files is set to /var/crash/. savecore is set to run automatically on reboot and save the crash dump in a compressed format.

When one or more options are specified, dumpadm verifies that your changes are valid, and if so, reconfigures the crash dump parameters and displays the resulting configuration. You must be root to view or change dump parameters.

Upon system installation, dumpadm establishes a dump device of sufficient size, based on kernel memory and other internal information, to accommodate a dump file. If you subsequently attempt to create a dump device that is too small to store the dump file, dumpadm issues an error message and the operation fails.

Options   The following options are supported:

-c *content-type*
  Modify the dump configuration so that the crash dump consists of the specified dump content. The content should be one of the following:

  kernel
    Kernel memory pages only.

  all
    All memory pages.

  curproc
    Kernel memory pages, and the memory pages of the process whose thread was currently executing on the CPU on which the crash dump was initiated. If the thread executing on that CPU is a kernel thread not associated with any user process, only kernel pages will be dumped.

-d *dump-device*
  Modify the dump configuration to use the specified dump device. The dump device may one of the following:

  dump-device
    A specific dump device specified as an absolute pathname, such as /dev/dsk/*cNtNdNsN* when the system is running a UFS root file system. Or, specify a ZFS volume, such as /dev/zvol/dsk/rpool/dump, when the system is running a ZFS root file system.

  swap
    If the special token swap is specified as the dump device, dumpadm examines the active swap entries and selects the most appropriate entry to configure as the dump device. See swap(1M). Refer to the NOTES below for details of the algorithm used to select an appropriate swap entry. When the system is first installed with a UFS root file system, dumpadm uses the value for swap to determine the initial dump device setting. A given ZFS volume cannot be configured for both the swap area and the dump device.

-m *min*k | *min*m | *min*%
  Create a minfree file in the current savecore directory indicating that savecore should maintain at least the specified amount of free space in the file system where the savecore directory is located. The min argument can be one of the following:

k

A positive integer suffixed with the unit k specifying kilobytes.

m

A positive integer suffixed with the unit m specifying megabytes.

%

A % symbol, indicating that the minfree value should be computed as the specified percentage of the total current size of the file system containing the savecore directory.

The savecore command will consult the minfree file, if present, prior to writing the dump files. If the size of these files would decrease the amount of free disk space below the minfree threshold, no dump files are written and an error message is logged. The administrator should immediately clean up the savecore directory to provide adequate free space, and re-execute the savecore command manually. The administrator can also specify an alternate directory on the savecore command-line.

-n

Modify the dump configuration to not run savecore automatically on reboot. This is not the recommended system configuration; if the dump device is a swap partition, the dump data will be overwritten as the system begins to swap. If savecore is not executed shortly after boot, crash dump retrieval may not be possible.

-r *root-dir*

Specify an alternate root directory relative to which dumpadm should create files. If no -r argument is specified, the default root directory / is used.

-s *savecore-dir*

Modify the dump configuration to use the specified directory to save files written by savecore. The directory should be an absolute path and exist on the system. If upon reboot the directory does not exist, it will be created prior to the execution of savecore. See the NOTES section below for a discussion of security issues relating to access to the savecore directory. The default savecore directory is /var/crash/.

-u

Forcibly update the kernel dump configuration based on the contents of /etc/dumpadm.conf. Normally this option is used only on reboot when starting svc:/system/dumpadm:default, when the dumpadm settings from the previous boot must be restored. Your dump configuration is saved in the configuration file for this purpose. If the configuration file is missing or contains invalid values for any dump properties, the default values are substituted. Following the update, the configuration file is resynchronized with the kernel dump configuration.

-y

Modify the dump configuration to automatically run savecore on reboot. This is the default for this dump setting. See NOTES.

-z on | off

Modify the dump configuration to control the operation of savecore on reboot. The options are on, to enable saving core files in a compressed format, and off, to automatically uncompress the crash dump file. The default is on, because crash dump files can be very large and require less file system space if saved in a compressed format.

Examples   EXAMPLE 1   Reconfiguring The Dump Device To A Dedicated Dump Device:

The following command reconfigures the dump device to a dedicated dump device:

```
example# dumpadm —d /dev/dsk/c0t2d0s2

        Dump content: kernel pages
         Dump device: /dev/dsk/c0t2d0s2 (dedicated)
   Savecore directory: /var/crash
     Savecore enabled: yes
      Save compressed: yes
```

Exit Status   The following exit values are returned:

0

Dump configuration is valid and the specified modifications, if any, were made successfully.

1

A fatal error occurred in either obtaining or modifying the dump configuration.

2

Invalid command line options were specified.

Files   /dev/dump
Dump device.

/etc/dumpadm.conf
Contains configuration parameters for dumpadm. Modifiable only through that command.

savecore-directory/minfree
Contains minimum amount of free space for *savecore-directory*. See savecore(1M).

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   svcs(1), uname(1), savecore(1M), svcadm(1M), swap(1M), attributes(5), smf(5)

Notes   The system crash dump service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/dumpadm:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Dump Device Selection   When the special swap token is specified as the argument to dumpadm -d the utility will attempt to configure the most appropriate swap device as the dump device. dumpadm configures the largest swap block device as the dump device; if no block devices are available for swap, the largest swap entry is configured as the dump device. If no swap entries are present, or none can be configured as the dump device, a warning message will be displayed. While local and remote swap files can be configured as the dump device, this is not recommended.

Dump Device/Swap Device Interaction (UFS File Systems Only)   In the event that the dump device is also a swap device, and the swap device is deleted by the administrator using the swap -d command, the swap command will automatically invoke dumpadm -d swap in order to attempt to configure another appropriate swap device as the dump device. If no swap devices remain or none can be configured as the dump device, the crash dump will be disabled and a warning message will be displayed. Similarly, if the crash dump is disabled and the administrator adds a new swap device using the swap -a command, dumpadm -d swap will be invoked to re-enable the crash dump using the new swap device.

Once dumpadm -d swap has been issued, the new dump device is stored in the configuration file for subsequent reboots. If a larger or more appropriate swap device is added by the administrator, the dump device is not changed; the administrator must re-execute dumpadm -d swap to reselect the most appropriate device fom the new list of swap devices.

Minimum Free Space   If the dumpadm -m option is used to create a minfree file based on a percentage of the total size of the file system containing the savecore directory, this value is not automatically recomputed if the file system subsequently changes size. In this case, the administrator must re-execute dumpadm -m to recompute the minfree value. If no such file exists in the savecore directory, savecore will default to a free space threshold of one megabyte. If no free space threshold is desired, a minfree file containing size 0 can be created.

Security Issues   If, upon reboot, the specified savecore directory is not present, it will be created prior to the execution of savecore with permissions 0700 (read, write, execute by owner only) and owner root. It is recommended that alternate savecore directories also be created with similar permissions, as the operating system crash dump files themselves may contain secure information.

Default for savecore   System installation software might reserve a dedicated dump device (for example, a disk slice or a ZFS volume). In such a case, the dumpadm default can be set to -n, meaning that savecore does not run automatically when the system reboots. A crash image will be preserved on the dump device. Run /usr/sbin/savecore manually as root to retrieve the crash image and copy it to a file under /var/crash. The crash image will remain on the dump device until overwritten by a later one.

Name editmap – query and edit single records in database maps for sendmail

Synopsis editmap -C *file* [-N] [-f] [-q | -u | -x] *maptype mapname key*
      ["*value*"]...

Description The editmap command queries or edits one record in a database maps used by the keyed map
        lookups in sendmail(1M). Arguments are passed on the command line and output (for
        queries) is directed to standard output.

        Depending on how it is compiled, editmap handles up to three different database formats,
        selected using the *maptype* parameter. See OPERANDS.

        If the TrustedUser option is set in the sendmail configuration file and editmap is invoked as
        root, the generated files are owned by the specified TrustedUser.

Options The following options are supported:

   -C *file*   Use the specified sendmail configuration file (*file*) to look up the TrustedUser
              option.

   -f   Disable the folding of all upper case letters in the key to lower case. Normally, all
              upper case letters in the key are folded to upper case. This is intended to mesh with
              the -f flag in the K line in sendmail.cf. The value is never case folded.

   -N   Include the null byte that terminates strings in the map (for alias maps).

   -q   Query the map for the specified key. If found, print value to standard output and
              exit with 0. If not found then print an error message to stdout and exit with
              EX_UNAVAILABLE.

   -u   Update the record for key with value or inserts a new record if one doesn't exist.
              Exits with 0 on success or EX_IOERR on failure.

   -x   Delete the specific key from the map. Exit with 0 on success or EX_IOERR on failure.

Operands The following operands are supported:

   key   The left hand side of a record.

                Each record is of the form:

                key value

                key and *value* are separated by white space.

   mapname   File name of the database map being created.

   maptype   Specifies the database format. The following *maptype* parameters are available:

                dbm   Specifies DBM format maps.

                btree   Specifies B-Tree format maps.

hash   Specifies hash format maps.

value   The right hand side of a record.

Each record is of the form:

key value

key and *value* are separated by white space.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/smtp/sendmail

See Also   makemap(1M), sendmail(1M), attributes(5)

Name edquota – edit user quotas for ufs file system

Synopsis edquota [-p *proto_user*] *username*...

edquota -t

Description edquota is a quota editor. One or more users may be specified on the command line. For each user a temporary file is created with an ASCII representation of the current disk quotas for that user for each mounted ufs file system that has a quotas file, and an editor is then invoked on the file. The quotas may then be modified, new quotas added, etc. Upon leaving the editor, edquota reads the temporary file and modifies the binary quota files to reflect the changes made.

The editor invoked is vi(1) unless the EDITOR environment variable specifies otherwise.

Only the super-user may edit quotas. In order for quotas to be established on a file system, the root directory of the file system must contain a file, owned by root, called quotas. (See quotaon(1M).)

proto_user and *username* can be numeric, corresponding to the UID of a user. Unassigned UIDs may be specified; unassigned names may not. In this way, default quotas can be established for users who are later assigned a UID.

If no options are specified, the temporary file created will have one or more lines of the format, where a block is considered to be a 1024 byte (1K) block:

```
fs mount_point blocks (soft =number, \
    hard =number ) inodes (soft =number, \
    hard =number)
```

The *number* fields may be modified to reflect desired values.

Options The following options are supported:

-p   Duplicate the quotas of the *proto_user* specified for each *username* specified. This is the normal mechanism used to initialize quotas for groups of users.

-t   Edit the soft time limits for each file system. If the time limits are zero, the default time limits in /usr/include/sys/fs/ufs_quota.h are used. The temporary file created will have one or more lines of the form

        fs *mount_point* blocks time limit = *number tmunit*, files time limit = *number tmunit*

tmunit may be one of "month", "week", "day", "hour", "min" or "sec"; characters appended to these keywords are ignored, so you may write "months" or "minutes" if you prefer. The *number* and *tmunit* fields may be modified to set desired values. Time limits are printed in the greatest possible time unit such that the value is greater than or equal to one. If "default" is printed after the *tmunit*, this indicates that the value shown is zero (the default).

Usage See largefile(5) for the description of the behavior of edquota when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files quotas   quota file at the file system root

      /etc/mnttab   table of mounted file systems

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also vi(1), quota(1M), quotacheck(1M), quotaon(1M), repquota(1M), attributes(5), largefile(5), quotactl(7I)

Notes All UIDs can be assigned quotas.

Name eeprom – EEPROM display and load utility

Synopsis /usr/sbin/eeprom [-] [-f *device*] [*parameter*[=*value*]]

Description eeprom displays or changes the values of parameters in the EEPROM. It processes parameters in the order given. When processing a *parameter* accompanied by a *value*, eeprom makes the indicated alteration to the EEPROM; otherwise, it displays the *parameter*'s value. When given no parameter specifiers, eeprom displays the values of all EEPROM parameters. A ' −' (hyphen) flag specifies that parameters and values are to be read from the standard input (one *parameter* or *parameter*=*value* per line).

Only the super-user may alter the EEPROM contents.

eeprom verifies the EEPROM checksums and complains if they are incorrect.

platform-name is the name of the platform implementation and can be found using the -i option of uname(1).

SPARC SPARC based systems implement firmware password protection with eeprom, using the security-mode, security-password and security-#badlogins properties.

x86 EEPROM storage is simulated using a file residing in the platform-specific boot area. The /boot/solaris/bootenv.rc file simulates EEPROM storage.

Because x86 based systems typically implement password protection in the system BIOS, there is no support for password protection in the eeprom program. While it is possible to set the security-mode, security-password and security-#badlogins properties on x86 based systems, these properties have no special meaning or behavior on x86 based systems.

Options -f *device*
    Use *device* as the EEPROM device.

Operands

x86 Only *acpi-user-options*
    A configuration variable that controls the use of Advanced Configuration and Power Interface (ACPI), a power management specification. The acceptable values for this variable depend on the release of the Solaris operating system you are using.

    For all releases of Solaris 10 and Solaris 11, a value of of 0x0 means that there will be an attempt to use ACPI if it is available on the system. A value of 0x2 disables the use of ACPI.

    For the Solaris 10 1/06 release, a value of 0x8 means that there will be an attempt to use ACPI in a mode compatible with previous releases of Solaris 10 if it is available on the system. The default for Solaris 10 1/06 is 0x8.

    For releases of Solaris 10 after the 1/06 release and for Solaris 11, the default is 0x0.

    Most users can safely accept the default value, which enables ACPI if available. If issues related to the use of ACPI are suspected on releases of Solaris after Solaris 1/06, it is suggested to first try a value of 0x8 and then, if you do not obtain satisfactory results, 0x02.

console

Specifies the console device. Possible values are ttya, ttyb, text, graphics and force-text. In text mode, console output goes to the frame buffer and input comes from the keyboard. A variant of text mode, graphics displays an image with an animation until either a key is pressed or console interaction is required by console login, sulogin, or kmdb. A further variant of text, force-text will avoid using a VGA adapter as a bitmapped device setting it to VGA text mode. When this property is not present, the console device falls back to the device specified by input-device and output-device. When neither the console property nor the input-device and output-device property pair are present, the console defaults to the frame buffer and keyboard.

screen-*#columns* screen-*#rows*

When screen is set to either graphics or text on a bitmapped device, screen-*#columns* and screen-*#rows* allow the desired number columns and rows of text to be specified. They default to 80 and 24 respectively.

Nvram Configuration Parameters
Not all OpenBoot systems support all parameters. Defaults vary depending on the system and the PROM revision. See the output in the "Default Value" column of the printenv command, as entered at the ok (OpenBoot) prompt, to determine the default for your system.

auto-boot?

If true, boots automatically after power-on or reset. Defaults to true. On x86, this parameter is controlled by the grub menu file. See installgrub(1M).

ansi-terminal?

Configuration variable used to control the behavior of the terminal emulator. The value false makes the terminal emulator stop interpreting ANSI escape sequences; instead, echoes them to the output device. Defaults to true.

boot-args

Holds a string of arguments that are passed to the boot subsystem. For example, you can use boot-args=' - install dhcp' to request a customer jumpstart installation. See boot(1M), kmdb(1), and kernel(1M).

boot-command

Command executed if auto-boot? is true. Defaults to boot.

boot-device

Device from which to boot. *boot-device* may contain 0 or more device specifiers separated by spaces. Each device specifier may be either a prom device alias or a prom device path. The boot prom will attempt to open each successive device specifier in the list beginning with the first device specifier. The first device specifier that opens successfully will be used as the device to boot from. Defaults to disk net.

boot-file

File to boot (an empty string lets the secondary booter choose default). Defaults to empty string.

boot-from

    Boot device and file (OpenBoot PROM version 1.*x* only). Defaults to `vmunix`.

boot-from-diag

    Diagnostic boot device and file (OpenBoot PROM version 1.*x* only). Defaults to
    `le( )unix`.

boot-ncpus

    Configuration variable that controls the number of processors with which the system
    should boot. By default, the system boots with maximum supported number of processors.

com*X*-noprobe

    Where *X* is the number of the serial port, prevents device probe on serial port *X*.

diag-device

    Diagnostic boot source device. Defaults to `net`.

diag-file

    File from which to boot in diagnostic mode. Defaults to empty string.

diag-level

    Diagnostics level. Values include `off`, `min`, `max` and `menus`. There may be additional
    platform-specific values. When set to `off`, POST is not called. If POST is called, the value is
    made available as an argument to, and is interpreted by POST. Defaults to
    `platform-dependent`.

diag-switch?

    If `true`, run in diagnostic mode. Defaults to `false` on most desktop systems, `true` on most
    servers.

error-reset-recovery

    Recover after an error reset trap. Defaults to platform-specific setting.

    On platforms supporting this variable, it replaces the `watchdog-reboot?`,
    `watchdog-sync?`, `redmode-reboot?`, `redmode-sync?`, `sir-sync?`, and `xir-sync?`
    parameters.

    The options are:

    none

        Print a message describing the reset trap and go to OpenBoot PROM's user interface,
        aka `OK` prompt.

    sync

        Invoke OpenBoot PROM's `sync` word after the reset trap. Some platforms may treat this
        as `none` after an externally initiated reset (XIR) trap.

    boot

        Reboot after the reset trap. Some platforms may treat this as `none` after an XIR trap.

fcode-debug?
  If `true`, include name parameter for plug-in device FCodes. Defaults to `false`.

hardware-revision
  System version information.

input-device
  Input device used at power-on (usually `keyboard`, `ttya`, or `ttyb`). Defaults to `keyboard`.

keyboard-click?
  If `true`, enable keyboard click. Defaults to `false`.

keyboard-layout
  A string that specifies the layout name for non-self-identifying keyboards (type 7c). Invoke `kbd -s` to obtain a list of acceptable layout names. See kbd(1).

keymap
  Keymap for custom keyboard.

last-hardware-update
  System update information.

load-base
  Default load address for client programs. Default value is `16384`.

local-mac-address?
  If true, network drivers use their own MAC address, not the system's. Defaults to `false`.

mfg-mode
  Manufacturing mode argument for POST. Possible values include `off` or `chamber`. The value is passed as an argument to POST. Defaults to `off`.

mfg-switch?
  If true, repeat system self-tests until interrupted with STOP-A. Defaults to `false`.

nvramrc
  Contents of NVRAMRC. Defaults to empty.

network-boot-arguments
  Arguments to be used by the PROM for network booting. Defaults to an empty string. `network-boot-arguments` can be used to specify the boot protocol (RARP/DHCP) to be used and a range of system knowledge to be used in the process.

  The syntax for arguments supported for network booting is:

  [*protocol*,] [*key=value*,]*

  All arguments are optional and can appear in any order. Commas are required unless the argument is at the end of the list. If specified, an argument takes precedence over any default values, or, if booting using DHCP, over configuration information provided by a DHCP server for those parameters.

protocol, above, specifies the address discovery protocol to be used.

Configuration parameters, listed below, are specified as *key=value* attribute pairs.

tftp-server
: IP address of the TFTP server

file
: file to download using TFTP or URL for WAN boot

host-ip
: IP address of the client (in dotted-decimal notation)

router-ip
: IP address of the default router (in dotted-decimal notation)

subnet-mask
: subnet mask (in dotted-decimal notation)

client-id
: DHCP client identifier

hostname
: hostname to use in DHCP transactions

http-proxy
: HTTP proxy server specification (IPADDR[:PORT])

tftp-retries
: maximum number of TFTP retries

dhcp-retries
: maximum number of DHCP retries

If no parameters are specified (that is, network-boot-arguments is an empty string), the PROM will use the platform-specific default address discovery protocol.

Absence of the protocol parameter when other configuration parameters are specified implies manual configuration.

Manual configuration requires that the client be provided with all the information necessary for boot. If using manual configuration, information required by the PROM to load the second-stage boot program must be provided in network-boot-arguments while information required for the second-stage boot program can be specified either as arguments to the boot program or by means of the boot program's interactive command interpreter.

Information required by the PROM when using manual configuration includes the booting client's IP address, name of the boot file, and the address of the server providing the boot file image. Depending on network configuration, it might be required that the subnet mask and address of the default router to use also be specified.

oem-banner
    Custom OEM banner (enabled by setting `oem-banner?` to `true`). Defaults to empty string.

oem-banner?
    If `true`, use custom OEM banner. Defaults to `false`.

oem-logo
    Byte array custom OEM logo (enabled by setting `oem-logo?` to `true`). Displayed in hexadecimal.

oem-logo?
    If `true`, use custom OEM logo (else, use Sun logo). Defaults to `false`.

pci-mem64?
    If true, the OpenBoot PROM allocates 64-bit PCI memory addresses to a PCI device that can support 64-bit addresses.

    This variable is available on SPARC platforms only and is optional. Some versions of SunOS do not support PCI `MEM64` addresses and will fail in unexpected ways if the OpenBoot PROM allocates PCI `MEM64` addresses.

    The default value is system-dependent. If the variable exists, the default value is appropriate to the lowest version of the SunOS that shipped with a specific platform.

output-device
    Output device used at power-on (usually `screen`, `ttya`, or `ttyb`). Defaults to `screen`.

redmode-reboot?
    Specify `true` to reboot after a redmode reset trap. Defaults to `true`. (Sun Enterprise 10000 only.)

redmode-sync?
    Specify `true` to invoke OpenBoot PROM's `sync` word after a redmode reset trap. Defaults to `false`. (Sun Enterprise 10000 only.)

rootpath
    Specifies the root device of the operating system.

sbus-probe-list
    Designate which SBus slots are probed and in what order. Defaults to `0123`.

screen-#columns
    Number of on-screen columns (characters/line). Defaults to `80`.

screen-#rows
    Number of on-screen rows (lines). Defaults to `34`.

scsi-initiator-id
    SCSI bus address of host adapter, range 0-7. Defaults to 7.

sd-targets

Map SCSI disk units (OpenBoot PROM version 1.*x* only). Defaults to `31204567`, which means that unit 0 maps to target 3, unit 1 maps to target 1, and so on.

security-#badlogins

Number of incorrect security password attempts.This property has no special meaning or behavior on x86 based systems.

security-mode

Firmware security level (options: `none`, `command`, or `full`). If set to `command` or `full`, system will prompt for PROM security password. Defaults to `none`.This property has no special meaning or behavior on x86 based systems.

security-password

Firmware security password (never displayed). Can be set only when `security-mode` is set to `command` or `full`.This property has no special meaning or behavior on x86 based systems.

```
example# eeprom security-password=
Changing PROM password:
New password:
Retype new password:
```

selftest-#megs

Megabytes of RAM to test. Ignored if `diag-switch?` is `true`. Defaults to `1`.

sir-sync?

Specify `true` to invoke OpenBoot PROM's `sync` word after a software-initiated reset (SIR) trap. Defaults to `false`. (Sun Enterprise 10000 only.)

skip-vme-loopback?

If `true`, POST does not do VMEbus loopback tests. Defaults to `false`.

st-targets

Map SCSI tape units (OpenBoot PROM version 1.*x* only). Defaults to `45670123`, which means that unit 0 maps to target 4, unit 1 maps to target 5, and so on.

sunmon-compat?

If `true`, display Restricted Monitor prompt (>). Defaults to `false`.

testarea

One-byte scratch field, available for read/write test. Defaults to `0`.

tpe-link-test?

Enable 10baseT link test for built-in twisted pair Ethernet. Defaults to `true`.

ttya-mode

TTYA (baud rate, #bits, parity, #stop, handshake). Defaults to `9600,8,n,1,-`.

Fields, in left-to-right order, are:

Baud rate:
110, 300, 1200, 4800, 9600 . . .

Data bits:
5, 6, 7, 8

Parity:
n(none), e(even), o(odd), m(mark), s(space)

Stop bits:
1, 1.5, 2

Handshake:
−(none), h(hardware:rts/cts), s(software:xon/xoff)

ttyb-mode
TTYB (baud rate, #bits, parity, #stop, handshake). Defaults to `9600,8,n,1,−`.

Fields, in left-to-right order, are:

Baud rate:
110, 300, 1200, 4800, 9600 . . .

Data bits:
5, 6, 7, 8

Stop bits:
1, 1.5, 2

Parity:
n(none), e(even), o(odd), m(mark), s(space)

Handshake:
−(none), h(hardware:rts/cts), s(software:xon/xoff)

ttya-ignore-cd
If `true`, operating system ignores carrier-detect on TTYA. Defaults to `true`.

ttyb-ignore-cd
If `true`, operating system ignores carrier-detect on TTYB. Defaults to `true`.

ttya-rts-dtr-off
If `true`, operating system does not assert DTR and RTS on TTYA. Defaults to `false`.

ttyb-rts-dtr-off
If `true`, operating system does not assert DTR and RTS on TTYB. Defaults to `false`.

use-nvramrc?
If `true`, execute commands in NVRAMRC during system start-up. Defaults to `false`.

verbosity
Controls the level of verbosity of PROM messages. Can be one of `debug`, `max`, `normal`, `min`, or `none`. Defaults to `normal`.

version2?
  If true, hybrid (1.*x*/2.*x*) PROM comes up in version 2.*x*. Defaults to true.

watchdog-reboot?
  If true, reboot after watchdog reset. Defaults to false.

watchdog-sync?
  Specify true to invoke OpenBoot PROM's sync word after a watchdog reset trap. Defaults
  to false. (Sun Enterprise 10000 only.)

xir-sync?
  Specify true to invoke OpenBoot PROM's sync word after an XIR trap. Defaults to false.
  (Sun Enterprise 10000 only.)

Examples   **EXAMPLE 1**   Changing the Number of Megabytes of RAM.

The following example demonstrates the method for changing from one to two the number of
megabytes of RAM that the system will test.

```
example# eeprom selftest-#megs
selftest-#megs=1

example# eeprom selftest-#megs=2

example# eeprom selftest-#megs
selftest-#megs=2
```

EXAMPLE 2   Setting the auto-boot? Parameter to true.

The following example demonstrates the method for setting the auto-boot? parameter to
true.

```
example# eeprom auto-boot?=true
```

When the eeprom command is executed in user mode, the parameters with a trailing question
mark (?) need to be enclosed in double quotation marks (" ") to prevent the shell from
interpreting the question mark. Preceding the question mark with an escape character (\) will
also prevent the shell from interpreting the question mark.

```
example% eeprom "auto-boot?"=true
```

EXAMPLE 3   Using network-boot-arguments

To use DHCP as the boot protocol and a hostname of abcd.example.com for network
booting, set these values in network-boot-arguments as:

```
example# eeprom network-boot-arguments="dhcp,hostname=abcd.example.com"
```

...then boot using the command:

```
ok boot net
```

EXAMPLE 3 Using `network-boot-arguments`   *(Continued)*

Note that network boot arguments specified from the PROM command line cause the contents of `network-boot-arguments` to be ignored. For example, with `network-boot-arguments` set as shown above, the `boot` command:

```
ok boot net:dhcp
```

...causes DHCP to be used, but the `hostname` specified in `network-boot-arguments` will not be used during network boot.

EXAMPLE 4 Setting System Console to Auxiliary Device

The command below assigns the device `/dev/term/a` as the system console device. You would make such an assignment prior to using `tip(1)` to establish a `tip` connection to a host.

On a SPARC machine:

```
# eeprom output-device=/dev/term/a
```

On an x86 machine:

```
# eeprom console=ttya
```

On a SPARC machine, the preceding command would be sufficient for assigning the console to an auxiliary device. For an x86 machine, you might, in addition, need to set the characteristics of the serial line, for which you would have to consult the BIOS documentation for that machine. Also, on some x86 machines, you might use a device other than device `a`, as shown above. For example, you could set console to `ttyb` if the second serial port is present.

EXAMPLE 5 Specifying that SPARC System Boots into kmdb

To specify that a SPARC machine boots into `kmdb(1)`, enter the following command:

```
# eeprom boot-command="boot -k"
```

Files `/boot/solaris/bootenv.rc`
      File storing `eeprom` values on x86 machines.

`/dev/openprom`
   Device file

`/usr/platform/`*platform-name*`/sbin/eeprom`
   Platform-specific version of `eeprom`. Use `uname -i` to obtain *platform-name*.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

OpenBoot 3.x Command Reference Manual

ONC+ Developer's Guide

Name   efdaemon – embedded FCode interpreter daemon

Synopsis   /usr/lib/efcode/sparcv9/efdaemon [-d]

Description   efdaemon, the embedded FCode interpreter daemon, invokes the embedded FCode interpreter when the daemon receives an interpretation request. A new session of the interpreter is started for each unique request by invoking the script /usr/lib/efcode/efcode.

efdaemon is used on selected platforms as part of the processing of some dynamic reconfiguration events.

Options   The following option is supported:

-d   Set debug output. Log debug messages as LOG_DEBUG level messages by using syslog().
See syslog(3C).

Files

/dev/fcode	FCode interpreter pseudo device, which is a portal for receipt of FCode interpretation requests
/usr/lib/efcode/efcode	Shell script that invokes the embedded FCode interpreter
/usr/lib/efcode/interpreter	Embedded FCode interpreter
/usr/lib/efcode/sparcv9/interpreter	Embedded FCode interpreter

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWefcx, SUNWefcux, system/embedded-fcode-interpreter, SUNWefclx

See Also   svcs(1), prtconf(1M), svcadm(1M), syslog(3C), attributes(5), smf(5)

Notes   The efdaemon service is managed by the service management facility, smf(5), under the service identifier:

svc:/platform/sun4u/efdaemon:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name embedded_su – allow an application to prompt for credentials and execute commands as the super user or another user

Synopsis /usr/lib/embedded_su [-] [*username* [arg...]]

Description The embedded_su command allows an application to prompt the user for security credentials and then use those credentials to execute a program as another user or role (see rbac(5) for information on role-based access control). The default *username* is root (super user).

embedded_su is identical to su(1M), except that the user interaction is packaged in a form suitable for another program to interpret and display. Typically, embedded_su would be used to allow a graphical program to prompt for the super user password and execute a command as the super user, without requiring that the requesting program be run as the super user.

PROTOCOL embedded_su implements a simple protocol over standard input, standard output, and standard error. This protocol consists of three phases, roughly corresponding to PAM initialization, the PAM dialog, and PAM completion.

Phase 1: Initialization

After starting embedded_su, the application must send an initialization block on embedded_su's standard input. This block is a text block, as described under "Text Blocks". There are currently no initialization parameters defined; the application should send an empty block by sending a line consisting solely of a period (.).

Phase 2: Conversation

embedded_su then emits zero or more conversation blocks on its standard output. Each conversation block may require zero or more responses.

A conversation block starts with a line consisting of the word CONV, followed by whitespace, followed by the number of messages in the conversation block as a decimal integer. The number of messages may be followed by whitespace and additional data. This data, if present, must be ignored.

Each message consists of a line containing a header followed by a text block, as described under "Text Blocks". A single newline is appended to each message, allowing the message to end with a line that does not end with a newline.

A message header line consists of a PAM message style name, as described in pam_start(3PAM). The message header values are:

PAM_PROMPT_ECHO_OFF   The application is to prompt the user for a value, with echoing disabled.

PAM_PROMPT_ECHO_ON   The application is to prompt the user for a value, with echoing enabled.

PAM_ERROR_MSG   The application is to display the message in a form appropriate for displaying an error.

PAM_TEXT_INFO   The application is to display the message in a form appropriate for
                       general information.

The PAM message style may be followed by whitespace and additional data. This data, if
present, must be ignored.

After writing all of the messages in the conversation block, if any of them were
PAM_PROMPT_ECHO_OFF or PAM_PROMPT_ECHO_ON, embedded_su waits for the response values. It
expects the response values one per line, in the order the messages were given.

Phase 3: Completion

After zero or more conversation blocks, embedded_su emits a result block instead of a
conversation block.

Upon success, embedded_su emits a single line containing the word "SUCCESS". The word
SUCCESS may be followed by whitespace and additional data. This data, if present, must be
ignored.

Upon failure, embedded_su emits a single line containing the word "ERROR", followed by a text
block as described under "Text Bocks". The text block gives an error message. The word ERROR
may be followed by whitespace and additional data. This data, if present, must be ignored.

Text Blocks

Initialization blocks, message blocks, and error blocks are all text blocks. These are blocks of
text that are terminated by a line containing a single period (.). Lines in the block that begin
with a "." have an extra "." prepended to them.

Internationalization   All messages are localized to the current locale; no further localization is required.

SECURITY   embedded_su uses pam(3PAM) for authentication, account management, and session
            management. Its primary function is to export the PAM conversation mechanism to an
            unprivileged program. Like su(1M), the PAM configuration policy can be used to control
            embedded_su. The PAM service name used is "embedded_su".

            embedded_su is almost exactly equivalent to su(1M) for security purposes. The only exception
            is that it is slightly easier to use embedded_su in writing a malicious program that might trick a
            user into providing secret data. For those sites needing maximum security, potentially at the
            expense of application functionality, the EXAMPLES section shows how to disable
            embedded_su.

Examples   In the following examples, left angle brackets (<<<) indicate a line written by embedded_su
            and read by the invoking application. Right angle brackets (>>>) indicate a line written by the
            application and read by embedded_su.

EXAMPLE 1 Executing a command with the Correct Password

The following example shows an attempt to execute "somecommand" as "someuser", with the correct password supplied:

```
/usr/lib/embedded_su someuser -c somecommand
    >>>.
    <<<CONV 1
    <<<PAM_PROMPT_ECHO_OFF
    <<<Password:
    <<<.
    >>>[ correct password ]
    <<<SUCCESS
    [ somecommand executes  ]
```

EXAMPLE 2 Executing a command with the Incorrect Password

The following example shows an attempt to execute "somecommand" as "someuser", with the incorrect password supplied:

```
/usr/lib/embedded_su someuser -c somecommand
    >>>.
    <<<CONV 1
    <<<PAM_PROMPT_ECHO_OFF
    <<<Password:
    <<<.
    >>>[ incorrect password ]
    [ delay ]
    <<<ERROR
    <<<embedded_su:Sorry
    <<<.
    [ exit ]
```

EXAMPLE 3 Message Examples

A pam_message structure with *msg_style* equal to PAM_TEXT_INFO and msg equal to "foo" produces:

```
PAM_TEXT_INFO
foo
.
```

A pam_message structure with *msg_style* equal to PAM_ERROR_MESSAGE and msg equal to "bar\n" produces:

```
PAM_ERROR_MESSAGE
bar
[ blank line ]
.
```

EXAMPLE 3 Message Examples   *(Continued)*

A pam_message structure with *msg_style* equal to PAM_ERROR_MESSAGE and msg equal to "aaa\nbbb" produces:

```
PAM_ERROR_MESSAGE
aaa
bbb
.
```

A pam_message structure with *msg_style* equal to PAM_TEXT_INFO and msg equal to ""
produces:

```
PAM_TEXT_INFO
[ blank line ]
.
```

A pam_message structure with *msg_style* equal to PAM_TEXT_INFO and msg equal to NULL
produces:

```
PAM_TEXT_INFO
.
```

EXAMPLE 4 Disabling embedded_su

To disable embedded_su, add a line to the /etc/pam.conf file similar to:

```
embedded_su  auth  requisite  pam_deny.so.1
```

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

Name etrn – start mail queue run

Synopsis etrn [-b] [-v] *server-host* [*client-hosts*]

Description SMTP's ETRN command allows an SMTP client and server to interact, giving the server an
opportunity to start the processing of its queues for messages to go to a given host. This is
meant to be used in start-up conditions, as well as for mail nodes that have transient
connections to their service providers.

The etrn utility initiates an SMTP session with the host *server-host* and sends one or more
ETRN commands as follows: If no *client-hosts* are specified, etrn looks up every host name for
which sendmail(1M) accepts email and, for each name, sends an ETRN command with that
name as the argument. If any *client-hosts* are specified, etrn uses each of these as arguments
for successive ETRN commands.

Options The following options are supported:

-b   System boot special case. Make sure localhost is accepting SMTP connections before
     initiating the SMTP session with server-host.

     This option is useful because it prevents race conditions between sendmail(1M)
     accepting connections and *server-host* attempting to deliver queued mail. This check is
     performed automatically if no *client-hosts* are specified.

-v   The normal mode of operation for etrn is to do all of its work silently. The -v option
     makes it verbose, which causes etrn to display its conversations with the remote SMTP
     server.

Environment Variables No environment variables are used. However, at system start-up,
svc:/network/smtp:sendmail reads /etc/default/sendmail. In this file, if the variable
ETRN_HOSTS is set, svc:/network/smtp:sendmail parses this variable and invokes etrn
appropriately. ETRN_HOSTS should be of the form:

"s1:c1.1,c1.2   s2:c2.1 s3:c3.1,c3.2,c3.3"

That is, white-space separated groups of *server:client* where *client* can be one or more
comma-separated names. The *:client* part is optional. *server* is the name of the server to prod; a
mail queue run is requested for each *client* name. This is comparable to running:

/usr/lib/sendmail -qR *client*

on the host *server*.

Examples EXAMPLE 1 Using etrn

Inserting the line:

ETRN_HOSTS="s1.domain.com:clnt.domain.com s2.domain.com:clnt.domain.com"

EXAMPLE 1 Using etrn   *(Continued)*

in /etc/default/sendmail results in svc:/network/smtp:sendmail invoking etrn such that ETRN commands are sent to both s1.domain.com and s2.domain.com, with both having clnt.domain.com as the ETRN argument.

The line:

ETRN_HOSTS="server.domain.com:client1.domain.com,client2.domain.com"

results in two ETRN commands being sent to server.domain.com, one with the argument client1.domain.com, the other with the argument client2.domain.com.

The line:

ETRN_HOSTS="server1.domain.com server2.domain.com"

results in set of a ETRN commands being sent to both server1.domain.com and server2.domain.com; each set contains one ETRN command for each host name for which sendmail(1M) accepts email, with that host name as the argument.

Files /etc/mail/sendmail.cf   sendmail configuration file

/etc/default/sendmail   Variables used by svc:/network/smtp:sendmail

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

RFC 1985

Notes Not all SMTP servers support ETRN.

Name fbconfig – frame buffer configuration utility

Synopsis fbconfig [-dev *device_file*] [-help]

fbconfig -list

fbconfig -gui

fbconfig -res \?

fbconfig [-dev *device_file*] [-file machine | system]
    [*device_specific_options*] [-res *video-mode*] [*defaults*]
    [-prconf] [-prdid[raw] [parsed]] [-propt]

Description fbconfig is the generic command line interface to query and/or to configure a frame buffer device. Depending on the command line options, fbconfig can invoke a GUI program, or it can invoke a device-specific configuration program. The choice of device configuration program depends both on the device (specified with -dev) and on the currently configured X server.

The options recognized by fbconfig are shown in the first three command forms in the SYNOPSIS section. The remaining forms illustrate options that may be passed to a device-specific configuration program that performs the actual operations. The interpretation of these options will depend upon the specific configuration program that is invoked. The options shown are supported by most device configuration programs.

If the -dev option is omitted, the default frame buffer (/dev/fb or /dev/fb0) is assumed.

Options The following options are supported by fbconfig:

-dev *device_file*
    Specify the frame buffer device by its full pathname or simple filename. Pathnames of installed devices can be displayed using the -list option. If the -dev option is omitted, the default device is /dev/fb.

-gui
    Invoke the Graphical User Interface (GUI). The GUI is available if the SUNWdcm package is installed. All other options are ignored.

    The GUI can configure devices (as an alternative to the fbconfig command line) and can update the Xservers file without directly editing the file. The GUI allows the user that is logged in on the graphics device or devices to configure which graphics displays the window system should use, their screen layout (where they appear on the user's desktop), and screen properties (X attributes).

    In addition, the GUI allows advanced users to create a new video format (resolution) that some graphics devices can select from fbconfig command line or from the device-dependent portion of the GUI. The GUI's online help explains all options and features.

-help
   Displays the supported fbconfig command line options, along with a brief explanation of
   each. Also displays the -help text of the device-specific configuration program, if any. The
   frame buffer device can be specified using the -dev option, otherwise the default is used.
   Other fbconfig options are ignored. This is the default fbconfig option.

-list
   Displays the pathnames of the installed frame buffer devices, the device model of each, and
   the configuration program that would be invoked for each device with the currently
   configured X server. Other fbconfig options are ignored.

   ```
   Device File Name          Device Model     Config Program
   ---------------           ------------     --------------
   /dev/fbs/kfb0             XVR-2500         SUNWkfb_config
   /dev/fbs/kfb1             XVR-2500         SUNWkfb_config
   /dev/fbs/nfb0 [a|b]       XVR-300          SUNWnfb_config
   /dev/fbs/pfb0 [a|b]       XVR-100          SUNWpfb_config
   ```

   The following options are commonly supported by the device-specific configuration
   programs:

   -defaults
      Sets configuration options to their default values.

   -file machine | system
      Specifies which xorg.conf configuration file to use.

   -prconf
      Display the current configuration for the frame buffer and display device(s).

   -predid [raw] [parsed]
      Display the E-EDID (Enhanced Extended Display Identification Data) information
      obtained from the display device(s), which must be online, connected to the frame
      buffer. The output will be raw hexadecimal and/or human-readable text. The default is
      parsed.

   -propt
      Display the current software configuration.

   -res \?
      Display the video modes (resolutions) that can be used with the -res *video-mode*
      option.

   Other supported options are determined by the device-specific configuration program:

   device-specific-options
      The syntax and descriptions of additional device-specific options are displayed in the
      -help output of fbconfig or the device-specific program. They are also contained in the
      man page for the device-specific program.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/graphics/fbconfig

See Also fbconf_xorg(1M), attributes(5)

Xserver(1), *Xorg(1)*, *Xsun(1)*, which are part of the OpenWindow, not the SunOS, man page collection.

Limitations Because of limitations in the m64 kernel driver and related software, fbconfig (with the -prconf option) is unable to distinguish between a current depth of 24 or 8+24. The -propt option returns the depth specified in the OWconfig file, which will be in effect following the next restart of the window system. The xwininfo utility, usually shipped in the package containing frame buffer software (such as SUNWxwplt), reports current depth of a specified window.

Name fbconf_xorg – configure frame buffer devices for Xorg

Synopsis /usr/lib/fbconfig/fbconf_xorg [-dev *device-file*]
         [-file machine | system | *config-path*]
         [-res *video-mode* [nocheck | noconfirm]]
         [*device-specific-options*]
         [-defaults] [-prconf] [-predid [raw] [parsed]] [-propt]

/usr/lib/fbconfig/fbconf_xorg [-dev *device-file*] [-prconf] [-propt]

/usr/lib/fbconfig/fbconf_xorg [-dev *device-file*] [-help] [-res ?]

Description The fbconf_xorg utility configures Frame Buffer devices and some of the X11 window system defaults for Xorg by updating the xorg.conf configuration file. Users should not normally need to run fbconf_xorg directly, as it is executed by fbconfig(1M) when the Xorg server is in use.

The first fbconf_xorg command form shown in the SYNOPSIS section stores the specified option values in the xorg.conf configuration file. These settings are used to initialize the frame buffer device the next time the window system is run on that device. The persistence of these settings across window system sessions and system reboots is determined by the xorg.conf file.

The second and third command forms display information, and do not alter the xorg.conf file. The presence of the -help and/or -res ? options causes any other option (not shown in the third form) to be ignored.

You can configure only one frame buffer device at a time. To configure multiple devices, invoke the fbconf_xorg utility separately for each device.

Only frame buffer device options can be specified with fbconf_xorg. Use the normal window system options to specify default depth (see svccfg(1M)), default visual class, and so forth. Specify these as device modifiers on the command line as specified in *Xserver(1)*.

You can specify which xorg.conf file to open. By default, fbconf_xorg opens the machine-specific file, /etc/X11/xorg.conf. Use the -file option to specify an alternate file. For example, the system-global file, /usr/lib/X11/xorg.conf, can be opened instead.

These standard xorg.conf files can be written only by the superuser or someone with the Desktop Configuration role.

Options The following options are supported for all frame buffer devices:

-defaults
   Sets configuration options for the specified device to their default values. This does not affect the -res video mode setting. See the device-specific portions of the DEFAULTS section below.

-dev *device-file*

Specifies the frame buffer device by either its full pathname or simple filename (for example, /dev/fbs/efb0 or efb0). Pathnames of installed devices can be displayed using the -list option to fbconfig(1M). If the -dev option is omitted, the default device, /dev/fb, is used.

-file machine | system | *config-path*

Specifies which xorg.conf file to open. If machine is specified, the machine-specific /etc/X11/xorg.conf file is opened. If system is specified, the global /usr/lib/X11/xorg.conf file is opened. The absolute pathname of a configuration file can be used instead. If the specified file does not exist and is to be updated, it is created. The file system that contains the xorg.conf file must be writeable by someone with superuser-like privileges. This option has no effect unless other options are specified. The default is machine.

-help

Display the fbconf_xorg command line options that are supported in conjunction with the frame buffer device, along with a brief explanation of each option. The frame buffer device can be specified using the -dev option.

-prconf

Display the current configuration for the frame buffer device and attached display device(s). The frame buffer device can be specified using the -dev option.

The -prconf output might resemble:

```
Monitor/Resolution Information:
    Monitor manufacturer: SUN
    Product Code:  4
    Serial Number: 12212555
    Manufacture date: 2000, week 9
    EDID Version:  1.1
    Monitor dimensions: 36x29 cm
    Default Gamma: 2.62
    Monitor preferred resolution: SUNW_STD_1280x1024x60
    Monitor supported resolutions from EDID: SUNW_STD_1280x1024x60,
        SUNW_STD_1280x1024x76, 1152x900x66, VESA_STD_1280x1024x75,
        VESA_STD_1280x1024x60, SUNW_STD_1152x900x66,
        VESA_STD_720x400x70, VESA_STD_640x480x60,
        VESA_STD_640x480x67, VESA_STD_640x480x72,
        VESA_STD_640x480x75, VESA_STD_800x600x56,
        VESA_STD_800x600x60, VESA_STD_800x600x72,
        VESA_STD_800x600x75, VESA_STD_832x624x75,
        VESA_STD_1024x768x60, VESA_STD_1024x768x70, 1024x768x75
    Current resolution setting: FALLBACK_1152x900x66

Framelock Configuration:
    Slave Mode: Disabled
```

-predid [raw] [parsed]

    Display the E-EDID (Enhanced Extended Display Identification Data) information obtained from the display device(s), which must be online, connected to the frame buffer. The frame buffer device can be specified using the -dev option. The output is raw hexadecimal and/or human-readable (parsed) text. The default is parsed.

    The -predid raw output might resemble:

```
--- EDID Data for /dev/fbs/kfb0 ---

Block 0: EDID Base Block
        0x00:  00 FF FF FF FF FF FF 00 04 43 06 F2 01 00 00 00
        0x10:  01 11 01 04 0F 2B 20 78 2B 9C 68 A0 57 4A 9B 26
        0x20:  12 48 4C FF FF 80 A9 59 A9 4F A9 4A A9 45 81 99
        0x30:  81 80 61 59 45 59 48 3F 40 30 62 B0 32 40 40 C0

        0x60:  F7 0F 03 87 C0 00 00 00 00 00 00 00 00 00 00 FC
        0x70:  00 41 42 43 20 4C 43 44 32 31 0A 20 20 20 00 0B
```

-propt

    Display all option settings for the frame buffer device, either as they currently are or as they are represented in the xorg.conf configuration file when fbconf_xorg completes. The device can be specified using the -dev option, and the file using the -file option.

    The -propt output might resemble:

```
--- Graphics Configuration for /dev/fbs/efb0 ---

xorg.conf: machine -- /etc/X11/xorg.conf
        Screen section:  "efb0"
        Device section:  "efb0"
        Monitor section: none

Video Mode: Not set

Screen Information:
        DoubleWide: Disable
        DoubleHigh: Disable
        Clone: Disable
        Offset/Overlap: [0, 0]
        Outputs:        Direct

Visual Information:
        Gamma Correction: Using default gamma value 2.22
```

-res ?

    Display a list of video modes that can be used with the -res *video-mode* option.

The ? argument might need to be escaped or placed in quotes (\?, "?", or '?'), to protect it from misinterpretation by the shell.

The -res ? output might resemble:

```
Video modes accepted by the -res option:
    AUTO                    [1][2]
    NONE                    [1][2]
    SUNW_STD_1920x1200x75
    SUNW_STD_1920x1200x70
    SUNW_DIG_1920x1200x60
    SUNW_STD_1920x1080x72
    SUNW_DIG_1920x1080x60
      ...
      ...
    VESA_STD_640x480x75     [1]
    VESA_STD_640x480x72     [1]
    VESA_STD_640x480x60     [1]

[1] Resolution is supported by monitor
[2] Preferred resolution for monitor
```

Abbreviations such as "1280x1024x75" might also be used.

-res *video-mode* [nocheck | noconfirm]
   Set the video mode for the display device that is connected to the frame buffer device.

   A list of video modes can be displayed using the -res ? option.

   The basic format of a video-mode is *widthxheightxrate*, where:

   - *width* is the screen width in pixels.
   - *height* is the screen height in pixels.
   - *rate* is the vertical frequency of the screen refresh.

   A video-mode argument might have an @ (at sign) instead of x preceding the refresh rate. For instance, 1280x1024x76 and 1280x1024@76 are equivalent.

   A video-mode name might carry additional information, as with SUNW_STD_1280x1024x76.

   The -res argument, auto, represents the video mode that is currently programmed into the device. The argument, none, is a synonym for auto.

   Note that some video modes might be inappropriate for certain frame buffer devices and/or display devices.

   The -res option accepts suboption keywords following the video-mode specification.

   nocheck
      The nocheck suboption causes the video-mode argument to be accepted, regardless of whether it is supported by the currently attached monitor, whether it is known within

the current configuration, and so forth. Note that using an unchecked, inappropriate video mode can leave the system without usable video output. This suboption is useful if a different monitor is to be connected to the frame buffer device. This suboption also implies `noconfirm`.

noconfirm

If the video-mode argument is unable to be validated, the default action is to display a warning message and ask the user whether to continue. The `noconfirm` suboption suppresses this confirmation request. This suboption is useful when `fbconf_xorg` is being run from a shell script.

The following device-specific options are supported for certain frame buffer devices. Unless specified otherwise, these options do not take effect until the user logs out and back in.

-deflinear true | false

This option selects the default X visual. Two types of visuals are supported, linear and nonlinear. Linear visuals are gamma corrected. Nonlinear visuals are not.

If the value of this option is `true`, the default visual is set to default depth 24 and the default class is `TrueColor` with gamma correction enabled. If `false`, a nonlinear visual that satisfies the other default visual selection options, such as the default depth and default class, is chosen as the default visual.

The -deflinear, -defoverlay, and -deftransparent options each select the default X visual. Only one of these might be enabled at a time. Enabling one causes the others to be disabled.

-defoverlay true | false

This option selects the default X visual. Some devices might provide an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual does not damage windows created in other visuals. The converse, however, is not true: Windows created in other visuals damage overlay windows.

If the value of this option is `true`, the overlay visual is the default visual. The default depth is 8–bit and the default class is PseudoColor. If `false`, the non-overlay visual that satisfies the other default visual selection options, such as the default depth and the default class, is chosen as the default visual.

The -deflinear, -defoverlay, and -deftransparent options each select the default X visual. Only one of these might be enabled at a time. Enabling one causes the others to be disabled.

-deftransparent true | false

This option selects the default X visual. Some devices might provide an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual does not damage windows created in other visuals.

If the value of this option is `true`, the overlay visual used as the default is a transparent overlay visual. A visual with transparency supports a colormap with 255 colors and one transparent pixel. The default depth is 8–bit and the default class is PseudoColor. If `false`, the nonoverlay visual that satisfies the other default visual selection options, such as the default depth and the default class, is chosen as the default visual.

The `-deflinear`, `-defoverlay`, and `-deftransparent` options each select the default X visual. Only one of these might be enabled at a time. Enabling one causes the others to be disabled.

`-doublehigh enable | disable`
Configures the two outputs of the frame buffer device into one vertical virtual display. The default is `disable`. The `-doublewide` and `-doublehigh` options are mutually exclusive. Enabling one causes the other to be disabled.

`-doublewide enable | disable`
Configures the two outputs of the frame buffer device into one horizontal virtual display. The default is `disable`. The `-doublewide` and `-doublehigh` options are mutually exclusive. Enabling one causes the other to be disabled.

`-g` *gamma-correction-value*
Sets the gamma correction value. All linear visuals provide gamma correction. The gamma correction value should be in the range, `0.1` to `10.0`. The default is `2.22`. This option can be used while the window system is running. Changing the gamma correction value affects all of the windows displayed by linear visuals.

`-gfile` *gamma-correction-file*
Loads the gamma correction table from the file specified by *gamma-correction-file*. This text file specifies the gamma correction values for the R, G, and B channels. Three consecutive values form an RGB triplet. For a kfb device, there must be exactly 256 RGB triplets. A value might be represented in hexadecimal, decimal, or octal format (for example, `0x3FF`, `1023`, or `01777`, respectively). Values are separated by one or more whitespace or new line characters. Comments begin with a hash sign character (#) and end at the end of the line.

You can load the gamma correction table with this option while the window system is running. The new gamma correction affects all the windows being displayed using the linear visuals. When gamma correction is done using a user-specified table, the gamma correction value (`-g`) is undefined. By default, the window system assumes a gamma correction value of `2.22` and loads the gamma table it creates corresponding to this value.

The following is an example of a *gamma-correction-file* file:

```
# Gamma Correction Table
0x00 0x00 0x00
0x01 0x01 0x01
0x02 0x02 0x02
 ... ... ...
```

```
           ...   ...   ...
          0xFF  0xFF  0xFF
```

-multisample available | disable | forceon

If set to disable, no multisample is possible. If set to available, multisample is possible but is selected on a per-window basis using a library interface. If set to forceon, all Sun OpenGL windows are rendered using multisampling. To query the number of samples used, specify the -propt option.

-offset *x-val y-val*

Adjusts the position of the specified stream by the value specified. This option is only implemented in -doublewide and -doublehigh modes. For -doublewide, use the *x-val* to position the rightmost stream. Negative is left (overlaps with the left stream). For -doublehigh, use the *y-val* to position the bottom stream. Negative is up (overlaps with top stream). The default is [0,0].

-samples 1 | 2 | 4 | 8 | 16

Requests the number of samples to compute per display pixel. The requested number of samples per pixel is used if -multisample is not disabled and resources exist for the request. To query the number of samples used, specify the -propt option or run the xglinfo utility. The xglinfo utility can return the number of multisamples after you specify the option -multisample available. The default is 4.

-slave disable | multiview

If you set the multiview argument for the -slave option, the device synchronizes video with a master through the multiview genlock ribbon cable. The system should be powered off whenever connecting or disconnecting this cable. Both devices should be running the same resolution and the option should be issued when the window system is running. The default is disable.

Defaults Certain options have implied default arguments. The default argument is used when the option is not present on the fbconf_xorg command line. For instance, a default argument for -dev is /dev/fb.

Options that set configuration state do not have implied defaults. The -res option is one example. If a configuration option is omitted from the fbconf_xorg command line, the corresponding xorg.conf configuration setting remains unchanged. The exception is that if configuration options are mutually exclusive, setting one automatically unsets each of the others. An example is -deflinear, -defoverlay, and -deftransparent.

If a configuration setting is not present in the configuration file when the window system is run, a default value is used. For instance, the default state associated with -res is auto. A setting might not be present in the file, or the file itself might not exist, until fbconf_xorg has been invoked with the corresponding command line option.

The -defaults option sets the default values for most configuration settings.

Options and their defaults are shown below.

Device-independent defaults:

```
Option          Default Argument
-dev            /dev/fb
-file           machine

Option          Default State
-res            auto
```

Examples   EXAMPLE 1   Switching the Resolution of the Monitor Type

The following example sets the video mode for the monitor on the /dev/fbs/efb0 device to 1280 x 1024 at 76 Hz:

```
example% fbconf_xorg -dev efb0 -res 1280x1024x76
```

Exit Status   The following exit values are returned:

0
   Execution completed successfully.

1
   Invalid command line usage.

2
   An error occurred.

Files   /dev/fb   Symbolic link to the default frame buffer
                                              device.

            /dev/fbs/efbn*n*   Device special file for an efb frame buffer

            /usr/lib/fbconfig/SunModes_xorg.conf Video mode definitions included in new
                                                  configuration files.

fcadm list-fcoe-ports *MAC_Interface*

fcadm force-lip *Port_WWN*

fcinfo [-V]

fcadm [-V]

fcinfo [-?]

fcadm [-?]

Description fcinfo and fcadm are command line interfaces that collect administrative information on fibre channel host bus adapter (HBA) ports on a host. They also collect data on any fibre channel targets that might be connected to those ports in a Storage Area Network (SAN).

A port can be either in initiator mode or target mode. The same FC attribute information and remote port information are applied to both the initiator and the target modes port except that SCSI-related operations described below do not apply for the target mode port.

SUBCOMMANDS The following subcommands are supported by both fcinfo and fcadm:

hba-port   Lists information for the HBA port referenced by the specified *HBA_port_WWN*. If *HBA_port_WWN* is not specified, all initiator mode and target mode fibre channel HBA ports on the host will be listed.

remote-port   Lists the *remote-port* information for those remote ports that are specified. If no *REMOTE_port_WWN* is specified, all remote ports that are visible through *HBA_port_WWN* are listed.

logical-unit | lu   Lists the logical unit referenced by the specified *device_path*. If *device_path* is not specified, all fibre channel logical units will be listed. This subcommand applies only to the initiator mode.

The following subcommands, which administer N_Port ID Virtualization (NPIV) HBA ports, are supported only by fcadm:

create-npiv-port
    Create an NPIV virtual port on the specified adapter.

delete-npiv-port
    Delete an NPIV virtual port. This delete only ports create by fcadm.

The following subcommands, which administer Fibre Channel over Ethernet (FCoE) ports, are supported only by fcadm:

create-fcoe-port
    Creates a FCoE port associated with the given MAC interface and the given *Port_WWN*/*Node_WWN*. If -p or -n is not specified, the Port WWN or Node WWN will be generated automatically. If the specified MAC interface does not support multiple unicast address, no FCoE port will be created and you receive a message indicating that you can add an -f option to force enabling promiscuous mode on the specified MAC interface to enable FCoE.

delete-fcoe-port
    Deletes the FCoE port associated with the specified MAC interface.

list-fcoe-ports
    List information of FCoE ports.

force-lip
    Force the link to reinitialize. When issuing this subcommand on the target port side, causes a reset of the target port. When issuing it from the host port side, resets the host port. When an FC switch is connected, other FC ports in the SAN will get a RSCN (Remote State Change Notification). Furthermore, other initiators will always rediscover the port after this, and the FC login session will be established or reused. Also, I/Os will be continued. This command is disruptive to I/Os, but it is not destructive, as it does not cause any data loss.

Options   The following options are supported:

-e, --fcoe
    Lists the information for all FCoE ports.

-f, --fcoe-promiscuous

Used with `create-fcoe-port` to create an FCoE port on a MAC interface associated with a NIC that does not support multiple unicast address. Promiscuous mode will be enabled for the specified MAC interface.

-l, --linkstat

Lists the link error statistics information for the port referenced by the specified *HBA_port_WWN* or *REMOTE_port_WWN*.

-n *HBA_node_WWN*, --node *HBA_node_WWN*

When used with NPIV options, specify a virtual node WWN. If used with `create-npiv-port`, it can be omitted, and a random based WWN will be used. It is mandatory for `delete-npiv-port`.

When used with `create-fcoe-port` subcommand, specify the node WWN for the FCoE port. It can be omitted, in which case a WWN will be generated based on the MAC address of the specified MAC interface.

-p *HBA_port_WWN*, --port *HBA_port_WWN*

Retrieve remote port information from the *HBA_port_WWN* of the local HBA port on the host. When used with the `remote-port` subcommand, the -p option is mandatory.

When used with NPIV options, specify a virtual port WWN. If used with `create-npiv-port`, it can be omitted, and a random based WWN will be used. It is mandatory for `delete-npiv-port`.

When used with `create-fcoe-port` subcommand, specify the port WWN for the FCoE port. It can be omitted, in which case a WWN will be generated based on the MAC address of the specified MAC interface.

-s, --scsi-target

Lists the SCSI target information for all remote ports the user has asked for. The -p, --port option must always be specified and must be a valid HBA port on the host. This HBA port will be used as the initiator for which to retrieve the SCSI level target information. Note that this will only function on remote port fibre channel World-Wide Names that support an FC4 type of SCSI. This option applies only to an initiator mode port.

-t [*HBA_node_WWN*], -target [*HBA_node_WWN*]

Lists the information for the port with the target mode referenced by the specified *HBA_node_WWN* or all target mode ports discovered in the host.

When used with `create-fcoe-port`, create a FCoE target mode port.

-v, --verbose

When used with the `logical-unit` subcommand, the -v displays additional information for the logical unit, including SCSI vendor and product information and device type as well as the FC World-Wide names for the local and remote fibre channel ports to which this device is attached.

-V, --version
   Displays the version information.

-?, --help
   Displays the usage information.

Examples   EXAMPLE 1   Listing All HBA Ports

The following command lists all initiator mode fibre channel HBA ports on the host:

```
# fcinfo hba-port

HBA Port WWN: 210000e08b074cb5
        Port Mode: Initiator
        OS Device Name: /dev/cfg/c1
        Manufacturer: QLogic Corp.
        Model: 375-3108-xx
        Firmware Version: 3.3.116
        FCode/BIOS Version: 1.13.08
        Serial Number: not available
        Driver Name: qlc
        Driver Version: 20070212-2.19
        Type: N-port
        State: online
        Supported Speeds: 1Gb 2Gb
        Current Speed: 2Gb
        Node WWN: 200000e08b074cb5
NPIV Port List:
        Virtual Port 1:
         Port WWN: 200000e08b074cb1
         Node WWN: 200000e08b074cb3
HBA Port WWN: 210100e08b274cb5
        Port Mode: Initiator
        OS Device Name: /dev/cfg/c2
        Manufacturer: QLogic Corp.
        Model: 375-3108-xx
        Firmware Version: 3.3.116
        FCode/BIOS Version: 1.13.08
        Serial Number: not available
        Driver Name: qlc
        Driver Version: 20070212-2.19
        Type: N-port
        State: online
        Supported Speeds: 1Gb 2Gb
        Current Speed: 2Gb
        Node WWN: 200100e08b274cb5
HBA Port WWN: 210000e08b072ab5
        Port Mode: Initiator
        OS Device Name: /dev/cfg/c3
```

EXAMPLE 1   Listing All HBA Ports   *(Continued)*

```
        Manufacturer: QLogic Corp.
        Firmware Version: 3.3.116
        FCode/BIOS Version: 1.13.08
        Model: 375-3108-xx
        Serial Number: not available
        Driver Name: qlc
        Driver Version: 20070212-2.19
        Type: L-port
        State: online
        Supported Speeds: 1Gb 2Gb
        Current Speed: 2Gb
        Node WWN: 200000e08b072ab5
HBA Port WWN: 210100e08b272ab5
        Port Mode: Initiator
        OS Device Name: /dev/cfg/c4
        Manufacturer: QLogic Corp.
        Model: 375-3108-xx
        Firmware Version: 3.3.116
        FCode/BIOS Version: 1.13.08
        Serial Number: 0402F00-0549112808
        Driver Name: qlc
        Driver Version: 20070212-2.19
        Type: N-port
        State: online
        Supported Speeds: 1Gb 2Gb
        Current Speed: 2Gb
        Node WWN: 200100e08b272ab5
```

EXAMPLE 2   Listing Target Mode HBA Ports

The following command lists all target mode fibre channel HBA ports on the host:

```
# fcinfo hba-port -t
  HBA Port WWN: 210100e08bb09221
     Port Mode: Target
     Port ID: 10700
     OS Device Name: Not Applicable
     Manufacturer: QLogic Corp.
     Model: d30ac7e0
     Firmware Version: 4.0.109
     FCode/BIOS Version: N/A
     Type: F-port
     State: online
     Supported Speeds: not established
     Current Speed: 2Gb
     Node WWN: 200100e08bb09221
  HBA Port WWN: 210000e08b909221
```

EXAMPLE 2 Listing Target Mode HBA Ports   *(Continued)*

```
     Port Mode: Target
     Port ID: 10900
     OS Device Name: Not Applicable
     Manufacturer: QLogic Corp.
     Model: d37ad1e0
     Firmware Version: 4.0.109
     FCode/BIOS Version: N/A
     Type: F-port
     State: online
     Supported Speeds: not established
     Current Speed: 2Gb
     Node WWN: 200000e08b909221
 HBA Port WWN: 200000144fc2d508
     Port Mode: Target
     Port ID: 9a0025
     OS Device Name: Not Applicable
     Manufacturer: Sun Microsystems, Inc.
     Model: FCoE Virtual FC HBA
     Firmware Version: N/A
     FCode/BIOS Version: N/A
     Serial Number: N/A
     Driver Name: COMSTAR FCOET
     Driver Version: 1.0
     Type: F-port
     State: online
     Supported Speeds: 1Gb 10Gb
     Current Speed: 10Gb
     Node WWN: 100000144fc2d508
 HBA Port WWN: 200000144fc2d509
     Port Mode: Target
     Port ID: 9a0023
     OS Device Name: Not Applicable
     Manufacturer: Sun Microsystems, Inc.
     Model: FCoE Virtual FC HBA
     Firmware Version: N/A
     FCode/BIOS Version: N/A
     Serial Number: N/A
     Driver Name: COMSTAR FCOET
     Driver Version: 1.0
     Type: F-port
     State: online
     Supported Speeds: 1Gb 10Gb
     Current Speed: 10Gb
     Node WWN: 100000144fc2d509
```

EXAMPLE 3   Listing HBA Ports and Link Statistics

The following command lists information for the HBA ports and the link statistics for those ports:

```
# fcinfo hba-port -l 210000e08b074cb5 210100e08b274cb5

HBA Port WWN: 210000e08b074cb5
        Port Mode: Initiator
        OS Device Name: /dev/cfg/c1
        Manufacturer: QLogic Corp.
        Model: 375-3108-xx
        Firmware Version: 3.3.116
        FCode/BIOS Version: 1.13.08
        Serial Number: 0402F00-0549112808
        Driver Name: qlc
        Driver Version: 20070212-2.19
        Type: N-port
        State: online
        Supported Speeds: 1Gb 2Gb
        Current Speed: 2Gb
        Node WWN: 200000e08b074cb5
        Link Error Statistics:
                Link Failure Count: 0
                Loss of Sync Count: 0
                Loss of Signal Count: 0
                Primitive Seq Protocol Error Count: 0
                Invalid Tx Word Count: 0
                Invalid CRC Count: 0
HBA Port WWN: 210100e08b274cb5
        Port Mode: Initiator
        OS Device Name: /dev/cfg/c2
        Manufacturer: QLogic Corp.
        Model: 375-3108-xx
        Firmware Version: 3.3.116
        FCode/BIOS Version: 1.13.08
        Serial Number: 0402F00-0549112808
        Driver Name: qlc
        Driver Version: 20070212-2.19
        Type: N-port
        State: online
        Supported Speeds: 1Gb 2Gb
        Current Speed: 2Gb
        Node WWN: 200100e08b274cb5
        Link Error Statistics:
                Link Failure Count: 0
                Loss of Sync Count: 0
                Loss of Signal Count: 0
                Primitive Seq Protocol Error Count: 0
```

EXAMPLE 3 Listing HBA Ports and Link Statistics   *(Continued)*

```
                Invalid Tx Word Count: 0
                Invalid CRC Count: 0
```

EXAMPLE 4 Listing All Remote Ports

The following command lists all remote ports that are visible through the given HBA port:

```
# fcinfo remote-port -p 210100e08b274cb5

Remote Port WWN: 50020f230000b4af
        Active FC4 Types: SCSI
        SCSI Target: yes
        Port Symbolic Name: unknown
        Node WWN: 50020f200000b4af
Remote Port WWN: 210000e08b07daa6
        Active FC4 Types: SCSI
        SCSI Target: no
        Port Symbolic Name: unknown
        Node WWN: 200000e08b07daa6
Remote Port WWN: 20030003ba27c788
        Active FC4 Types: SCSI
        SCSI Target: yes
        Port Symbolic Name: unknown
        Node WWN: 10000003ba27c788
Remote Port WWN: 210000e08b096a60
        Active FC4 Types: SCSI,IP
        SCSI Target: no
        Port Symbolic Name: unknown
        Node WWN: 200000e08b096a60
```

EXAMPLE 5 Listing Remote Ports and Link Statistics

The following command lists information for the remote ports and the link statistics for those ports:

```
# fcinfo remote-port -l -p 210100e08b272ab5

Remote Port WWN: 210100e08b296a60
        Active FC4 Types: SCSI,IP
        SCSI Target: no
        Port Symbolic Name: unknown
        Node WWN: 200100e08b296a60
        Link Error Statistics:
                Link Failure Count: 0
                Loss of Sync Count: 0
                Loss of Signal Count: 0
                Primitive Seq Protocol Error Count: 0
                Invalid Tx Word Count: 0
```

EXAMPLE 5   Listing Remote Ports and Link Statistics   *(Continued)*

```
                     Invalid CRC Count: 0
Remote Port WWN: 20030003ba27d56d
        Active FC4 Types: SCSI
        SCSI Target: yes
        Port Symbolic Name: unknown
        Node WWN: 10000003ba27d56d
        Link Error Statistics:
                Link Failure Count: 0
                Loss of Sync Count: 4765165
                Loss of Signal Count: 4765165

```

EXAMPLE 8 Listing the Logical Unit

The following command lists the logical unit:

fcinfo logical-unit

```
/dev/rdsk/c0t600C0FF0000000000036223AE73EB705d0s2
/dev/rdsk/c0t600C0FF00000000000362272539E5B03d0s2
/dev/rmt/0n
```

EXAMPLE 9 Displaying Additional Information for the Logical Unit

The following command displays additional information about the logical unit using the -v option for device /dev/rmt/On:

fcinfo lu -v /dev/rmt/On

```
 OS Device Name: /dev/rmt/0n
        HBA Port WWN: 210000e07c030b91
                Remote Port WWN: 21010003b7830a6
```

EXAMPLE 9 Displaying Additional Information for the Logical Unit   *(Continued)*

```
                      LUN: 0
       Vendor: STK
       Product: 9940A
       Device Type: Tape device
```

The following command displays additional information about the logical unit using the -v option for device /dev/rdsk/c0t600C0FF0000000000036223AE73EB705d0s2

```
# fcinfo logical-unit -v \
     /dev/rdsk/c0t600C0FF0000000000036223AE73EB705d0s2

 OS Device Name: /dev/rdsk/c0t600C0FF0000000000036223AE73EB705d0s2
       HBA Port WWN: 210100e08b27a8a1
               Remote Port WWN: 256000c0ffc03622
                       LUN: 0
               Remote Port WWN: 216000c0ff803622
                       LUN: 0
       HBA Port WWN: 210000e08b07a8a1
               Remote Port WWN: 256000c0ffc03622
                       LUN: 0
               Remote Port WWN: 216000c0ff803622
                       LUN: 0
       Vendor: SUN
       Product: StorEdge 3510
       Device Type: Disk device
```

EXAMPLE 10 Adding an NIPV Port

The following command adds an NPIV port to the HBA with a port name:

210000e08b170f1c

The NPIV port has a port name of 2000000000000001 and a node name of 2100000000000001.

```
# fcadm create-npiv-port  -p 2000000000000001 -n 2100000000000001 \
210000e08b170f1c

Created NPIV Port:
    HBA Port WWN: 2000000000000001
    Node WWN: 2100000000000001
    Physical HBA Port WWN: 210000e08b170f1c
```

EXAMPLE 11 Adding an NIPV Port with Random WWN

The following command adds an NPIV port to the HBA with a randomly assigned port name of 210000e08b170f1c.

EXAMPLE 11 Adding an NIPV Port with Random WWN   *(Continued)*

```
# fcadm create-npiv-port 210000e08b170f1c

Created NPIV Port:
    HBA Port WWN: 2038295824942801
    Node WWN: 2100392849248001
    Physical HBA Port WWN: 210000e08b170f1c
```

EXAMPLE 12 Deleting an NIPV Port

The following command deletes an NPIV port.

```
# fcadm delete-npiv-port -p 2000000000000001 -w 2100000000000001 \
2100000e08b170f1c
```

EXAMPLE 13 Creating an FCoE Target Port

The following command creates an FCoE port associated with the MAC interface nxge0.

```
# fcadm create-fcoe-port -t nxge0
```

EXAMPLE 14 Deleting an FCoE Port

The following command deletes the FCoE port associated with the MAC interface nxge0.

```
# fcadm delete-fcoe-port -t nxge0
```

EXAMPLE 15 Listing Information for an FCoE Port

The following command lists information for FCoE ports.

```
# fcadm list-fcoe-ports
HBA Port WWN: 200000144fc2d508
        Port Type: Target
        MAC Name: nxge0
        MTU Size: 9194
        MAC Factory Address: 00144fc2d508
        MAC Current Address: 00144fc2d508
HBA Port WWN: 200000144fc2d509
        Port Type: Target
        MAC Name: nxge1
        MTU Size: 9194
        MAC Factory Address: 00144fc2d509
        MAC Current Address: 00144fc2d509
```

EXAMPLE 16 Reinitializing the Link of an FC Port

The following command forces the link connected with the port 200000144fc2d508 to
reinitialize.

```
# fcadm force-lip 200000144fc2d508
```

Error Messages Errors that can occur in addition to the errors normally associated with system administration commands:

- *HBA_port_WWN*: not found
- *Remote_port_WWN*: not found
- *HBA_port_WWN*: NPIV not supported on this HBA

Name fdetach – detach a name from a STREAMS-based file descriptor

Synopsis fdetach *path*

Description The fdetach command detaches a STREAMS-based file descriptor from a name in the file system. Use the *path* operand to specify the path name of the object in the file system name space, which was previously attached. See fattach(3C).

The user must be the owner of the file or a user with the appropriate privileges. All subsequent operations on *path* will operate on the underlying file system entry and not on the STREAMS file. The permissions and status of the entry are restored to the state they were in before the STREAMS file was attached to the entry.

Operands The following operands are supported:

path Specifies the path name of the object in the file system name space, which was previously attached.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also fattach(3C), fdetach(3C), attributes(5), streamio(7I)

STREAMS Programming Guide

Name fdisk – create or modify fixed disk partition table

Synopsis fdisk [-o *offset*] [-s *size*] [-P *fill_patt*] [-S *geom_file*]
  [-w | -r | -d | -n | -I | -B | -t | -T | -g | -G | -R | -E]
  [--F *fdisk_file*] [[-v] -W {*fdisk_file* | −}]
  [-h] [-b *masterboot*]
  [-A *id* : *act* : *bhead* : *bsect* : *bcyl* : *ehead* : *esect* :
    ecyl : *rsect* : *numsect*]
  [-D *id* : *act* : *bhead*: *bsect* : *bcyl* : *ehead*: *esect* :
    ecyl : *rsect* : *numsect*] *rdevice*

Description This command is used to do the following:

- Create and modify an fdisk partition table on x86 systems

- Create and modify an fdisk partition table on removable media on SPARC or x86 systems

- Install the master boot record that is put in the first sector of the fixed disk on x86 systems only

This table is used by the first-stage bootstrap (or firmware) to identify parts of the disk reserved for different operating systems, and to identify the partition containing the second-stage bootstrap (the *active* Solaris partition). The *rdevice* argument must be used to specify the raw device associated with the fixed disk, for example, /dev/rdsk/c0t0d0p0.

The program can operate in three different modes. The first is interactive mode. In interactive mode, the program displays the partition table as it exists on the disk, and then presents a menu allowing the user to modify the table. The menu, questions, warnings, and error messages are intended to be self-explanatory.

In interactive mode, if there is no partition table on the disk, the user is given the options of creating a default partitioning or specifying the initial table values. The default partitioning allocates the entire disk for the Solaris system and makes the Solaris system partition active. In either case, when the initial table is created, fdisk also writes out the first-stage bootstrap (x86 only) code along with the partition table. In this mode, (x86 only) when creating an entry for a non-EFI partition on a disk that is larger than 2 TB (terabytes), fdisk warns that the maximum size of the partition is 2 TB. Under these conditions percentages displayed by fdisk are based on 2 TB.

The second mode of operation is used for automated entry addition, entry deletion, or replacement of the entire fdisk table. This mode can add or delete an entry described on the command line. In this mode the entire fdisk table can be read in from a file replacing the original table. fdisk can also be used to create this file. There is a command line option that will cause fdisk to replace any fdisk table with the default of the whole disk for the Solaris system.

The third mode of operation is used for disk diagnostics. In this mode, a section of the disk can be filled with a user-specified pattern and mode sections of the disk can also be read or written.

Note – The third mode of operation is not currently supported for extended partitions

When fdisk creates a partition, the space is allocated in the fdisk partition table, but the allocated disk space is not initialized. newfs(1M) is required to create and write file system metadata to the new partition, and format(1M) is required to write the VTOC or EFI/GPT metadata.

Menu Options   The menu options for interactive mode given by the fdisk program are:

Create a partition
    This option allows the user to create a new partition. The maximum number of partitions is 4. The program will ask for the type of the partition (SOLARIS, MS-DOS, UNIX, or other). It will then ask for the size of the partition as a percentage of the disk. The user may also enter the letter c at this point, in which case the program will ask for the starting cylinder number and size of the partition in cylinders. If a c is not entered, the program will determine the starting cylinder number where the partition will fit. In either case, if the partition would overlap an existing partition or will not fit, a message is displayed and the program returns to the original menu.

Change Active (Boot from) partition
    This option allows the user to specify the partition where the first-stage bootstrap will look for the second-stage bootstrap, otherwise known as the *active* partition.

Delete a partition
    This option allows the user to delete a previously created partition. Note that this will destroy all data in that partition.

Change between Solaris and Solaris2 Partition IDs
    This option allows the user to switch between the current fdisk operating system partition identifier and the previous one. This does not affect any data in the disk partition and is provided for compatibility with older software.

Edit/View extended partitions
    This option provides the extended partition menu to the user. Use the extended partition menu to add and delete logical drives, change the sysid of the logical drives, and display logical drive information. To commit the changes made in the extended partition, you must return to the main menu using the extended partition submenu option r. There is also an option to display the list of options that the extended partition submenu supports. Given below is the list:

    a   Add a logical drive.

            Use this submenu option to add a logical drive. There are three pieces of information that are required: The beginning cylinder, the size (in cylinders or in human readable form - KB, MB, or GB), and the partition ID. While specifying the partition ID, there is an option (I) that you can use to list the supported partitions.

    d   Delete a logical drive.

            Use this submenu option to delete a logical drive. The only input required is the number of the logical drive that is to be deleted.

h   Display the help menu.

This submenu option displays the supported operations in the extended partition submenu.

i   Change the id of the logical drive.

Use this submenu option to change the system ID of the existing logical drives. A list of supported system IDs is displayed when you use the I option when in this submenu.

p   Display the logical drive layout.

Displays the logical drive information to stdout. This output reflects any changes made during the current run of the fdisk program. The changes are not committed to the disk until return to the main menu (using the submenu r) and choose the option to commit the changes to the disk.

r   Return to the main fdisk menu.

Exit the extended partition submenu and return to the main menu.

Note the dynamic nature of the numbering of extended partitions. For example, consider a Solaris system with the partitions p1, p2, p3, and p4. Following creation of an extended partition, the same system has a logical device node, p5, and successive nodes numbered consecutively up to a maximum of p36. If one logical drive is deleted, say, p8, then all nodes following p8 (p9 up to p36) move up one in the list of partitions, so that p9 becomes p8, p10 becomes p9, and so forth.

Use the following options to include your modifications to the partition table at this time or to cancel the session without modifying the table:

Exit   This option writes the new version of the table created during this session with fdisk out to the fixed disk, and exits the program.

Cancel   This option exits without modifying the partition table.

Options The following options apply to fdisk:

-A *id:act:bhead:bsect:bcyl:ehead:esect:ecyl:rsect:numsect*
Add a partition as described by the argument (see the -F option below for the format). Use of this option will zero out the VTOC on the Solaris partition if the fdisk table changes.

-b *master_boot*
Specify the file *master_boot* as the master boot program. The default master boot program is /usr/lib/fs/ufs/mboot.

-B

Default to one Solaris partition that uses the whole disk. On an x86 machine, if the disk is larger than 2 TB (terabytes), the default size of the Solaris partition will be limited to 2 TB.

-d

Turn on verbose *debug* mode. This will cause fdisk to print its state on stderr as it is used. The output from this option should not be used with -F.

-D *id:act:bhead:bsect:bcyl:ehead:esect:ecyl:rsect:numsect*

Delete a partition as described by the argument (see the -F option below for the format). Note that the argument must be an exact match or the entry will not be deleted! Use of this option will zero out the VTOC on the Solaris partition if the fdisk table changes.

-E

Create an EFI partition that uses the entire disk.

-F *fdisk_file*

Use fdisk file *fdisk_file* to initialize table. Use of this option will zero out the VTOC on the Solaris partition if the fdisk table changes.

The *fdisk_file* contains four specification lines for the primary partitions followed by specification lines for the logical drives. You must have four lines for the primary partitions if there is at least one logical drive. In this case, if the number of primary partitions to be configured is less than four, the remaining lines should be filled with zeros.

Each line is composed of entries that are position-dependent, are separated by whitespace or colons, and have the following format:

id act bhead bsect bcyl ehead esect ecyl rsect numsect

...where the entries have the following values:

id	This is the type of partition and the correct numeric values may be found in fdisk.h.
act	This is the active partition flag; 0 means not active and 128 means active. For logical drives, this flag will always be set to 0 even if specified as 128 by the user.
bhead	This is the head where the partition starts. If this is set to 0, fdisk will correctly fill this in from other information.
bsect	This is the sector where the partition starts. If this is set to 0, fdisk will correctly fill this in from other information.
bcyl	This is the cylinder where the partition starts. If this is set to 0, fdisk will correctly fill this in from other information.
ehead	This is the head where the partition ends. If this is set to 0, fdisk will correctly fill this in from other information.

esect	This is the sector where the partition ends. If this is set to 0, fdisk will correctly fill this in from other information.
ecyl	This is the cylinder where the partition ends. If this is set to 0, fdisk will correctly fill this in from other information.
rsect	The relative sector from the beginning of the disk where the partition starts. This must be specified and can be used by fdisk to fill in other fields. For logical drives, you must make sure that there are at least 63 free sectors before the *rsect* specified for a logical drive.
numsect	The size in sectors of this disk partition. This must be specified and can be used by fdisk to fill in other fields.

-g

Get the label geometry for disk and display on stdout (see the -S option for the format).

-G

Get the physical geometry for disk and display on stdout (see the -S option for the format).

-h

Issue verbose message; message will list all options and supply an explanation for each.

-I

Forgo device checks. This is used to generate a file image of what would go on a disk without using the device. Note that you must use -S with this option (see above).

-n

Don't update fdisk table unless explicitly specified by another option. If no other options are used, -n will only write the master boot record to the disk. In addition, note that fdisk will not come up in interactive mode if the -n option is specified.

-o *offset*

Block offset from start of disk. This option is used for -P, -r, and -w. Zero is assumed when this option is not used.

-P *fill_patt*

Fill disk with pattern *fill_patt*. *fill_patt* can be decimal or hex and is used as number for constant long word pattern. If *fill_patt* is #, then pattern is block # for each block. Pattern is put in each block as long words and fills each block (see -o and -s).

-r

Read from disk and write to stdout. See -o and -s, which specify the starting point and size of the operation.

-R

Treat disk as read-only. This is for testing purposes.

-s *size*

Number of blocks to perform operation on (see -o).

-S *geom_file*

Set the label geometry to the content of the *geom_file*. The *geom_file* contains one specification line. Each line is delimited by a new-line character (\n). If the first character of a line is an asterisk (*), the line is treated as a comment. Each line is composed of entries that are position-dependent, are separated by white space, and have the following format:

pcyl ncyl acyl bcyl nheads nsectors sectsiz

where the entries have the following values:

pcyl   This is the number of physical cylinders for the drive.

ncyl   This is the number of usable cylinders for the drive.

acyl   This is the number of alt cylinders for the drive.

bcyl   This is the number of offset cylinders for the drive (should be zero).

nheads   The number of heads for this drive.

nsectors The number of sectors per track.

sectsiz   The size in bytes of a sector.

-t

Adjust incorrect slice table entries so that they will not cross partition table boundaries.

-T

Remove incorrect slice table entries that span partition table boundaries.

-v

Output the HBA (virtual) geometry dimensions. This option must be used in conjunction with the -W flag. This option will work for platforms which support virtual geometry. (x86 only)

-w

Write to disk and read from stdin. See -o and -s, which specify the starting point and size of the operation.

-W —

Output the disk table to stdout.

-W *fdisk_file*

Create an fdisk file *fdisk_file* from disk table. This can be used with the -F option above.

Files /dev/rdsk/c0t0d0p0   Raw device associated with the fixed disk.

/usr/lib/fs/ufs/mboot   Default master boot program.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	x86 and SPARC
Availability	system/core-os

See Also uname(1), fmthard(1M), format(1M), newfs(1M), parted(1M), prtvtoc(1M), attributes(5)

Diagnostics Most messages will be self-explanatory. The following may appear immediately after starting the program:

Fdisk: cannot open <device>
  This indicates that the device name argument is not valid.

Fdisk: unable to get device parameters for device <device>
  This indicates a problem with the configuration of the fixed disk, or an error in the fixed disk driver.

Fdisk: error reading partition table
  This indicates that some error occurred when trying initially to read the fixed disk. This could be a problem with the fixed disk controller or driver, or with the configuration of the fixed disk.

Fdisk: error writing boot record
  This indicates that some error occurred when trying to write the new partition table out to the fixed disk. This could be a problem with the fixed disk controller, the disk itself, the driver, or the configuration of the fixed disk.

Name   ff – list file names and statistics for a file system

Synopsis   ff [-F *FSType*] [-V] [*generic_options*] [-o *specific_options*] *special*...

Description   ff prints the pathnames and inode numbers of files in the file system which resides on the special device *special*. Other information about the files may be printed using options described below. Selection criteria may be used to instruct ff to only print information for certain files. If no selection criteria are specified, information for all files considered will be printed (the default); the -i option may be used to limit files to those whose inodes are specified.

Output is sorted in ascending inode number order. The default line produced by ff is:

path-name i-number

The maximum information the command will provide is:

path-name i-number size uid

Options   -F   Specify the *FSType* on which to operate. The *FSType* should either be
                                specified here or be determinable from /etc/vfstab by matching the
                                special with an entry in the table, or by consulting /etc/default/fs.

                -V   Echo the complete command line, but do not execute the command. The
                                command line is generated by using the options and arguments provided
                                by the user and adding to them information derived from /etc/vfstab.
                                This option may be used to verify and validate the command line.

          generic_options   Options that are supported by most FSType-specific modules of the
                                command. The following options are available:

                      -I   Do not print the i-node number after each path name.

                      -l   Generate a supplementary list of all path names for
                                      multiply-linked files.

                      -p *prefix*   The specified *prefix* will be added to each generated path
                                      name. The default is '.' (dot).

                      -s   Print the file size, in bytes, after each path name.

                      -u   Print the owner's login name after each path name.

                      -a -*n*   Select if the file has been accessed in *n* days.

                      -m -*n*   Select if the file has been written or created in *n* days.

                      -c -*n*   Select if file's status has been changed in *n* days.

                      -n *file*   Select if the file has been modified more recently than
                                      the argument file.

| | -i *i-node-list* | Generate names for only those i-nodes specified in *i-node-list*. *i-node-list* is a list of numbers separated by commas (with no intervening spaces). |

| | -o | Specify *FSType*-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType*-specific module of the command. |

Operands *special* A special device.

Usage See largefile(5) for the description of the behavior of ff when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files /etc/default/fs default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs

| | LOCAL | The default partition for a command if no FSType is specified. |

/etc/vfstab list of default parameters for each file system

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also find(1), ncheck(1M), stat(2), vfstab(4), attributes(5), largefile(5) Manual pages for the *FSType*-specific modules of ff.

Notes This command may not be supported for all *FSTypes*.

The -a, -m, and -c flags examine the st_atime, st_mtime, and st_ctime fields of the stat structure respectively. (See stat(2).)

Name ff_ufs – list file names and statistics for a ufs file system

Synopsis ff -F ufs [*generic_options*] [-o a,m,s] *special*...

Description ff prints the pathnames and inode numbers of files in the file system which resides on the special device *special*.

See ff(1M) for information regarding the ff command. See OPTIONS for information regarding the ufs-specific options.

Options The following options are supported:

-o   Specify ufs file system specific options. The following options available are:

a   Print the '.' and '..' directory entries.

m   Print mode information. This option must be specified in conjunction with the -i *i-node-list* option (see ff(1M)).

s   Print only special files and files with set-user-ID mode.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also find(1), ff(1M), ncheck(1M), attributes(5)

Name fiocompress – file compression utility

Synopsis /usr/sbin/fiocompress -c [-m] [-b *block_size*] *input_file output_file*

/usr/sbin/fiocompress -d *input_file output_file*

Description The fiocompress utility is a file compression tool that works together with the dcfs(7FS) file system to perform per-file compression. You can use fiocompress to decompress a compressed file or mark a compressed file as compressed, causing automatic decompression on read. The primary use of fiocompress is to compress files in the boot archive.

Note that this utility is not a Committed interface. See attributes(5).

Options The following options are supported:

-b *block_size*
  Specify a block size for compression. The default block size is 8192.

-c
  Compress the specified file.

-d
  Decompress the specified file.

-m
  Mark the compressed file for automatic decompression on read. Can be used only in conjunction with -c.

Exit Status 0
  The command completed successfully.

−1
  The command exited due to an error.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Private

See Also boot(1M), bootadm(1M), dcfs(7FS), ufs(7FS), attributes(5)

Notes This compression/decompression utility works only with files stored in a UFS file system.

There is no obvious way to determine whether a given file is compressed, other than copying the file and comparing the number of disk blocks of the copy against the original.

Name   flowadm – administer bandwidth resource control for protocols, services, containers, and virtual machines

Synopsis   flowadm show-flow [-P] [[-p] -o *field*[,...]] [-l *link*] [*flow*]

flowadm add-flow [-t] [-R *root-dir*] -l *link* -a *attr*=*value*[,...]
        [-p *prop*=*value*[,...]] *flow*
flowadm remove-flow [-t] [-R *root-dir*] {-l *link* | *flow*}

flowadm set-flowprop [-t] [-R *root-dir*] -p *prop*=*value*[,...] *flow*
flowadm reset-flowprop [-t] [-R *root-dir*] [-p *prop*[,...]] *flow*
flowadm show-flowprop [-P] [[-c] -o *field*[,...]] [-l *link*]
        [-p *prop*[,...]] [*flow*]

Description   The flowadm command is used to create, modify, remove, and show networking bandwidth and associated resources for a type of traffic on a particular link.

The flowadm command allows users to manage networking bandwidth resources for a transport, service, or a subnet. The service is specified as a combination of transport and local port. The subnet is specified by its IP address and subnet mask. The command can be used on any type of data link, including physical links, virtual NICs, and link aggregations.

A flow is defined as a set of attributes based on Layer 3 and Layer 4 headers, which can be used to identify a protocol, service, or a virtual machine. When a flow is identified based on flow attributes, separate kernel resources including layer 2, 3, and 4 queues, their processing threads, and other resources are uniquely created for it, such that other traffic has minimal or zero impact on it.

Inbound and outbound packet are matched to flows in a very fast and scalable way, so that limits can be enforced with minimal performance impact.

The flowadm command can be used to identify a flow without imposing any bandwidth resource control. This would result in the traffic type getting its own resources and queues so that it is isolated from rest of the networking traffic for more observable and deterministic behavior.

Flows can be created, modified, and removed in both global and non-global zones. A zone administrator can create a flow only in his zone, global or non-global. However, a flow created in the global zone can migrate to a non-global zone, as described in the following paragraph. An administrator can modify or remove a flow only from within the zone, global or non-global, in which the flow was created. From the global zone, one can view all flows on a system, within the global and any non-global zones. From a non-global zone, one can view only those flows in that zone.

After an administrator creates a flow in the global zone, the data link associated with that flow can be assigned to a non-global zone. In such a case, the associated flow is also assigned to the same non-global zone. When this non-global zone is halted, the data link and its associated flow return to the global zone.

Different zone names distinguish flows of the same name. For example, one can have three flows named fastpak, if each fastpak is in a different zone. For example, zone1/fastpak, zone2/fastpak, and zone3/fastpak are all valid zone names.

flowadm is implemented as a set of subcommands with corresponding options. Options are described in the context of each subcommand.

Sub-commands The following subcommands are supported:

flowadm show-flow [-pP] [-o *field*[,...]] [-l *link*] [*flow*]
    Show flow configuration information (the default) or statistics, either for all flows, all flows on a link, or for the specified *flow*.

    -o *field*[,...]
        A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or a special value all, to display all fields. For each flow found, the following fields can be displayed:

        flow
            The name of the flow.

        link
            The name of the link the flow is on.

        ipaddr
            IP address of the flow. This can be either local or remote depending on how the flow was defined.

        transport
            The name of the layer for protocol to be used.

        port
            Local port of service for flow.

        dsfield
            Differentiated services value for flow and mask used with DSFIELD value to state the bits of interest in the differentiated services field of the IP header.

    -p, -—parseable
        Display using a stable machine-parseable format.

    -P, -—persistent
        Display persistent flow property information.

    -l *link*, -—link=*link* | *flow*
        Display information for all flows on the named link or information for the named flow.

flowadm add-flow [-t] [-R *root-dir*] -l *link* -a *attr=value*[,...] -p *prop=value*[,...] *flow*
    Adds a flow to the system. The flow is identified by its flow attributes and properties.

As part of identifying a particular flow, its bandwidth resource can be limited. If no bandwidth limit is specified, the traffic still gets its unique layer 2, 3, and 4 queues and processing threads, including NIC hardware resources (when supported), so that the selected traffic can be separated from others and can flow with minimal impact from other traffic.

-t, --temporary
    The changes are temporary and will not persist across reboots. Persistence is the default.

-R *root-dir*, --root-dir=*root-dir*
    Specifies an alternate root directory where flowadm should apply persistent creation.

-l *link*, --link=*link*
    Specify the link to which the flow will be added.

-a *attr=value*[,...], --attr=*value*
    A comma-separated list of attributes to be set to the specified values.

-p *prop=value*[,...], --prop=*value*[,...]
    A comma-separated list of properties to be set to the specified values.

flowadm remove-flow [-t] [-R *root-dir*] -l {*link* | *flow*}
Remove an existing flow identified by its link or name.

-t, --temporary
    The changes are temporary and will not persist across reboots. Persistence is the default.

-R *root-dir*, --root-dir=*root-dir*
    Specifies an alternate root directory where flowadm should apply persistent removal.

-l *link* | *flow*, --link=*link* | *flow*
    If a link is specified, remove all flows from that link. If a single flow is specified, remove only that flow.

flowadm set-flowprop [-t] [-R *root-dir*] -p *prop=value*[,...] *flow*
Set values of one or more properties on the flow specified by name. The complete list of properties can be retrieved using the show-flow subcommand.

-t, --temporary
    The changes are temporary and will not persist across reboots. Persistence is the default.

-R *root-dir*, --root-dir=*root-dir*
    Specifies an alternate root directory where flowadm should apply persistent setting of properties.

-p *prop=value*[,...], --prop=*value*[,...]
    A comma-separated list of properties to be set to the specified values.

flowadm reset-flowprop [-t] [-R *root-dir*] -p [*prop=value*[,...]] *flow*
Resets one or more properties to their default values on the specified flow. If no properties are specified, all properties are reset. See the show-flowprop subcommand for a description of properties, which includes their default values.

-t, -—temporary
   Specifies that the resets are temporary. Temporary resets last until the next reboot.

-R *root-dir*, -—root-dir=*root-dir*
   Specifies an alternate root directory where flowadm should apply persistent setting of
   properties.

-p *prop=value*[,...], -—prop=*value*[,...]
   A comma-separated list of properties to be reset.

flowadm show-flowprop [-cP] [-l *link*] [-p *prop*[,...]] [*flow*]
   Show the current or persistent values of one or more properties, either for all flows, flows
   on a specified link, or for the specified flow.

   By default, current values are shown. If no properties are specified, all available flow
   properties are displayed. For each property, the following fields are displayed:

   FLOW
      The name of the flow.

   PROPERTY
      The name of the property.

   VALUE
      The current (or persistent) property value. The value is shown as - - (double hyphen), if
      it is not set, and ? (question mark), if the value is unknown. Persistent values that are not
      set or have been reset will be shown as - - and will use the system DEFAULT value (if any).

   DEFAULT
      The default value of the property. If the property has no default value, - - (double
      hyphen), is shown.

   POSSIBLE
      A comma-separated list of the values the property can have. If the values span a numeric
      range, the minimum and maximum values might be shown as shorthand. If the possible
      values are unknown or unbounded, - - (double hyphen), is shown.

   Flow properties are documented in the "Flow Properties" section, below.

   -c, -—parseable
      Display using a stable machine-parseable format.

   -P, -—persistent
      Display persistent flow property information.

   -p *prop*[,...], -—prop=*prop*[,...]
      A comma-separated list of properties to show.

Flow Attributes The flow operand that identifies a flow in a flowadm command is a comma-separated list of one or more keyword, value pairs from the list below.

local_ip[/*prefix_len*]
    Identifies a network flow by the local IP address. *value* must be a IPv4 address in dotted-decimal notation or an IPv6 address in colon-separated notation. *prefix_len* is optional.

    If *prefix_len* is specified, it describes the netmask for a subnet address, following the same notation convention of ifconfig(1M) and route(1M) addresses. If unspecified, the given IP address will be considered as a host address for which the default prefix length for a IPv4 address is /32 and for IPv6 is /128.

remote_ip[/*prefix_len*]
    Identifies a network flow by the remote IP address. The syntax is the same as local_ip attributes

transport={tcp|udp|sctp|icmp|icmpv6}
    Identifies a layer 4 protocol to be used. It is typically used in combination with local_port or remote_port to identify the local or remote service that needs special attention.

local_port
    Identifies a service specified by the local port.

remote_port
    Identifies a service specified by the remote port.

dsfield[:*dsfield_mask*]
    Identifies the 8-bit differentiated services field (as defined in RFC 2474).

    The optional *dsfield_mask* is used to state the bits of interest in the differentiated services field when comparing with the dsfield value. A 0 in a bit position indicates that the bit value needs to be ignored and a 1 indicates otherwise. The mask can range from 0x01 to 0xff. If *dsfield_mask* is not specified, the default mask 0xff is used. Both the dsfield value and mask must be in hexadecimal.

The following types of combinations of attributes are supported:

```
local_ip[/prefixlen]=address
remote_ip[/prefixlen]=address
transport={tcp|udp|sctp|icmp|icmpv6}
transport={tcp|udp|sctp},local_port=port
transport={tcp|udp|sctp},remote_port=port
dsfield=val[:dsfield_mask]
```

On a given link, the combinations above are mutually exclusive. An attempt to create flows of different combinations will fail.

Restrictions   There are individual flow restrictions and flow restrictions per zone.

Individual Flow Restrictions

Restrictions on individual flows do not require knowledge of other flows that have been added to the link.

An attribute can be listed only once for each flow. For example, the following command is not valid:

```
# flowadm add-flow -l vnic1 -a local_port=80,local_port=8080 httpflow
```

`transport` and `local_port` or `transport` and `remote_port`:

TCP, UDP, or SCTP flows can be specified with a local port or with a remote port. An ICMP or ICMPv6 flow that specifies a port is not allowed.

If either `local_port` or `remote_port` is specifed, the transport must be either TCP, UDP or SCTP.

The following commands are valid:

```
# flowadm add-flow -l e1000g0 -a transport=udp udpflow
# flowadm add-flow -l e1000g0 -a transport=tcp,local_port=80 \
udp80flow
```

The following commands are not valid:

```
# flowadm add-flow -l e1000g0 -a remote_port=25 flow25
# flowadm add-flow -l e1000g0 -a transport=icmpv6,remote_port=16 \
flow16
```

Flow Restrictions Per Zone

Within a zone, no two flows can have the same name. After adding a flow with the link specified, the link will not be required for display, modification, or deletion of the flow.

Flow Properties   The following flow properties are supported. Note that the ability to set a given property to a given value depends on the driver and hardware.

maxbw
   Sets the full duplex bandwidth for the flow. The bandwidth is specified as an integer with one of the scale suffixes(K, M, or G for Kbps, Mbps, and Gbps). If no units are specified, the input value will be read as Mbps. The default is no bandwidth limit.

Examples   EXAMPLE 1   Creating a Policy Around a Mission-Critical Port

The command below creates a policy around inbound HTTPS traffic on an HTTPS server so that HTTPS obtains dedicated NIC hardware and kernel TCP/IP resources. The name specified, https-1, can be used later to modify or delete the policy.

EXAMPLE 1   Creating a Policy Around a Mission-Critical Port   *(Continued)*

```
# flowadm add-flow -l bge0 -a transport=TCP,local_port=443 https-1
# flowadm show-flow -l bge0
FLOW          LINK        IP ADDR           PROTO  PORT  RPORT   DSFLD
https1        bge0        --                tcp    443   --      --
```

EXAMPLE 2   Modifying an Existing Policy to Add Bandwidth Resource Control

The following command modifies the https-1 policy from the preceding example. The command adds bandwidth control.

```
# flowadm set-flowprop -p maxbw=500M https-1
# flowadm show-flow https-1
FLOW          LINK        IP ADDR           PROTO  PORT  RPORT   DSFLD
https1        bge0        --                tcp    443   --      --

# flowadm show-flowprop https-1
FLOW          PROPERTY    VALUE    DEFAULT     POSSIBLE
https-1       maxbw       500      --          --
```

EXAMPLE 3   Limiting the UDP Bandwidth Usage

The following command creates a policy for UDP protocol so that it cannot consume more than 100Mbps of available bandwidth. The flow is named limit-udp-1.

```
# flowadm add-flow -l bge0 -a transport=UDP -p maxbw=100M, \
limit-udp-1
```

EXAMPLE 4   Setting Policy, Making Use of dsfield Attribute

The following command sets a policy for EF PHB (DSCP value of 101110 from RFC 2598) with a bandwidth of 500 Mbps. The dsfield value for this flow will be 0x2e (101110) with the dsfield_mask being 0xfc (because we want to ignore the 2 least significant bits).

```
# flowadm add-flow -l bge0 -a dsfield=0x2e:0xfc \
-p maxbw=500M efphb-flow
```

EXAMPLE 5   Viewing Flows in Multiple Zones

The following command shows two flows of the same name. The first flow is in the global zone, the second is in the zone zone1. The command is invoked from the global zone, enabling you to view all flows on the system

```
# flowadm show-flow
FLOW            LINK      IPADDR            PROTO  LPORT  RPORT   DSFLD
tcpflow         e1000g2   --                tcp    --     --      --
zone1/tcpflow   e1000g1   --                tcp    --     --      --
```

Exit Status 0

Notes The show-usage subcommand, present in previous releases of flowadm, has been replaced by the flowstat(1M) -h command.

Name flowstat – report flow statistics

Synopsis flowstat [-r | -t] [-i *interval*] [-l *link*] [*flow*]

flowstat [-S] [-A] [-i *interval*] [-p] [-o *field*[,...]]
    [-u R|K|M|G|T|P] [*link*] [-l *link*] [*flow*]

flowstat -h [-a] -f *filename* [-d] [-F *format*] [-s *time*]
    [-e time] [*flow*]

Description The flowstat command reports run time statistics about user defined flows. flowadm
show-flow provides the flow name information for this command.

Options The flowstat command has the following options and operands that are common among a
number of command forms shown under "Subcommands," below.

Sub-commands flowstat supports the following command forms.

flowstat [-r | -t] [-i *interval*] [-l *link*] [*flow*]
    This form of the command iteratively examines all flows and reports statistics. The output
    is sorted in descending order of flow utilization. If no flow is specified, the system displays
    statistics for all flows.

-r
    Display receive-side statistics only. Includes bytes and packets received, drops, and so
    forth. See examples for complete listing.

-t
    Display transmit-side statistics only. Includes bytes and packets sent, drops, and so
    forth. See examples below.

-i *interval*
    Specify an interval in seconds at which statistics are refreshed. The default interval is one
    second.

-l *link* | *flow*]
    Display statistics for all flows on the specified link or statistics for the specified flow.

flowstat [-S] [-A] [-i *interval*] [-p] [-o *field*[,...]] [-u R|K|M|G|T|P] [-l *link*] [*flow*]
    This form of the command allows you to specify which statistics to display.

-A
    Dump all statistics fields for this flow. Output statistics of this command are inclusive of
    all the statistics reported by all other flowstat commands.

-i *interval*
    Specify an interval in seconds at which statistics are refreshed. The default interval is one
    second.

{-l *link*} | *flow*
    Display statistics for all flows on the specified link or for the specified flow.

-o *field*[,...]

Display a case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all` to display all supported fields.

List of supported RX fields:

- `flow`
- `rbytes`
- `ipkts`
- `idrops`

List of TX fields:

- `flow`
- `obytes`
- `opkts`
- `odrops`

-p

Display output in a stable, machine-parseable format.

-S

Continuously display network utilization by flow in a manner similar to the way that `prstat(1M)` displays CPU utilization by process.

-u R|K|M|G|T|P

If used, allows choosing the unit in which to display all statistics, for example, `R`: Raw Numbers, `K`:Kilobits, `M`:Megabits, `T`:Terabits, `P`:Petabits. If not used, then different units, as appropriate, are used to display the statistics.

flowstat -h [-a] -f *filename* [-d] [-F *format*] [-s *time*] [-e *time*] [*flow*]

Show the network usage history from a stored extended accounting file. Use of this syntax requires that net accounting has been previously configured and enabled by using `acctadm(1M)`. The default output is the summary of network usage of the existing links for the entire period when extended accounting was enabled.

-a

Display all historical network usage for the specified period when extended accounting is enabled. This includes usage information for the flows that have already been deleted.

-f *filename*

Specify the file from which extended accounting records of network flow usage history are read.

-d

Display the dates for which there is logging information. The date is in the format *mm*/*dd*/*yyyy*.

-F *format*

Specify the output format of the network flow usage history information. gnuplot is the only supported format.

-s *time*

-e *time*

Specify start and stop times for data display. Time is in the format *MM*/*DD*/*YYYY*,*hh*:*mm*:*ss*. *hh* uses 24-hour clock notation.

Operands flowstat command forms have a single, optional operand.

flow

If specified, report only on the named flow. Otherwise, report on all flows. A flow has a name of the form *zonename*/*flowname*. A *flowname* without a *zonename* modifier is understood to be in the global zone.

Examples **EXAMPLE 1** Displaying Statistics

To display statistics for all the flows, enter following command. Statistics are displayed as 3-digit numbers with the appropriate unit. Default interval is one second.

```
# flowstat -i 1
 FLOW   IPKTS   RBYTES  IDROPS   OPKTS  OBYTES  ODROPS
flow1 528.54K 787.39M      0 179.39K 11.85M       0
flow2 742.81K   1.10G      0      0      0        0
flow3      0       0       0      0      0        0
flow1  67.73K 101.02M      0  21.04K  1.39M       0
flow2      0       0       0      0      0        0
flow3      0       0       0      0      0        0
           .       .       .       .      .       .
           .       .       .       .      .       .
           .       .       .       .      .       .
```

EXAMPLE 2 Displaying RX-Side Statistics

The following command displays receive-side statistics

```
# flowstat -r
 FLOW   IPKTS   RBYTES  IDROPS
flow1   4.01M   5.98G       0
flow2 742.81K   1.10G       0
flow3      0       0        0
```

EXAMPLE 3 Displaying TX-Side Statistics

The following command displays transmit-side statistics at a five-second interval.

```
# flowstat -t
 FLOW   OPKTS  OBYTES  ODROPS
flow1  24.37M   1.61G       0
flow2      0       0        0
```

EXAMPLE 3 Displaying TX-Side Statistics   *(Continued)*

```
flow3      4     216      0
```

EXAMPLE 4 Displaying Particular Set of Statistics

The following command displays a specified set of statistics fields.

```
# flowstat -o FLOW,IPKTS
 FLOW   IPKTS
flow1  68.58M
flow2 742.81K
flow3      4
```

EXAMPLE 5 Show Historical Network Usage

Flow usage statistics can be stored by using the extended accounting facility, acctadm(1M).

```
# acctadm -e extended -f /var/log/net.log net
# acctadm net
        Network accounting: active
   Network accounting file: /var/log/net.log
  Tracked Network resources: extended
Untracked Network resources: none
```

The saved historical data can be retrieved as follows:

```
# flowstat -h -f /var/log/net.log
LINK      DURATION  IPACKETS RBYTES     OPACKETS OBYTES     BANDWIDTH
flowtcp   100       1031     546908     0        0          43.76Kbps
flowudp   0         0        0          0        0          0.00Mbps
```

Display logging information for flowtcp starting at February 19, 2008 at 10:38:46 and ending on the same day at 10:40:06:

```
# flowstat -h -s 02/19/2008,10:39:06 -e 02/19/2008,10:40:06 \
-f /var/log/net.log flowtcp
FLOW      START      END        RBYTES    OBYTES    BANDWIDTH
flowtcp   10:39:06   10:39:26   1546      6539       3.23 Kbps
flowtcp   10:39:26   10:39:46   3586      9922       5.40 Kbps
flowtcp   10:39:46   10:40:06   240       216       182.40 bps
flowtcp   10:40:06   10:40:26   0         0          0.00 bps
```

Generate the same output information as above as a plotfile:

```
# flowstat -h -s 02/19/2008,10:39:06 -e 02/19/2008,10:40:06 \
-F gnuplot -f /var/log/net.log flowtcp
# Time tcp-flow
10:39:06 3.23
10:39:26 5.40
10:39:46 0.18
```

EXAMPLE 5 Show Historical Network Usage   *(Continued)*

```
10:40:06 0.00
```

Exit Status   0

Name fmadm – fault management configuration tool

Synopsis fmadm [-q] [*subcommand* [*arguments*]]

Description The fmadm utility can be used by administrators and service personnel to view and modify system configuration parameters maintained by the Solaris Fault Manager, fmd(1M). fmd receives telemetry information relating to problems detected by the system software, diagnoses these problems, and initiates proactive self-healing activities such as disabling faulty components.

fmadm can be used to:

- view the set of diagnosis engines and agents that are currently participating in fault management,
- view the list of system components that have been diagnosed as faulty, and
- perform administrative tasks related to these entities.

The Fault Manager attempts to automate as many activities as possible, so use of fmadm is typically not required. When the Fault Manager needs help from a human administrator, service repair technician, or Oracle, it produces a message indicating its needs. It also refers you to a knowledge article on Sun's web site. The web site might ask you to use fmadm or one of the other fault management utilities to gather more information or perform additional tasks. The documentation for fmd(1M), fmdump(1M), and fmstat(1M) describe more about tools to observe fault management activities.

One responsibility of the Fault Manager is to keep track of the location of components. At the chassis level, the fmadm *-alias subcommands manages a chassis *product-id.chassis-id* to *alias-id* mapping. The administered *alias-id* is intended to describe, in some meaningful way, the physical location of a chassis.

The fmadm utility requires the user to possess the SYS_CONFIG privilege. Refer to the *Oracle Solaris Administration: Security Services* for more information about how to configure Solaris privileges. The fmadm load subcommand requires that the user possess all privileges.

SUBCOMMANDS fmadm accepts the following subcommands. Some of the subcommands accept or require additional options and operands. The load, unload, reset, and rotate subcommands are intended for trained technical personnel. We recommend against use of these subcommands without the specific guidance of, for example, a Knowledge Base article.

fmadm acquit *fmri* | *label* [*uuid*]
    Notify the Fault Manager that the specified resource is not to be considered to be a suspect in the fault event identified by *uuid*, or if no UUID is specified, then in any fault or faults that have been detected. The fmadm acquit subcommand should be used only at the direction of a documented Sun repair procedure. Administrators might need to apply additional commands to re-enable a previously faulted resource.

fmadm acquit *uuid*

  Notify the Fault Manager that the fault event identified by *uuid* can be safely ignored. The fmadm acquit subcommand should be used only at the direction of a documented Sun repair procedure. Administrators might need to apply additional commands to re-enable any previously faulted resources.

fmadm config

  Display the configuration of the Fault Manager itself, including the module name, version, and description of each component module. Fault Manager modules provide services such as automated diagnosis, self-healing, and messaging for hardware and software present on the system.

fmadm faulty [-afgiprsv] [-n *max*] [-u *uid*]

  Display status information for resources that the Fault Manager currently believes to be faulty.

  The following options are supported:

  -a   Display all faults. By default, the fmadm faulty command only lists output for resources that are currently present and faulty. If you specify the -a option, all resource information cached by the Fault Manager is listed, including faults which have been automatically corrected or where no recovery action is needed. The listing includes information for resources that might no longer be present in the system.

  -f   Display faulty fru's (Field replaceable units).

  -g   Group together faults which have the same fru, class and fault message.

  -i   Display persistent cache identifier for each resource in the Fault Manager.

  -n *max*   If faults or resources are grouped together with the -a or -g options, limit the output to *max* entries.

  -p   Pipe output through pager with form feed between each fault.

  -r   Display Fault Management Resource with their Identifier (FMRI) and their fault management state.

  -s   Display 1 line fault summary for each fault event.

  -u *uid*   Only display fault with given uid.

  -v   Display full output.

  The percentage certainty is displayed if a fault has multiple suspects, either of different classes or on different fru's. If more than one resource is on the same fru and it is not 100% certain that the fault is associated with the fru, the maximum percentage certainty of the possible suspects on the fru is displayed.

The Fault Manager associates the following states with every resource for which telemetry information has been received:

ok

> The resource is present and in use and has no known problems so far as the Fault Manager is concerned.

unknown

> The resource is not present or not usable but has no known problems. This might indicate the resource has been disabled or deconfigured by an administrator. Consult appropriate management tools for more information.

faulted

> The resource is present but is not usable because one or more problems have been diagnosed by the Fault Manager. The resource has been disabled to prevent further damage to the system.

degraded

> The resource is present and usable, but one or more problems have been diagnosed in the resource by the Fault Manager.

> If all affected resources are in the same state, this is reflected in the message at the end of the list. Otherwise the state is given after each affected resource.

fmadm flush *fmri*

> Flush the information cached by the Fault Manager for the specified resource, named by its FMRI. This subcommand should only be used when indicated by a documented Sun repair procedure. Typically, the use of this command is not necessary as the Fault Manager keeps its cache up-to-date automatically. If a faulty resource is flushed from the cache, administrators might need to apply additional commands to enable the specified resource.

fmadm load *path*

> Load the specified Fault Manager module. *path* must be an absolute path and must refer to a module present in one of the defined directories for modules. Typically, the use of this command is not necessary as the Fault Manager loads modules automatically when Solaris initially boots or as needed.

fmadm unload *module*

> Unload the specified Fault Manager module. Specify *module* using the basename listed in the fmadm config output. Typically, the use of this command is not necessary as the Fault Manager loads and unloads modules automatically based on the system configuration

fmadm repaired *fmri* | *label*

> Notify the Fault Manager that a repair procedure has been carried out on the specified resource. The fmadm repaired subcommand should be used only at the direction of a documented Sun repair procedure. Administrators might need to apply additional commands to re-enable a previously faulted resource.

fmadm replaced *fmri* | *label*
> Notify the Fault Manager that the specified resource has been replaced. This command should be used in those cases where the Fault Manager is unable to automatically detect the replacement. The fmadm replaced subcommand should be used only at the direction of a documented Sun repair procedure. Administrators might need to apply additional commands to re-enable a previously faulted resource.

fmadm reset [-s *serd*] *module*
> Reset the specified Fault Manager module or module subcomponent. If the -s option is present, the specified Soft Error Rate Discrimination (SERD) engine is reset within the module. If the -s option is not present, the entire module is reset and all persistent state associated with the module is deleted. The fmadm reset subcommand should only be used at the direction of a documented Sun repair procedure. The use of this command is typically not necessary as the Fault Manager manages its modules automatically.

fmadm rotate errlog | fltlog | infolog | infolog_hival
> The rotate subcommand is a helper command for logadm(1M), so that logadm can rotate live log files correctly. It is not intended to be invoked directly (and invoking it directly is likely to lose log history). Use one of the following commands to cause the appropriate logfile to be rotated, if the current one is not zero in size:
>
> ```
> # logadm -p now -s 1b /var/fm/fmd/errlog
> # logadm -p now -s 1b /var/fm/fmd/fltlog
> # logadm -p now -s 1b /var/fm/fmd/infolog
> # logadm -p now -s 1b /var/fm/fmd/infolog_hival
> ```

fmadm add-alias *product-id.chassis-id alias-id* ['*comment*']
> The add-alias subcommand is used to establish *alias-id* as a managed alias for the *product-id.chassis-id* chassis. When a managed alias is defined, the /dev/chassis devchassis(7FS) name space representation of the chassis will use the more meaningful *alias-id* instead of the *product-id.chassis-id*.
>
> ```
> # fmadm add-alias SUN-Storage-J4410.1039QAQ007 RACK29.U25-28
> ```
>
> The command shown above will verify that the new mapping does not conflict with existing mappings. In the case of conflict, no mapping change occurs. This subcommand completes when the associated name space updates are complete. If the updated name space does not use the new *alias-id*, a warning if printed, but the mapping is updated. If the name space update takes too long, a warning is printed.
>
> If an optional comment is provided, the comment is preserved and will be displayed by a subsequent lookup-alias or list-alias command.

fmadm remove-alias *alias-id* | *product-id.chassis-id*
> The remove-alias subcommand is used to remove an *product-id.chassis-id* to *alias-id* mapping.
>
> ```
> # fmadm remove-alias RACK29.U25-28
> ```
>
> The subcommand above completes when the associated name space updates are complete.

fmadm lookup-alias *alias-id* | *product-id.chassis-id*
    The lookup-alias subcommand can be used to determine what the current mapping is.
    The following is an example command.

    # **fmadm lookup-alias SUN-Storage-J4410.1039QAQ007**

fmadm list-alias
    The list-alias subcommand is used to display all comments and mappings.

fmadm sync-alias
    The sync-alias subcommand is used to hand-import a set of mappings in bulk. Two
    copies of the current mappings are maintained:

    ■ /etc/dev/chassis_aliases
    ■ /etc/dev/.chassis_aliase

    To import a set of mappings in bulk, you can update the /etc/dev/chassis_aliases file
    and then run sync-alias.

Options The following options are supported:

    -q   Set quiet mode. fmadm does not produce messages indicating the result of successful
        operations to standard output.

Operands The following operands are supported:

    cmd   The name of a subcommand listed in SUBCOMMANDS.

    args   One or more options or arguments appropriate for the selected *subcommand*, as
           described in SUBCOMMANDS. Among these arguments are fmri, uuid, and label. These
           identify resources that are the objects of fmadm subcommands. Use fmadm faulty to
           obtain the fmri, uuid, and label for a targeted resource. See EXAMPLES. In general,
           label is the most user-friendly of these operands.

Examples EXAMPLE 1   Invoking faulty Subcommand

    The following command invokes the faulty subcommand, which displays the uuid, label,
    and fmri for a component.

    # **fmadm faulty**
```
------------ ------------------------------------ ------------ ---------
TIME         EVENT-ID                             MSG-ID       SEVERITY
------------ ------------------------------------ ------------ ---------
Sep 09 16:15 96609fae-113c-e48c-b1cf-ebf4b0902d72 DISK-8000-3E Critical
                                                               injected

Host    : x4170-brm-02
Platform : SUN-FIRE-X4170-SERVER    Chassis_id : 0920XF508B
Product_sn:

Fault class: fault.io.scsi.cmd.disk.dev.rqs.derr
```

EXAMPLE 1 Invoking fa ulty Subcommand   *(Continued)*

```
Affects : dev:///:devid=id1,sd@n5000c5000940edbb//scsi_vhci/disk@g5000c\
5000940edbb  out of service, but associated components no longer faulty
FRU     : "DISK 11"
(hc://:product-id=SUN-Storage-J4410:server-id=:chassis-id=:serial=000930\

ses-enclosure=0/bay=11/disk=0)
replaced
...
...
```

In the preceding output, the uuid is the first item in the EVENT-ID column,
96609fae-113c-e48c-b1cf-ebf4b0902d72. The label is in the FRU row, DISK 11. The fmris
are:

```
dev:///:devid=id1,sd@n5000c5000940edbb//scsi_vhci/disk@g5000c\
5000940edbb
```

```
hc://:product-id=SUN-Storage-J4410:server-id=:chassis-id=:serial=000930\
G01CN4--------3SJ01CN4:part=SEAGATE-ST330057SSUN300G:revision=0205/\
ses-enclosure=0/bay=11/disk=0)
```

The same values are available with fmdump -v:

```
# fmdump -v
Sep 09 16:15:36.9252 96609fae-113c-e48c-b1cf-ebf4b0902d72 DISK-8000-3E \
Diagnosed 100%  fault.io.scsi.cmd.disk.dev.rqs.derr
```

```
Problem in: hc://:scheme=:product-id=SUN-Storage-J4410:chassis-id=:\
server-id=/ses-enclosure=0/bay=11/disk=0
```

```
Affects: dev:///:devid=id1,sd@n5000c5000940edbb//\
scsi_vhci/disk@g5000c5000940edbb
FRU: hc://:product-id=SUN-Storage-J4410:server-id=:chassis-id=:\
serial=000930G01CN4--------3SJ01CN4:part=SEAGATE-ST330057SSUN300G:\
revision=0205/ses-enclosure=0/bay=11/disk=0
```

```
Location: DISK 11
```

Note that label is the easiest-to-use identifier.

EXAMPLE 2 Obtaining Module Name

The following command displays the module name for each component. The module name is
specified as input to the fmadm unload command.

```
# fmadm config
MODULE                  VERSION STATUS  DESCRIPTION
```

EXAMPLE 2 Obtaining Module Name   *(Continued)*

```
cpumem-retire           1.1     active  CPU/Memory Retire Agent
disk-transport          1.0     active  Disk Transport Agent
eft                     1.16    active  eft diagnosis engine
..
```

Exit Status The following exit values are returned:

0   Successful completion.

1   An error occurred. Errors include a failure to communicate with fmd or insufficient privileges to perform the requested operation.

2   Invalid command-line options were specified.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/fault-management
Interface Stability	See below.

The command-line options are Committed. The human-readable output is not-an-interface.

Oracle Solaris Administration: Common Tasks

Name   fmd – fault manager daemon

Synopsis   /usr/lib/fm/fmd/fmd [-V] [-f *file*] [-o *opt=val*] [-R *dir*]

Description   fmd is a daemon that runs in the background on each Solaris system. fmd receives telemetry information relating to problems detected by the system software, diagnoses these problems, and initiates proactive self-healing activities such as disabling faulty components. When appropriate, the fault manager also sends a message to the syslogd(1M) service to notify an administrator that a problem has been detected. The message directs administrators to a knowledge article on Oracle's web site, https://support.oracle.com, which explains more about the problem impact and appropriate responses.

Each problem diagnosed by the fault manager is assigned a Universal Unique Identifier (UUID). The UUID uniquely identifes this particular problem across any set of systems. The fmdump(1M) utility can be used to view the list of problems diagnosed by the fault manager, along with their UUIDs and knowledge article message identifiers. The fmadm(1M) utility can be used to view the resources on the system believed to be faulty. The fmstat(1M) utility can be used to report statistics kept by the fault manager. The fault manager is started automatically when Solaris boots, so it is not necessary to use the fmd command directly. Sun's web site explains more about what capabilities are currently available for the fault manager on Solaris.

Notification Services   syslog (package system/fault-management)
   The standard notification mechanism for new diagnoses is by means of syslog, using the syslog-msgs fmd module delivered in the same package as fmd itself.

   By default, only new problem diagnoses are messaged by means of syslog-msgs, using the syslog facility and severity as listed in the table below. An administrator can use svccfg(1M) to request that other events in the problem resolution lifecycle are messaged through syslog-msgs:

   # **svccfg setnotify** *event* **syslog:{active|inactive}**

   See svccfg(1M) for additional detail.

Event	Disposition	Facility	Severity
problem-diagnosed	active	LOG_DAEMON	LOG_ERR
problem-updated	inactive	LOG_DAEMON	LOG_NOTICE
problem-repaired	inactive	LOG_DAEMON	LOG_NOTICE
problem-resolved	inactive	LOG_DAEMON	LOG_NOTICE

   Email (package system/fault-management/smtp-notify)
   Notification by means of email is an option for which an additional package must be installed. The SMF service, svc:/system/fm/smtp-notify:default, is delivered by means of the package system/fault-management/smtp-notify and notification preferences configured by means of svccfg(1M). See smtp-notify(1M) for additional detail. Note that in addition to configuring notification preferences for the problem lifecycle events listed

above (problem-diagnosed, and so forth) this mechanism can also be configured through svccfg(1M) to provide notification of SMF instance state transition and other events.

SNMP (package system/fault-management/snmp-notify)
Notification of new events using SNMP traps is an option delivered by the package system/fault-management/snmp-notify. The service svc:/system/fm/snmp-notify:default is responsible for raising SNMP traps for problem lifecycle and other designated events (including SMF instance state transition events, if so configured). See snmp-notify(1M) for additional detail.

Global and Non-Global Solaris Zones
The fault manager service svc:/system/fmd:default service is configured in both global and non-global Solaris zones. In non-global zones, various hardware-oriented fault manager modules are not delivered, so it is a cut-down fault manager that runs there. In a non-global zone, the fault manager is focussed on software events.

Options The following options are supported

-f *file*
Read the specified configuration *file* prior to searching for any of the default fault manager configuration files.

-o *opt=value*
Set the specified fault manager option to the specified value. Fault manager options are currently a Private interface; see attributes(5) for information about Private interfaces.

-R *dir*
Use the specified root directory for all pathnames evaluated by the fault manager, instead of the default root (/).

-V
Print the fault manager's version to stdout and exit.

Exit Status The following exit values are returned:

0   Successful completion

1   An error occurred which prevented the fault manager from initializing, such as failure to open the telemetry transport.

2   Invalid command-line options were specified.

Files /etc/fm/fmd   Fault manager configuration directory

/usr/lib/fm/fmd   Fault manager library directory

/var/fm/fmd   Fault manager log directory

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/fault-management
Interface Stability	Committed

See Also svcs(1), fmadm(1M), fmdump(1M), fmstat(1M), smtp-notify(1M), snmp-notify(1M), svccfg(1M), syslogd(1M), attributes(5), smf(5)

http://www.sun.com/msg/

Notes The Fault Manager is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/fmd:default
```

The service's status can be queried using the svcs(1) command. Administrators should not disable the Fault Manager service.

Name   fmdump – fault management log viewer

Synopsis   fmdump [[-e | -i | -I] | -A] [-f] [-mvVp] [-c *class*] [-R *root*]
             [-t *time*] [-T *time*] [-u *uid*] [-n *name*[.*name*]*[=*value*]]
             [-E *ENA*] [*file*] ...

Description   The fmdump utility can be used to display the contents of any of the log files associated with the Solaris Fault Manager, fmd(1M). The Fault Manager runs in the background on each Solaris system. It receives telemetry information relating to problems detected by the system software, diagnoses these problems, and initiates proactive self-healing activities such as disabling faulty components.

The fmdump utility is not intended as the primary administrative interface to the Fault Manager. For that purpose, use fmadm (and see fmadm(1M)). The fmdump utility simply dumps Fault Manager historical logs with little further interpretation, and can include implementation detail without explanation. See the ATTRIBUTES section below.

The Fault Manager maintains several sets of log files for use by service personnel and, to a lesser extent, administrators:

error log   A log that records error telemetry, the symptoms of problems detected by the system.

info log   A log that records informational events. This is realized as two sets of log files: high-value informational events, and other informational events.

fault log   A log that records fault diagnosis information, the problems believed to explain the symptoms recorded in the error and info logs.

A log file set consists of the current active log file together with a possible number of older rotated log files in that set. All logs are managed with logadm(1M) and have entries in /etc/logadm.conf.

Note that the fmdump utility dumps the current log file and all rotated log files for the target set. It therefore displays the entire log history. For the fault log, in particular, it is important to recognize that fmdump will show all problems *ever* diagnosed and is not limited to still-current problems. (Use fmadm faulty for that information.)

By default, fmdump displays the contents of the fault log, which records the result of each diagnosis made by the fault manager or one of its component modules. The error log can be selected using -e, the info log with -i, and the high-value info log with -I; or a specific log file path may be specified as [*file*] on the command line (which will dump just that file and not look for rotated versions of the log). One can also use option -A to aggregate all logs, or a set of log file paths listed on the command line.

An example of a default fmdump display follows:

```
# fmdump
TIME                    UUID                              SUNW-MSG-ID EVENT
```

```
Mar 23 14:06:35.2682 0a11a1a7-a8ce-c941-8527-8d7a9d320071 ZFS-8000-CS Diagnosed
Mar 25 14:51:41.2261 0a11a1a7-a8ce-c941-8527-8d7a9d320071 FMD-8000-4M Repaired
Mar 25 14:51:41.2523 0a11a1a7-a8ce-c941-8527-8d7a9d320071 FMD-8000-6U Resolved
May 31 23:35:39.9146 c63ac52e-506b-c1cc-e965-ff3b8544490d SMF-8000-YX Diagnosed
...
```

(Output wraps on displays of 80 or fewer characters.)

This dumps the fault log, because no command line options or arguments selected any other log. The fault log records the lifecycle of problems diagnosed by the Fault Manager or its component modules, from initial problem diagnosis to problem resolution.

Each problem recorded in the fault log is identified by:

- The timestamp of the event describing the problem lifecycle state change.

- A Universal Unique Identifier (UUID) that can be used to uniquely identify this particular problem across any set of systems. All events describing problem lifecycle state changes for a given problem will use the same UUID (as above: we see initial diagnosis and, later, repair and resolution all quoting the same problem UUID).

- A message identifier that can be used to access a corresponding knowledge article located at Sun's web site, http://www.oracle.com/us/sun/msg/

If a problem requires action by a human administrator or service technician or affects system behavior, the Fault Manager also issues a human-readable message to syslogd(1M). This message provides a summary of the problem and a reference to the knowledge article on the Sun web site, http://www.oracle.com/us/sun/msg/. The fmdump utility can dump fltlog entries in a similar format to that rendered to syslog through use of the -m option.

You can use the -v and -V options to expand the display from a single-line summary to increased levels of detail for each event recorded in the log. The -p option can be used with -V to request "prettier" output.

The -c, -t, -T, -n and -u options can be used to filter the output by selecting only those events that match the specified class, range of times, or uuid. If more than one filter option is present on the command-line, the options combine to display only those events that are selected by the logical AND of the options. If more than one instance of the same filter option is present on the command-line, the like options combine to display any events selected by the logical OR of the options. For example, the command:

 # fmdump -u uuid1 -u uuid2 -t 02Dec09

...selects events whose attributes are (uuid1 OR uuid2) AND (time on or after 02Dec09).

Options   The following options are supported:

-A

Perform log aggregation. If one of more log file paths are listed on the command line, then aggregate those files; otherwise aggregate all known log types, including all logadm-rotated files. Logs are merged in time order but with the characteristic that any two records from the same log file are ordered in the aggregation exactly as they were in the original log file (which is in the order they were received and processed by the Fault Manager, which will be an approximate time order).

You cannot use other log set selection options with -A: -e, -i, or -I. Filter options such as -c, -t, -T, and -n can be used, but -u cannot. Output options -v, -V, and -p are available, but -m is not. Option -f will follow all the selected logs.

-c *class*

Select events that match the specified class. The class argument can use the glob pattern matching syntax described in sh(1). The class represents a hierarchical classification string indicating the type of telemetry event. More information about Sun's telemetry protocol is available at Sun's web site, http://www.oracle.com/us/sun/msg/.

-e

Display events from the fault management error log instead of the fault log.

The error log contains Private telemetry information used by Sun's automated diagnosis software. This information is recorded to facilitate post-mortem analysis of problems and event replay, and should not be parsed or relied upon for the development of scripts and other tools. See attributes(5) for information about Sun's rules for Private interfaces.

-E *ENA*

Select events, of any generation, that match the specified ENA value. For detectors that support ENA, this option can be used to show multiple events associated with the same operation.

-f

Follow the growth of the log file (or files if using -A) by waiting for additional data. fmdump enters an infinite loop where it will sleep for a second, attempt to read and format new data from the log file, and then go back to sleep. This loop can be terminated at any time by sending an interrupt (Control-C).

-m

Print the localized diagnosis message associated with each entry in the fault log.

-n *name*[.*name*]*[=*value*]

Select log events (from the log(s) selected on the command line) that have properties with a matching name (and optionally a matching value). For string properties the value can be a regular expression match. Regular expression syntax is described in the EXTENDED REGULAR EXPRESSIONS section of the regex(5) manual page. Be careful when using the characters:

$ * { ^ | ( ) \

...or a regular expression, because these are meaningful to the shell. It is safest to enclose any of these in single quotes. For numeric properties, the value can be octal, hex, or decimal.

-p

Combined with -V (very verbose) option, requests that the pretty-printing options that are available are, in fact, performed.

-R *dir*

Use the specified root directory for the log files accessed by fmdump, instead of the default root (/).

-t *time*

Select events that occurred at or after the specified time. The time can be specified using any of the following forms:

mm/*dd*/*yy hh*:*mm*:*ss*

Month, day, year, hour in 24-hour format, minute, and second. Any amount of whitespace can separate the date and time. The argument should be quoted so that the shell interprets the two strings as a single argument.

mm/*dd*/*yy hh*:*mm*

Month, day, year, hour in 24-hour format, and minute. Any amount of whitespace can separate the date and time. The argument should be quoted so that the shell interprets the two strings as a single argument.

mm/*dd*/*yy*

12:00:00AM on the specified month, day, and year.

ddMonyy hh:*mm*:*ss*

Day, month name, year, hour in 24-hour format, minute, and second. Any amount of whitespace can separate the date and time. The argument should be quoted so that the shell interprets the two strings as a single argument.

ddMonyy hh:*mm*

Day, month name, year, hour in 24-hour format, and minute. Any amount of whitespace can separate the date and time. The argument should be quoted so that the shell interprets the two strings as a single argument.

Mon dd hh:*mm*:*ss*

Month, day, hour in 24-hour format, minute, and second of the current year.

yyyy-*mm*-*dd* [T *hh*:*mm*[:*ss*]]

Year, month, day, and optional hour in 24-hour format, minute, and second. The second, or hour, minute, and second, can be optionally omitted.

ddMonyy

12:00:00AM on the specified day, month name, and year.

hh:*mm*:*ss*

Hour in 24-hour format, minute, and second of the current day.

hh:*mm*
>   Hour in 24-hour format and minute of the current day.

*T*ns | *T*nsec
>   *T* nanoseconds ago where T is an integer value specified in base 10.

*T*us | *T*usec
>   *T* microseconds ago where T is an integer value specified in base 10.

*T*ms | *T*msec
>   T milliseconds ago where T is an integer value specified in base 10.

*T*s | *T*sec
>   T seconds ago where *T* is an integer value specified in base 10.

*T*m | *T*min
>   *T* minutes ago where *T* is an integer value specified in base 10.

*T*h | *T*hour
>   *T* hours ago where *T* is an integer value specified in base 10.

*T*d | *T*day
>   *T* days ago where *T* is an integer value specified in base 10.

You can append a decimal fraction of the form .*n* to any -t option argument to indicate a fractional number of seconds beyond the specified time.

-T *time*
>   Select events that occurred at or before the specified time. *time* can be specified using any of the time formats described for the -t option.

-u *uuid*
>   Select problem diagnosis events in the fault log that exactly match the specified *uuid*. Each diagnosis is associated with a Universal Unique Identifier (UUID) for identification purposes. The -u option can be combined with other options, such as -v, to show all of the details associated with a particular diagnosis. Note that multiple fault log events can be associated with the same problem diagnosis UUID—all events describing the lifecycle of a single problem (from initial diagnosis to final resolution) quote the same problem UUID.
>
>   If the -e option and -u option are both present, the error events that are cross-referenced by the specified diagnosis are displayed.

-v
>   Display verbose event detail. The event display is enlarged to show additional common members of the selected events.

-V
>   Display very verbose event detail. The event display is enlarged to show every member of the name-value pair list associated with each event. In addition, for fault logs, the event display includes a list of cross-references to the corresponding errors that were associated with the diagnosis.

Use -p with -V to request pretty-printing.

Operands   The following operands are supported:

file   Specifies an alternate log file (or files if using -A) to display instead of the system fault
log. The fmdump utility determines the type of the specified log automatically and
produces appropriate output for the selected log.

Examples   EXAMPLE 1   Retrieving Given Class from fmd Log

Use any of the following commands to retrieve information about a specified class from the
fmd log. The complete class name is ereport.io.ddi.context.

```
# fmdump -Ve -c 'ereport.io.ddi.context'
# fmdump -Ve -c 'ereport.*.context'
# fmdump -Ve -n 'class=ereport.io.ddi.context'
# fmdump -Ve -n 'class=ereport.*.context'
```

Any of the preceding commands produces the following output:

```
Oct 06 2007 11:53:20.975021712 ereport.io.ddi.context
        nvlist version: 0
                class = ereport.io.ddi.context
                ena = 0x1b03a15ecf00001
                detector = (embedded nvlist)
                nvlist version: 0
                        version = 0x0
                        scheme = dev
                        device-path = /
                (end detector)

                __ttl = 0x1
                __tod = 0x470706b0 0x3a1da690
```

EXAMPLE 2   Retrieving Specific Detector Device Path from fmd Log

The following command retrieves a detector device path from the fmd log.

```
# fmdump -Ve -n 'detector.device-path=.*/disk@1,0$'
Oct 06 2007 12:04:28.065660760 ereport.io.scsi.disk.rqs
nvlist version: 0
      class = ereport.io.scsi.disk.rqs
      ena = 0x453ff3732400401
      detector = (embedded nvlist)
                nvlist version: 0
                        version = 0x0
                        scheme = dev
                        device-path = /pci@0,0/pci1000,3060@3/disk@1,0
                (end detector)
```

EXAMPLE 2 Retrieving Specific Detector Device Path from fmd Log *(Continued)*

```
__ttl = 0x1
__tod = 0x4707094c 0x3e9e758
```

Exit Status The following exit values are returned:

0   Successful completion. All records in the log file were examined successfully.

1   A fatal error occurred. This prevented any log file data from being examined, such as failure to open the specified file.

2   Invalid command-line options were specified.

3   The log file was opened successfully, but one or more log file records were not displayed, either due to an I/O error or because the records themselves were malformed. fmdump issues a warning message for each record that could not be displayed, and then continues on and attempts to display other records.

Files /var/fm/fmd   Fault management log directory

/var/fm/fmd/errlog   Fault management error log

/var/fm/fmd/fltlog   Fault management fault log

/var/fm/fmd/infolog_hival   High-value informational log

/var/fm/fmd/infolog   Informational log

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/fault-management
Interface Stability	See below.

The command-line options are Uncommitted. The human-readable error log and informational log output is Private. The human-readable fault log output is Uncommitted.

Oracle Solaris Administration: Security Services

http://www.oracle.com/us/sun/msg/

Notes Fault logs contain references to records stored in error logs that can be displayed using fmdump -V to understand the errors that were used in the diagnosis of a particular fault. These links are preserved if an error log is renamed as part of log rotation. They can be broken by removing

an error log file, or by moving it to another filesystem directory. fmdump can not display error information for such broken links. It continues to display any and all information present in the fault log.

Name fmstat – report fault management module statistics

Synopsis fmstat [-astTz] [-d u | d] [-m *module*] [*interval* [*count*]]

Description The fmstat utility can be used by administrators and service personnel to report statistics associated with the Solaris Fault Manager, fmd(1M) and its associated set of modules. The Fault Manager runs in the background on each Solaris system. It receives telemetry information relating to problems detected by the system software, diagnoses these problems, and initiates proactive self-healing activities such as disabling faulty components.

You can use fmstat to view statistics for diagnosis engines and agents that are currently participating in fault management. The documentation for fmd(1M), fmadm(1M), and fmdump(1M) describes more about tools to observe fault management activities.

If the -m option is present or the -t option is present, fmstat reports any statistics kept by the specified fault management module. The module list can be obtained using fmadm config.

If the -m option is not present, fmstat reports the following statistics for each of its client modules:

module	The name of the fault management module, as reported by fmadm config.
ev_recv	The number of telemetry events received by the module.
ev_acpt	The number of events accepted by the module as relevant to a diagnosis.
wait	The average number of telemetry events waiting to be examined by the module.
svc_t	The average service time for telemetry events received by the module, in milliseconds.
%w	The percentage of time that there were telemetry events waiting to be examined by the module.
%b	The percentage of time that the module was busy processing telemetry events.
open	The number of active cases (open problem investigations) owned by the module.
solve	The total number of cases solved by this module since it was loaded.
memsz	The amount of dynamic memory currently allocated by this module.
bufsz	The amount of persistent buffer space currently allocated by this module.

The fmstat utility requires the user to posses the SYS_ADMIN privilege. Refer to the *Oracle Solaris Administration: Security Services* for more information about how to configure Solaris privileges.

Options The following options are supported:

-a   Print all statistics for a module, including those kept on its behalf by fmd. If the
            -a option is not present, only those statistics kept by the module are reported. If
            the -a option is used without the -m *module*, a set of global statistics associated
            with fmd are displayed.

-d u | d   Display a time stamp.

            Specify u for a printed representation of the internal representation of time. See
            time(2). Specify d for standard date format. See date(1).

-m *module* Print a report on the statistics associated with the specified fault management
            module, instead of the default statistics report. Modules can publish an
            arbitrary set of statistics to help Sun service the fault management software
            itself. The module statistics constitute a Private interface. See attributes(5)
            for information on Sun's rules for Private interfaces. Scripts should not be
            written that depend upon the values of fault management module statistics as
            they can change without notice.

-s   Print a report on Soft Error Rate Discrimination (SERD) engines associated
            with the module instead of the default module statistics report. A SERD engine
            is a construct used by fault management software to determine if a statistical
            threshold measured as *N* events in some time *T* has been exceeded. The -s
            option can only be used in combination with the -m option.

-t   Print a report on the statistics associated with each fault management event
            transport. Each fault management module can provide the implementation of
            one or more event transports.

-T   Print a table of the authority information associated with each fault
            management event transport. If the -m option is present, only transports
            associated with the specified module are displayed.

-z   Omit statistics with a zero value from the report associated with the specified
            fault management module. The -z option can only be used in combination
            with the -m option.

Operands The following operands are supported:

count   Print only count reports, and then exit.

interval Print a new report every *interval* seconds.

If no *interval* and no *count* are specified, a single report is printed and fmstat exits. If an
interval is specified but no *count* is specified, fmstat prints reports every *interval* seconds
indefinitely until the command is interrupted.

Exit Status The following exit values are returned:

0   Successful completion.

1   A fatal error occurred. A fatal error could be the failure to communicate with fmd(1M).
     It could also be that insufficient privileges were available to perform the requested
     operation.

2   Invalid command-line options were specified.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/fault-management
Interface Stability	See below.

The command-line options are Committed. The human-readable default report is
Uncommitted. The human-readable module report is Private.

Oracle Solaris Administration: Security Services

Name fmthard – populate label on hard disks

Synopsis

  SPARC fmthard -d *data* | -n *volume_name* | -s *datafile* [-i] /dev/rdsk/c?
         [t?] d?s2

     x86 fmthard -d *data* | -n *volume_name* | -s *datafile* [-i] /dev/rdsk/c?
         [t?] d?s2

Description The fmthard command updates the VTOC (Volume Table of Contents) on hard disks and, on x86 systems, adds boot information to the Solaris fdisk partition. One or more of the options -s *datafile*, -d *data*, or -n *volume_name* must be used to request modifications to the disk label. To print disk label contents, see prtvtoc(1M). The /dev/rdsk/c?[t?]d?s2 file must be the character special file of the device where the new label is to be installed. On x86 systems, fdisk(1M) must be run on the drive before fmthard.

If you are using an x86 system, note that the term "partition" in this page refers to *slices* within the x86 fdisk partition on x86 machines. Do not confuse the partitions created by fmthard with the partitions created by fdisk.

Options The following options are supported:

-d *data*

  The *data* argument of this option is a string representing the information for a particular partition in the current VTOC. The string must be of the format *part:tag:flag:start:size* where *part* is the partition number, *tag* is the ID TAG of the partition, *flag* is the set of permission flags, *start* is the starting sector number of the partition, and *size* is the number of sectors in the partition. See the description of the *datafile* below for more information on these fields.

-i

  This option allows the command to create the desired VTOC table, but prints the information to standard output instead of modifying the VTOC on the disk.

-n *volume_name*

  This option is used to give the disk a *volume_name* up to 8 characters long.

-s *datafile*

  This option is used to populate the VTOC according to a *datafile* created by the user. If the *datafile* is – (a hyphen), fmthard reads from standard input. The *datafile* format is described below. This option causes all of the disk partition timestamp fields to be set to zero.

  Every VTOC generated by fmthard will also have partition 2, by convention, that corresponds to the whole disk. If the input in *datafile* does not specify an entry for partition 2, a default partition 2 entry will be created automatically in VTOC with the tag V_BACKUP and size equal to the full size of the disk.

The *datafile* contains one specification line for each partition, starting with partition 0. Each line is delimited by a new-line character (\n). If the first character of a line is an asterisk (*), the line is treated as a comment. Each line is composed of entries that are position-dependent, separated by white space and having the following format:

partition tag flag starting_sector size_in_sectors

where the entries have the following values:

partition
> The partition number. Currently, for Solaris SPARC, a disk can have up to 8 partitions, 0–7. Even though the *partition* field has 4 bits, only 3 bits are currently used. For x86, all 4 bits are used to allow slices 0–15. Each Solaris fdisk partition can have up to 16 slices.

tag
> The partition tag: a decimal number. The following are reserved codes: 0 (V_UNASSIGNED), 1 (V_BOOT), 2 (V_ROOT), 3 (V_SWAP), 4 (V_USR), 5 (V_BACKUP), 6 (V_STAND), 7 (V_VAR), 8 (V_HOME), 12 (V_SYSTEM), and 24 (V_BIOS_BOOT).

flag
> The flag allows a partition to be flagged as unmountable or read only, the masks being: V_UNMNT 0x01, and V_RONLY 0x10. For mountable partitions use 0x00.

starting_sector
> The sector number (decimal) on which the partition starts.

size_in_sectors
> The number (decimal) of sectors occupied by the partition.

You can save the output of a prtvtoc command to a file, edit the file, and use it as the *datafile* argument to the -s option.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also uname(1), format(1M), prtvtoc(1M), attributes(5)

x86 Only fdisk(1M), installgrub(1M)

Notes Special care should be exercised when overwriting an existing VTOC, as incorrect entries could result in current data being inaccessible. As a precaution, save the old VTOC.

For disks under two terabytes, fmthard cannot write a VTOC on an unlabeled disk. Use format(1M) for this purpose.

Name   format – disk partitioning and maintenance utility

Synopsis   format [-f *command-file*] [-l *log-file*] [-x *data-file*]
            [-d *disk-name*] [-t *disk-type*] [-p *partition-name*]
            [-s] [-m] [-M] [-e] [*disk-list*]

format -L *label-type* -d *disk-name*

Description   format enables you to format, label, repair, and analyze disks on your system. Unlike previous disk maintenance programs, format runs under SunOS. Because there are limitations to what can be done to the system disk while the system is running, format is also supported within the memory-resident system environment. For most applications, however, running format under SunOS is the more convenient approach.

format first uses the disk list defined in *data-file* if the -x option is used. format then checks for the FORMAT_PATH environment variable, a colon-separated list of filenames and/or directories. In the case of a directory, format searches for a file named format.dat in that directory; a filename should be an absolute pathname, and is used without change. format adds all disk and partition definitions in each specified file to the working set. Multiple identical definitions are silently ignored. If FORMAT_PATH is not set, the path defaults to /etc/format.dat.

disk-list is a list of disks in the form c?t?d?, or /dev/rdsk/c?t?d?s?, /dev/chassis/?/disk. With the last two forms, shell wildcard specifications are supported. For example, specifying /dev/rdsk/c2* causes format to work on all drives connected to controller c2 only. If no *disk-list* is specified, format lists all the disks present in the system that can be administered by format.

Removable media devices are listed only when users execute format in expert mode (option -e). This feature is provided for backward compatibility. Use rmformat(1) for rewritable removable media devices.

Options   The following options are supported:

-d *disk-name*   Specify which disk should be made current upon entry into the program. The disk is specified by its logical name (for instance, -d c0t1d0 or /dev/chassis/SYS/HD0/disk). This can also be accomplished by specifying a single disk in the disk list.

-e   Enable SCSI expert menu. Note this option is not recommended for casual use.

-f *command-file*   Take command input from *command-file* rather than the standard input. The file must contain commands that appear just as they would if they had been entered from the keyboard. With this option, format does not issue continue? prompts; there is no need to specify y(es) or n(o) answers in the *command-file*. In non-interactive mode, format does not initially expect the input of a disk selection number. The user

must specify the current working disk with the -d *disk-name* option
when format is invoked, or specify disk and the disk selection number
in the *command-file*.

-l *log-file*   Log a transcript of the format session to the indicated *log-file*, including
the standard input, the standard output and the standard error.

-L *label-type*   Immediately, and non-interactively, write a default label of type
label-type, to the disk specified with -d. *label-type* must be either efi or
vtoc. Existing label, if any, will be overwritten with *label-type*. On an
x86 machine, the whole disk will default to one Solaris partition labeled
with *label-type*; all fdisk partitions will be lost.

-m   Enable extended messages. Provides more detailed information in the
event of an error.

-M   Enable extended and diagnostic messages. Provides extensive
information on the state of a SCSI device's mode pages, during
formatting.

-p *partition-name*   Specify the partition table for the disk which is current upon entry into
the program. The table is specified by its name as defined in the data
file. This option can be used only if a disk is being made current, and its
type is either specified or available from the disk label.

-s   Silent. Suppress all of the standard output. Error messages are still
displayed. This is generally used in conjunction with the -f option.

-t *disk-type*   Specify the type of disk which is current upon entry into the program.
A disk's type is specified by name in the data file. This option can only
be used if a disk is being made current as described above.

-x *data-file*   Use the list of disks contained in *data-file*.

Usage   When you invoke format with no options or with the -e, -l, -m, -M, or -s options, the program
displays a numbered list of available disks and prompts you to specify a disk by list number. If
the machine has more than a screenful of disks, press SPACE to see the next screenful of disks.

You can specify a disk by list number even if the disk is not displayed in the current screenful.
For example, if the current screen shows disks 11-20, you can enter 25 to specify the
twenty-fifth disk on the list. If you enter a number for a disk that is not currently displayed,
format prompts you to verify your selection. If you enter a number from the displayed list,
format silently accepts your selection.

After you specify a disk, format displays its main menu. This menu enables you to perform the
following tasks:

analyze   Run read, write, compare tests, and data purge. The data purge function implements the National Computer Security Center Guide to Understanding Data Remnance (NCSC-TG-025 version 2) Overwriting Algorithm. See NOTES.

backup   Search for backup labels.

cache   Enable, disable, and query the state of the write cache and read cache. This menu item only appears when format is invoked with the -e option, and is only supported on SCSI devices..

current   Display the device name, the disk geometry, and the pathname to the disk device.

defect   Retrieve and print defect lists. This option is supported only on SCSI devices. IDE disks perform automatic defect management. Upon using the defect option on an IDE disk, you receive the message:

```
Controller does not support defect management
or disk supports automatic defect management.
```

disk   Choose the disk that will be used in subsequent operations (known as the current disk.)

fdisk   Run the fdisk(1M) program to create a fdisk partition for Solaris software (x86 based systems only).

format   Format and verify the current disk. This option is supported only on SCSI devices. IDE disks are pre-formatted by the manufacturer. Upon using the format option on an IDE disk, you receive the message:

```
Cannot format this drive. Please use your
manufacturer-supplied formatting utility.
```

inquiry   Display the vendor, product name, and revision level of the current drive.

label   Write a new label to the current disk.

partition   Create and modify slices.

quit   Exit the format menu.

repair   Repair a specific block on the disk.

save   Save new disk and slice information.

type   Select (define) a disk type.

verify   Read and display labels. Print information such as the number of cylinders, alternate cylinders, heads, sectors, and the partition table.

volname   Label the disk with a new eight character volume name.

Environment Variables	FORMAT_PATH	a colon-separated list of filenames and/or directories of disk and partition definitions. If a directory is specified, format searches for the file format.dat in that directory.

Files /etc/format.dat   default data file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	**ATTRIBUTE VALUE**
Availability	system/core-os

See Also fmthard(1M), prtvtoc(1M), rmformat(1), format.dat(4), attributes(5), sd(7D)

Oracle Solaris Administration: Common Tasks

x86 Only fdisk(1M)

Warnings When the format function is selected to format the Maxtor 207MB disk, the following message displays:

```
Mode sense page(4) reports rpm value as 0, adjusting it to 3600
```

This is a drive bug that may also occur with older third party drives. The above message is not an error; the drive will still function correctly.

Cylinder 0 contains the partition table (disk label), which can be overwritten if used in a raw disk partition by third party software.

format supports writing EFI-compliant disk labels in order to support disks or LUNs with capacities greater than one terabyte. However, care should be exercised since many software components, such as filesystems and volume managers, are still restricted to capacities of one terabyte or less. See the *Oracle Solaris Administration: Common Tasks* for additional information.

By default, on an unlabeled disk, EFI labels will be written on disks larger than 2 TB. When format is invoked with the -e option, on writing the label, the label type can be chosen. Booting is not currently supported on a disk with an EFI label.

Notes format provides a help facility you can use whenever format is expecting input. You can request help about what information is expected by simply entering a question mark (?) and format prints a brief description of what type of input is needed. If you enter a ? at the menu prompt, a list of available commands is displayed.

For SCSI disks, formatting is done with both Primary and Grown defects list by default. However, if only Primary list is extracted in defect menu before formatting, formatting will be done with Primary list only.

Changing the state of the caches is only supported on SCSI devices, and not all SCSI devices support changing or saving the state of the caches.

The NCSC-TG-025 algorithm for overwriting meets the DoD 5200.28-M (ADP Security Manual) Eraser Procedures specification. The NIST Guidelines for Media Sanitization (NIST SP 800-88) also reference this algorithm.

Name fpsd – Fp-scrubber daemon

Synopsis /usr/lib/fps/fpsd

Description fpsd is a user-level daemon that periodically runs non-intrusive tests to validate proper functioning of FPU (Floating Point Unit) hardware in the system. A fault management action is initiated by means of fmd(1M), in case an error is detected by the test.

fpsd is not supported on all Sun systems. On a system on which it is not supported, fpsd is automatically disabled.

Exit Status The following exit values are returned:

0
  Successful completion.

non-zero
  An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/floating-point-scrubber
Interface Stability	Uncommitted

See Also svcs(1), fmd(1M), svcadm(1M), svccfg(1M), attributes(5), smf(5)

Notes The fpsd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/fpsd:default

You can use svccfg(1M) to change the default fpsd behavior:

```
Property Name          Type      Description
-------------          ----      -----------
config/exclude_cpus    astring   comma delimited list of
                                 CPU IDs to be excluded
                                 from proactive testing.
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Disabling the service can increase system's vulnerability to silent data corruption, if a fault were to develop in an FPU within the system.

Name fruadm – prints and updates customer data associated with FRUs

Synopsis /usr/platform/sun4u/sbin/fruadm

/usr/platform/sun4u/sbin/fruadm -l

/usr/platform/sun4u/sbin/fruadm [-r] *path* [*text*]

Description fruadm prints or sets the customer data for Field-Replaceable Units (FRUs).

Without arguments, fruadm prints the paths of all FRU ID-capable FRUs (containers) in the system, along with the contents of the customer data record, if present, for each such FRU; for FRUs without customer data, fruadm prints only the container's path.

Only a privileged user can create or update data in containers. The privileges required to perform these write operations are hardware dependent. Typically, a default system configuration restricts write operations to the superuser or to the platform-administrator user.

Options The following options are supported:

-l   List the system's frutree paths.

-r   Recursively display or update the data for all containers rooted at the argument *path*.

Operands The following operands are supported:

path   A full or partial system frutree path for or under which to print or set the customer data. The first field of each line of output of fruadm -l gives the valid full frutree paths for the system.

Paths can include shell meta-characters; such paths should be quoted appropriately for the user's shell. For partial paths, the first matching full path is selected for display or update. Without the -r option, the path must be that of a container; with the -r option, all containers (if any) under *path* will be selected.

text   Up to 80 characters of text set as the customer data. If the text contains white space or shell metacharacters, it should be quoted appropriately for the user's shell.

Examples **EXAMPLE 1** Displaying All Customer Data

The following example prints all customer data available from FRUs on the system. For containers with no customer data, only the containers' paths will be listed.

example% fruadm

EXAMPLE 2 Displaying Customer Data For a Single FRU

The following command prints the customer data, if present, for the specified FRU:

example% fruadm /frutree/chassis/system-board

EXAMPLE 3 Displaying Customer Data For a Single FRU

The following command prints the customer data, if present, for the first mem-module found:

```
example% fruadm mem-module
```

EXAMPLE 4 Setting Customer Data

The following example sets the customer data for a FRU:

```
example# fruadm system-board 'Asset Tag 123456'
```

EXAMPLE 5 Setting Customer Data

The following command sets the customer data for all FRUs under chassis:

```
example# fruadm -r /frutree/chassis "Property of XYZ, Inc."
```

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

Name fsck – check and repair file systems

Synopsis fsck [-F *FSType*] [-m] [-V] [-v] [*special*]...

fsck [-F *FSType*] [-n | N | y | Y] [-V] [-v]
    [-o *FSType-specific-options*] [*special*]...

Description fsck audits and interactively repairs inconsistent file system conditions. If the file system is inconsistent the default action for each correction is to wait for the user to respond yes or no. If the user does not have write permission fsck defaults to a no action. Some corrective actions will result in loss of data. The amount and severity of data loss can be determined from the diagnostic output.

FSType-specific-options are options specified in a comma-separated (with no intervening spaces) list of options or keyword-attribute pairs for interpretation by the *FSType*-specific module of the command.

special represents the character special device on which the file system resides, for example, /dev/rdsk/c1t0d0s7. Note: the character special device, not the block special device, should be used. fsck will not work if the block device is mounted.

If no *special* device is specified fsck checks the file systems listed in /etc/vfstab. Those entries in /etc/vfstab which have a character special device entry in the fsckdev field and have a non-zero numeric entry in the fsckpass field will be checked. Specifying -F *FSType* limits the file systems to be checked to those of the type indicated.

If *special* is specified, but -F is not, the file system type will be determined by looking for a matching entry in /etc/vfstab. If no entry is found, the default local file system type specified in /etc/default/fs will be used.

If a file system type supports parallel checking, for example, ufs, some file systems eligible for checking may be checked in parallel. Consult the file system-specific man page (for example, fsck_ufs(1M)) for more information.

Options The following generic options are supported:

-F *FSType*
    Specify the file system type on which to operate.

-m
    Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, fsck displays a message such as:

    ufs fsck: sanity check: /dev/rdsk/c0t3d0s1 okay

-n | -N
    Assume a no response to all questions asked by fsck; do not open the file system for writing.

-V

Echo the expanded command line but do not execute the command. This option may be used to verify and to validate the command line.

-v

Enables verbose output. Might not be supported by all filesystem-specific fsck implementations.

-y | Y

Assume a yes response to all questions asked by fsck.

-o *specific-options*

These *specific-options* can be any combination of the following separated by commas (with no intervening spaces).

b=*n*

Use block *n* as the super block for the file system. Block 32 is always one of the alternate super blocks. Determine the location of other super blocks by running newfs(1M) with the -Nv options specified.

c

If the file system is in the old (static table) format, convert it to the new (dynamic table) format. If the file system is in the new format, convert it to the old format provided the old format can support the file system configuration. In interactive mode, fsck will list the direction the conversion is to be made and ask whether the conversion should be done. If a negative answer is given, no further operations are done on the file system. In preen mode, the direction of the conversion is listed and done if possible without user interaction. Conversion in preen mode is best used when all the file systems are being converted at once. The format of a file system can be determined from the first line of output from fstyp(1M). Note: the c option is seldom used and is included only for compatibility with pre-4.1 releases. There is no guarantee that this option will be included in future releases.

f

Force checking of file systems regardless of the state of their super block clean flag.

p

Check and fix the file system non-interactively ("preen"). Exit immediately if there is a problem requiring intervention. This option is required to enable parallel file system checking.

w

Check writable file systems only.

Exit Status 0

file system is unmounted and OK

1

erroneous parameters are specified

32
file system is unmounted and needs checking (fsck -m only)

33
file system is already mounted

34
cannot stat device

35
a filesystem that is mounted read/write was modified – reboot

36
uncorrectable errors detected - terminate normally

37
a signal was caught during processing

39
uncorrectable errors detected - terminate immediately

40
file system is mounted read-only and is OK

Usage The fsck command is *large file aware* for UFS file systems, per the largefile(5) man page.

Files /etc/default/fs
default local file system type. Default values can be set for the following flags in
/etc/default/fs. For example: LOCAL=ufs.

LOCAL
The default partition for a command if no FSType is specified.

/etc/vfstab
list of default parameters for each file system

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also clri(1M), fsck_ufs(1M), fsdb_ufs(1M), fsirand(1M), fstyp(1M), mkfs(1M),
mkfs_ufs(1M), mountall(1M), newfs(1M), reboot(1M), vfstab(4), attributes(5),
largefile(5), ufs(7FS)

Warnings The operating system buffers file system data. Running fsck on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, the file system should be *unmounted* when fsck is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after fsck is run. Quite often, however, this will not be sufficient. A panic will probably occur if running fsck on a file system modifies the file system.

Notes This command may not be supported for all *FSTypes*.

Starting with Solaris 9, fsck manages extended attribute data on the disk. (See fsattr(5) for a description of extended file attributes.) A file system with extended attributes can be mounted on versions of Solaris that are not attribute-aware (versions prior to Solaris 9), but the attributes will not be accessible and fsck will strip them from the files and place them in lost+found. Once the attributes have been stripped, the file system is completely stable on versions of Solaris that are not attribute-aware, but would be considered corrupted on attribute-aware versions. In the latter circumstance, run the attribute-aware fsck to stabilize the file system before using it in an attribute-aware environment.

Name fsck_pcfs – file system consistency check and interactive repair

Synopsis `fsck -F pcfs` [*generic_options*] *special*

`fsck -F pcfs` [*generic_options*] [`-o` *specific_options*] *special*

Description The `fsck` utility audits and interactively repairs inconsistent conditions on file systems. *special* represents the character special device on which the file system resides, for example `/dev/disk`. The character special device, not the block special device, should be used.

In the case of correcting serious inconsistencies, by default, `fsck` asks for confirmation before making a repair and waits for the operator to respond either `yes` or `no`. If the operator does not have write permission on the file system, `fsck` defaults to a `-n` (no corrections) action. See `fsck`(1M).

Repairing some file system inconsistencies may result in loss of data. The amount and severity of data loss may be determined from the diagnostic output.

When executed with the verify option (`-o v`), `fsck_pcfs` automatically scans the entire file system to verify that all of its allocation units are accessible. If it finds any units inaccessible, it updates the file allocation table (FAT) appropriately. It also updates any effected directory entries to reflect the problem. This directory update includes truncating the file at the point in its allocation chain where the file data is no longer accessible. Any remaining accessible allocation units become orphaned.

Orphaned chains of accessible allocation units are, with the operator's concurrence, linked back into the file system as files in the root directory. These files are assigned names of the form file*NNNN*.chk, where the *N*s are digits in the integral range from `0` through `9`.

After successfully scanning and correcting any errors in the file system, `fsck` displays a summary of information about the file system. This summary includes the size of the file system in bytes, the number of bytes used in directories and individual files, and the number of available allocation units remaining in the file system.

Options *generic_options* The following generic options are supported:

`-m`	Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, `fsck` displays a message such as:
	
	`pcfs fsck: sanity check:`
	`/dev/disk okay`

`-n` | `-N`	Assume a no response to all questions asked by `fsck`; do not open the file system for writing.
`-V`	Echo the expanded command line, but do not execute the command. This option may be used to verify and to validate the command line.

-y | -Y   Assume a yes response to all questions asked by fsck.

-o *specific_options*   Specify pcfs file system specific options in a comma-separated list, in any combination, with no intervening spaces.

     v   Verify all allocation units are accessible prior to correcting inconsistencies in the metadata.

     p   Check and fix the file system non-interactively (preen). Exit immediately if there is a problem requiring intervention.

     w   Check writable file systems only.

Files   *special*   The device which contains the pcfs. A hard disk device or high-capacity removable device name much be qualified with a suffix to indicate the proper FDISK partition.

For example, in the names: /dev/rdsk/c0t0d0p0:c and /dev/rdsk/c0t4d0s2:c, the :c suffix indicates the first partition on the disk contains the pcfs.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/pcfs
Interface Stability	Committed

See Also   fsck(1M), fstyp(1M), fdisk(1M), mkfs(1M), mkfs_pcfs(1M), mountall(1M), attributes(5), pcfs(7FS),

Warnings   The operating system buffers file system data. Running fsck on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, the file system should be unmounted when fsck is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after fsck is run. Quite often, however, this is not sufficient. A panic will probably occur if running fsck on a file system modifies the file system.

Name fsck_udfs – file system consistency check and interactive repair

Synopsis fsck -F udfs [*generic_options*] [*special* ...]

fsck -F udfs [*generic_options*] [-o *specific_options*]
    [*special* ...]

Description fsck audits and interactively repairs inconsistent conditions on file systems. A file system to be checked can be specified by giving the name of the block or character special device or by giving the name of its mount point if a matching entry exists in /etc/vfstab.

special represents the character special device, for example, /dev/rdsk/c0t2d0s0, on which the file system resides. The character special device, not the block special device should be used. fsck does not work on a mounted block device.

If no special device is specified, all udfs file systems specified in the vfstab file with a fsckdev entry are checked. If the -p (preen) option is specified, udfs file systems with an fsckpass number greater than 1 are checked in parallel. See fsck(1M).

In the case of correcting serious inconsistencies, by default, fsck asks for confirmation before making a repair and waits for the operator to respond with either yes or no. If the operator does not have write permission on the file system, fsck defaults to the -n (no corrections) option. See fsck(1M).

Repairing some file system inconsistencies can result in loss of data. The amount and severity of data loss can be determined from the diagnostic output.

fsck automatically corrects innocuous inconsistencies. It displays a message for each corrected inconsistency that identifies the nature of the correction which took place on the file system. After successfully correcting a file system, fsck prints the number of files on that file system and the number of used and free blocks.

Inconsistencies checked are as follows:

- Blocks claimed by more than one file or the free list
- Blocks claimed by a file or the free list outside the range of the file system
- Incorrect link counts in file entries
- Incorrect directory sizes
- Bad file entry format
- Blocks not accounted for anywhere
- Directory checks, file pointing to unallocated file entry and absence of a parent directory entry
- Descriptor checks, more blocks for files than there are in the file system
- Bad free block list format
- Total free block count incorrect

Options   The following options are supported:

generic_options   The following *generic_options* are supported:

-m   Check but do not repair. This option checks to be sure that the file system is suitable for mounting, and returns the appropriate exit status. If the file system is ready for mounting, fsck displays a message such as:

```
udfs fsck: sanity check: /dev/rdsk/c0t2d0s0 okay
```

-n | -N   Assume a no response to all questions asked by fsck; do not open the file system for writing.

-V   Echo the expanded command line, but do not execute the command. This option can be used to verify and to validate the command line.

-y | -Y   Assume a yes response to all questions asked by fsck.

-o *specific_options*   Specify udfs file system specific options in a comma-separated list with no intervening spaces. The following *specific_options* are available:

f   Force checking of file systems regardless of the state of their logical volume integrity state.

p   Check and fix the file system non-interactively (preen). Exit immediately if there is a problem that requires intervention. This option is required to enable parallel file system checking.

w   Check writable file systems only.

Files   /etc/vtstab   List of default parameters for each file system.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/udfs

See Also   fsck(1M), fsdb_udfs(1M), fstyp(1M), mkfs(1M), mkfs_udfs(1M), mountall(1M), reboot(1M), vfstab(4), attributes(5)

Warnings   The operating system buffers file system data. Running fsck on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, use fsck only when the file system is unmounted. If this is not possible, take care that the system is quiescent and that it is rebooted immediately after running fsck. A panic will probably occur if running fsck on a file system that modifies the file system while it is mounted.

If an unmount of the file system is not done before the system is shut down, the file system might become corrupted. In this case, a file system check needs to be completed before the next mount operation.

Diagnostics not writable
    You cannot write to the device.

Currently Mounted on
    The device is already mounted and cannot run `fsck`.

FILE SYSTEM WAS MODIFIED
    File system has been modified to bring it to a consistent state.

Can't read allocation extent
    Cannot read the block containing allocation extent.

Bad tag on alloc extent
    Invalid tag detected when expecting an allocation extent.

Volume sequence tag error
    Invalid tag detected in the volume sequence.

Space bitmap tag error
    Invalid tag detected in the space bitmap.

UNEXPECTED INCONSISTENCY; RUN fsck MANUALLY
    Use `fsck` in interactive mode.

Name fsck_ufs – file system consistency check and interactive repair

Synopsis fsck -F ufs [*generic-options*] [*special*]...

fsck -F ufs [*generic-options*] [-o *specific-options*]
[*special*]...

Description The fsck utility audits and interactively repairs inconsistent conditions on file systems. A file system to be checked may be specified by giving the name of the block or character *special* device or by giving the name of its mount point if a matching entry exists in /etc/vfstab.

The *special* parameter represents the character special device, for example, /dev/rdsk/c1t0d0s7, on which the file system resides. The character special device, not the block special device should be used. The fsck utility will not work if the block device is mounted, unless the file system is error-locked.

If no *special* device is specified, all ufs file systems specified in the vfstab with a fsckdev entry will be checked. If the -p ("preen") option is specified, ufs file systems with an fsckpass number greater than 1 are checked in parallel. See fsck(1M).

In the case of correcting serious inconsistencies, by default, fsck asks for confirmation before making a repair and waits for the operator to respond either yes or no. If the operator does not have write permission on the file system, fsck will default to a -n (no corrections) action. See fsck(1M).

Repairing some file system inconsistencies can result in loss of data. The amount and severity of data loss can be determined from the diagnostic output.

The fsck utility automatically corrects innocuous inconsistencies such as unreferenced inodes, too-large link counts in inodes, missing blocks in the free list, blocks appearing in the free list and also in files, or incorrect counts in the super block. It displays a message for each inconsistency corrected that identifies the nature of the correction on the file system which took place. After successfully correcting a file system, fsck prints the number of files on that file system, the number of used and free blocks, and the percentage of fragmentation.

Inconsistencies checked include:

- Blocks claimed by more than one inode or the free list.
- Blocks claimed by an inode or the free list outside the range of the file system.
- Incorrect link counts.
- Incorrect directory sizes.
- Bad inode format.
- Blocks not accounted for anywhere.
- Directory checks, file pointing to unallocated inode, inode number out of range, and absence of '.' and '..' as the first two entries in each directory.
- Super Block checks: more blocks for inodes than there are in the file system.

- Bad free block list format.

- Total free block and/or free inode count incorrect.

Orphaned files and directories (allocated but unreferenced) are, with the operator's concurrence, reconnected by placing them in the lost+found directory. The name assigned is the inode number. If the lost+found directory does not exist, it is created. If there is insufficient space in the lost+found directory, its size is increased.

An attempt to mount a ufs file system with the -o nolargefiles option will fail if the file system has ever contained a large file (a file whose size is greater than or equal to 2 Gbyte). Invoking fsck resets the file system state if no large files are present in the file system. A successful mount of the file system after invoking fsck indicates the absence of large files in the file system. An unsuccessful mount attempt indicates the presence of at least one large file. See mount_ufs(1M).

Options   The *generic-options* consist of the following options:

-m   Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, fsck displays a message such as:

    ufs fsck: sanity check: /dev/rdsk/c0t3d0s1 okay

-n | N   Assume a no response to all questions asked by fsck; do not open the file system for writing.

-V   Echo the expanded command line, but do not execute the command. This option may be used to verify and to validate the command line.

-v   Enables verbose output. Might not be supported by all filesystem-specific fsck implementations.

-y | Y   Assume a yes response to all questions asked by fsck.

See generic fsck(1M) for the details for specifying *special*.

-o *specific-options*   Specify ufs file system specific options. These options can be any combination of the following separated by commas (with no intervening spaces).

                         b=*n*   Use block *n* as the super block for the file system. Block 32 is always one of the alternate super blocks. Determine the location of other super blocks by running newfs(1M) with the -Nv options specified.

                         f   Force checking of file systems regardless of the state of their super block clean flag.

p	Check and fix the file system non-interactively ("preen"). Exit immediately if there is a problem requiring intervention. This option is required to enable parallel file system checking.
w	Check writable file systems only.

Files /etc/vfstab   list of default parameters for each file system

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also clri(1M), fsck(1M), fsdb_ufs(1M), fsirand(1M), fstyp(1M), mkfs(1M), mkfs_ufs(1M), mount_ufs(1M), mountall(1M), newfs(1M), reboot(1M), vfstab(4), attributes(5), largefile(5), ufs(7FS)

Warnings The operating system buffers file system data. Running fsck on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, the file system should be *unmounted* when fsck is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after fsck is run. Quite often, however, this will not be sufficient. A panic will probably occur if running fsck on a file system modifies the file system.

Notes It is usually faster to check the character special device than the block special device.

Running fsck on file systems larger than 2 Gb fails if the user chooses to use the block interface to the device:

fsck /dev/dsk/c?t?d?s?

rather than the raw (character special) device:

fsck /dev/rdsk/c?t?d?s?

Name fsdb – file system debugger

Synopsis fsdb [-F *FSType*] [-V] [-o *FSType-specific_options*] *special*

Description fsdb is a file system debugger that allows for the manual repair of a file system after a crash. *special* is a special device used to indicate the file system to be debugged. fsdb is intended for experienced users only. *FSType* is the file system type to be debugged. Since different *FSTypes* have different structures and hence different debugging capabilities, the manual pages for the *FSType*-specific fsdb should be consulted for a more detailed description of the debugging capabilities.

Options -F Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from /etc/vfstab by matching the *special* with an entry in the table, or by consulting /etc/default/fs.

-V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option may be used to verify and validate the command line.

-o Specify *FSType*-specific options.

Usage See largefile(5) for the description of the behavior of fsdb when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files /etc/default/fs   default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs

LOCAL: The default partition for a command if no FSType is specified.

/etc/vfstab   list of default parameters for each file system

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also vfstab(4), attributes(5), largefile(5) Manual pages for the *FSType*-specific modules of fsdb.

Notes This command may not be supported for all *FSTypes*.

Name fsdb_udfs – udfs file system debugger

Synopsis `fsdb [-F] udfs [`*generic_option*`] [-o `*specific_option*`] `*special*

Description The `fsdb_udfs` command is an interactive tool that can be used to patch up a damaged udfs file system. `fsdb_udfs` has conversions to translate block and i-numbers into their corresponding disk addresses. Mnemonic offsets to access different parts of an inode are also included. Mnemonic offsets greatly simplify the process of correcting control block entries or descending the file system tree.

`fsdb` contains several error-checking routines to verify inode and block addresses. These can be disabled if necessary by invoking `fsdb` with the `-o` option or by using the `o` command.

`fsdb` reads one block at a time, and therefore works with raw as well as block I/O devices. A buffer management routine is used to retain commonly used blocks of data in order to reduce the number of read system calls. All assignment operations result in an immediate write-through of the corresponding block. In order to modify any portion of the disk, `fsdb` must be invoked with the `-w` option.

Wherever possible, `adb`-like syntax has been adopted to promote the use of `fsdb` through familiarity.

Options The following options are supported:

-o *specific_option*   Specify udfs file system specific options in a comma-separated list with no intervening spaces. The following specific options are supported:

        o   Override some error conditions.

        p=*string*   Set prompt to *string*.

        w   Open for write.

        ?   Display usage.

Usage Numbers are considered hexadecimal by default. The user has control over how data is to be displayed or accepted. The `base` command displays or sets the input and output base. Once set, all input defaults to this base and all output displays in this base. The base can be overriden temporarily for input by preceding hexadecimal numbers by `0x`, preceding decimal numbers with a `0t`, or octal numbers with a `0`. Hexadecimal numbers beginning with a-f or A-F must be preceded with a `0x` to distinguish them from commands.

Disk addressing by `fsdb` is at the byte level. However, `fsdb` offers many commands to convert a desired inode, directory entry, block, and so forth, to a byte address. After the address has been calculated, `fsdb` records the result in the current address (dot).

Several global values are maintained by `fsdb`:

- Current base (referred to as `base`)
- Current address (referred to as `dot`)

- Current inode (referred to as `inode`)
- Current count (referred to as `count`)
- Current type (referred to as `type`)

Most commands use the preset value of `dot` in their execution. For example,

```
 > 2:inode
```

first sets the value of dot (`.`) to 2, colon (`:`), signifies the start of a command, and the `inode` command sets `inode` to 2. A count is specified after a comma (`,`). Once set, count remains at this value until a new command is encountered that resets the value back to `1` (the default).

So, if

```
> 2000,400/X
```

is entered, `400` hex longs are listed from `2000`, and when completed, the value of dot is `2000 + 400 *` sizeof (long). If a RETURN is then entered, the output routine uses the current values of dot, count, and type and displays `400` more hex longs. An asterisk (`*`) causes the entire block to be displayed. An example showing several commands and the use of RETURN would be:

```
> 2:ino; 0:dir?d
```

or

```
> 2:ino; 0:db:block?d
```

The two examples are synonymous for getting to the first directory entry of the root of the file system. Once there, subsequently entering a RETURN, plus (`+`), or minus (`-`) advances to subsequent entries. Notice that

```
> 2:inode; :ls
```

or

```
> :ls /
```

is again synonymous.

Expressions   The following symbols are recognized by `fsdb`:

RETURN   Update the value of dot by the current value of *type* and *display* using the current value of *count*.

Update the value of dot by specifying a numeric expression. Specify numeric expressions using addition, subtraction, multiplication, and division operators (`+`, `-`, `*`, and `%`). Numeric expressions are evaluated from left to right and can use parentheses. After evaluation, the value of dot is updated.

, *count*	Update the count indicator. The global value of *count* is updated to *count*. The value of *count* remains until a new command is run. A *count* specifier of * attempts to show a blocks's worth of information. The default for *count* is 1.
? *f*	Display in structured style with format specifier f. See Formatted Output.
/ *f*	Display in unstructured style with format specifier f. See Formatted Output.
.	Display the value of dot.
+*e*	Increment the value of dot by the expression *e*. The amount actually incremented is dependent on the size of type: dot = dot + *e* * sizeof (*type*) The default for *e* is 1.
−*e*	Decrement the value of dot by the expression *e*. See +.
**e*	Multiply the value of dot by the expression *e*. Multiplication and division don't use *type*. In the above calculation of dot, consider the sizeof (*type*) to be 1.
%*e*	Divide the value of dot by the expression *e*. See *.
< *name*	Restore an address saved in register *name*. *name* must be a single letter or digit.
> *name*	Save an address in register *name*. *name* must be a single letter or digit.
= *f*	Display indicator. If *f* is a legitimate format specifier (see Formatted Output), then the value of dot is displayed using format specifier *f*. Otherwise, assignment is assumed. See = [s] [e].
= [*s*] [*e*]	Change the value of dot using an assignment indicator. The address pointed to by dot has its contents changed to the value of the expression *e* or to the ASCII representation of the quoted (") string *s*. This can be useful for changing directory names or ASCII file information.
=+ *e*	Change the value of dot using an incremental assignment. The address pointed to by dot has its contents incremented by expression *e*.
=- e	Change the value of dot using a decremental assignment. Decrement the contents of the address pointed to by dot by expression *e*.

Commands   A command must be prefixed by a colon (:). Only enough letters of the command to uniquely distinguish it are needed. Multiple commands can be entered on one line by separating them by a SPACE, TAB, or semicolon (;).

To view a potentially unmounted disk in a reasonable manner, fsdb supports the cd, pwd, ls, and find commands. The functionality of each of these commands basically matches that of its UNIX counterpart. See cd(1), pwd(1),ls(1), andfind(1) for details. The *, ,, ?, and - wildcard characters are also supported.

The following commands are supported:

base[=*b*]	Display or set the base. All input and output is governed by the current base. Without the = *b*, displays the current base. Otherwise, sets the current base to *b*. Base is interpreted using the old value of base, so to ensure correctness use the `0`, `0t`, or `0x` prefix when changing the base. The default for base is hexadecimal.
block	Convert the value of dot to a block address.
cd [*dir*]	Change the current directory to directory *dir*. The current values of inode and dot are also updated. If `dir` is not specified, changes directories to inode 2, root (`/`).
directory	If the current inode is a directory, converts the value of dot to a directory slot offset in that directory, and dot now points to this entry.
file	Set the value of dot as a relative block count from the beginning of the file. The value of dot is updated to the first byte of this block.
find *dir* [`-name` *n*] | [`-inum` *i*]	Find files by name or i-number. Recursively searches directory *dir* and below for file names whose i-number matches *i* or whose name matches pattern *n*. Only one of the two options (`-name` or `-inum`) can be used at one time. The find `-print` is not necessary or accepted.
fill=*p*	Fill an area of disk with pattern *p*. The area of disk is delimited by dot and count.
inode	Convert the value of dot to an inode address. If successful, the current value of inode is updated as well as the value of dot. As a convenient shorthand, if `:inode` appears at the beginning of the line, the value of dot is set to the current inode and that inode is displayed in inode format.
ls [`-R`] [`-l`] *pat1 pat2*...	List directories or files. If no file is specified, the current directory is assumed. Either or both of the options can be used (but, if used, must be specified before the filename specifiers). Wild card characters are available and multiple arguments are acceptable. The long listing shows only the i-number and the name; use the inode command with `?i` to get more information.
override	Toggle the value of override. Some error conditions might be overridden if override is toggled to on.
prompt "*p*"	Change the `fsdb` prompt to *p*. *p* must be enclosed in quotes.

pwd	Display the current working directory.
quit	Quit fsdb.
tag	Convert the value of dot and if this is a valid tag, print the volume structure according to the tag.
!	Escape to the shell.

Inode Commands   In addition to the above commands, several other commands deal with inode fields and operate directly on the current inode (they still require the colon (:). They can be used to more easily display or change the particular fields. The value of dot is only used by the :db and :ib commands. Upon completion of the command, the value of dot is changed so that it points to that particular field. For example,

```
> :ln=+1
```

increments the link count of the current inode and sets the value of dot to the address of the link count field.

The following inode commands are supported:

at	Access time
bs	Block size
ct	Creation time
gid	Group id
ln	Link number
mt	Modification time
md	Mode
maj	Major device number
min	Minor device number
nm	This command actually operates on the directory name field. Once poised at the desired directory entry (using the directory command), this command allows you to change or display the directory name. For example,

```
 > 7:dir:nm="foo"
```

gets the 7th directory entry of the current inode and changes its name to foo. Directory names cannot be made larger than the field allows. If an attempt is made to make a directory name larger than the field allows,, the string is truncated to fit and a warning message is displayed.

sz	File size

uid　　User ID

uniq　　Unique ID

Formatted Output　Formatted output comes in two styles and many format types. The two styles of formatted output are: structured and unstructured. Structured output is used to display inodes, directories, and so forth. Unstructured output displays raw data.

Format specifiers are preceded by the slash (/) or question mark (?) character. *type* is updated as necessary upon completion.

The following format specifiers are preceded by the ? character:

i　　Display as inodes in the current base.

d　　Display as directories in the current base.

The following format specifiers are preceded by the / character:

b　　　Display as bytes in the current base.

c　　　Display as characters.

o | O　　Display as octal shorts or longs.

d | D　　Display as decimal shorts or longs.

x | X　　Display as hexadecimal shorts or longs.

Examples　**EXAMPLE 1**　Using fsdb as a calculator for complex arithmetic

The following command displays 2010 in decimal format, and is an example of using fsdb as a calculator for complex arithmetic.

```
> 2000+400%(20+20)=D
```

EXAMPLE 2　Using fsdb to display an i-number in idode fomat

The following command displays the i-number 386 in inode format.386 becomes the current inode.

```
> 386:ino?i
```

EXAMPLE 3　Using fsdb to change the link count

The following command changes the link count for the current inode to 4.

```
> :ln=4
```

EXAMPLE 4 Using fsdb to increment the link count

The following command increments the link count by 1.

```
> :ln=+1
```

EXAMPLE 5 Using fsdb to display the creation time as a hexadecimal long

The following command displays the creation time as a hexadecimal long.

```
> :ct=X
```

EXAMPLE 6 Using fsdb to display the modification time in time format

The following command displays the modification time in time format.

```
> :mt=t
```

EXAMPLE 7 Using fsdb to display in ASCII

The following command displays, in ASCII, block 0 of the file associated with the current inode.

```
> 0:file/c
```

EXAMPLE 8 Using fsdb to display the directory entries for the root inode

The following command displays the first block's directory entries for the root inode of this file system. This command stops prematurely if the EOF is reached.

```
> 2:ino,*?d
```

EXAMPLE 9 Using fsdb to change the current inode

The following command changes the current inode to that associated with the 5th directory entry (numbered from 0) of the current inode. The first logical block of the file is then displayed in ASCII.

```
> 5:dir:inode; 0:file,*/c
```

EXAMPLE 10 Using fsdb to change the i-number

The following command changes the i-number for the 7th directory slot in the root directory to 3.

```
> 2:inode; 7:dir=3
```

EXAMPLE 11 Using fsdb to change the name field

The following command changes the *name* field in the directory slot to name.

```
 > 7:dir:nm="name"
```

EXAMPLE 12 Using fsdb to display the a block

The following command displays the 3rd block of the current inode as directory entries.

EXAMPLE 13 Using fsdb to set the contents of address

The following command sets the contents of address 2050 to 0xffffffff. 0xffffffff can be truncated, depending on the current type.

```
> 2050=0xffff
```

EXAMPLE 14 Using fsdb to place an ASCII string at an address

The following command places the ASCII string this is some text at address 1c92434.

```
> 1c92434="this is some text"
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/udfs

See Also clri(1M), fsck_udfs(1M), dir(4), attributes(5)

Name fsdb_ufs – ufs file system debugger

Synopsis `fsdb -F ufs [`*generic_options*`] [`*specific_options*`]` *special*

Description The `fsdb_ufs` command is an interactive tool that can be used to patch up a damaged UFS file system. It has conversions to translate block and i-numbers into their corresponding disk addresses. Also included are mnemonic offsets to access different parts of an inode. These greatly simplify the process of correcting control block entries or descending the file system tree.

`fsdb` contains several error-checking routines to verify inode and block addresses. These can be disabled if necessary by invoking `fsdb` with the `-o` option or by the use of the `o` command.

`fsdb` reads a block at a time and will therefore work with raw as well as block I/O devices. A buffer management routine is used to retain commonly used blocks of data in order to reduce the number of read system calls. All assignment operations result in an immediate write-through of the corresponding block. Note that in order to modify any portion of the disk, `fsdb` must be invoked with the `w` option.

Wherever possible, `adb`-like syntax was adopted to promote the use of `fsdb` through familiarity.

Options The following option is supported:

-o   Specify UFS file system specific options. These options can be any combination of the following separated by commas (with no intervening spaces). The options available are:

?	Display usage
o	Override some error conditions
p='string'	set prompt to string
w	open for write

Usage Numbers are considered hexadecimal by default. However, the user has control over how data is to be displayed or accepted. The `base` command will display or set the input/output base. Once set, all input will default to this base and all output will be shown in this base. The base can be overridden temporarily for input by preceding hexadecimal numbers with '`0x`', preceding decimal numbers with '`0t`', or octal numbers with '`0`'. Hexadecimal numbers beginning with a-f or A-F must be preceded with '`0x`' to distinguish them from commands.

Disk addressing by `fsdb` is at the byte level. However, `fsdb` offers many commands to convert a desired inode, directory entry, block, superblock and so forth to a byte address. Once the address has been calculated, `fsdb` will record the result in dot (`.`).

Several global values are maintained by `fsdb`:

- the current base (referred to as base),

- the current address (referred to as dot),
- the current inode (referred to as inode),
- the current count (referred to as count),
- and the current type (referred to as type).

Most commands use the preset value of dot in their execution. For example,

```
> 2:inode
```

will first set the value of dot to 2, ':', will alert the start of a command, and the inode command will set inode to 2. A count is specified after a ','. Once set, count will remain at this value until a new command is encountered which will then reset the value back to 1 (the default). So, if

```
> 2000,400/X
```

is typed, 400 hex longs are listed from 2000, and when completed, the value of dot will be 2000 + 400 * sizeof (long). If a RETURN is then typed, the output routine will use the current values of dot, count, and type and display 400 more hex longs. A '*' will cause the entire block to be displayed.

End of fragment, block and file are maintained by fsdb. When displaying data as fragments or blocks, an error message will be displayed when the end of fragment or block is reached. When displaying data using the db, ib, directory, or file commands an error message is displayed if the end of file is reached. This is mainly needed to avoid passing the end of a directory or file and getting unknown and unwanted results.

An example showing several commands and the use of RETURN would be:

```
> 2:ino; 0:dir?d
      or
> 2:ino; 0:db:block?d
```

The two examples are synonymous for getting to the first directory entry of the root of the file system. Once there, any subsequent RETURN (or +, -) will advance to subsequent entries. Note that

```
> 2:inode; :ls
      or
> :ls /
```

is again synonymous.

Expressions The symbols recognized by fsdb are:

RETURN   update the value of dot by the current value of type and display using the
            current value of count.

#	numeric expressions may be composed of +, -, *, and % operators (evaluated left to right) and may use parentheses. Once evaluated, the value of dot is updated.
, *count*	count indicator. The global value of count will be updated to count. The value of count will remain until a new command is run. A count specifier of '*' will attempt to show a *blocks's* worth of information. The default for count is 1.
? *f*	display in structured style with format specifier *f*. See FormattedOutput.
/ *f*	display in unstructured style with format specifier *f* See FormattedOutput.
.	the value of dot.
+*e*	increment the value of dot by the expression *e*. The amount actually incremented is dependent on the size of type:
	dot = dot + e * sizeof (type)
	The default for *e* is 1.
-*e*	decrement the value of dot by the expression *e*. See +.
*e	multiply the value of dot by the expression *e.* Multiplication and division don't use type. In the above calculation of dot, consider the sizeof(type) to be 1.
%*e*	divide the value of dot by the expression *e*. See *.
< *name*	restore an address saved in register *name. name* must be a single letter or digit.
> *name*	save an address in register *name. name* must be a single letter or digit.
= *f*	display indicator. If *f* is a legitimate format specifier. then the value of dot is displayed using the format specifier *f*. See FormattedOutput. Otherwise, assignment is assumed See =.
= [*s*] [*e*]	assignment indicator. The address pointed to by dot has its contents changed to the value of the expression *e* or to the ASCII representation of the quoted (") string *s*. This may be useful for changing directory names or ASCII file information.
=+ *e*	incremental assignment. The address pointed to by dot has its contents incremented by expression *e*.
=- *e*	decremental assignment. The address pointed to by dot has its contents decremented by expression *e*.

Commands   A command must be prefixed by a ':' character. Only enough letters of the command to uniquely distinguish it are needed. Multiple commands may be entered on one line by separating them by a SPACE, TAB or ';'.

In order to view a potentially unmounted disk in a reasonable manner, fsdb offers the cd, pwd, ls and find commands. The functionality of these commands substantially matches those of its UNIX counterparts. See individual commands for details. The '*', '?', and '[-]' wild card characters are available.

base=b	display or set base. As stated above, all input and output is governed by the current base. If the =b is omitted, the current base is displayed. Otherwise, the current base is set to *b*. Note that this is interpreted using the old value of base, so to ensure correctness use the '0', '0t', or '0x' prefix when changing the base. The default for base is hexadecimal.
block	convert the value of dot to a block address.
cd *dir*	change the current directory to directory *dir*. The current values of inode and dot are also updated. If no *dir* is specified, then change directories to inode 2 ("/").
cg	convert the value of dot to a cylinder group.
directory	If the current inode is a directory, then the value of dot is converted to a directory slot offset in that directory and dot now points to this entry.
file	the value of dot is taken as a relative block count from the beginning of the file. The value of dot is updated to the first byte of this block.
find *dir* [-name *n*] [-inum *i*]	find files by name or i-number. find recursively searches directory dir and below for filenames whose i-number matches *i* or whose name matches pattern *n*. Note that only one of the two options (-name or -inum) may be used at one time. Also, the -print is not needed or accepted.
fill=*p*	fill an area of disk with pattern *p*. The area of disk is delimited by dot and count.
fragment	convert the value of *dot* to a fragment address. The only difference between the fragment command and the block command is the amount that is able to be displayed.
inode	convert the value of *dot* to an inode address. If successful, the current value of inode will be updated as well as the value of *dot*. As a convenient shorthand, if ':inode' appears at the beginning of the line, the value of *dot* is set to the current inode and that inode is displayed in inode format.
log_chk	run through the valid log entries without printing any information and verify the layout.

log_delta	count the number of deltas into the log, using the value of dot as an offset into the log. No checking is done to make sure that offset is within the head/tail offsets.
log_head	display the header information about the file system logging. This shows the block allocation for the log and the data structures on the disk.
log_otodb	return the physical disk block number, using the value of dot as an offset into the log.
log_show	display all deltas between the beginning of the log (BOL) and the end of the log (EOL).
ls	[-R] [-l] *pat1 pat2* . . . list directories or files. If no file is specified, the current directory is assumed. Either or both of the options may be used (but, if used, *must* be specified before the filename specifiers). Also, as stated above, wild card characters are available and multiple arguments may be given. The long listing shows only the i-number and the name; use the inode command with '?i' to get more information.
override	toggle the value of override. Some error conditions may be overriden if override is toggled on.
prompt *p*	change the fsdb prompt to *p*. *p* must be surrounded by (")s.
pwd	display the current working directory.
quit	quit fsdb.
sb	the value of *dot* is taken as a cylinder group number and then converted to the address of the superblock in that cylinder group. As a shorthand, ':sb' at the beginning of a line will set the value of *dot* to *the* superblock and display it in superblock format.
shadow	if the current inode is a shadow inode, then the value of *dot* is set to the beginning of the shadow inode data.
!	escape to shell

Inode Commands   In addition to the above commands, there are several commands that deal with inode fields and operate directly on the current inode (they still require the ':'). They may be used to more easily display or change the particular fields. The value of *dot* is only used by the ':db' and ':ib' commands. Upon completion of the command, the value of *dot* is changed to point to that particular field. For example,

```
> :ln=+1
```

would increment the link count of the current inode and set the value of *dot* to the address of the link count field.

at   access time.

bs   block size.

ct   creation time.

db   use the current value of *dot* as a direct block index, where direct blocks number from 0 - 11. In order to display the block itself, you need to 'pipe' this result into the `block` or `fragment` command. For example,

```
> 1:db:block,20/X
```

would get the contents of data block field 1 from the inode and convert it to a block address. 20 longs are then displayed in hexadecimal. See `FormattedOutput`.

gid   group id.

ib   use the current value of *dot* as an indirect block index where indirect blocks number from 0 - 2. This will only get the indirect block itself (the block containing the pointers to the actual blocks). Use the `file` command and start at block 12 to get to the actual blocks.

ln   link count.

mt   modification time.

md   mode.

maj   major device number.

min   minor device number.

nm   although listed here, this command actually operates on the directory name field. Once poised at the desired directory entry (using the *directory* command), this command will allow you to change or display the directory name. For example,

```
> 7:dir:nm="foo"
```

will get the 7th directory entry of the current inode and change its name to foo. Note that names cannot be made larger than the field is set up for. If an attempt is made, the string is truncated to fit and a warning message to this effect is displayed.

si   shadow inode.

sz   file size.

uid   user id.

Formatted Output There are two styles and many format types. The two styles are structured and unstructured. Structured output is used to display inodes, directories, superblocks and the like. Unstructured displays raw data. The following shows the different ways of displaying:

?

	c	display as cylinder groups
	i	display as inodes
	d	display as directories
	s	display as superblocks
	S	display as shadow inode data

/

	b	display as bytes
	c	display as characters
	o O	display as octal shorts or longs
	d D	display as decimal shorts or longs
	x X	display as hexadecimal shorts or longs

The format specifier immediately follows the '/' or '?' character. The values displayed by '/b' and all '?' formats are displayed in the current base. Also, type is appropriately updated upon completion.

Examples EXAMPLE 1 Displaying in Decimal

The following command displays 2010 in decimal (use of fsdb as a calculator for complex arithmetic):

```
> 2000+400%(20+20)=D
```

EXAMPLE 2 Displaying an i-number in Inode Format

The following command displays i-number 386 in an inode format. This now becomes the current inode:

```
> 386:ino?i
```

EXAMPLE 3 Changing the Link Count

The following command changes the link count for the current inode to 4:

```
> :ln=4
```

EXAMPLE 4   Incrementing the Link Count

The following command increments the link count by 1:

```
> :ln=+1
```

EXAMPLE 5   Displaying the Creation Time

The following command displays the creation time as a hexadecimal long:

```
> :ct=X
```

EXAMPLE 6   Displaying the Modification Time

The following command displays the modification time in time format:

```
> :mt=t
```

EXAMPLE 7   Displaying in ASCII

The following command displays in ASCII, block zero of the file associated with the current `inode`:

```
> 0:file/c
```

EXAMPLE 8   Displaying the First Block's Worth of Directorty Entries

The following command displays the first block's worth of directory entries for the root inode of this file system. It will stop prematurely if the EOF is reached:

```
> 2:ino,*?d
```

EXAMPLE 9   Displaying Changes to the Current Inode

The following command displays changes the current inode to that associated with the 5th directory entry (numbered from zero) of the current `inode`. The first logical block of the file is then displayed in ASCII:

```
> 5:dir:inode; 0:file,*/c
```

EXAMPLE 10   Displaying the Superblock

The following command displays the superblock of this file system:

```
> :sb
```

EXAMPLE 11   Displaying the Cylinder Group

The following command displays cylinder group information and summary for cylinder group 1:

```
> 1:cg?c
```

EXAMPLE 12 Changing the i-number

The following command changes the i-number for the seventh directory slot in the root directory to 3:

```
> 2:inode; 7:dir=3
```

EXAMPLE 13 Displaying as Directory Entries

The following command displays the third block of the current `inode` as directory entries:

```
> 2:db:block,*?d
```

EXAMPLE 14 Changing the Name Field

The following command changes the name field in the directory slot to *name*:

```
> 7:dir:nm="name"
```

EXAMPLE 15 Getting and Filling Elements

The following command gets fragment `3c3` and fill `20` type elements with `0x20`:

```
> 3c3:fragment,20:fill=0x20
```

EXAMPLE 16 Setting the Contents of an Address

The following command sets the contents of address `2050` to `0xffffffff`. `0xffffffff` may be truncated depending on the current `type`:

```
> 2050=0xffff
```

EXAMPLE 17 Placing ASCII

The following command places the ASCII for the string at `1c92434`:

```
> 1c92434="this is some text"
```

EXAMPLE 18 Displaying Shadow Inode Data

The following command displays all of the shadow inode data in the shadow inode associated with the root inode of this file system:

```
> 2:ino:si:ino;0:shadow,*?S
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   clri(1M), fsck_ufs(1M), dir_ufs(4), attributes(5), ufs(7FS)

Warnings   Since fsdb reads the disk raw, extreme caution is advised in determining its availability of fsdb on the system. Suggested permissions are 600 and owned by bin.

Notes   The old command line syntax for clearing i-nodes using the ufs-specific '-z i-number' option is still supported by the new debugger, though it is obsolete and will be removed in a future release. Use of this flag will result in correct operation, but an error message will be printed warning of the impending obsolesence of this option to the command. The equivalent functionality is available using the more flexible clri(1M) command.

Name fsirand – install random inode generation numbers

Synopsis fsirand [-p] *special*

Description fsirand installs random inode generation numbers on all the inodes on device *special*, and also installs a file system ID in the superblock. This helps increase the security of file systems exported by NFS.

fsirand must be used only on an unmounted file system that has been checked with fsck(1M) The only exception is that it can be used on the root file system in single-user mode, if the system is immediately re-booted afterwards.

Options -p   Print out the generation numbers for all the inodes, but do not change the generation numbers.

Usage See largefile(5) for the description of the behavior of fsirand when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also fsck(1M), attributes(5), largefile(5)

Name   fssnap – create temporary snapshots of a file system

Synopsis   fssnap [-F *FSType*] [-V] -o *special_options* /*mount/point*

fssnap -d [-F *FSType*] [-V] /*mount/point* | *dev*

fssnap -i [-F *FSType*] [-V] [-o *special_options*]
          [/*mount/point* | *dev*]

Description   The fssnap command creates a stable, read-only snapshot of a file system when given either
an active mount point or a special device containing a mounted file system, as in the first form
of the synopsis. A snapshot is a temporary image of a file system intended for backup
operations.

While the snapshot file system is stable and consistent, an application updating files when the
snapshot is created might leave these files in an internally inconsistent, truncated, or otherwise
unusable state. In such a case, the snapshot will contain these partially written or corrupted
files. It is a good idea to ensure active applications are suspended or checkpointed and their
associated files are also consistent during snapshot creation.

File access times are not updated while the snapshot is being created.

A path to the virtual device that contains this snapshot is printed to standard output when a
snapshot is created.

Options   The following options are supported:

-d   Deletes the snapshot associated with the given file system.

-F *FSType*   Specifies the file system type to be used. The FSType should either be
                      specified here or be determined by matching the block special device
                      with an entry in the /etc/vfstab table, or by consulting
                      /etc/default/fs.

-i   Displays the state of any given FSType snapshot. If a mount-point or
                      device is not given, a list of all snapshots on the system is displayed.
                      When a mount-point or device is specified, detailed information is
                      provided for the specified file system snapshot by default. The format
                      and meaning of this information is file-system dependent. See the
                      FSType-specific fssnap man page for details.

-o *special_options* See the FSType-specific man page for fssnap.

-V   Echoes the complete command line, but does not execute the
                      command.

Operands   The following operands are supported:

/*mount/point*   The directory where the file system resides.

Examples See FSType-specific man pages for examples.

Exit Status The following exit values are returned:

    0   Successful completion.

    >0   An error occurred.

Files /etc/vfstab   Specifies file system type.

    /etc/default/fs   Specifies the default local file system type.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also fssnap_ufs(1M), attributes(5)

Notes This command might not be supported for all FSTypes.

Name fssnap_ufs – create a temporary snapshot of a UFS file system

Synopsis `fssnap [-F ufs] [-V] -o` *backing-store=path,*
        `[`*specific-options*`]` */mount/point*

  `fssnap -d [-F ufs] [-V]` */mount/point | dev*

  `fssnap -i [-F ufs] [-V] [-o` *specific-options*`]` */mount/point | dev*

Description The `fssnap` command queries, creates, or deletes a temporary snapshot of a UFS file system. A snapshot is a point-in-time image of a file system that provides a stable and unchanging device interface for backups.

When creating a file system snapshot, you must specify the file system to be captured and the backing-store file. The backing-store file(s) are where the snapshot subsystem saves old file system data before it is overwritten. Beyond the first backing-store file, `fssnap` automatically creates additional backing-store files on an as-needed basis.

The number and size of the backing store files varies with the amount of activity in the file system. The destination path must have enough free space to hold the backing-store file(s). This location must be different from the file system that is being captured in a snapshot. The backing-store file(s) can reside on any type of file system, including another UFS file system or an NFS–mounted file system.

Options The following options are supported:

`-d`
  Deletes the snapshot associated with the given file system.

`-i`
  Displays the state of one or all UFS snapshots. If a mount-point or device is not specified, a list of all snapshots on the system is displayed. When a mount-point or device is specified, detailed information is provided for the specified file system snapshot by default.

  Use the `-o` options with the `-i` option to specify what snapshot information is displayed. Since this feature is provided primarily for use in scripts and on the command line, no labels are displayed for the data. Sizes are all in bytes, and the output is not internationalized or localized. The information is displayed on one line per option. Unrecognized options display a single `?` on the line. One line per option guarantees that there are the same number of lines as options specified and there is a one–to–one correspondence between an output line and an option.

  The following `-o` options display specific information for a given snapshot. See the EXAMPLES section for examples of how to use these options.

  `snapnumber`
    Display the snapshot number.

  `blockdevname`
    Display the block device path.

rawdevname

    Display the raw device path.

mountpoint

    Display the mount point of the master file system.

state

    Display the state of the snapshot device.

backing-store

    Display the location of the first backing-store file for this snapshot. If there are multiple backing-store files, subsequent files have the same name as the first file, with the suffixes .2, .3, and so forth.

backing-store-len

    Display the sum of the sizes of the backing-store files.

maxsize

    Display the maxsize value specified for the backing-store file(s).

createtime

    Display the time that the snapshot was created.

chunksize

    Display the copy-on-write granularity.

-o *specific-options*

    Without -d or -i, the default action is to create a snapshot. Specify the following options when creating a snapshot. All of these options are discretionary, except for the backing-store file, which is required.

backing-store=*path*

    Uses *path* in the creation of the backing-store file(s). *path* must not reside on the file system that is being captured in a snapshot and must not be the name of an existing file. If *path* is a directory, then a backing-store file is created within it using a name that is generated automatically. If *path* is not a directory and does not already exist, then a backing-store file with that name is created. If more than one backing-store file is required, fssnap creates subsequent files automatically. The second and subsequent files have the same name as the first file, with suffixes of .2, .3, and so forth.

    This option can be abbreviated as bf=*path* or bs=*path*.

unlink

    Unlinks the backing-store file after the snapshot is created. This option specifies that the backing-store file does not need to be removed manually when the snapshot is deleted. This might make administration more difficult since the file is not visible in the file system. If this option is not specified, the backing-store files should be removed manually after the snapshot is deleted.

chunksize=*n* [k,m,g]
> Uses *n* for the chunk size. Chunk size is the granularity of the data that is sent to the backing store.
>
> Specify chunksize in the following units: k for kilobytes, m for megabytes, or g for gigabytes. By default, chunk size is four times the block size of the file system (typically 32k).

maxsize=*n*[k,m,g]
> Does not allow the sum of the sizes of the backing-store file(s) to exceed *n*, where *n* is the unit specified. The snapshot is deleted automatically when the sum of the sizes of the backing-store file(s) exceeds maxsize.
>
> Specify maxsize in the following units: k for kilobytes, m for megabytes, or g for gigabytes.

raw
> Displays to standard output the name of the raw device instead of the block device when a snapshot is created. The block device is printed by default (when raw is not specified). This option makes it easier to embed fssnap commands in the command line for commands that require the raw device instead. Both devices are always created. This option affects only the output.

Operands   The following operands are supported:

mount-point
> The directory where the file system resides.

special
> The physical device for the file system, such as /dev/dsk/c0t0d0s7.

Examples   **EXAMPLE 1**   Creating a Snapshot of a File System

The following example creates a snapshot of a file system. The block special device created for the snapshot is /dev/fssnap/0.

```
# fssnap -F ufs -o backing-store=/var/tmp /export/home
/dev/fssnap/0
```

EXAMPLE 2   Backing Up a File System Snapshot Without Having To Unmount the File System

The following example backs up a file system snapshot without having to unmount the file system. Since ufsdump requires the path to a raw device, the raw option is used. The /export/home file system snapshot is removed in the second command.

```
# ufsdump 0uf /dev/rmt/0 `fssnap -F ufs
    -o raw,bs=/export/snap /export/home`
<output from ufsdump>
# fssnap -F ufs -d /export/home
```

EXAMPLE 3 Backing Up a File System

When backing up a file system, do not let the backing-store file(s) exceed 400 Mbytes. The second command removes the /export/home file system snapshot.

```
# ufsdump 0uf /dev/rmt/0 `fssnap -F ufs
     -o maxsize=400m,backing-store=/export/snap,raw
     /export/home`
# fssnap -F ufs -d /export/home
```

EXAMPLE 4 Performing an Incremental Dump of a Snapshot

The following example uses ufsdump to back up a snapshot of /var. Note the use of the N option to ufsdump, which writes the name of the device being dumped, rather than the name of the snapshot device, to /etc/dumpdates file. See ufsdump(1M) for details on the N flag.

```
# ufsdump lfNu /dev/rmt/0 /dev/rdsk/c0t3d0s2 `fssnap -F ufs
-o raw,bs=/export/scratch,unlink /var`
```

EXAMPLE 5 Finding Out What Snapshots Currently Exist

The following command displays the currently existing snapshots.

```
# fssnap -i
0  /src
1  /export/home
<output continues>
```

EXAMPLE 6 Mounting a File System Snapshot

The following example creates a file system snapshot. After you create a file system snapshot, mount it on /tmp/mount for temporary read-only access.

```
# fssnap -F ufs -o backing-store=/nfs/server/scratch /export/home
/dev/fssnap/1
# mkdir /tmp/mount
# mount -F ufs -o ro /dev/fssnap/1 /tmp/mount
```

EXAMPLE 7 Creating a File System Snapshot and Unlinking the Backing-store File

The following example creates a file system snapshot and unlinks the backing-store file. After creating a file system snapshot and unlinking the backing-store file, check the state of the snapshot.

```
# fssnap -o bs=/scratch,unlink /src
/dev/fssnap/0
# fssnap -i /src
Snapshot number          : 0
Block Device             : /dev/fssnap/0
Raw Device               : /dev/rfssnap/0
Mount point              : /src
Device state             : active
```

EXAMPLE 7 Creating a File System Snapshot and Unlinking the Backing-store File   *(Continued)*

```
Backing store path           : /scratch/snapshot2 <UNLINKED>
Backing store size           : 192 KB
Maximum backing store size   : Unlimited
Snapshot create time         : Sat May 06 10:55:11 2000
Copy-on-write granularity    : 32 KB
```

EXAMPLE 8 Displaying the Size and Location of the Backing-store File(s) and the Creation Time for the Snapshot

The following example displays the size of the backing-store file(s) in bytes, the location of the backing store, and the creation time for the snapshot of the /test file system.

```
# fssnap -i -o backing-store-len,backing-store,createtime /test
196608
/snapshot2
Sat May 6 10:55:11 2000
```

Note that if there are multiple backing-store files stored in /snapshot2, they will have names of the form *file* (for the first file), *file*.1, *file*.2, and so forth.

Exit Status   The following exit values are returned:

0
   Successful completion.

>0
   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

The script-readable output mode is a stable interface that can be added to, but will not change. All other interfaces are subject to change.

See Also   mlock(3C), attributes(5)

See the ntpd man page, delivered in the SUNWntpu package (not a SunOS man page).

Notes   The fssnap device files should be treated like a regular disk block or character device.

The association between a file system and the snapshot is lost when the snapshot is deleted or the system reboots. Snapshot persistence across reboots is not currently supported.

To avoid unnecessary performance impacts, perform the snapshot and system backup when the system is least active.

It is not possible to perform a snapshot of a file system if any of the following conditions are true:

- The file system is in use by system accounting

- The file system contains a local swap file

- The file system is used as backing store by an application that uses mlock(3C) to lock its pages. Typically, these are real time applications, such as ntpd (delivered in the SUNWntpu package).

These conditions result in fssnap being unable to write lock the file system prior to performing the snapshot.

Name fsstat – report file system statistics

Synopsis `fsstat [-a|f|i|n|v] [-T | u|d] {-F | {`*fstype*`|`*path*`}...}`
                       `[`*interval* `[`*count*`]]`

Description `fsstat` reports kernel file operation activity by the file system type (*fstype*) or by the path name, which is converted to a mount point. The first set of lines of output reports all activity since:

- The file system module was loaded (in the case of *fstype*)
- The file system was mounted (in the case of mount point)

Statistics are gathered at the file system independent layer at both the *fstype* and the mount point levels. However, not all file system types are represented in the gathering of statistics. (See the NOTES section of this man page.)

The output of `fsstat` is dependent on the mode (option) requested. All statistic fields are displayed using "smart numbers" which automatically scale the units in a human readable form that fits in a maximum of 5 characters. For example:

100   is displayed as 100

2048   is displayed as 2K

3000000   is displayed as 2.86M

The unit modifiers are: K (Kbyte), M (Mbyte), G (Gbyte), T (terabyte), P (petabyte), and E (exabyte).

During the execution of `fsstat`, the state of the system can change. If relevant, a state change message is included in the `fsstat` output in one of the following forms:

```
<<mount point no longer available: {path}>>
<<file system module no longer loaded: {fstype}>>
```

After the state change messages are displayed, `fsstat` continues to display the statistics as directed. If all of the *fstypes* and mount points that `fsstat` was reporting on are no longer available, then `fsstat` exits.

The user is required to specify the `-F` option (all available file system types) or a list of one or more *fstypes* and/or mount points.

The default report shows general file system activity. This display combines similar operations into general categories as follows:

new file   Number of creation operations for file system objects (for example, files, directories, symlinks, etc.)

name remov   Number of name removal operations

name chng   Number of name change operations

attr get	Number of object attribute retrieval operations
attr set	Number of object attribute change operations
lookup ops	Number of object lookup operations
rddir ops	Number of read directory operations
read ops	Number of data read operations
read bytes	Bytes transferred by data read operations
write ops	Number of data write operations
write bytes	Bytes transferred by data write operations

The entity being reported on (*fstype* or mount point) is displayed in the last column.

Options The following options are supported:

-a Report the activity for kernel attribute operations. The following statistics are reported:

getattr	Number of file attribute retrieval calls
setattr	Number of file attribute modification calls
getsec	Number of file security attribute retrieval calls
setsec	Number of file security attribute modification calls

The entity being reported on (*fstype* or mount point) is displayed in the last column.

-f Report the full activity for all kernel file operations. Each file operation is listed in the left column. The following statistics are reported for each operation:

#ops	Number of calls for this operation
bytes	Average transfer size in bytes (only applies to read, write, readdir)

The entity being reported on (*fstype* or mount point) is displayed in the first row.

-i Reports the activity for kernel I/O operations. The following statistics are reported:

read ops	Number of data read calls
read bytes	Number of bytes read
write ops	Number of data write calls
write bytes	Number of bytes written
rddir ops	Number of read directory calls

	rddir bytes	Number of bytes read by reading directories
	rwlock ops	Number of internal file system lock operations
	rwulock ops	Number of internal file system unlock operations

The entity being reported on (*fstype* or mount point) is displayed in the last column.

-n
Reports the activity for kernel naming operations. The following statistics are reported:

lookup	Number of file name retrieval calls
creat	Number of file creation calls
remov	Number of file remove calls
link	Number of link calls
renam	Number of file renaming calls
mkdir	Number of directory creation calls
rmdir	Number of directory removal calls
rddir	Number of directory read calls
symlink	Number of symlink creation calls
rdlink	Number of symlink read calls

The entity being reported on (*fstype* or mount point) is displayed in the last column.

-v
Reports the activity for calls to the virtual memory operations. The following statistics are reported.

map	Number of calls mapping a file
addmap	Number of calls setting additional mapping to a mapped file
delmap	Number of calls deleting mapping to a file
getpag	Number of calls retrieving a page of data from a file
putpag	Number of calls writing a page of data to a file
pagio	Number of calls to transfer pages in file system swap files

The entity being reported on (fstype or mount point) is displayed in the last column.

-F
Report on all available file system types.

-T *u*|*d*   Display a time stamp.

Specify *u* for a printed representation of the internal representation of time (see time(2)) Specify *d* for the standard date format. (See date(1)). The time stamp is only used when an interval is set.

Operands   The following operands are supported:

count   Display only *count* reports.

fstype   Explicitly specify the file system type(s) to be reported. The file system module must be loaded.

interval   Report once each *interval* seconds.

path   Specify the path(s) of the mount point(s) to be reported. If path is not a mount point, the mount point containing path will be determined and displayed in the output.

If no *interval* and no *count* are specified, a single report is printed and fsstat exits. If an *interval* is specified but no *count* is specified, fsstat prints reports every *interval* seconds indefinitely until the command is interrupted.

Examples   **EXAMPLE 1**   Displaying General Activity

The following example shows general activity for all file system types.

```
$ fsstat -F
 new   name    name  attr    attr lookup rddir  read read   write write
 file remov   chng   get     set    ops   ops    ops bytes   ops bytes
  313K  214K 38.5K 2.16M 56.2K  8.36M 52.8K 19.7M 39.9G 18.8M 39.1G ufs
     0     0     0 2.95K     0  3.81K   282 2.52K  466K     0     0 proc
     0     0     0     0     0      0     0     0     0     0     0 nfs
    10     8     2    86     9     98    15   413  103M 8.43K 1.05G zfs
    13    14     4    98    16    125    10 1.01K  258M 15.9K  127M lofs
 8.73K 3.29K 5.25K 55.3K    37  1.20M    44 37.9K 38.3M 47.2K 35.9M tmpfs
     0     0     0 4.93K     0      0     0 1.08K  913K     0     0 mntfs
     3     2     1   503     3    897    13   122 25.8K   128  272K nfs3
    10     8     0   615    10  10.1K    18    61 45.6K   292 2.26M nfs4
```

EXAMPLE 2   Displaying Naming Activity

The following example shows the naming activity for ufs, nfs, nfs3, nfs4, and tmpfs:

```
$ fsstat -n ufs nfs nfs3 nfs4 tmpfs
lookup creat remov  link renam mkdir rmdir rddir symlnk rdlnk
3.57M 3.10K   586     6    24   115   100 30.2K     5  330K ufs
    0     0     0     0     0     0     0     0     0     0 nfs
18.3K     3     5     0     0     0     0 1.03K     2   346 nfs3
  535     0     0     0     0     0     0    46     0     4 nfs4
```

EXAMPLE 2 Displaying Naming Activity   *(Continued)*

```
 146    24   15   0    0    4    0    4    0    0 tmpfs
```

EXAMPLE 3 Displaying Attribute Activity

The following example shows the attribute activity for the FS type ufs and the mounted file
systems "/" and "/export/home" every three seconds for every third iteration:

```
# fsstat -a ufs / /export/home 3 3
getattr setattr getsec setsec
  378K    91.9K  11.8K      0 ufs
  367K    82.3K  11.6K      0 /
 11.3K     9.6K    198      0 /export/home
 4.97K    2.27K    163      0 ufs
 3.94K    1.36K    162      0 /
 1.03K      927      1      0 /export/home
 2.30K    1.06K     73      0 ufs
 1.95K      766     71      0 /
   361      317      2      0 /export/home
 2.33K    1.06K     78      0 ufs
 1.64K      451     77      0 /
   711      631      1      0 /export/home
```

EXAMPLE 4 Displaying File Operation Statistics

The following example shows the statistics for each file operation for "/" (using the - f option):

```
$ fsstat -f /
Mountpoint: /
 operation  #ops  bytes
      open 8.54K
     close 9.8K
      read 43.6K  65.9M
     write 1.57K  2.99M
     ioctl 2.06K
     setfl     4
   getattr 40.3K
   setattr    38
    access 9.19K
    lookup  203K
    create   595
    remove    56
      link     0
    rename     9
     mkdir    19
     rmdir     0
   readdir 2.02K  2.27M
   symlink     4
```

EXAMPLE 4 Displaying File Operation Statistics   *(Continued)*

```
  readlink 8.31K
     fsync   199
  inactive 2.96K
       fid     0
    rwlock 47.2K
  rwunlock 47.2K
      seek 29.1K
       cmp 42.9K
    frlock 4.45K
     space     8
    realvp 3.25K
   getpage  104K
   putpage 2.69K
       map 13.2K
    addmap 34.4K
    delmap 33.4K
      poll   287
      dump     0
  pathconf    54
    pageio     0
   dumpctl     0
   dispose 23.8K
 getsecattr   697
 setsecattr     0
   shrlock     0
   vnevent     0
```

Environment Variables See environ(5) for descriptions of the following environment variables that affect the execution of fsstat: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, LC_TIME, and NLSPATH.

Exit Status The following exit values are returned:

0   Successful completion.

1   A fatal error occurred. A fatal error could be a failed system call or another internal error.

2   Invalid command-line options were specified.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
CSI	Enabled

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	See below.

The command-line options are Uncommitted. The human-readable output is not considered an interface.

See Also   date(1), time(2), attributes(5)

Notes   All display options (-a, -f, -i, -n, -v) are mutually exclusive. Entering more than one of these options will result in an error.

The *fstype* and *path* operands must appear after the option, but before the *interval* or *count* on the command line. For example, "fsstat -a *fstype interval*". Preference is given to *fstype* so that if a user wishes to see the statistics for a directory that has the same name as an *fstype* (for example, ufs), then the path must be specified unambiguously (for example, ./ufs). Similarly, in order to define a file with a numeric name (for example, "10") from an interval or count operand, the name should be prefixed accordingly (for example, ./10).

When an interval is used, headers repeat after more than 12 lines of statistics have been displayed and the set of lines to be displayed in the current interval have completed.

Statistics are not displayed for all pseudo-filesystems. The output displayed with the -F option shows which of the loaded filesystem types are supported.

Unbundled file systems may not be recognized by fsstat.

The command-line options are classified as Uncommitted and could change. The output is not considered to be an interface. The construction of higher level software tools depend on either the command-line options or the output of fsstat is not recommended.

Name fstyp – determine file system type

Synopsis fstyp [-a | -v] *special* [:*logical-drive*]

Description fstyp allows the user to determine the file system type of unmounted file systems using heuristic programs.

An fstyp module for each file system type to be checked is executed; each of these modules applies an appropriate heuristic to determine whether the supplied *special* file is of the type for which it checks. If it is, the program prints on standard output the usual file system identifier for that type (for example, "ufs") and exits with a return code of 0; if none of the modules succeed, the error message unknown_fstyp (no matches) is returned and the exit status is 1. If more than one module succeeds, the error message unknown_fstyp (multiple matches) is returned and the exit status is 2. Other errors are printed in the same format.

This command is unreliable and its results should not be used to make any decisions about subsequent use of a storage device or disk partition.

Options -a Output all available file system attributes. If a file system has been successfully identified, and this option is specified, the *FSType* identifier is followed by one or more "name-value" pairs, one per line, in the format:

```
name: value
```

The following conventions are recognized for the file system attributes:

- String values are put in single quotes.

- Nested "name-value" list increases the indentation of its values by four whitespaces.

- For an array of "name-value" pairs, one array entry is printed per line, with the index following the name in square brackets.

For instance, in the following example, "*top_list*" is a "name-value" list, consisting of a string array "*string_array*" and a "name-value" list array "*list_array*". The second "list_array" element is an integer array "*int_array*" containing three elements.

```
top_string: 'String'
top_list:
    string_array[0]: 'S0'
    string_array[1]: 'S1'
    list_array[0]:
        int_one: 1
        string_two: 'S2'
    list_array[1]:
        int_array[0]: 1
        int_array[1]: 2
        int_array[2]: 3
```

In addition to the *FSType*-specific attributes, the following generic attributes may be present:

	gen_clean	Allowable values are "true" or "false". If the value is "false", the file system is damaged or was not unmounted cleanly and the fsck(1M) command must be run before this file system can be mounted.
	gen_guid	Globally unique identifier. This string uniquely identifies the file system.
	gen_version	A string describing the file system version.
	gen_volume_label	Volume label, a human-readable string used to either describe or identify the file system.
-v		Produce verbose output. This is usually information about the file systems superblock and varies across different *FSTypes*. See ufs(7FS), mkfs_ufs(1M), and tunefs(1M) for details.

Usage See largefile(5) for the description of the behavior of fstyp when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also fsck(1M), mkfs_ufs(1M), tunefs(1M), attributes(5), libfstyp(3LIB), largefile(5), hsfs(7FS), ufs(7FS), pcfs(7FS)

Notes The use of heuristics implies that the result of fstyp is not guaranteed to be accurate.

This command is unreliable and its results should not be used to make any decisions about subsequent use of a storage device or disk partition.

Name fuser – identify users of files and devices

Synopsis /usr/sbin/fuser [-c | -d | -f] [-nu] [-k | -s *sig*] *files*
      [[-] [-c | -d | -f] [-nu] [-k | -s *sig*] *files*] ...

Description The fuser utility displays the process IDs of the processes that are using the *files* specified as arguments.

Each process ID is followed by a letter code. These letter codes are interpreted as follows. If the process is using the file as

c   Indicates that the process is using the file as its current directory.

m   Indicates that the process is using a file mapped with mmap(2). See mmap(2) for details.

n   Indicates that the process is holding a non-blocking mandatory lock on the file.

o   Indicates that the process is using the file as an open file.

r   Indicates that the process is using the file as its root directory.

t   Indicates that the process is using the file as its text file.

y   Indicates that the process is using the file as its controlling terminal.

For block special devices with mounted file systems, all processes using any file on that device are listed. For all types of files (text files, executables, directories, devices, and so forth), only the processes using that file are reported.

For all types of devices, fuser also displays any known kernel consumers that have the device open. Kernel consumers are displayed in one of the following formats:

[*module_name*]
[*module_name*,dev_path=*path*]
[*module_name*,dev=(*major*,*minor*)]
[*module_name*,dev=(*major*,*minor*),dev_path=*path*]

If more than one group of files are specified, the options may be respecified for each additional group of files. A lone dash cancels the options currently in force.

The process IDs are printed as a single line on the standard output, separated by spaces. All other output, including the single terminating newline, is written on standard error.

Any user can run fuser, but only the superuser can terminate another user's process.

Options The following options are supported:

-c   Reports on files that are mount points for file systems, and any files within that mounted file system.

-d   Report device usage information for all minor nodes bound to the same device node as the specified minor node. This option does not report file usage for files within a mounted file system.

-f   Prints a report for the named file, not for files within a mounted file system.

-k   Sends the SIGKILL signal to each process. Since this option spawns kills for each process, the kill messages may not show up immediately (see kill(2)). No signals will be sent to kernel file consumers.

-n   Lists only processes with non-blocking mandatory locks on a file.

-s *sig* Sends a signal to each process. The *sig* option argument specifies one of the symbolic names defined in the <signal.h> header, or a decimal integer signal number. If *sig* is a symbolic name, it is recognized in a case-independent fashion, without the SIG prefix. The -k option is equivalent to -s KILL or -s 9. No signals will be sent to kernel file consumers.

-u   Displays the user login name in parentheses following the process ID.

Examples   **EXAMPLE 1**   Reporting on the Mount Point and Files

The following example reports on the mount point and files within the mounted file system.

```
example% fuser -c /export/foo
```

EXAMPLE 2   Restricting Output when Reporting on the Mount Point and Files

The following example reports on the mount point and files within the mounted file system, but the output is restricted to processes that hold non-blocking mandatory locks.

```
example% fuser -cn /export/foo
```

EXAMPLE 3   Sending SIGTERM to Processes Holding a Non-blocking Mandatory Lock

The following command sends SIGTERM to any processes that hold a non-blocking mandatory lock on file /export/foo/my_file.

```
example% fuser -fn -s term /export/foo/my_file
```

Environment Variables   See environ(5) for descriptions of the following environment variables that affect the execution of fuser: LANG, LC_ALL LC_CTYPE, LC_MESSAGES, and NLSPATH.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Standard	See standards(5).

See Also ps(1), mount(1M), kill(2), mmap(2), signal(3C), attributes(5), environ(5), standards(5)

Notes Because fuser works with a snapshot of the system image, it may miss processes that begin using a file while fuser is running. Also, processes reported as using a file may have stopped using it while fuser was running. These factors should discourage the use of the -k option.

Name   fwflash – firmware query and update utility

Synopsis /usr/sbin/fwflash [-l [-c *device_class* | ALL]]
              | [-v] | [-h]

fwflash [-f *file1*,*file2*,*file3*,... | -r *file*]
              [-y] [-d *device_path*]

Description   The fwflash command writes a binary image file to supported flashable devices attached to a
              Solaris host. It also provides the ability to read firmware to a file if supported by the device.
              Because changing the firmware in a device can have significant impact on the stability of a
              system, only users with the privilege All are allowed to execute this command. Users
              authorized to run fwflash can be granted the "Firmware Flash Update" Rights Profile.

              The first form of the command, above, provides information about devices. It lists all devices
              currently available on the system that are supported by fwflash for firmware upgrade. You
              can filter the list operation, to display only specified classes of devices. The second form of the
              command provides the operations to read or write the firmware images to specific devices.

Options   The following options are supported:

-c *device_class*
       An optional parameter, valid only when used with the -l option. This option causes the
       command to list only devices of a specific class type. Currently supported classes are IB,
       ses, sesgen, or ALL. If -c is not specified for the -l option, the class defaults to ALL.

-d *dev_path*
       The *dev_path* is absolute path name of the device that the user wants to modify with the
       -f or -r operation. If the device cannot be found, the command fails. If the -d option is
       specified, then either -f or -r must also be specified.

-f *file1*,*file2*,*file3*,...
       Specify the path to one or more binary firmware image files you want to write to the device.
       fwflash will verify that each file is a valid firmware image for the specified device. If it is
       not, the command fails with an appropriate error message.

       If multiple firmware image files are specified, each image is verified and flashed to the
       device in the order given on the command line. If any of the specified files cannot be
       successfully flashed, then an appropriate message is displayed.

       After a new firmware image is flashed to a device, a reboot is required to correctly activate
       the new firmware.

-h
       Display the command line usage message for fwflash.

-l
       List the devices on a system available for firmware upgrade and display information
       specific to each device or device class.

For InfiniBand (IB) devices, the list operation displays the guids (Globally Unique Identifier) currently set for the HCA, as well as the current firmware revision installed. There are four separate guids on the HCA; two of them can be set with the same value.

For SCSI Enclosure Services (ses or sgen) devices, an identifying target-port worldwide name is displayed, if available.

-r *file*

Specify the path to a file to create when reading the firmware from the device. The -f and -r options are mutually exclusive.

Not all flashable devices support reading firmware images back from the device. At present, only InfiniBand (IB) devices are supported for this operation. A message will be displayed if the selected device does not support this operation.

-v

Display fwflash version information and exit.

-y

Valid only when a flash read (-r) or write (-f) operation is specified. This option causes fwflash not to prompt for confirmation during operation and operate non-interactively. Note that there is no option that allows you to forcibly flash an incompatible firmware image onto a device.

Examples EXAMPLE 1 Entering Command Without Arguments

The following command shows fwflash when the command is entered without arguments.

```
example# fwflash
Usage:
Usage:
     fwflash [-l [-c device_class | ALL]] | [-v] | [-h]
     fwflash [-f file1,file2,file3,... | -r file] [-y] -d device_path

     -l             list flashable devices in this system
     -c device_class limit search to a specific class
                    eg IB for InfiniBand, ses for SCSI Enclosures
     -v             print version number of fwflash utility
     -h             print this usage message

     -f file1,file2,file3,...
                    firmware image file list to flash
     -r file        file to dump device firmware to
     -y             answer Yes/Y/y to prompts
     -d device_path pathname of device to be flashed

     If -d device_path is specified, then one of -f <files>
     or -r <file> must also be specified
```

EXAMPLE 1 Entering Command Without Arguments   *(Continued)*

```
    If multiple firmware images are required to be flashed
    they must be listed together, separated by commas. The
    images will be flashed in the order specified.
```

EXAMPLE 2 Listing Devices Available to Flash

The following command lists the devices available to be flashed.

```
example# fwflash -l
List of available devices:
Device[0], /devices/pci@0,0/pci8086,3595@2/pci8086,32a@0,2/\
         pci15b3,5a46@c/pci15b3,5a44@0:devctl
   Class [IB]
       GUID: System Image - 0002c901081e33b3
             Node        - 0000000000003446
             Port 1      - 0002c901081e33b1
             Port 2      - 0002c901081e33b2
       Firmware revision: 3.3.0002
       No hardware information available for this device

Device[1], /devices/pci@0,0/pci8086,3597@4/pci15b3,6278@0:devctl
   Class [IB]
       GUID: System Image - 0002c9010a99e3b3
             Node        - 0002c9010a99e3b0
             Port 1      - 0002c9010a99e3b1
             Port 2      - 0002c9010a99e3b2
       Firmware revision: 4.8.00c8
       Product           : MTLP25208-CF256T (Lion cub)
       PSID              : MT_00B0000001
```

Alternatively, for a SAS Expander presented as a SCSI Enclosure Services device , we might see output such as this:

```
example# fwflash -l
List of available devices:
Device[0] /devices/pci@0/pci@0/pci@2/scsi@0/ses@3,0:ses
  Class [sgen]
       Target port WWN  : 500605b00002453d
       Vendor           : SUN
       Product          : 16Disk Backplane
       Firmware revision: 5021
```

EXAMPLE 3 Flash Upgrading an IB HCA Device

The following command flash upgrades an IB HCA device.

```
example# fwflash -f ./version.3.2.0000 \
   -d /devices/pci@0,0/pci8086,3597@4/pci15b3,6278@0:devctl
About to update firmware on:
```

EXAMPLE 3 Flash Upgrading an IB HCA Device   *(Continued)*

```
  /devices/pci@0,0/pci8086,3597@4/pci15b3,6278@0:devctl
Continue (Y/N): Y

Updating . . . . . . . . . . . .
Done.  New image will be active after the system is rebooted.
```

Note that you are prompted before the upgrading proceeds and that it is mandatory that you reboot your host to activate the new firmware image.

The following command adds the -y option to the command.

```
example# fwflash -y -f ./version.3.2.0000 \
  -d /devices/pci@0,0/pci8086,3597@4/pci15b3,6278@0:devctl
About to update firmware on:
  /devices/pci@0,0/pci8086,3597@4/pci15b3,6278@0:devctl

Updating . . . . . . . . . . . .
Done.  New image will be active after the system is rebooted.
```

EXAMPLE 4 Reading Device Firmware to File

The command shown below reads the device firmware to a file. The command uses the -y option so that read occurs without prompting.

```
example# fwflash -y -r /firmware.bin \
  -d /devices/pci@1d,700000/pci@1/pci15b3,5a44@0:devctl
About to read firmware on:
        /devices/pci@1d,700000/pci@1/pci15b3,5a44@0:devctl
to filename: /firmware.bin

Reading . . .
Done.
```

EXAMPLE 5 When No Flashable Devices Are Found

The command output shown below informs the user that there are no supported flashable devices found in the system:

```
example# fwflash -l
fwflash: No flashable devices attached with the ses driver in this system
fwflash: No flashable devices attached with the sgen driver in this system
fwflash: No flashable devices attached with the tavor driver in this system
fwflash: No flashable devices in this system
```

Each plugin found in /usr/lib/fwflash/identify is loaded in turn, and walks the system device tree, determining whether any currently-attached devices can be flashed. For the list of device types and drivers that are currently supported, please see the NOTES section below.

Return Values The fwflash command returns the following values:

0
  Success

1
  Failure

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/firmware-utilities
Interface Stability	Committed

See Also attributes(5), hermon(7D), ses(7D), tavor(7D)

The InfiniBand Trade Association website, http://www.infinibandta.org

The SCSI Storage Interfaces committee website, http://www.t10.org

SCSI Primary Commands-4, SPC4

SCSI Enclosure Services-2, SES2

Serial Attached SCSI-2, SAS2

Notes The fwflash command supports:

- InfiniBand Host Channel Adapters (IB HCAs) containing either the AMD or the Intel parallel flash parts.
- SCSI Enclosure Services devices such as SAS Expanders, attached with ses(7D) drivers.

Name fwtmp, wtmpfix – manipulate connect accounting records

Synopsis /usr/lib/acct/fwtmp [-ic]

/usr/lib/acct/wtmpfix [*file*]...

Description fwtmp reads from the standard input and writes to the standard output, converting binary records of the type found in /var/adm/wtmpx to formatted ASCII records. The ASCII version is useful when it is necessary to edit bad records.

wtmpfix examines the standard input or named files in utmpx format, corrects the time/date stamps to make the entries consistent, and writes to the standard output. A hyphen (−) can be used in place of *file* to indicate the standard input. If time/date corrections are not performed, acctcon(1M) will fault when it encounters certain date-change records.

Each time the date is set, a pair of date change records are written to /var/adm/wtmpx. The first record is the old date denoted by the string "old time" placed in the line field and the flag OLD_TIME placed in the type field of the utmpx structure. The second record specifies the new date and is denoted by the string new time placed in the line field and the flag NEW_TIME placed in the type field. wtmpfix uses these records to synchronize all time stamps in the file.

In addition to correcting time/date stamps, wtmpfix will check the validity of the name field to ensure that it consists solely of alphanumeric characters or spaces. If it encounters a name that is considered invalid, it will change the login name to INVALID and write a diagnostic to the standard error. In this way, wtmpfix reduces the chance that acctcon will fail when processing connect accounting records.

Options -ic   Denotes that input is in ASCII form, and output is to be written in binary form.

Files /var/adm/wtmpx   history of user access and administration information

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/accounting/legacy-accounting

Oracle Solaris Administration: Common Tasks

Name getdevpolicy – inspect the system's device policy

Synopsis /usr/sbin/getdevpolicy [*device*...]

Description Without arguments, getdevpolicy outputs the device policy in effect to standard output.

With arguments, each argument is treated as a pathname to a device and the device policy in effect for that specific device is printed preceded by the supplied pathname.

Usage The device policy adds access restrictions over and above the file permissions.

Exit Status The following exit values are returned:

0   Successful completion.

non-zero   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below

The invocation is evolving. The output is unstable.

See Also add_drv(1M), rem_drv(1M), update_drv(1M), attributes(5), privileges(5), devfs(7FS)

Name getent – get entries from administrative database

Synopsis getent *database* [*key*]...

Description getent gets a list of entries from the administrative database specified by *database*. The information generally comes from one or more of the sources that are specified for the *database* in /etc/nsswitch.conf.

database is the name of the database to be examined. This can be passwd, group, hosts, ipnodes, services, protocols, auth_attr or exec_attr. For each of these databases, getent uses the appropriate library routines described in getpwnam(3C), getgrnam(3C), gethostbyaddr(3NSL), gethostbyname(3NSL), getipnodebyaddr(3SOCKET), getipnodebyname(3SOCKET), getservbyname(3SOCKET), getprotobyname(3SOCKET), getprofattr(3C), getauthattr(3C), and getexecattr(3C), respectively.

Each *key* must be in a format appropriate for searching on the respective database. For example, it can be a *username* or *numeric-uid* for passwd; *hostname* or *IP address* for hosts; or *service*, *service/protocol*, *port*, or *port/proto* for services.

getent prints out the database entries that match each of the supplied keys, one per line, in the format of the matching administrative file: passwd(4), group(4), project(4), networks(4), netmasks(4), user_attr(4), prof_attr(4), auth_attr(4), or exec_attr(4). The key for exec_attr(4) is a profile name. If no key is given, all entries returned by the corresponding enumeration library routine, for example, getpwent() or gethostent(), are printed. Enumeration is not supported on ipnodes, ethers, and netmasks.

Key Interpretation for passwd and group Databases
When getent is invoked with database set to passwd, each key value is processed as follows:

- If the key value consists only of numeric characters, getent assumes that the key value is a numeric user ID and searches the user database for a matching user ID.

- If the user ID is not found in the user database or if the key value contains any non-numeric characters, getent assumes the key value is a user name and searches the user database for a matching user name.

Similarly, when getent is invoked with database set to group, each key value is processed as follows:

- If the key value consists only of numeric characters, getent assumes that the key value is a numeric group ID and searches the group database for a matching group ID.

- If the group ID is not found in the group database or if the key value contains any non-numeric characters, getent assumes the key value is a group name and searches the group database for a matching group name.

When getent is invoked with database set to user_attr(4), each key value is processed as follows:

- If the key value consists only of numeric characters, getent assumes that the key value is a numeric user ID and searches the user database for a matching user ID.

- If the key value contains any non-numeric characters, getent assumes the key value is a user name and searches the user database for a matching user name.

Exit Status The following exit values are returned:

0   Successful completion.

1   Command syntax was incorrect, an invalid option was used, or an internal error occurred.

2   At least one of the specified entry names was not found in the database.

3   There is no support for enumeration on this database.

Name gettable – get DoD Internet format host table from a host

Synopsis /usr/sbin/gettable *host*

Description gettable is a simple program used to obtain the DoD Internet host table from a "hostname" server. The specified *host* is queried for the table. The table is placed in the file hosts.txt.

gettable operates by opening a TCP connection to the port indicated in the service specification for "hostname". A request is then made for all names and the resultant information is placed in the output file.

gettable is best used in conjunction with the htable(1M) program which converts the DoD Internet host table format to that used by the network library lookup routines.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

See Also htable(1M), attributes(5) Harrenstien, Ken, Mary Stahl, and Elizabeth Feinler, HOSTNAME *Server*, RFC 953, Network Information Center, SRI International, Menlo Park, California, October 1985.

Notes Should allow requests for only part of the database.

Name getty – set terminal type, modes, speed, and line discipline

Synopsis /usr/lib/saf/ttymon [-h] [-t *timeout*] *line*
            [*speed* [*type* [*linedisc*]]]

/usr/lib/saf/ttymon -c *file*

Description getty sets terminal type, modes, speed, and line discipline. getty is a symbolic link to /usr/lib/saf/ttymon. It is included for compatibility with previous releases for the few applications that still call getty directly.

getty can only be executed by the super-user, (a process with the user ID root). Initially getty prints the login prompt, waits for the user's login name, and then invokes the login command. getty attempts to adapt the system to the terminal speed by using the options and arguments specified on the command line.

Without optional arguments, getty specifies the following: The *speed* of the interface is set to 300 baud, either parity is allowed, NEWLINE characters are converted to carriage return-line feed, and tab expansion is performed on the standard output. getty types the login prompt before reading the user's name a character at a time. If a null character (or framing error) is received, it is assumed to be the result of the user pressing the BREAK key. This will cause getty to attempt the next *speed* in the series. The series that getty tries is determined by what it finds in /etc/ttydefs .

Options The following options are supported:

-h   If the -h flag is not set, a hangup will be forced by setting the speed to zero before setting the speed to default or a specified speed.

-t *timeout*   Specifies that getty should exit if the open on the line succeeds and no one types anything in *timeout* seconds.

-c *file*   The -c option is no longer supported. Instead use /usr/sbin/sttydefs -l to list the contents of the /etc/ttydefs file and perform a validity check on the file.

Operands The following operands are supported:

line   The name of a TTY line in /dev to which getty is to attach itself. getty uses this string as the name of a file in the /dev directory to open for reading and writing.

speed   The *speed* argument is a label to a speed and TTY definition in the file /etc/ttydefs. This definition tells getty at what speed to run initially, what the initial TTY settings are, and what speed to try next, (should the user press the BREAK key to indicate that the speed is inappropriate). The default *speed* is 300 baud.

type and *linedisc*   These options are obsolete and will be ignored.

Files   /etc/ttydefs

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   ct(1C), login(1), sttydefs(1M), ttymon(1M), ioctl(2), attributes(5), tty(7D)

Name gkadmin – Kerberos principals and policies administration GUI

Synopsis /usr/sbin/gkadmin

Description gkadmin is an interactive graphical user interface (GUI) that enables you to maintain Kerberos principals and policies. gkadmin provides much the same functionality as the kadmin(1M) command.

gkadmin does not support the management of keytabs. You must use kadmin for keytabs management. gkadmin uses Kerberos authentication and an encrypted RPC to operate securely from anywhere on the network.

When gkadmin is invoked, the login window is populated with default values. For the principal name, gkadmin determines your user name from the USER environment variable. It appends /admin to the name (*username*/admin) to create a default user instance in the same manner as kadmin. It also selects appropriate defaults for realm and master KDC (*admin_server*) from the /etc/krb5/krb5.conf file.

You can change these defaults on the login window. When you enter your password, a session is started with kadmind. Operations performed are subject to permissions that are granted or denied to the chosen user instance by the Kerberos ACL file. See kadm5.acl(4).

After the session is started, a tabbed folder is displayed that contains a principal list and a policy list. The functionality is mainly the same as kadmin, with addition, deletion, and modification of principal and policy data available.

gkadmin also includes an interface to specify principal key encryption types when modifying or creating principal records. The default set of encryption types is used if they are not selected through this interface. The default set of encryption types can be found in krb5.conf(4) under the default_tkt_enctypes section.

In addition, gkadmin provides the following features:

- New principal or policy records can be added either from default values or from the settings of an existing principal.

- A comment field is available for principals.

- Default values are saved in $HOME/.gkadmin.

- A logout option permits you to log back in as another user instance without exiting the tool.

- Principal and policy lists and attributes can be printed or saved to a file.

- Online context-sensitive help and general help is available in the Help menu.

Files /etc/krb5/krb5.conf   Kerberos configuration information on a Kerberos client. Used to search for default realm and master KDC (admin_server), including a port number for the master KDC.

$HOME/.gkadmin   Default parameters used to initialize new principals created during the session.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/security/kerberos-5
Interface Stability	Committed

See Also   kpasswd(1), kadmin(1M), kadmind(1M), kadmin.local(1M), kdb5_util(1M), kadm5.acl(4), kdc.conf(4), krb5.conf(4), attributes(5), kerberos(5)

Diagnostics   The gkadmin interface is currently incompatible with the MIT kadmind daemon interface, so you cannot use this interface to administer an MIT-based Kerberos database. However, clients running the Solaris implementation of Kerberos can still use an MIT-based KDC.

Name groupadd – add (create) a new group definition on the system

Synopsis `/usr/sbin/groupadd [-g` *gid* `[-o]] [-S` *repository*`]`
`[-U` *user1*`[,`*user2..*`] ]` *group*

Description The groupadd command creates a new group definition on the system by adding the
appropriate entry to the group database in the files and ldap repositories.

An administrator must be granted the User Management rights profile or have
solaris.group.manage authorization to be able to add a group. Once the group is
successfully added, the administrator is granted the authorization to modify and delete the
group. The format of the authorization is solaris.group.assign/*groupname*, and can be
managed by means of usermod(1M).

Options The following options are supported:

-g *gid*

Assigns the group id *gid* for the new group. This group id must be a non-negative decimal
integer below MAXUID as defined in /usr/include/sys/param.h. The group ID defaults to
the next available (unique) number above the highest number currently assigned. For
example, if groups 100, 105, and 200 are assigned as groups, the next default group number
is 201. (Group IDs from 0–99 are reserved by SunOS for future applications.)

-o

Allows the *gid* to be duplicated (non-unique). An administrator must have
solaris.group.assign authorization to use this option.

-S *repository*

The valid repositories are files and ldap. The repository specifies which name service will
be updated. When *repository* is not specified, the files repository is used. When the
repository is files, the user name and other items can be present in other name service
repositories and can be assigned to a group in the files repository. When the repository is
ldap, all the assignable attributes must be present in the ldap repository.

-U *user1*[,*user2*]
Adds a list of users *user1*, *user2* to the group.

Operands The following operands are supported:

group   A string consisting of characters from the set of lower case alphabetic characters
and numeric characters. A warning message is written if the string exceeds
MAXGLEN-1, which is usually eight characters. The *group* field must contain at least
one character; it accepts lower case or numeric characters or a combination of both,
and must not contain a colon (:) or NEWLINE.

Exit Status The following exit values are returned:

0   Successful completion.

2   Invalid command syntax. A usage message for the groupadd command is displayed.

3   An invalid argument was provided to an option.

4   The *gid* is not unique (when -o option is not used).

9   The *group* is not unique.

10   The group database cannot be updated.

Files
- /etc/group
- /usr/include/userdefs.h

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also users(1B), groupdel(1M), groupmod(1M), grpck(1M), logins(1M), pwck(1M), useradd(1M), userdel(1M), usermod(1M), group(4), attributes(5)

Notes groupadd adds a group definition to the system. If a network name service is being used to supplement the local /etc/group file with additional entries, groupadd verifies the uniqueness of a specified group name and group ID against the external name service and uses the entries in the files repository.

If the number of characters in a group entry exceeds 2047, group maintenance commands, such as groupdel(1M) and groupmod(1M), fail.

Name   groupdel – delete a group definition from the system

Synopsis   `/usr/sbin/groupdel [-S` *repository*`]` *group*

Description   The `groupdel` utility deletes a group definition from the system. It deletes the appropriate entry from the `/etc/group` file.

In addition to `solaris.group.manage` authorization, an administrator must have either `solaris.group.assign` or a matching authorization of the form `solaris.group.assign/`*groupname* to delete a group. The authorization `solaris.group.assign/`*groupname* is automatically assigned to the administrator who created the group.

Options   `groupdel` supports the following option.

`-S` *repository*
  The valid repositories are `files` and `ldap`. The repository specifies which name service will be updated. When *repository* is not specified, `groupdel` consults `nsswitch.conf(4)`.

Operands   *group*   An existing group name to be deleted.

Exit Status   The following exit values are returned:

0   Success.

2   Invalid command syntax. A usage message for the `groupdel` command is displayed.

6   *group* does not exist.

10   Cannot update the `/etc/group` file.

Files   `/etc/group`   system file containing group definitions

Attributes   See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   `users(1B)`, `groupadd(1M)`, `groupmod(1M)`, `logins(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `nsswitch.conf(4)`, `attributes(5)`

Notes   The `groupdel` utility deletes a group definition that is in the group database in the repository.

`groupdel` fails if a group entry (a single line in `/etc/group`) exceeds 2047 characters.

Name groupmod – modify a group definition on the system

Synopsis /usr/sbin/groupmod [-S *repository*] [-g *gid* [-o]] [-n *name*]
                [-U [+|-]*user1*[,*user2*]...] *group*

Description The groupmod command modifies the definition of the specified group by modifying the appropriate entry in the group database in the repository.

An administrator can modify any group for which it has a matching authorization of the form solaris.group.assign/*groupname*. This authorization is automatically assigned to the administrator who created the group. An administrator must have solaris.group.assign authorization to modify all other groups.

Options The following options are supported:

-g *gid*
Specify the new group ID for the group. This group ID must be a non-negative decimal integer less than MAXUID, as defined in <param.h>. The group ID defaults to the next available (unique) number above 99. (Group IDs from 0-99 are reserved by SunOS for future applications.)

-n *name*
Specify the new name for the group. The *name* argument is a string of no more than eight bytes consisting of characters from the set of lower case alphabetic characters and numeric characters. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept group fields that do not meet these requirements. The *name* argument must contain at least one character and must not include a colon (:) or NEWLINE (\n).

-o
Allow the *gid* to be duplicated (non-unique). An administrator must have solaris.group.assign authorization to use this option.

-S *repository*
The valid repositories are files and ldap. The repository specifies which name service will be updated. When *repository* is not specified, groupmod consults nsswitch.conf(4). When the repository is files, the user name and other items can be present in other name service repositories and can be assigned to a group in the files repository. When the repository is ldap, all the assignable attributes must be present in the ldap repository.

-U [+|-]*user1*[,*user2*]
Updates the list of users for the group as follows:

- A prefix + before the list adds that list to existing users list.

- A prefix - before the list removes each user in the list from the existing users list.

- With no prefix before the list, replaces the existing users list with the new list of users specified.

Operands The following operands are supported:

group   An existing group name to be modified.

Exit Status The groupmod utility exits with one of the following values:

0   Success.

2   Invalid command syntax. A usage message for the groupmod command is displayed.

3   An invalid argument was provided to an option.

4   *gid* is not unique (when the -o option is not used).

6   *group* does not exist.

9   *name* already exists as a group name.

10   Cannot update the /etc/group file.

Files /etc/group   group file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also users(1B), groupadd(1M), groupdel(1M), logins(1M), useradd(1M), userdel(1M), usermod(1M), group(4), nsswitch.conf(4), attributes(5)

Notes The groupmod utility only modifies group definitions in the group database in the repository. If a network name service such as NIS is being used to supplement the local /etc/group file with additional entries, groupmod cannot change information supplied by the network name service. groupmod verifies the uniqueness of group name and group ID against the external name service and uses the entries in the files repository.

groupmod fails if a group entry (a single line in /etc/group) exceeds 2047 characters.

Name   growfs – non-destructively expand a UFS file system

Synopsis   /usr/sbin/growfs [-M *mount-point*] [*newfs-options*]
        [*raw-device*]

Description   growfs non-destructively expands a mounted or unmounted UNIX file system (UFS) to the
size of the file system's slice(s).

Typically, disk space is expanded by first adding a slice to a metadevice, then running the
growfs command. When adding space to a mirror, you expand each submirror before
expanding the file system.

growfs will "write-lock" (see lockfs(1M)) a mounted file system when expanding. The length
of time the file system is write-locked can be shortened by expanding the file system in stages.
For instance, to expand a 1 Gbyte file system to 2 Gbytes, the file system can be grown in 16
Mbyte stages using the -s option to specify the total size of the new file system at each stage.
The argument for -s is the number of sectors, and must be a multiple of the cylinder size.
Note: The file system cannot be grown if a cylinder size of less than 2 is specified. Refer to the
newfs(1M) man page for information on the options available when growing a file system.

growfs displays the same information as mkfs during the expansion of the file system.

If growfs is aborted, recover any lost free space by unmounting the file system and running
the fsck command, or run the growfs command again.

Note: If growfs is aborted and the file system is used before fsck is run on it, UFS metadata
might be left in an incomplete state, with the result that the file system would be corrupted. In
such a circumstance, you would have to restore the file system from backups.

Options   Root privileges are required for all of the following options.

-M *mount-point*   The file system to be expanded is mounted on *mount-point*. File system
                     locking (lockfs) will be used.

newfs-options   The options are documented in the newfs man page.

raw-device   Specifies the name of a raw metadevice or raw special device, residing in
                     /dev/md/rdsk, or /dev/rdsk, respectively, including the disk slice, where
                     you want the file system to be grown.

Examples   EXAMPLE 1   Expanding nonmetadevice slice for /export file system

The following example expands a nonmetadevice slice for the /export file system. In this
example, the existing slice, /dev/dsk/c1t0d0s3, is converted to a metadevice so additional
slices can be concatenated.

```
# metainit -f d8 2 1 c1t0d0s3 1 c2t0d0s3
# umount /export
```

EXAMPLE 2 Associate /export with new metadevice

Edit the /etc/vfstab file to change the entry for /export to the newly defined metadevice, d8.

```
# mount /export
# growfs -M /export /dev/md/rdsk/d8
```

The first example starts by running the metainit command with the -f option to force the creation of a new concatenated metadevice d8, which consists of the existing slice /dev/dsk/c1t0d0s3 and a new slice /dev/dsk/c2t0d0s3. Next, the file system on /export must be unmounted. The /etc/vfstab file is edited to change the entry for /export to the newly defined metadevice name, rather than the slice name. After the file system is remounted, the growfs command is run to expand the file system. The file system will span the entire metadevice when growfs completes. The -M option enables the growfs command to expand a mounted file system. During the expansion, write access for /export is suspended until growfs unlocks the file system. Read access is not affected, though access times are not kept when the lock is in effect.

EXAMPLE 3 Dynamic Expansion of /export file system

The following example picks up from the previous one. Here, the /export file system mounted on metadevice d8 is dynamically expanded.

```
# metattach d8 c0t1d0s2
# growfs -M /export /dev/md/rdsk/d8
```

This example begins by using the metattach command to dynamically concatenate a new slice, /dev/dsk/c0t1d0s2, to the end of an existing metadevice, d8. Next, the growfs command specifies that the mount-point is /export and that it is to be expanded onto the raw metadevice /dev/md/rdsk/d8. The file system will span the entire metadevice when growfs completes. During the expansion, write access for /export is suspended until growfs unlocks the file system. Read access is not affected, though access times are not kept when the lock is in effect.

EXAMPLE 4 Expanding mounted file system to existing mirror

The following example expands a mounted file system /files, to an existing mirror, d80, which contains two submirrors, d9 and d10.

```
# metattach d9 c0t2d0s5
# metattach d10 c0t3d0s5
# growfs -M /files /dev/md/rdsk/d80
```

In this example, the metattach command dynamically concatenates the new slices to each submirror. The metattach command must be run for each submirror. The mirror will automatically grow when the last submirror is dynamically concatenated. The mirror will grow to the size of the smallest submirror. The growfs command then expands the file system. The growfs command specifies that the mount-point is /files and that it is to be expanded

EXAMPLE 4 Expanding mounted file system to existing mirror   *(Continued)*

onto the raw metadevice /dev/md/rdsk/d80. The file system will span the entire mirror when the growfs command completes. During the expansion, write access for the file system is suspended until growfs unlocks the file system. Read access is not affected, though access times are not kept when the lock is in effect.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm

See Also fsck(1M), lockfs(1M), mkfs(1M), metattach(1M), newfs(1M), attributes(5)

Solaris Volume Manager Administration Guide

Limitations Only UFS file systems (either mounted or unmounted) can be expanded using the growfs command. Once a file system is expanded, it cannot be decreased in size. The following conditions prevent you from expanding file systems: When acct is activated and the accounting file is on the target device. When C2 security is activated and the logging file is on the target file system. When there is a local swap file in the target file system. When the file system is root (/), /usr, or swap.

Name gsscred – add, remove, and list gsscred table entries

Synopsis gsscred [-n *user* [-o *oid*] [-u *uid*]] [-c *comment*] -m *mech* -a

gsscred [-n *user* [-o *oid*]] [-u *uid*] [-m *mech*] -r

gsscred [-n *user* [-o *oid*]] [-u *uid*] [-m *mech*] -l

Description The gsscred utility is used to create and maintain a mapping between a security principal name and a local UNIX *uid*. The format of the user name is assumed to be GSS_C_NT_USER_NAME. You can use the -o option to specify the object identifier of the *name* type. The OID must be specified in dot-separated notation, for example: 1.2.3.45464.3.1

The gsscred table is used on server machines to lookup the *uid* of incoming clients connected using RPCSEC_GSS.

When adding users, if no *user* name is specified, an entry is created in the table for each user from the passwd table. If no *comment* is specified, the gsscred utility inserts a comment that specifies the user name as an ASCII string and the GSS-APIsecurity mechanism that applies to it. The security mechanism will be in string representation as defined in the /etc/gss/mech file.

The parameters are interpreted the same way by the gsscred utility to delete users as they are to create users. At least one of the following options must be specified: -n, -u, or -m. If no security mechanism is specified, then all entries will be deleted for the user identified by either the *uid* or *user* name. If only the security mechanism is specified, then all *user* entries for that security mechanism will be deleted.

Again, the parameters are interpreted the same way by the gsscred utility to search for users as they are to create users. If no options are specified, then the entire table is returned. If the *user* name or *uid* is specified, then all entries for that *user* are returned. If a security mechanism is specified, then all *user* entries for that security mechanism are returned.

Options

-a	Add a table entry.
-c *comment*	Insert comment about this table entry.
-l	Search table for entry.
-m *mech*	Specify the mechanism for which this name is to be translated.
-n *user*	Specify the optional principal name.
-o *oid*	Specify the OID indicating the name type of the user.
-r	Remove the entry from the table.
-u *uid*	Specify the *uid* for the *user* if the *user* is not local.

Examples **EXAMPLE 1** Creating a gsscred Table for the Kerberos v5 Security Mechanism

The following shows how to create a gsscred table for the kerberos v5 security mechanism. gsscred obtains *user* names and *uid*'s from the passwd table to populate the table.

```
example% gsscred -m kerberos_v5 -a
```

EXAMPLE 2 Adding an Entry for root/host1 for the Kerberos v5 Security Mechanism

The following shows how to add an entry for root/host1 with a specified *uid* of 0 for the kerberos v5 security mechanism.

```
example% gsscred -m kerberos_v5 -n root/host1 -u 0 -a
```

EXAMPLE 3 Listing All User Mappings for the Kerberos v5 Security Mechanism

The following lists all user mappings for the kerberos v5 security mechanism.

```
example% gsscred -m kerberos_v5 -l
```

EXAMPLE 4 Listing All Mappings for All Security Mechanism for a Specified User

The following lists all mappings for all security mechanisms for the user bsimpson.

```
example% gsscred -n bsimpson -l
```

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library/security/gss
Interface Stability	Committed

See Also gssd(1M), gsscred.conf(4), attributes(5)

Notes Some GSS mechanisms, such as kerberos_v5, provide their own authenticated-name-to-local-name (uid) mapping and thus do not usually have to be mapped using gsscred. See gsscred.conf(4) for more information.

Name gssd – generates and validates GSS-API tokens for kernel RPC

Synopsis /usr/lib/gss/gssd

Description gssd is the user mode daemon that operates between the kernel rpc and the Generic Security Service Application Program Interface (GSS-API) to generate and validate GSS-API security tokens. In addition, gssd maps the GSS-API principal names to the local user and group ids. By default, all groups that the requested user belongs to will be included in the grouplist credential. gssd is invoked by the Internet daemon inetd(1M) the first time that the kernel RPC requests GSS-API services.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/kernel/security/gss
Interface Stability	Committed

See Also kill(1), pkill(1), svcs(1), inetadm(1M), inetd(1M), gsscred(1M), svcadm(1M), gsscred.conf(4), resolv.conf(4), attributes(5), smf(5)

RFC 2078

Notes The following signal has the specified effect when sent to the server process using the kill(1) command:

SIGHUP   gssd rereads the gsscred.conf(4) options.

When one of the mechanisms being used is Kerberos, then the gssd process must be restarted after adding or changing the resolv.conf(4) file.

The gssd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/gss:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name   hald – daemon that supports hardware abstraction layer

Synopsis   /usr/lib/hal/hald [--daemon={yes | no}]] [--help] [--use-syslog]
    [--verbose={yes | no}] [--version]

Description   The hald daemon supports the recognition of hardware changes for devices that conform to
    the Hardware Abstraction Layer (HAL) specification.

    The enabling and disabling of hald can be performed through the service management facility
    (SMF) (see smf(5)). hald is managed using the fault management resource identifier (FMRI)
    svc:/system/hal.

Options   The following options are supported:

    --daemon=yes|no   Run as a daemon.

    --help   Display usage information and exit.

    --use-syslog   Display debug messages to syslog instead of stderr. Use this option
                         to record debug messages if HAL runs as daemon.

    --verbose=yes|no   Display debug information.

    --version   Display version information and exit.

Files   /usr/lib/hal   HAL-related files

    /etc/hal/fdi   Device information files

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/hal
Interface Stability	Volatile

See Also   svccfg(1M), attributes(5), hal(5)

Name hal-device – manage HAL devices

Synopsis hal-device [-h] [--a *udi* | --r *udi*]

Description The Hardware Abstraction Layer (HAL) provides a view of the various hardware attached to a system. The hal-device command enables you to manage devices that conform to the HAL standard. Specifically, hal-device lets you add or remove a device to or from the HAL global device list. Device properties are read from stdin in lshal(1M) syntax.

Options The following options are supported:

-a, --add *udi*   Add device specified by Universal Device Identifier *udi* to HAL's global device list.

-h   Display usage information.

-r, --remove *udi* Remove device specified by Universal Device Identifier *udi* from HAL's global device list.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/hal
Interface Stability	Volatile

See Also hald(1M), attributes(5), hal(5)

Name hal-fdi-validate – validate HAL device information files

Synopsis hal-fdi-validate [-f *dtd*] *file* [*file*]...

Description The hal-fdi-validate command validates one or more device information files. See fdi(4). The standard DTD file will be used unless the -f option is used to specify a different file.

Options The following option is supported:

-f *dtd*   Specify path to a DTD file.

Operands The hal-fdi-validate command accepts the following operand(s):

file [*file*...]   One or more DTD files to be validated.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/hal
Interface Stability	Volatile

See Also hald(1M), fdi(4), attributes(5), hal(5)

Name hal-find, hal-find-by-capability, hal-find-by-property – search HAL global device list

Synopsis `hal-find-by-capability --capability` *capability* `[--help]`
`[--verbose] [--version]`

`hal-find-by-property  --key` *key* `--string` *value* `[--help]`
`[--verbose] [--version]`

Description The `hal-find` commands, `hal-find-by-capability` and `hal-find-by-property`, search the
Hardware Abstraction Layer (HAL) device list by specified criteria and displays results on the
standard output. `hal-find-by-capability` searches by capability, such as `volume` or `block`.
`hal-find-by-property` searches by property, such as `block.is_volume` or
`volume.disc.has_audio`.

Options The following options are supported:

`--capability` *capability*	HAL device capability to search for.
`--help`	Display list of options.
`--key` *key*	The *key* to the property that is the basis of the search.
`--string` *value*	The string *value* associated with the property that is the basis of the search.
`--verbose`	Verbose mode.
`--version`	Display version and exit.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/hal
Interface Stability	Volatile

See Also `hald(1M)`, `attributes(5)`, `hal(5)`

Name hal-get-property, hal-set-property – get and set HAL device properties

Synopsis hal-get-property --udi *udi* --key *key* [--help] [--verbose]
[--version]

hal-set-property --udi *udi* --key *key* {--int *value* | --uint64 *value*
| --string *value* | --bool *value* | --strlist-pre *value*
| --strlist-post *value* | --strlist-rem *value* | --double *value*
| --remove *value*} [--help] [--version]

Description The Hardware Abstraction Layer (HAL) provides a view of the various hardware attached to a system. This view is updated dynamically as hardware configuration changes by means of hotplug or other mechanisms. HAL represents a piece of hardware as a device object. A device object is identified by a unique identifer and carries a set of key/value pairs, referred to as device properties. Some properties are derived from the actual hardware, some are merged from device information files (.fdi files), and some are related to the actual device configuration.

The hal-get-property and hal-set-property commands allow you to get and set properties of hardware that conforms to HAL specifications.

Options The following options are supported:

--udi *udi*
    Unique device ID.

--key *key*
    Key of the property to set.

--int
    Set value to an integer. Accepts decimal or hexadecimal value prefixed with 0x or x.

--uint64
    Set value to an integer. Accepts decimal or hexadecimal value prefixed with 0x or x.

--string *value*
    Set value to a string.

--double *value*
    Set value to a floating point number.

--boolean *value*
    Set value to a boolean, that is, true or false

--strlist-pre *value*
    Prepend a string to a list.

--strlist-post *value*
    Append a string to a list.

--strlist-rem *value*
    Remove a string from a list.

--remove *value*
    Indicates that the property should be removed.

--version
    Display version and exit.

--help
    Display list of options and exit

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/hal
Interface Stability	Volatile

See Also hald(1M), attributes(5), hal(5)

Name halt, poweroff – stop the processor

Synopsis /usr/sbin/halt [-dlnqy]

/usr/sbin/poweroff [-dlnqy]

Description The halt and poweroff utilities write any pending information to the disks and then stop the processor. The poweroff utility has the machine remove power, if possible.

The halt and poweroff utilities normally log the system shutdown to the system log daemon, syslogd(1M), and place a shutdown record in the login accounting file /var/adm/wtmpx. These actions are inhibited if the -n or -q options are present.

Options The following options are supported:

-d   Force a system crash dump before rebooting. See dumpadm(1M) for information on configuring system crash dumps.

-l   Suppress sending a message to the system log daemon, syslogd(1M), about who executed halt.

-n   Prevent the sync(1M) before stopping.

-q   Quick halt. No graceful shutdown is attempted.

-y   Halt the system, even from a dialup terminal.

Files /var/adm/wtmpx   History of user access and administration information.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also dumpadm(1M), init(1M), reboot(1M), shutdown(1M), sync(1M), syslogd(1M), inittab(4), attributes(5), smf(5)

Notes The halt and poweroff utilities do not cleanly shutdown smf(5) services, execute the scripts in /etc/rc*num*.d, or execute shutdown actions in inittab(4). To ensure a complete shutdown of system services, use shutdown(1M) or init(1M) to reboot a Solaris system.

Name hextoalabel – convert an internal text label to its human readable equivalent

Synopsis /usr/sbin/hextoalabel [*internal-text-sensitivity-label*]

/usr/sbin/hextoalabel -c [*internal-text-clearance*]

Description hextoalabel converts an internal text label into its human readable equivalent and writes the result to the standard output file. This internal form is often hexadecimal. If no option is supplied, the label is assumed to be a sensitivity label.

If no internal text label is specified, the label is read from the standard input file. The expected use of this command is emergency repair of labels that are stored in internal databases.

Options -c Identifies the internal text label as a clearance.

Exit Status The following exit values are returned:

0 On success.

1 On failure, and writes diagnostics to the standard error file.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/trusted
Interface Stability	See below.

The command output is Committed for systems with the same label_encodings file. The command invocation is Committed for systems that implement the DIA MAC policy.

Files /etc/security/tsol/label_encodings
The label encodings file contains the classification names, words, constraints, and values for the defined labels of this system.

Oracle Solaris Trusted Extensions Configuration and Administration

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

This file is part of the Defense Intelligence Agency (DIA) Mandatory Access Control (MAC) policy. This file might not be applicable to other MAC policies that might be developed for future releases of Solaris Trusted Extensions software.

Name   host – DNS lookup utility

Synopsis   host [-aCdilmrsTvw] [-c *class*] [-N *ndots*] [-R *number*]
             [-t *type*] [-W *wait*] [-4 | -6] *name* [*server*]

Description   The host utility performs simple DNS lookups. It is normally used to convert names to IP
             addresses and IP addresses to names. When no arguments or options are given, host prints a
             short summary of its command line arguments and options.

             The *name* argument is the domain name that is to be looked up. It can also be a
             dotted-decimal IPv4 address or a colon-delimited IPv6 address, in which case host by default
             performs a reverse lookup for that address. The optional *server* argument is either the name or
             IP address of the name server that host should query instead of the server or servers listed in
             /etc/resolv.conf.

Options   The following options are supported:

             -4

                 Use only IPv4 transport. By default, both IPv4 and IPv6 transports can be used. Options -4
                 and -6 are mutually exclusive.

             -6

                 Use only IPv6 transport. By default, both IPv4 and IPv6 transports can be used. Options -4
                 and -6 are mutually exclusive.

             -a

                 Equivalent to setting the -v option and asking host to make a query of type ANY.

             -c *class*

                 Make a DNS query of class *class*. This can be used to lookup Hesiod or Chaosnet class
                 resource records. The default class is IN (Internet).

             -C

                 Attempt to display the SOA records for zone *name* from all the listed authoritative name
                 servers for that zone. The list of name servers is defined by the NS records that are found
                 for the zone.

             -d

                 Generate verbose output. This option is equivalent to -v. These two options are provided
                 for backward compatibility. In previous versions, the -d option switched on debugging
                 traces and -v enabled verbose output.

             -i

                 Specifies that reverse lookups of IPv6 addresses should use the IP6.INT domain as defined
                 in RFC 1886. The default is to use RFC 3152 domain IP6.ARPA.

-l

List mode. This option makes `host` perform a zone transfer for zone *name*, displaying the NS, PTR and address records (A/AAAA). If combined with `-a`, all records will be displayed. The argument is provided for compatibility with previous implementations. Options `-la` is equivalent to making a query of type AXFR.

-m

Sets the memory usage debugging flags: record, usage, and trace.

-N *ndots*

Set the number of dots that have to be in *name* for it to be considered absolute. The default value is that defined using the ndots statement in `/etc/resolv.conf`, or 1 if no ndots statement is present. Names with fewer dots are interpreted as relative names and will be searched for in the domains listed in the `search` or `domain` directive in `/etc/resolv.conf`.

-r

Make a non-recursive query. Setting this option clears the RD (recursion desired) bit in the query made by `host`. The name server receiving the query does not attempt to resolve *name*. The `-r` option enables `host` to mimic the behaviour of a name server by making non-recursive queries and expecting to receive answers to those queries that are usually referrals to other name servers.

-R *number*

Change the number of UDP retries for a lookup. The *number* argument indicates how many times `host` will repeat a query that does not get answered. The default number of retries is 1. If *number* is negative or zero, the number of retries will default to 1.

-s

Specifies that the host not send the query to the next name server if any server responds with a SERVFAIL response, which is the reverse of normal stub resolver behavior.

-t *type*

Select the query type. The *type* argument can be any recognised query type: CNAME, NS, SOA, SIG, KEY, and AXFR, among others. When no query type is specified, `host` automatically selects an appropriate query type. By default it looks for A, AAAA, and MX records, but if the `-C` option is specified, queries are made for SOA records. If *name* is a dotted-decimal IPv4 address or colon-delimited IPv6 address, `host` queries for PTR records.

If a query type of IXFR is chosen the starting serial number can be specified by appending an equal followed by the starting serial number (for example: `-t IXFR=12345678`).

-T

Use a TCP connection when querying the name server. TCP is automatically selected for queries that require it, such as zone transfer (AXFR) requests. By default `host` uses UDP when making queries.

-v

Generate verbose output. This option is equivalent to `-d`.

-w

Wait forever for a reply. The time to wait for a response will be set to the number of seconds given by the hardware's maximum value for an integer quantity.

-W *wait*

Wait for *wait* seconds for a reply. If *wait* is less than one, the wait interval is set to one second.

Name hostconfig – configure a system's host parameters

Synopsis /usr/sbin/hostconfig -p *protocol* [-d] [-h] [-n] [-v]
[-i *interface*] [-f *hostname*]

Description The hostconfig program uses a network protocol to acquire a machine's *host parameters* and set these parameters on the system.

The program selects which protocol to use based on the argument to the required -p flag. Different protocols may set different host parameters. Currently, only one protocol (bootparams) is defined.

Options The following options are supported:

-d Enable debug output.

-f *hostname* Run the protocol as if this machine were named hostname.

-h Echo the received hostname to stdout, rather than setting hostname using the system name directly.

-i *interface* Use only the named network interface to run the protocol.

-n Run the network protocol, but do not set the acquired parameters into the system.

-p *protocol* Run hostconfig using *protocol*. Currently, only one protocol (bootparams) is available. This option is required.

Specifying the -p bootparams option uses the whoami call of the RPC bootparams protocol. This sets the system's hostname, domainname, and default IP router parameters.

-v Enable verbose output.

Examples EXAMPLE 1 Configuring Host Parameters with Verbose Output

The following command configures a machine's host parameters using the whoami call of the RPC bootparams protocol with a verbose output.

```
example# hostconfig -p bootparams -v
```

EXAMPLE 2 Displaying Host Parameters

The following command displays the parameters that would be set using the whoami call of the RPC bootparams protocol.

```
example# hostconfig -p bootparams -n -v
```

EXAMPLE 3 Configuring Host Parameters Less the System Name

The following command configures a machine's host parameters, less the system name, using the whoami call of the RPC bootparams protocol.

```
example# hostconfig='hostconfig -p bootparams -h'
```

Name hotplug – configure hotplug connectors and ports

Synopsis hotplug list [-c] [-d] [-l] [-v] [*path* [*connection*]]

hotplug online *path port*

hotplug offline [-f] [-q] *path port*

hotplug enable [*path*] *connector*

hotplug disable [-f] [-q] [*path*] *connector*

hotplug poweron [*path*] *connector*

hotplug poweroff [-f] [-q] [*path*] *connector*

hotplug set -o *options* [*path*] *connector*

hotplug get -o*options* [*path*] *connector*

hotplug install *path port*

hotplug uninstall [-f] [-q] *path port*

hotplug -?

Description The hotplug command is used to manage hotplug connections. A connection can be a connector or port. A hotplug connector is a representation of a physical point in the system where components can be inserted or removed. A hotplug port is a representation of a logical point in the system device tree where the connection of a device to the system is managed.

The hotplug command only supports hotplug operations on hotplug connectors for PCI Express buses and PCI buses that implement the Standard PCI Hotplug feature. Hotplug ports on PCI Expresss and PCI buses in systems with PCI Express fabrics are also supported. Additional buses may be supported in the future.

The hotplug command operates on the following kinds of objects:

path
  Hotplug connectors and ports are integrated into the Solaris device tree. The names of connectors and ports are unique relative only to their bus controller. A device path is required to uniquely reference a connector and the parent path of the device is required to uniquely reference a port.

  The hotplug command can accept the case that a user specifies only a physical hotplug connector for the state-change operation subcommands. If no such connector exists, the command will fail. If multiple connectors exist with the same name in the system, the state change operations interact with the user to determine which connector needs to be operated upon. See the "Examples" section, below.

connector
  If a hardware component supports being physically inserted or removed, then a hotplug connector represents the location where this action may occur. When a connector exists, it has a hierarchy of ports and device nodes that depend upon it.

port

All device nodes can be virtually hotplugged, even if their hardware does not support physical hotplugging. A hotplug port exists between a device node and its parent node in the system device tree. It represents the location where the device node and its dependents can be managed.

connection

A hotplug connection is a generic term to refer to either a hotplug connector or a hotplug port.

Hotplug connectors and ports are managed according to a state model. The hotplug command can list information about the hotplug connections in a system, or it can initiate change of state operations on specific hotplug connections.

Hotplug connectors can be in the following states:

empty

A component is not physically inserted in the connector.

present

A component is physically inserted in the connector, but the component is powered off. The component is not in use.

powered

A component is physically inserted in the connector, and the component is powered on. The component is disabled and is not in use.

enabled

A component is physically inserted in the connector. The component is powered on and has been probed and tested. The component is enabled and devices that represent its functions can be used.

Hotplug ports can be in the following states:

port-empty

No device exists for the hotplug port.

port-present

A device exists for the hotplug port, but the device has not been probed and it has no attached device driver. The device is not in use.

offline

A device exists for the hotplug port, and the device has been probed. A device driver is not attached, and the device is not in use.

online

A device exists for the hotplug port, and its device driver is fully attached. The device is in use.

maintenance

A device exists for the hotplug port, and its device driver is fully attached. The device is in use, but not fully operational. A maintenance or fault management operation is affecting the device. The reason that caused the device to enter maintenance state may vary. It is described by a sub-state under maintenance state. Currently there is only one sub-state defined:

maintenance-suspended

The device is live suspended.

The `hotplug` command can also access bus private properties for each hotplug connector. The current values of bus private properties can be displayed. New values for each bus private property can be set directly.

Sub-commands The following subcommands are supported:

list

Show information for hotplug connectors, ports, and their associated devices. Hotplug connectors and hotplug ports are integrated into the Solaris device tree hierarchy. The `list` subcommand therefore displays the hierarchy of device nodes with additional information included to show the locations of hotplug connectors and hotplug ports. The names of hotplug connectors are enclosed in square brackets, and the names of hotplug ports are enclosed in angled brackets. The current state of each hotplug connection is displayed next to its name.

online

Change the state of a hotplug port to the `online` state.

offline

Change the state of a hotplug port to the `offline` state.

enable

Change the state of a hotplug connector to the `enabled` state. All of the hotplug connector's dependent ports will be automatically probed and initialized into the `online` state.

disable

Change the state of a hotplug connector from the `enabled` state to the `powered` state. All dependent ports that are in the `online` state will first be transitioned to the `port-present` state.

poweron

Change the state of a hotplug connector from the `present` state to the `powered` state.

poweroff

Change the state of a hotplug connector from the `powered` or `enabled` state to the `present` state. All dependent ports that are in the `online` state will first be transitioned to the `port-present` state, and will then be removed.

set

    Set bus-specific properties for a hotplug connector. The specified option string is a bus specific string of name and value pairs, as could be parsed by getsubopt(3C). The names and values will be passed directly to the bus controller that manages the specified hotplug connector to perform a bus-specific function.

get

    Display the current values of bus specific properties for a hotplug connector. The specified option string is a bus specific string of named properties, as could be parsed by getsubopt(3C). The names will be passed directly to the bus controller to specify which properties should be returned. The current values of each named property will then be displayed.

The install and uninstall subcommands install and uninstall services the drivers of the ports can support.

install

    The install subcommand install services the drivers of the hotplug port's device can support.

    For example, this subcommand can be applied to the port of physical function of PCIe IO virtualization devices. It upgrades the port to ONLINE state (if it is not yet in that state) and then installs the virtual functions that the physical function (driver) supports. New hotplug ports will be created to represent each virtual function as a dependent of the specified physical function. The newly created ports will be initiated to OFFLINE state.

uninstall

    The uninstall subcommand uninstall services the drivers of the hotplug port's device can support.

    This subcommand can be applied to the ports of physical functions of PCIe IO virtualization devices. If the specified hotplug port has any dependent ports of virtual functions, the dependent ports and corresponding virtual function nodes will be removed.

Options The following options are supported:

-l, --list-path

    Show full paths to connections and device nodes. By default, the list subcommand shows hotplug connectors, ports, and devices in the format of a tree. This option enables the display of full paths to each connection and device node.

-c, --connectors

    Display a table that summarizes the current status of all physical hotplug connectors. Device topologies and hierachical information are not included. In general, the names of physical hotplug connectors should be unique. If multiple connectors of the same name exist in the system, hotplug displays a message specifying the same-named hotplug connectors and prompts for information to distinguish among those connectors. See "Examples," below.

-d, --drivers

  Show the binding driver names and the instance number of the device nodes. By default, the list subcommand shows only hotplug connectors, ports, and devices. This option enables the display of the binding driver names and the instance numbers of the device nodes.

-v, --verbose

  Show verbose usage details. By default, the list subcommand shows only hotplug connectors, ports, and devices. This option enables the display of more detailed information about how the devices are currently consumed. Examples include mounted filesystems or plumbed network interfaces associated with individual devices.

  Note that the -v option does not display information for disks under ZFS control.

-f, --force

  Force the operation. Some change state operations that impact resources currently in use will fail with a warning. A forced operation will attempt to ignore these warnings and proceed.

  This option should be used with extreme caution.

-n, --non-interactive

  Disable the interactive feature. If the flag is specified and an ambiguous input is encountered, the command will exit immediately, returning a unique exit status to indicate the problem.

-q, --query

  Query the operation. Instead of actually performing a change state operation, perform a test to predict if the operation would succeed or fail. If it would fail, show the error messages that would be expected if the operation had really been attempted.

  It is not possible to predict every failure. An operation that succeeds during a query could still fail for another reason when actually attempted.

  This option will not actually change the state of the system.

-o *options*, --=*options*

  Specify bus-specific properties for a set or get command. The options string conforms to the getsubopt(3C) syntax convention.

  For the get subcommand, there are two special options that can be used. The special options value of help will display all supported properties and their possible values. The special options value of all will display the current value of all supported properties.

  For the set subcommand, there is one special option that can be used. The special options value of help will display all supported properties which can be set and their possible values.

  See "Notes" section for the properties supported by bus controllers.

-?, --help
     Display a brief help message on proper use of the command.

Examples   EXAMPLE 1   Showing All Hotplug Connections

The following command shows all hotplug connections:

```
# hotplug list -v
pci@0,0
pci108e,534a@2,1 <pci.2,1> ONLINE
        [pci30] EMPTY
pci10de,5d@e <pci.e,0> ONLINE
        display@b <pci.b,0> ONLINE
        [NEM0] ENABLED
        pci108e,534a@a,0 <pci.a,0> ONLINE
                { Network interface nge0 }
                { nge0: hosts IP addresses: 10.0.0.1 }
        pci108e,534a@a,1 <pci.a,1> (MAINTENANCE)
                        [NEM1] (EMPTY)
pci108e,534a@c <pci.c,0> OFFLINE
pci108e,534a@d <pci.d,0> ONLINE
                        pci1028,40d@0 <pci.0,0> (MAINTENANCE-SUSPENDED,
"activities=dma+pio+intr,reason=resource-rebalance")
                        { Network interface bge0 }
                        { bge0: hosts IP addresses: 10.0.1.1 }
```

To show the full paths of hotplug connections and devices, enter the following command:

```
# hotplug list -l
/pci@0,0
/pci@0,0/pci108e,4341  <pci.0,0>  OFFLINE
/pci@0,0/pci8086,3408  <pci.1,0>  OFFLINE
/pci@0,0/pci8086,340a@3  <pci.3,0>  ONLINE
/pci@0,0/pci8086,340a@3 [Slot2]  EMPTY
/pci@0,0/pci8086,340c@5  <pci.5,0>  ONLINE
/pci@0,0/pci8086,340c@5 [Slot1]  ENABLED
/pci@0,0/pci8086,340c@5/pci111d,8018@0  <pci.0,0>  ONLINE
/pci@0,0/pci8086,340e@7  <pci.7,0>  ONLINE
/pci@0,0/pci8086,340e@7 [pcie4]  ENABLED
/pci@0,0/pci8086,3410@9  <pci.9,0>  ONLINE
/pci@0,0/pci8086,3410@9 [pcie3]  ENABLED
/pci@0,0/pci8086,342d  <pci.13,0>  OFFLINE
/pci@0,0/pci8086,342e  <pci.14,0>  OFFLINE
```

To show the binding driver names and instance numbers of the devices, enter the following command:

```
# hotplug list -d
pci@0,0  npe#0
    pci108e,4341  <pci.0,0>  OFFLINE  #0
```

EXAMPLE 1 Showing All Hotplug Connections   *(Continued)*

```
pci8086,3408  <pci.1,0>  OFFLINE  pcieb#0
pci8086,340a@3  <pci.3,0>  ONLINE  pcieb#1
    [Slot2]  EMPTY
pci8086,340c@5  <pci.5,0>  ONLINE  pcieb#2
    [Slot1]  ENABLED
    pci111d,8018@0  <pci.0,0>  ONLINE  pcieb#0
        pci111d,8018@2  <pci.2,0>  ONLINE  pcieb#6
            pci108e,f1bc@0  <pci.0,0>  ONLINE  e1000g#0
            pci108e,f1bc@0,1  <pci.0,1>  OFFLINE  e1000g#1
pci8086,340e@7  <pci.7,0>  ONLINE  pcieb#3
    [pcie4]  ENABLED
pci8086,3410@9  <pci.9,0>  ONLINE  pcieb#4
    [pcie3]  ENABLED
pci8086,342d  <pci.13,0>  OFFLINE  #0
pci8086,342e  <pci.14,0>  OFFLINE  #0
```

To show the status of all physical hotplug connectors. enter the following command:

```
# hotplug list -c
Connection          State          Description
----------------------------------------------------------
NEM0                ENABLED        PCIe-Native
PCI-EM0             ENABLED        PCIe-Native
NEM1                ENABLED        PCIe-Native
PCI-EM1             ENABLED        PCIe-Native
```

The table in the condition that multiple connectors with the same exist in the system:

```
# hotplug list -c
Connection    Note    State          Description
----------------------------------------------------------
NEM0                  ENABLED        PCIe-Native
PCI-EM0       *1      ENABLED        PCIe-Native
PCI-EM0       *2      ENABLED        PCIe-Native
NEM1                  ENABLED        PCIe-Native

Note:
Multiple connectors with the same name exist:

  [1] PCI-EM0   /pci@0,0/pci108e,4341@1a,2
  [2] PCI-EM0   /pci@1,0/pci108e,4341@1a,2
```

EXAMPLE 2 Reporting Failure During State Change Operation

If a change of state operation fails, an explanation is displayed to describe the failure. An attempt to offline a hotplug port with dependent devices that are currently in use by the system might fail as follows:

EXAMPLE 2 Reporting Failure During State Change Operation   *(Continued)*

```
# hotplug offline /pci@0,0/pci10de,5d@e pci.a,0
ERROR: devices or resources are busy.
pci108e,534a@a,0:
    { Network interface nge0 }
    { nge0: hosts IP addresses: 10.0.0.1 }
    { Plumbed IP Address }
```

EXAMPLE 3 Enabling User Interaction During State Change Operation

If there are multiple connectors with the same name in a system, the state change operations interact with the user to specify which connector needs to be operated upon.

```
# hotplug enable PCI-EM0
Multiple connectors with the same name exist:

    [1] PCI-EM0  /pci@0,0/pci108e,4341@1a,2
    [2] PCI-EM0  /pci@1,0/pci108e,4341@1a,2

Please select a connector, then press ENTER:
```

EXAMPLE 4 Displaying Bus-Specific Properties and Values

The following command displays all supported bus-specific properties and their possible values:

```
# hotplug get -o help /pci@0,0 pci.2,1
power_led=<on|off|blink>
fault_led=<on|off|blink>
active_led=<on|off|blink>
attn_led=<on|off|blink>
card_type=<type description>
board_type=<type description>
```

EXAMPLE 5 Displaying Bus-Specific Options

The following command displays the card type and the current state of the Power LED of a PCI hotplug connector:

```
# hotplug get -o card_type,power_led /pci@0,0 pci.2,1
card_type=fibre
power_led=on
```

EXAMPLE 6 Setting a Bus-Specific Property

The following command turns on the attention LED of a PCI hotplug connector:

```
# hotplug set -o attn_led=on /pci@0,0 pci.2,1
```

EXAMPLE 7 Installing Port Dependents

The following commands install dependent ports of an IOV physical function and then display the resulting IOV virtual functions that were probed.

```
# hotplug install /pci@400/pci@1/pci@0/pci@4 pci.0,1
```

```
# hotplug list -v /pci@400/pci@1/pci@0/pci@4 pci.0,1
<pci.0,1>  (ONLINE)
     { IOV physical function }
     { IOV virtual function 'pci.0,81' }
     { IOV virtual function 'pci.0,83' }
     { IOV virtual function 'pci.0,85' }
     { IOV virtual function 'pci.0,87' }
<pci.0,81>  (OFFLINE)
ethernet@0,81
<pci.0,83>  (OFFLINE)
ethernet@0,83
<pci.0,85>  (OFFLINE)
ethernet@0,85
<pci.0,87>  (OFFLINE)
ethernet@0,87
```

EXAMPLE 8 Uninstalling Port Dependents

The following command attempts to uninstall dependent ports of an IOV physical function, but fails when a dependent IOV virtual function is busy.

```
# hotplug uninstall /pci@400/pci@1/pci@0/pci@4 pci.0,0
ERROR: devices or resources are busy.
ethernet@0,81:
     { Network interface igvbf1 }
     { igvbf1: hosts IP addresses: 10.0.0.1 }
     { Plumbed IP Address }
```

Exit Status   0

Successful completion.

1

Invalid command line options were specified.

2

The specified path or connection does not exist.

3

A fatal error occurred. One or more error messages are displayed on standard error.

4

The hotplug service is not available.

5

The connector name specified refers to multiple ports.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also cfgadm(1M), hotplugd(1M), getsubopt(3C), attributes(5)

Diagnostics The following error message is displayed on systems that do not have any supported IO buses:

```
ERROR: there are no connections to display.
(See hotplug(1m) for more information.)
```

If this error message is seen, note that the system might still have other IO devices that support hotplugging, through the cfgadm(1M) command instead of hotplug.

Notes The hotplug service (FMRI svc:/system/hotplug) must be enabled as a prerequisite for using the hotplug command. The service is disabled by default. See hotplugd(1M).

The authorization solaris.hotplug.modify must be granted in order to perform change-of-state operations, or to install and uninstall dependent ports. Alternatively, the rights profile "Hotplug Management" can be granted, which includes that authorization.

Verbose usage information is gathered from the RCM framework. Its format and content is subject to change.

The following bus specific properties are supported in PCI bus controllers:

power_led | fault_led | attn_led | active_led
  States of a specific LED of a slot. The value could be on, off, or blink.

  They can all be used with get subcommand, but only property attn_led can be used with set subcommand.

card_type | board_type
  Type of a card or board of a slot.

  They can all be used with get subcommand, but neither can be used with set subcommand.

Name hotplugd – hotplug daemon

Synopsis /usr/lib/hotplugd [-d]

Description The hotplug daemon, hotplugd, provides user-level services for the management of hotplug connections. It is a system daemon started by the Service Management Facility (see smf(5)). Its fault management resource identifier (FMRI) is:

svc:/system/hotplug:default

Note that hotplugd is a Consolidation Private interface. See attributes(5).

The hotplug(1M) command and any other client program that uses the private libhotplug library to query information about hotplug connections or initiate hotplug commands depends upon this daemon. The hotplug daemon is a door server which services requests from all libhotplug clients. The door interface is private.

Client applications use the private libhotplug interface to administer hotplug connections. libhotplug uses the door interface to administer hotplug connections through the hotplug daemon service. The hotplug daemon acts as a central location to serialize all hotplug operations and coordinate activities with all other parts of the system.

Options The following option is supported:

-d, --debug
Run the daemon in standalone debug mode. Messages will be displayed on the controlling terminal instead of to syslog. And increased verbosity will be enabled to display more details about the internal operations of the daemon.

Examples EXAMPLE 1 Enabling the Hotplug Service

The following command enables the hotplug service:

svcadm enable svc:/system/hotplug:default

EXAMPLE 2 Disabling the Hotplug Service

The following command disables the hotplug service:

svcadm disable svc:/system/hotplug:default

Errors The hotplug daemon uses syslog(3C) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_INFO priority. The default entries in the /etc/syslog.conf file log all of the hotplug daemon error messages to the /var/adm/messages log.

Files /var/run/hotplugd_door
Hotplug daemon door

/var/run/hotplugd_pid
Hotplug daemon lock file

/usr/lib/hotplugd
    Hotplug daemon binary

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Consolidation Private

See Also svcs(1), hotplug(1M), svcadm(1M), syslog(3C), syslog.conf(4), attributes(5), smf(5)

Notes The hotplugd service is managed by the service management facility, smf(5), under the fault management resource identifier (FMRI):

svc:/system/hotplug:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command. To administer the service, the authorization solaris.smf.manage.hotplug must be granted. Alternatively, the rights profile "Hotplug Management" can be granted.

The hotplug service must be enabled for the hotplug(1M) command and any other libhotplug client applications to function properly.

Name htable – convert DoD Internet format host table

Synopsis /usr/sbin/htable *filename*

Description htable converts a host table in the format specified by RFC 952 to the format used by the network library routines. Three files are created as a result of running htable: hosts, networks, and gateways. The hosts file is used by the gethostbyname(3NSL) routines in mapping host names to addresses. The networks file is used by the getnetbyname(3SOCKET) routines in mapping network names to numbers. The gateways file is used by the routing daemon to identify "passive" Internet gateways.

If any of the files localhosts, localnetworks, or localgateways are present in the current directory, the file's contents is prepended to the output file without interpretation. This allows sites to maintain local aliases and entries which are not normally present in the master database.

htable is best used in conjunction with the gettable(1M) program which retrieves the DoD Internet host table from a host.

Files localhosts

localnetworks

localgateways

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

See Also gettable(1M), gethostbyname(3NSL), getnetbyname(3SOCKET), attributes(5)

Notes htable does not properly calculate the gateways file.

Name ickey – install a client key for WAN boot

Synopsis /usr/lib/inet/wanboot/ickey [-d] [-o type=3des]

/usr/lib/inet/wanboot/ickey [-d] [-o type=aes]

/usr/lib/inet/wanboot/ickey [-d] [-o type=sha1]

Description The ickey command is used to install WAN boot keys on a running UNIX system so that they can be used the next time the system is installed. You can store three different types of keys: 3DES and AES for encryption and an HMAC SHA-1 key for hashed verification.

ickey reads the key from standard input using getpass(3C) so that it does not appear on the command line. When installing keys on a remote system, you must take proper precautions to ensure that any keying materials are kept confidential. At a minimum, use ssh(1) to prevent interception of data in transit.

Keys are expected to be presented as strings of hexadecimal digits; they can (but need not) be preceded by a 0x or 0X.

The ickey command has a single option, described below. An argument of the type -o type=*keytype* is required.

Options The ickey command the following option.

-d Delete the key specified by the *keytype* argument.

Exit Status On success, ickey exits with status 0; if a problem occurs, a diagnostic message is printed and ickey exits with non-zero status.

Files /dev/openprom WAN boot key storage driver

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/boot/wanboot
Interface Stability	Uncommitted

Name   id – return user identity

Synopsis   /usr/bin/id [-p] [*user*]

/usr/bin/id -a [-p] [*user*]

/usr/bin/id -G [-n] [*user*]

/usr/bin/id -g [-nr] [*user*]

/usr/bin/id -u [-nr] [*user*]

/usr/xpg4/bin/id [-p] [*user*]

/usr/xpg4/bin/id -a [-p] [*user*]

/usr/xpg4/bin/id -G [-n] [*user*]

/usr/xpg4/bin/id -g [-nr] [*user*]

/usr/xpg4/bin/id -u [-nr] [*user*]

Description   If no *user* operand is provided, the id utility writes the user and group IDs and the corresponding user and group names of the invoking process to standard output. If the effective and real IDs do not match, both are written. If multiple groups are supported by the underlying system, /usr/xpg4/bin/id also writes the supplementary group affiliations of the invoking process.

If a *user* operand is provided and the process has the appropriate privileges, the user and group IDs of the selected user are written. In this case, effective IDs are assumed to be identical to real IDs. If the selected user has more than one allowable group membership listed in the group database, /usr/xpg4/bin/id writes them in the same manner as the supplementary groups described in the preceding paragraph.

Formats   The following formats are used when the LC_MESSAGES locale category specifies the "C" locale. In other locales, the strings uid, gid, euid, egid, and groups may be replaced with more appropriate strings corresponding to the locale.

"uid=%u(%s) gid=%u(%s)\n" <*real user ID*>, <*user-name*>,
    <*real group ID*>, <*group-name*>

If the effective and real user IDs do not match, the following are inserted immediately before the \n character in the previous format:

" euid=%u(%s)"

with the following arguments added at the end of the argument list:

<*effective user ID*>, <*effective user-name*>

If the effective and real group IDs do not match, the following is inserted directly before the \n character in the format string (and after any addition resulting from the effective and real user IDs not matching):

" egid=%u(%s)"

with the following arguments added at the end of the argument list:

<*effectivegroup-ID*>, <*effectivegroupname*>

If the process has supplementary group affiliations or the selected user is allowed to belong to multiple groups, the first is added directly before the NEWLINE character in the format string:

`" groups=%u(%s)"`

with the following arguments added at the end of the argument list:

<*supplementary group ID*>, <*supplementary group name*>

and the necessary number of the following added after that for any remaining supplementary group IDs:

`",%u(%s)"`

and the necessary number of the following arguments added at the end of the argument list:

<*supplementary group ID*>, <*supplementary group name*>

If any of the user ID, group ID, effective user ID, effective group ID or supplementary/multiple group IDs cannot be mapped by the system into printable user or group names, the corresponding (%s) and name argument is omitted from the corresponding format string.

When any of the options are specified, the output format is as described under OPTIONS.

Options The following options are supported by both /usr/bin/id and /usr/xpg4/bin/id. The -p and -a options are invalid if specified with any of the -G, -g, or -u options.

-p   Reports additionally the current project membership of the invoking process. The project is reported using the format:

`"projid=%u(%s)"`

which is inserted prior to the \n character of the default format described in the Formats section. The arguments

<*project ID*>,<*project name*>

are appended to the end of the argument list. If the project ID cannot be mapped by the system into a printable project name, the corresponding (%s) and name argument is omitted from the corresponding format string.

-a   Reports user name, user ID and all the groups to which the user belongs.

-G   Outputs all different group IDs (effective, real and supplementary) only, using the format "%u\n". If there is more than one distinct group affiliation, output each such affiliation, using the format " %u", before the NEWLINE character is output.

-g   Outputs only the effective group ID, using the format "%u\n".

-n   Outputs the name in the format "%s" instead of the numeric ID using the format "%u".

-r   Outputs the real ID instead of the effective ID.

-u   Outputs only the effective user ID, using the format "%u\n".

Operands   The following operand is supported:

user   The user (login) name for which information is to be written.

Environment Variables   See environ(5) for descriptions of the following environment variables that affect the execution of id: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

/usr/bin/id

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os, system/library/processor
Interface Stability	Committed

/usr/xpg4/bin/id

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/xopen/xcu4
Interface Stability	Standard

See Also   fold(1), logname(1), who(1), getgid(2), getgroups(2), getprojid(2), getuid(2), attributes(5), environ(5), standards(5)

Notes   Output produced by the -G option and by the default case could potentially produce very long lines on systems that support large numbers of supplementary groups.

Name   idmap – configure and manage the Native Identity Mapping service

Synopsis   idmap

idmap -f *command-file*

idmap add [-d] *name1 name2*

idmap dump [-n] [-v]

idmap export [-f *file*] *format*

idmap flush [-a]

idmap get-namemap *name*

idmap help

idmap import [-F] [-f *file*] *format*

idmap list

idmap remove [-t|-f] *name*

idmap remove -a

idmap remove [-d] *name1 name2*

idmap set-namemap [-a *authenticationMethod*] [-D *bindDN*]
      [-j *passwdfile*] *name1 name2*

idmap show [-c] [-v] [-V] *identity* [*target-type*]

idmap unset-namemap [-a *authenticationMethod*] [-D *bindDN*]
      [-j *passwdfile*] *name* [*target-type*]

Description   The idmap utility is used to configure and manage the Native Identity Mapping service.

The Native Identity Mapping service supports the following types of mappings between
Windows security identitier (SIDs) and POSIX user IDs and group IDs (UIDs and GIDs):

- **Name-based mapping.** An administrator maps Windows and UNIX users and groups by name.
- **Ephemeral ID mapping.** A UID or GID is dynamically allocated for every SID that is not already mapped by name.
- **Local-SID mapping.** A non-ephemeral UID or GID is mapped to an algorithmically generated local SID.

The idmap utility can be used to create and manage the name-based mappings and to monitor
the mappings in effect.

If the idmap utility is invoked without a subcommand or option, it reads the subcommands
from standard input. When standard input is a TTY, the idmap command prints the usage
message and exits.

Mapping Mechanisms The idmapd(1M) daemon maps Windows user and group SIDs to UNIX UIDs and GIDs as follows:

1. SIDs are mapped by name.

   This mapping uses the name-based mappings that are manually set up by the system administrator.

2. If no name-based mapping is found, the SID is mapped to a dynamically allocated ephemeral ID.

   This allocation uses the next available UID or GID from 2^{31} to 2^{32} - 2.

Local SID mappings are used to map from UNIX to Windows.

To prevent aliasing problems, all file systems, archive and backup formats, and protocols must store SIDs or map all UIDs and GIDs in the 2^{31} to 2^{32} - 2 range to the nobody user and group.

It is possible to create also diagonal mappings. They are the mappings between Windows groups and Solaris users and between Solaris groups and Windows users. They are needed when Windows uses a group identity as a file owner or vice versa.

Name-based Mappings Name-based mappings establish name equivalence between Windows users and groups and their counterparts in the UNIX name service. These mappings persist across reboots. For example, the following command maps Windows users to UNIX users with the same name:

 # idmap add "winuser:*@mywindomain.com" "unixuser:*"

If configured to use a directory service, idmapd(1M) will first try to use the mapping information that is stored in user or group objects in the Active Directory (AD) and/or the native LDAP directory service. For example, an AD object for a given Windows user or group can be augmented to include the corresponding Solaris user or group name or numeric id. Similarly, the native LDAP object for a given Solaris user or group can be augmented to include the corresponding Windows user or group name.

idmapd(1M) can be configured to use AD and/or native LDAP directory-based name mappings by setting the appropriate service management facility (SMF) properties of the idmap service. See "Service Properties," below, for more details.

If directory-based name mapping is not configured or if configured but not found, then idmapd(1M) will process locally stored name-based mapping rules.

idmap supports the mapping of Windows well-known names. A few of these are listed below:

```
Administrator
Guest
KRBTGT
Domain Admins
Domain Users
Domain Guest
Domain Computers
Domain Controllers
```

When idmap rules are added, these well-known names will be expanded to canonical form. That is, either the default domain name will be added (for names that are not well-known) or an appropriate built-in domain name will be added. Depending on the particular well-known name, this domain name might be null, BUILTIN, or the local host name.

The following sequence of idmap commands illustrate the treatment of the non-well-known name fred and the well-known names administrator and guest.

```
# idmap add winname:fred unixuser:fredf
add     winname:fred     unixuser:fredf

# idmap add winname:administrator unixuser:root
add     winname:administrator    unixuser:root

# idmap add winname:guest unixuser:nobody
add     winname:guest    unixuser:nobody

# idmap add wingroup:administrators sysadmin
add     wingroup:administrators unixgroup:sysadmin

# idmap list
add     winname:Administrator@examplehost  unixuser:root
add     winname:Guest@examplehost  unixuser:nobody
add     wingroup:Administrators@BUILTIN unixgroup:sysadmin
add     winname:fred@example.com       unixuser:fredf
```

Ephemeral Mappings   The idmapd daemon attempts to preserve ephemeral ID mappings across daemon restarts. However, when IDs cannot be preserved, the daemon maps each previously mapped SID to a new ephemeral UID or GID value. The daemon will never re-use ephemeral UIDs or GIDs. If the idmapd daemon runs out of ephemeral UIDs and GIDs, it returns an error as well as a default UID or GID for SIDs that cannot be mapped by name.

The dynamic ID mappings are not retained across reboots. So, any SIDs that are dynamically mapped to UNIX UIDs or GIDs are most likely mapped to different IDs after rebooting the system.

Local SID Mappings   If no name-based mapping is found, a non-ephemeral UID or GID is mapped to an algorithmically generated local SID. The mapping is generated as follows:

```
local SID for UID = <machine SID> - <1000 + UID>
local SID for GID = <machine SID> - <2^31 + GID>
```

<machine SID> is a unique SID generated by the idmap service for the host on which it runs.

Rule Lookup Order   When mapping a Windows name to a UNIX name, lookup for name-based mapping rules is performed in the following order:

1. *windows-name@domain* to ""
2. *windows-name@domain* to *unix-name*

3. *windows-name*@* to ""
4. *windows-name*@* to *unix-name*
5. *@*domain* to *
6. *@*domain* to ""
7. *@*domain* to *unix-name*
8. *@* to *
9. *@* to ""
10. *@* to *unix-name*

When mapping a UNIX name to a Windows name, lookup for name-based mapping rules is performed in the following order:

1. *unix-name* to ""
2. *unix-name* to *windows-name*@*domain*
3. * to *@*domain*
4. * to ""
5. * to *windows-name*@*domain*

Service Properties The service properties determine the behavior of the idmapd(1M) daemon. These properties are stored in the SMF repository (see smf(5)) under property group config. They can be accessed and modified using svccfg(1M), which requires solaris.smf.value.idmap authorization. The service properties for the idmap service are:

config/ad_unixuser_attr
> Specify the name of the AD attribute that contains the UNIX user name. There is no default.

config/ad_unixgroup_attr
> Specify the name of the AD attribute that contains the UNIX group name. There is no default.

config/nldap_winname_attr
> Specify the name of the Native LDAP attribute that contains the Windows user/group name. There is no default.

config/directory_based_mapping
> Controls support for identity mapping using data stored in a directory service.
>
> none disables directory-based mapping.
>
> name enables name-based mapping using the properties described above.
>
> idmu enables mapping using Microsoft's Identity Management for UNIX (IDMU). This Windows component allows the administrator to specify a UNIX user ID for each Windows user, mapping the Windows identity to the corresponding UNIX identity. Only IDMU data from the domain the Solaris system is a member of is used.

Changes to service properties do not affect a running idmap service. The service must be refreshed (with svcadm(1M)) for the changes to take effect.

Operands   The idmap command uses the following operands:

format

Specifies the format in which user name mappings are described for the export and import subcommands. The Netapp usermap.cfg and Samba smbusers external formats are supported. These external formats are *only* for users, not groups.

- The usermap.cfg rule-mapping format is as follows:

  windows-username [*direction*] *unix-username*

  windows-username is a Windows user name in either the *domain\username* or *username@domain* format.

  unix-username is a UNIX user name.

  direction is one of the following:

  - == means a bidirectional mapping, which is the default.
  - => or <= means a unidirectional mapping.

  The IP qualifier is not supported.

- The smbusers rule-mapping format is as follows:

  unixname = *winname1* *winname2* ...

  If *winname* includes whitespace, escape the whitespace by enclosing the value in double quotes. For example, the following file shows how to specify whitespace in a valid format for the idmap command:

  ```
  $ cat myusermap
  terry="Terry Maddox"
  pat="Pat Flynn"
  cal=cbrown
  ```

  The mappings are imported as unidirectional mappings from Windows names to UNIX names.

  The format is based on the "username map" entry of the smb.conf man page, which is available on the samba.org web site. The use of an asterisk (*) for *windows-name* is supported. However, the @group directive and the chaining of mappings are not supported.

  By default, if no mapping entries are in the smbusers file, Samba maps a *windows-name* to the equivalent *unix-name*, if any. If you want to set up the same mapping as Samba does, use the following idmap command:

  ```
  idmap add -d "winuser:*@*" "unixuser:*"
  ```

identity

Specifies a user name, user ID, group name, or group ID. *identity* is specified as *type*:*value*. *type* is one of the following:

usid	Windows user SID in text format
gsid	Windows group SID in text format
sid	Windows group SID in text format that can belong either to a user or to a group
uid	Numeric POSIX UID
gid	Numeric POSIX GID
unixuser	UNIX user name
unixgroup	UNIX group name
winuser	Windows user name
wingroup	Windows group name
winname	Windows user or group name

value is a number or string that is appropriate to the specified *type*. For instance, `unixgroup:staff` specifies the UNIX group name, `staff`. The identity `gid:10` represents GID 10, which corresponds to the UNIX group `staff`.

name

Specifies a UNIX name (`unixuser`, `unixgroup`) or a Windows name (`winuser`, `wingroup`) that can be used for name-based mapping rules.

A Windows security entity name can be specified in one of these ways:

- *domain\name*
- *name@domain*
- *name*, which uses the default mapping domain

If *name* is the empty string (`""`), mapping is inhibited. Note that a name of `""` should not be used to preclude logins by unmapped Windows users.

If *name* uses the wildcard (`*`), it matches all names that are not matched by other mappings. Similarly, if *name* is the wildcard Windows name (`*@*`), it matches all names in all domains that are not matched by other mappings.

If *name* uses the wildcard on both sides of the mapping rule, the name is the same for both Windows and Solaris users. For example, if the rule is `"*@domain" == "*"`, the `jp@domain` Windows user name matches this rule and maps to the `jp` Solaris user name.

Specifying the type of *name* is optional if the type can be deduced from other arguments or types specified on the command line.

target-type

Used with the `show` and `unset-namemap` subcommands. For `show`, specifies the mapping type that should be shown. For example, if *target-type* is `sid`, `idmap show` returns the SID

mapped to the identity specified on the command line. For unset-namemap, identifies an attribute within the object specified by the *name* operand.

Options   The idmap command supports one option and a set of subcommands. The subcommands also have options.

Command-Line Option   -f *command-file*
Reads and executes idmap subcommands from *command-file*. The idmap -f - command reads from standard input. This option is not used by any subcommands.

Subcommands   The following subcommands are supported:

add [-d] *name1 name2*
Adds a name-based mapping rule. By default, the name mapping is bidirectional. If the -d option is used, a unidirectional mapping is created from *name1* to *name2*.

Either *name1* or *name2* must be a Windows name, and the other must be a UNIX name. For the Windows name, the winname identity type must not be used. Instead, specify one of the winuser or wingroup types. See "Operands" for information about the *name* operand.

Note that two unidirectional mappings between the same two names in two opposite directions are equivalent to one bidirectional mapping.

This subcommand requires the solaris.admin.idmap.rules authorization.

dump [-n] [-v]
Dumps all the mappings cached since the last system boot. The -n option shows the names, as well. By default, only sids, uids, and gids are shown. The -v option shows how the mappings were generated.

export [-f *file*] *format*
Exports name-based mapping rules to standard output in the specified *format*. The -f *file* option writes the rules to the specified output file.

flush [-a]
Flushes the identity mapping cache so that future mapping requests will be fully processed based on the current rules and directory information. This is a non-disruptive operation. A rule change automatically flushes the cache; this manual operation can be used to force newly changed directory information to take effect.

With -a, the cache is wiped clean. This operation can potentially disrupt operations that are in process and so should be used only on a quiet system. It should not normally be necessary, but might be appropriate to use -a to set up "clean slate" test cases.

get-namemap *name*
Get the directory-based name mapping information from the AD or native LDAP user or group object represented by the specified name.

help
Displays the usage message.

import [-F] [-f *file*] *format*
    Imports name-based mapping rules from standard input by using the specified *format*. The
    -f *file* option reads the rules from the specified file. The -F option flushes existing
    name-based mapping rules before adding new ones.

    Regardless of the external format used, the imported rules are processed by using the
    semantics and order described in the section "Rule Lookup Order," above.

    This subcommand requires the solaris.admin.idmap.rules authorization.

list
    Lists all name-based mapping rules. Each rule appears in its idmap add form.

remove [-t|-f] *name*
    Removes any name-based mapping rule that involves the specified name. *name* can be
    either a UNIX or Windows user name or group name.

    The -f option removes rules that use *name* as the source. The -t option removes rules that
    use *name* as the destination. These options are mutually exclusive.

    This subcommand requires the solaris.admin.idmap.rules authorization.

remove -a
    Removes all name-based mapping rules.

    This subcommand requires the solaris.admin.idmap.rules authorization.

remove [-d] *name1 name2*
    Removes name-based mapping rules between *name1* and *name2*. If the -d option is
    specified, rules from *name1* to *name2* are removed.

    Either *name1* or *name2* must be a Windows name, and the other must be a UNIX name.

    This subcommand requires the solaris.admin.idmap.rules authorization.

set-namemap [-a *authenticationMethod*] [-D *bindDN*] [-j *passwdfile*] *name1 name2*
    Sets name mapping information in the AD or native LDAP user or group object. Either
    name1 or *name2* must be a Windows name, and the other must be a UNIX name.

    If *name1* is a Windows name, then the UNIX name *name2* is added to the AD object
    represented by *name1*. Similarly, if *name1* is a UNIX name then the Windows name *name2*
    is added to the native LDAP entry represented by *name1*.

    The following options are supported:

    -a *authenticationMethod*
        Specify authentication method when modifying native LDAP entry. See
        ldapaddent(1M) for details. Default value is sasl/GSSAPI.

    -D *bindDN*
        Uses the distinguished name *bindDN* to bind to the directory.

-j *passwdfile*
    Specify a file containing the password for authentication to the directory.

show [-c] [-v] [-V] *name* [*target-type*]
    Shows the identity of type, *target-type*, that the specified *name* maps to. If the optional
    target-type is omitted, the non-diagonal mapping is shown.

    By default, this subcommand shows only mappings that have been established already. The
    -c option forces the evaluation of name-based mapping configurations or the dynamic
    allocation of IDs.

    The -v option shows how the mapping was generated and also whether the mapping was
    just generated or was retrieved from the cache. The -V option details the exact steps taken
    to determine the mapping, including interim steps and approaches that were rejected.

unset-namemap [-a *authenticationMethod*] [-D *bindDN*] [-j *passwdfile*] *name* [*target-type*]
    Unsets directory-based name mapping information from the AD or native LDAP user or
    group object represented by the specified name and optional target type.

    See the set-namemap subcommand for options.

Examples   EXAMPLE 1   Using a Wildcard on Both Sides of a Name-Based Mapping Rule

The following command maps all Windows user names in the xyz.com domain to the UNIX
users with the same names provided that one exists and is not otherwise mapped. If such a rule
is matched but the UNIX user name does not exist, an ephemeral ID mapping is used.

 # idmap add "winuser:*@xyz.com" "unixuser:*"

EXAMPLE 2   Using a Wildcard on One Side of a Name-Based Mapping Rule

The following command maps all unmapped Windows users in the xyz.com domain to the
guest UNIX user. The -d option specifies a unidirectional mapping from *@xyz.com users to
the guest user.

 # idmap add -d "winuser:*@xyz.com" unixuser:guest

EXAMPLE 3   Adding a Bidirectional Name-Based Mapping Rule

The following command maps Windows user, foobar@example.com, to UNIX user, foo, and
conversely:

 # idmap add winuser:foobar@example.com unixuser:foo

This command shows how to remove the mapping added by the previous command:

 # idmap remove winuser:foobar@example.com unixuser:foo

EXAMPLE 4   Showing a UID-to-SID Mapping

■ The following command shows the SID that the specified UID, uid:50000, maps to:

EXAMPLE 4 Showing a UID-to-SID Mapping   *(Continued)*

```
# idmap show uid:50000 sid
uid:50000 -> usid:S-1-5-21-3223191800-2000
```

- The following command shows the UNIX user name that the specified Windows user name, joe@example.com, maps to:

```
# idmap show joe@example.com unixuser
winuser:joe@example.com -> unixuser:joes
```

EXAMPLE 5 Listing the Cached SID-to-UID Mappings

The following command shows all of the SID-to-UID mappings that are in the cache:

```
# idmap dump | grep "uid:"
usid:S-1-5-21-3223191800-2000    ==    uid:50000
usid:S-1-5-21-3223191800-2001    ==    uid:50001
usid:S-1-5-21-3223191800-2006    ==    uid:50010
usid:S-1-5-21-3223191900-3000    ==    uid:2147491840
usid:S-1-5-21-3223191700-4000    =>    uid:60001
```

EXAMPLE 6 Batching idmap Requests

The following commands show how to batch idmap requests. This particular command sequence does the following:

- Removes any previous rules for foobar@example.com.
- Maps Windows user foobar@example.com to UNIX user bar and vice-versa.
- Maps Windows group members to UNIX group staff and vice-versa.

```
# idmap <<EOF
        remove winuser:foobar@example.com
        add winuser:foobar@example.com unixuser:bar
        add wingroup:members unixgroup:staff
EOF
```

EXAMPLE 7 Listing Name-Based Mapping Rules

The following command shows how to list the name-based mapping rules:

```
# idmap list
add winuser:foobar@example.com unixuser:bar
add wingroup:members unixgroup:staff
```

EXAMPLE 8 Importing Name-Based Mapping Rules From the usermap.cfg File

The usermap.cfg file can be used to configure name-based mapping rules. The following usermap.cfg file shows mapping rules that map Windows user foo@example.com to UNIX user foo, and that map foobar@example.com to the UNIX user foo.

EXAMPLE 8 Importing Name-Based Mapping Rules From the `usermap.cfg` File *(Continued)*

```
# cat usermap.cfg
foo@example.com == foo
foobar@example.com => foo
```

The following `idmap` command imports `usermap.cfg` information to the `idmapd` database:

```
# cat usermap.cfg | idmap import usermap.cfg
```

This command does the same as the previous command:

```
# idmap import -f usermap.cfg usermap.cfg
```

The following commands are equivalent to the previous `idmap import` commands:

```
# idmap <<EOF
       add winuser:foo@example.com unixuser:foo
       add -d winuser:foobar@example.com unixuser:foo
EOF
```

EXAMPLE 9 Using Name-Based and Ephemeral ID Mapping With Identity Function Mapping and Exceptions

The following commands map all users in the `example.com` Windows domain to UNIX user accounts of the same name. The command also specifies mappings for the following Windows users: `joe@example.com`, `jane.doe@example.com`, `administrator@example.com`. The `administrator` from all domains is mapped to `nobody`. Any Windows users without corresponding UNIX accounts are mapped dynamically to available ephemeral UIDs.

```
# idmap import usermap.cfg <<EOF
       joe@example.com == joes
       jane.doe@example.com == janed
       administrator@* => nobody
       *@example.com == *
       *@example.com => nobody
EOF
```

EXAMPLE 10 Adding Directory-based Name Mapping to AD User Object

The following command maps Windows user `joe@example.com` to UNIX user `joe` by adding the UNIX name to AD object for `joe@example.com`.

```
# idmap set-namemap winuser:joe@example.com joes
```

EXAMPLE 11 Adding Directory-based Name Mapping to Native LDAP User Object

The following command maps UNIX user `foo` to Windows user `foobar@example.com` by adding the Windows name to native LDAP object for `foo`.

```
# idmap set-namemap unixuser:foo foobar@example.com
```

EXAMPLE 12   Removing Directory-based Name Mapping from AD User Object

The following command removes the UNIX username unixuser from the AD object representing joe@example.com.

```
# idmap unset-namemap winuser:joe@example.com unixuser
```

Exit Status   **0**   Successful completion.

   >0   An error occurred. A diagnostic message is written to standard error.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Uncommitted

See Also   svcs(1), idmapd(1M), ldapaddent(1M), svcadm(1M), svccfg(1M), ad(5), attributes(5), smf(5)

Notes   The idmapd service is managed by the service management facility, smf(5). The service identifier for the idmapd service is svc:/system/idmap.

Use the svcadm command to perform administrative actions on this service, such as enabling, disabling, or restarting the service. These actions require the solaris.smf.manage.idmap authorization. Use the svcs command to query the service's status.

Windows user names are case-insensitive, while UNIX user names are case-sensitive. The case of Windows names as they appear in idmap name-rules and idmap show command lines is irrelevant.

Because common practice in UNIX environments is to use all-lowercase user names, wildcard name-rules map Windows names to UNIX user/group names as follows: first, the canonical Windows name (that is, in the case as it appears in the directory) is used as a UNIX user or group name. If there is no such UNIX entity, then the Windows name's case is folded to lowercase and the result is used as the UNIX user or group name.

As a result of this differing treatment of case, user names that appear to be alike might not be recognized as matches. You must create rules to handle such pairings of strings that differ only in case. For example, to map the Windows user sam@example to the Solaris user Sam, you must create the following rules:

```
# idmap add "winuser:*@example" "unixuser:*"
# idmap add winuser:sam@example unixuser:Sam
```

For guidance on modifying an Active Directory schema, consult the Microsoft document, *Step-by-Step Guide to Using Active Directory Schema and Display Specifiers*, which you can find at their technet web site, http://technet.microsoft.com/.

Name idmapd – Native Identity Mapping service daemon

Synopsis /usr/lib/idmapd

Description The idmapd daemon maps Windows Security Identifiers (SIDs) to POSIX Identifiers
(UIDs/GIDs) and conversely.

The idmap(1M) utility provides a front end to the idmapd daemon.

Files /var/idmap/idmap.db
Database in which to store local name-based ID mapping rules. The contents of the
database are private. The database should not be accessed or modified directly.

/var/run/idmap/idmap.db
Database in which to cache ID mappings that are generated by ephemeral ID mapping and
by name-based mapping. The contents of the database are private. The database should not
be accessed or modified directly.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

Interface stability for these components is as follows:

svc:/system/idmap
Committed

/var/idmap/idmap.db
Project Private

/var/run/idmap/idmap.db
Project Private

See Also svcs(1), idmap(1M), svcadm(1M), svccfg(1M), defaultdomain(4), attributes(5), smf(5)

Notes The idmapd service is managed by the service management facility (SMF). The service
identifier for the idmapd service is svc:/system/idmap.

Use the svcadm command to perform administrative actions on this service, such as enabling,
disabling, or restarting the service. These actions require the solaris.smf.manage.idmap
authorization. Use the svcs command to query the service's status.

The functionality of this daemon might change in a future release of the Solaris operating
system.

Name idsconfig – prepare a Directory Server Enterprise Edition (DSEE) to be populated with data and serve LDAP clients

Synopsis /usr/lib/ldap/idsconfig [-v] [-i *input_configfile*]
        [-o *output_configfile*]

Description Use the idsconfig tool to set up a Directory Server Enterprise Edition (DSEE). You can specify the input configuration file with the -i option on the command line. Alternatively, the tool will prompt the user for configuration information. The input configuration file is created by idsconfig with the -o option on a previous run.

The first time a server is set up, the user is prompted for all the required information. Future installations on that machine can use the configuration file previously generated by idsconfig using the -o option.

The output configuration file contains the directory administrator's password in clear text. Thus, if you are creating an output configuration file, take appropriate security precautions.

You should back up the directory server's configuration and data prior to running this command.

Options The following options are supported:

-i *input_configfile*
    Specify the file name for idsconfig to use as a configuration file. This file will be read by idsconfig, and the values in the file will be used to configure the server. Do not manually edit *input_configfile*. The *input_configfile* is only partially validated, as idsconfig assumes that the file was created by a previous invocation of the command.

-o *output_configfile*
    Create a configuration file.

-v
    Verbose output.

Operands The following operands are supported:

input_configfile
    Name of configuration file for idsconfig to use.

output_configfile
    Configuration file created by idsconfig.

Examples EXAMPLE 1 Prompting the User for Input

In the following example, the user is prompted for information to set up DSEE.

example# **idsconfig**

EXAMPLE 2 Creating an Output Configuration File

In the following example, the user is prompted for information to set up DSEE, and an output configuration file, config.1, is created when completed.

```
example# idsconfig -o config.1
```

EXAMPLE 3 Setting up DSEE Using the Specified Configuration File

In the following example, DSEE is set up by using the values specified in the configuration file, config.1. The verbose mode is specified, so detailed information will print to the screen.

```
example# idsconfig -v -i config.1
```

Exit Status The following exit values are returned:

0
   Successful completion.

>0
   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis
Interface Stability	Committed

ifconfig [*address_family*] *interface* {auto-dhcp | dhcp} [primary]
[wait *seconds*] drop | extend | inform | ping
| release | start | status

Description The command ifconfig is used to assign an address to a network interface and to configure
network interface parameters. Network interfaces configured by the ifconfig command do
not survive a reboot. The ipadm(1M) command must be used to configure network interfaces
persistently. If no option is specified, ifconfig displays the current configuration for a
network interface. If an address family is specified, ifconfig reports only the details specific
to that address family. Only privileged users may modify the configuration of a network
interface. Options appearing within braces ({ }) indicate that one of the options must be
specified.

DHCP Configuration The forms of ifconfig that use the auto-dhcp or dhcp arguments are used to control the
Dynamic Host Configuration Protocol ("DHCP") configuration of the interface. In this mode,
ifconfig is used to control operation of dhcpagent(1M), the DHCP client daemon. Once an
interface is placed under DHCP control by using the start operand, ifconfig should not, in
normal operation, be used to modify the address or characteristics of the interface. If the
address of an interface under DHCP is changed, dhcpagent will remove the interface from its
control.

Options The following options are supported:

addif *address*
   Create the next unused logical interface on the specified physical interface.

all-zones
> Make the interface available to every shared-IP zone on the system. The appropriate zone to which to deliver data is determined using the tnzonecfg database. This option is available only if the system is configured with the Solaris Trusted Extensions feature.
>
> The tnzonecfg database is described in the tnzonecfg(4) man page, which is part of the *Solaris Trusted Extensions Reference Manual*.

anycast
> Marks the logical interface as an anycast address by setting the ANYCAST flag. See "INTERFACE FLAGS," below, for more information on anycast.

-anycast
> Marks the logical interface as not an anycast address by clearing the ANYCAST flag.

arp
> Enable the use of the Address Resolution Protocol ("ARP") in mapping between network level addresses and link level addresses (default). This is currently implemented for mapping between IPv4 addresses and MAC addresses.

-arp
> Disable the use of the ARP on a physical interface. ARP cannot be disabled on an IPMP IP interface.

auth_algs *authentication algorithm*
> For a tunnel, enable IPsec AH with the authentication algorithm specified. The algorithm can be either a number or an algorithm name, including *any* to express no preference in algorithm. All IPsec tunnel properties must be specified on the same command line. To disable tunnel security, specify an auth_alg of none.
>
> It is now preferable to use the ipsecconf(1M) command when configuring a tunnel's security properties. If ipsecconf was used to set a tunnel's security properties, this keyword will not affect the tunnel.

auto-dhcp
> Use DHCP to automatically acquire an address for this interface. This option has a completely equivalent alias called dhcp.
>
> For IPv6, the interface specified must be the zeroth logical interface (the physical interface name), which has the link-local address.

primary
> Defines the interface as the primary. The interface is defined as the preferred one for the delivery of client-wide configuration data. Only one interface can be the primary at any given time. If another interface is subsequently selected as the primary, it replaces the previous one. Nominating an interface as the primary one will not have much significance once the client work station has booted, as many applications will already have started and been configured with data read from the previous primary interface.

wait *seconds*

The ifconfig command will wait until the operation either completes or for the interval specified, whichever is the sooner. If no wait interval is given, and the operation is one that cannot complete immediately, ifconfig will wait 30 seconds for the requested operation to complete. The symbolic value forever may be used as well, with obvious meaning.

drop

Remove the specified interface from DHCP control without notifying the DHCP server, and record the current lease for later use. Additionally, for IPv4, set the IP address to zero. For IPv6, unplumb all logical interfaces plumbed by dhcpagent.

extend

Attempt to extend the lease on the interface's IP address. This is not required, as the agent will automatically extend the lease well before it expires.

inform

Obtain network configuration parameters from DHCP without obtaining a lease on IP addresses. This is useful in situations where an IP address is obtained through mechanisms other than DHCP.

ping

Check whether the interface given is under DHCP control, which means that the interface is managed by the DHCP agent and is working properly. An exit status of 0 means success.

release

Relinquish the IP addresses on the interface by notifying the server and discard the current lease. For IPv4, set the IP address to zero. For IPv6, all logical interfaces plumbed by dhcpagent are unplumbed.

start

Start DHCP on the interface.

status

Display the DHCP configuration status of the interface.

auto-revarp

Use the Reverse Address Resolution Protocol (RARP) to automatically acquire an address for this interface. This will fail if the interface does not support RARP; for example, IPoIB (IP over InfiniBand), and on IPv6 interfaces.

broadcast *address*

For IPv4 only. Specify the address to use to represent broadcasts to the network. The default broadcast address is the address with a host part of all 1's. A "+" (plus sign) given for the broadcast value causes the broadcast address to be reset to a default appropriate for the (possibly new) address and netmask. The arguments of ifconfig are interpreted left to right. Therefore

example% ifconfig -a netmask + broadcast +

and

```
example% ifconfig -a broadcast + netmask +
```

may result in different values being assigned for the broadcast addresses of the interfaces.

deprecated

Marks the logical interface as deprecated. An address associated with a deprecated interface will not be used as source address for outbound packets unless either there are no other addresses available on the interface or the application has bound to this address explicitly. The status display shows DEPRECATED as part of flags. See INTERFACE FLAGS for information on the flags supported by ifconfig.

-deprecated

Marks a logical interface as not deprecated. An address associated with such an interface could be used as a source address for outbound packets.

preferred

Marks the logical interface as preferred. This option is only valid for IPv6 addresses. Addresses assigned to preferred logical interfaces are preferred as source addresses over all other addresses configured on the system, unless the address is of an inappropriate scope relative to the destination address. Preferred addresses are used as source addresses regardless of which physical interface they are assigned to. For example, you can configure a preferred source address on the loopback interface and advertise reachability of this address by using a routing protocol.

-preferred

Marks the logical interface as not preferred.

destination *dest_address*

Set the destination address for a point-to point interface.

dhcp

This option is an alias for option auto-dhcp

down

Mark a logical interface as "down". (That is, turn off the IFF_UP bit.) When a logical interface is marked "down," the system does not attempt to use the address assigned to that interface as a source address for outbound packets and will not recognize inbound packets destined to that address as being addressed to this host. Additionally, when all logical interfaces on a given physical interface are "down," the physical interface itself is disabled.

When a logical interface is down, all routes that specify that interface as the output (using the -ifp option in the route(1M) command or RTA_IFP in a route(7P) socket) are removed from the forwarding table. Routes marked with RTF_STATIC are returned to the table if the interface is brought back up, while routes not marked with RTF_STATIC are simply deleted.

When all logical interfaces that could possibly be used to reach a particular gateway address are brought down (specified without the interface option as in the previous paragraph), the

affected gateway routes are treated as though they had the RTF_BLACKHOLE flag set. All matching packets are discarded because the gateway is unreachable.

encaplimit *n*
Set the tunnel encapsulation limit for the interface to n. This option applies to IPv4–in–IPv6 and IPv6–in–IPv6 tunnels only, and it simply modifies the encaplimit link property of the underlying IPv6 tunnel link (see dladm(1M)). The tunnel encapsulation limit controls how many more tunnels a packet can enter before it leaves any tunnel, that is, the tunnel nesting level.

This option is obsolete, superseded by the dladm(1M) encaplimit link property.

-encaplimit
Disable generation of the tunnel encapsulation limit. This option applies only to IPv4–in–IPv6 and IPv6–in–IPv6 tunnels. This simply sets the encaplimit link property of the underlying IPv6 tunnel link to 0 (see dladm(1M) encaplimit).

This option is obsolete, superseded by the dladm(1M) encaplimit link property.

encr_auth_algs *authentication algorithm*
For a tunnel, enable IPsec ESP with the authentication algorithm specified. It can be either a number or an algorithm name, including any or none, to indicate no algorithm preference. If an ESP encryption algorithm is specified but the authentication algorithm is not, the default value for the ESP authentication algorithm will be any.

It is now preferable to use the ipsecconf(1M) command when configuring a tunnel's security properties. If ipsecconf was used to set a tunnel's security properties, this keyword will not affect the tunnel.

encr_algs *encryption algorithm*
For a tunnel, enable IPsec ESP with the encryption algorithm specified. It can be either a number or an algorithm name. Note that all IPsec tunnel properties must be specified on the same command line. To disable tunnel security, specify the value of encr_alg as none. If an ESP authentication algorithm is specified, but the encryption algorithm is not, the default value for the ESP encryption will be null.

It is now preferable to use the ipsecconf(1M) command when configuring a tunnel's security properties. If ipsecconf was used to set a tunnel's security properties, this keyword will not affect the tunnel.

ether [*address*]
If no address is given and the user is root or has sufficient privileges to open the underlying datalink, then display the current Ethernet address information.

Otherwise, if the user is root or has sufficient privileges, set the Ethernet address of the interfaces to *address*. The address is an Ethernet address represented as *x:x:x:x:x:x* where *x* is a hexadecimal number between 0 and FF. Similarly, for the IPoIB (IP over InfiniBand) interfaces, the address will be 20 bytes of colon-separated hex numbers between 0 and FF.

Some, though not all, Ethernet interface cards have their own addresses. To use cards that do not have their own addresses, refer to section 3.2.3(4) of the IEEE 802.3 specification for a definition of the locally administered address space. Note that all IP interfaces in an IPMP group must have unique hardware addresses; see in.mpathd(1M).

-failover

Set NOFAILOVER on the logical interface. This makes the associated address available for use by in.mpathd to perform probe-based failure detection for the associated physical IP interface. As a side effect, DEPRECATED will also be set on the logical interface. This operation is not permitted on an IPMP IP interface.

failover

Clear NOFAILOVER on the logical interface. This is the default. These logical interfaces are subject to migration when brought up (see IP MULTIPATHING GROUPS).

group [*name* | ""]

When applied to a physical interface, it places the interface into the named group. If the group does not exist, it will be created, along with one or more IPMP IP interfaces (for IPv4, IPv6, or both). Any UP addresses that are not also marked NOFAILOVER are subject to migration to the IPMP IP interface (see IP MULTIPATHING GROUPS). Specifying a group name of "" removes the physical IP interface from the group.

When applied to a physical IPMP IP interface, it renames the IPMP group to have the new name. If the name already exists, or a name of "" is specified, it fails. Renaming IPMP groups is discouraged. Instead, the IPMP IP interface should be given a meaningful name when it is created by means of the ipmp subcommand, which the system will also use as the IPMP group name.

index *n*

Change the interface index for the interface. The value of *n* must be an interface index (*if_index*) that is not used on another interface. *if_index* will be a non-zero positive number that uniquely identifies the network interface on the system.

ipmp

Create an IPMP IP interface with the specified name. An interface must be separately created for use by IPv4 and IPv6. The *address_family* parameter controls whether the command applies to IPv4 or IPv6 (IPv4 if unspecified). All IPMP IP interfaces have the IPMP flag set.

metric *n*

Set the routing metric of the interface to *n*; if no value is specified, the default is 0. The routing metric is used by the routing protocol. Higher metrics have the effect of making a route less favorable. Metrics are counted as addition hops to the destination network or host.

modinsert *mod_name@pos*

Insert a module with name *mod_name* to the stream of the device at position *pos*. The position is relative to the stream head. Position 0 means directly under stream head.

Based upon the example in the `modlist` option, use the following command to insert a
module with name `ipqos` under the `ip` module and above the firewall module:

```
example% ifconfig eri0 modinsert ipqos@2
```

A subsequent listing of all the modules in the stream of the device follows:

```
example% ifconfig eri0 modlist
0 arp
1 ip
2 ipqos
3 firewall
4 eri
```

modlist
    List all the modules in the stream of the device.

    The following example lists all the modules in the stream of the device:

```
example% ifconfig eri0 modlist
0 arp
1 ip
2 firewall
4 eri
```

modremove *mod_name@pos*
    Remove a module with name *mod_name* from the stream of the device at position *pos*. The
    position is relative to the stream head.

    Based upon the example in the `modinsert` option, use the following command to remove
    the firewall module from the stream after inserting the `ipqos` module:

```
example% ifconfig eri0 modremove firewall@3
```

    A subsequent listing of all the modules in the stream of the device follows:

```
example% ifconfig eri0 modlist
0 arp
1 ip
2 ipqos
3 eri
```

    Note that the core IP stack modules, for example, `ip` and `tun` modules, cannot be removed.

mtu *n*
    Set the maximum transmission unit of the interface to *n*. For many types of networks, the
    `mtu` has an upper limit, for example, `1500` for Ethernet. This option sets the FIXEDMTU flag
    on the affected interface.

netmask *mask*
    For IPv4 only. Specify how much of the address to reserve for subdividing networks into
    subnetworks. The mask includes the network part of the local address and the subnet part,
    which is taken from the host field of the address. The mask contains 1's for the bit positions

in the 32-bit address which are to be used for the network and subnet parts, and 0's for the host part. The mask should contain at least the standard network portion, and the subnet field should be contiguous with the network portion. The mask can be specified in one of four ways:

1. with a single hexadecimal number with a leading 0x,

2. with a dot-notation address,

3. with a "+" (plus sign) address, or

4. with a pseudo host name/pseudo network name found in the network database networks(4).

If a "+" (plus sign) is given for the netmask value, the mask is looked up in the netmasks(4) database. This lookup finds the longest matching netmask in the database by starting with the interface's IPv4 address as the key and iteratively masking off more and more low order bits of the address. This iterative lookup ensures that the netmasks(4) database can be used to specify the netmasks when variable length subnetmasks are used within a network number.

If a pseudo host name/pseudo network name is supplied as the netmask value, netmask data may be located in the hosts or networks database. Names are looked up by first using gethostbyname(3NSL). If not found there, the names are looked up in getnetbyname(3SOCKET). These interfaces may in turn use nsswitch.conf(4) to determine what data store(s) to use to fetch the actual value.

For both inet and inet6, the same information conveyed by *mask* can be specified as a *prefix_length* attached to the *address* parameter.

nud

Enables the neighbor unreachability detection mechanism on a point-to-point physical interface.

-nud

Disables the neighbor unreachability detection mechanism on a point-to-point physical interface.

plumb

For a physical IP interface, open the datalink associated with the physical interface name and set up the plumbing needed for IP to use the datalink. When used with a logical interface name, this command is used to create a specific named logical interface on an existing physical IP interface.

An interface must be separately plumbed for IPv4 and IPv6 according to the *address_family* parameter (IPv4 if unspecified). Before an interface has been plumbed, it will not be shown by ifconfig -a.

Note that IPMP IP interfaces are not tied to a specific datalink and are instead created with the ipmp subcommand.

private

Tells the in.routed routing daemon that a specified logical interface should not be advertised.

-private

Specify unadvertised interfaces.

removeif *address*

Remove the logical interface on the physical interface specified that matches the *address* specified.

router

Enable IP forwarding on the interface. When enabled, the interface is marked ROUTER, and IP packets can be forwarded to and from the interface. Enabling ROUTER on any IP interface in an IPMP group enables it on all IP interfaces in that IPMP group.

-router

Disable IP forwarding on the interface. IP packets are not forwarded to and from the interface. Disabling ROUTER on any IP interface in an IPMP group disables it on all IP interfaces in that IPMP group.

set

Set the *address*, *prefix_length* or both, for a logical interface.

standby

Mark the physical IP interface as a STANDBY interface. If an interface is marked STANDBY and is part of an IPMP group, the interface will not be used for data traffic unless another interface in the IPMP group becomes unusable. When a STANDBY interface is functional but not being used for data traffic, it will also be marked INACTIVE. This operation is not permitted on an IPMP IP interface.

-standby

Clear STANDBY on the interface. This is the default.

subnet

Set the subnet *address* for an interface.

tdst *tunnel_dest_address*

Set the destination address of a tunnel. The address should not be the same as the dest_address of the tunnel, because no packets leave the system over such a tunnel.

This option is obsolete, superseded by the dladm(1M) create-iptun and modify-iptun subcommands.

thoplimit *n*

Set the hop limit for a tunnel interface. The hop limit value is used as the TTL in the IPv4 header for the IPv6–in-IPv4 and IPv4–in-IPv4 tunnels. For IPv6–in-IPv6 and IPv4–in-IPv6 tunnels, the hop limit value is used as the hop limit in the IPv6 header. This option simply modifies the hoplimit link property of the underlying IP tunnel link (see dladm(1M)).

This option is obsolete, superseded by the dladm(1M) hoplimit link property.

token *address*/*prefix_length*

Set the IPv6 token of an interface to be used for address autoconfiguration.

example% **ifconfig eri0 inet6 token ::1/64**

trailers

This flag previously caused a nonstandard encapsulation of IPv4 packets on certain link levels. Drivers supplied with this release no longer use this flag. It is provided for compatibility, but is ignored.

-trailers

Disable the use of a "trailer" link level encapsulation.

tsrc *tunnel_src_address*

Set the source address of a tunnel. This is the source address on an outer encapsulating IP header. It must be an address of another interface already configured using ifconfig.

This option is obsolete, superseded by the dladm(1M) create-iptun and modify-iptun subcommands.

unplumb

For a physical or IPMP interface, remove all associated logical IP interfaces and tear down any plumbing needed for IP to use the interface. For an IPMP IP interface, this command will fail if the group is not empty. For a logical interface, the logical interface is removed.

An interface must be separately unplumbed for IPv4 and IPv6 according to the *address_family* parameter (IPv4 if unspecified). Upon success, the interface name will no longer appear in the output of ifconfig -a.

up

Mark a logical interface UP. As a result, the IP module will accept packets destined to the associated address (unless the address is zero), along with any associated multicast and broadcast IP addresses. Similarly, the IP module will allow packets to be sent with the associated address as a source address. At least one logical interface must be UP for the associated physical interface to send or receive packets

usesrc [*name* | none]

Specify a physical interface to be used for source address selection. If the keyword none is used, then any previous selection is cleared.

When an application does not choose a non-zero source address using bind(3SOCKET), the system will select an appropriate source address based on the outbound interface and the address selection rules (see ipaddrsel(1M)).

When usesrc is specified and the specified interface is selected in the forwarding table for output, the system looks first to the specified physical interface and its associated logical interfaces when selecting a source address. If no usable address is listed in the forwarding table, the ordinary selection rules apply. For example, if you enter:

```
# ifconfig eri0 usesrc vni0
```

...and vni0 has address 10.0.0.1 assigned to it, the system will prefer 10.0.0.1 as the source address for any packets originated by local connections that are sent through eri0. Further examples are provided in the EXAMPLES section.

While you can specify any physical interface (or even loopback), be aware that you can also specify the virtual IP interface (see vni(7d)). The virtual IP interface is not associated with any physical hardware and is thus immune to hardware failures. You can specify any number of physical interfaces to use the source address hosted on a single virtual interface. This simplifies the configuration of routing-based multipathing. If one of the physical interfaces were to fail, communication would continue through one of the remaining, functioning physical interfaces. This scenario assumes that the reachability of the address hosted on the virtual interface is advertised in some manner, for example, through a routing protocol.

Because the ifconfig preferred option is applied to all interfaces, it is coarser-grained than the usesrc option. It will be overridden by usesrc and setsrc (route subcommand), in that order.

xmit
  Enable a logical interface to transmit packets. This is the default behavior when the logical interface is up.

-xmit
  Disable transmission of packets on an interface. The interface will continue to receive packets.

zone *zonename*
  Place the logical interface in zone *zonename*. The named zone must be active in the kernel in the ready or running state. The interface is unplumbed when the zone is halted or rebooted. The zone must be configure to be an shared-IP zone. zonecfg(1M) is used to assign network interface names to exclusive-IP zones.

-zone
  Place IP interface in the global zone. This is the default.

Operands The *interface* operand, as well as address parameters that affect it, are described below.

interface
  A string of one of the following forms:

  - *name physical-unit*, for example, eri0 or ce1
  - *name physical-unit*:*logical-unit*, for example, eri0:1
  - ip.tun*N*, ip6.tun*N*, or ip6to4.tun*N* for implicit IP tunnel links

  If the interface name starts with a dash (-), it is interpreted as a set of options which specify a set of interfaces. In such a case, -a must be part of the options and any of the additional options below can be added in any order. If one of these interface names is given, the commands following it are applied to all of the interfaces that match.

-a

Apply the command to all interfaces of the specified address family. If no address family is supplied, either on the command line or by means of /etc/default/inet_type, then all address families will be selected.

-d

Apply the commands to all "down" interfaces in the system.

-D

Apply the commands to all interfaces not under DHCP (Dynamic Host Configuration Protocol) control.

-u

Apply the commands to all "up" interfaces in the system.

-Z

Apply the commands to all interfaces in the user's zone.

-4

Apply the commands to all IPv4 interfaces.

-6

Apply the commands to all IPv6 interfaces.

address_family

The address family is specified by the *address_family* parameter. The ifconfig command currently supports the following families: inet and inet6. If no address family is specified, the default is inet.

ifconfig honors the DEFAULT_IP setting in the /etc/default/inet_type file when it displays interface information . If DEFAULT_IP is set to IP_VERSION4, then ifconfig will omit information that relates to IPv6 interfaces. However, when you explicitly specify an address family (inet or inet6) on the ifconfig command line, the command line overrides the DEFAULT_IP settings.

address

For the IPv4 family (inet), the *address* is either a host name present in the host name data base (see hosts(4)) or in the Network Information Service (NIS) map hosts, or an IPv4 address expressed in the Internet standard "dot notation".

For the IPv6 family (inet6), the *address* is either a host name present in the host name data base (see hosts(4)) or in the Network Information Service (NIS) map ipnode, or an IPv6 address expressed in the Internet standard colon-separated hexadecimal format represented as *x:x:x:x:x:x:x:x* where *x* is a hexadecimal number between 0 and FFFF.

prefix_length

For the IPv4 and IPv6 families (inet and inet6), the *prefix_length* is a number between 0 and the number of bits in the address. For inet, the number of bits in the address is 32; for inet6, the number of bits in the address is 128. The *prefix_length* denotes the number of leading set bits in the netmask.

dest_address
> If the *dest_address* parameter is supplied in addition to the *address* parameter, it specifies the address of the correspondent on the other end of a point-to-point link.

tunnel_dest_address
> An address that is or will be reachable through an interface other than the tunnel being configured. This tells the tunnel where to send the tunneled packets. This address must not be the same as the interface destination address being configured.

tunnel_src_address
> An address that is attached to an already configured interface that has been configured "up" with ifconfig.

Interface Flags The ifconfig command supports the following interface flags. The term "address" in this context refers to a logical interface, for example, eri0:0, while "interface" refers to the physical interface, for example, eri0.

ADDRCONF
> The address is from stateless addrconf. The stateless mechanism allows a host to generate its own address using a combination of information advertised by routers and locally available information. Routers advertise prefixes that identify the subnet associated with the link, while the host generates an "interface identifier" that uniquely identifies an interface in a subnet. In the absence of information from routers, a host can generate link-local addresses. This flag is specific to IPv6.

ANYCAST
> Indicates an anycast address. An anycast address identifies the nearest member of a group of systems that provides a particular type of service. An anycast address is assigned to a group of systems. Packets are delivered to the nearest group member identified by the anycast address instead of being delivered to all members of the group.

BROADCAST
> This broadcast address is valid. This flag and POINTTOPOINT are mutually exclusive

CoS
> This interface supports some form of Class of Service (CoS) marking. An example is the 802.1D user priority marking supported on VLAN interfaces. For IPMP IP interfaces, this will only be set if all interfaces in the group have CoS set.
>
> Note that this flag is only set on interfaces over VLAN links and over Ethernet links that have their dladm(1M) tagmode link property set to normal.

DEPRECATED
> This address is deprecated. This address will not be used as a source address for outbound packets unless there are no other addresses on this interface or an application has explicitly bound to this address. An IPv6 deprecated address is part of the standard mechanism for renumbering in IPv6 and will eventually be deleted when not used. For both IPv4 and IPv6, DEPRECATED is also set on all NOFAILOVER addresses, though this may change in a future release.

DHCPRUNNING

The logical interface's address is managed by dhcpagent(1M). For IPv6, this will also be set on the zeroth logical interface if DHCPv6 has been started on the interface; see in.ndpd(1M).

DUPLICATE

The logical interface has been disabled because the IP address configured on the interface is a duplicate. Some other node on the network is using this address. If the address was configured by DHCP or is temporary, the system will choose another automatically, if possible. Otherwise, the system will attempt to recover this address periodically and the interface will recover when the conflict has been removed from the network. Changing the address or netmask, or setting the logical interface to up will restart duplicate detection. Setting the interface to down terminates recovery and removes the DUPLICATE flag.

FAILED

The in.mpathd daemon has determined that the interface has failed. FAILED interfaces will not be used to send or receive IP data traffic. If this is set on a physical IP interface in an IPMP group, IP data traffic will continue to flow over other usable IP interfaces in the IPMP group. If this is set on an IPMP IP interface, the entire group has failed and no data traffic can be sent or received over any interfaces in that group.

FIXEDMTU

The MTU has been set using the -mtu option. This flag is read-only. Interfaces that have this flag set have a fixed MTU value that is unaffected by dynamic MTU changes that can occur when drivers notify IP of link MTU changes.

INACTIVE

The physical interface is functioning but is not used to send or receive data traffic according to administrative policy. This flag is initially set by the standby subcommand and is subsequently controlled by in.mpathd. It also set when FAILBACK=no mode is enabled (see in.mpathd(1M)) to indicate that the IP interface has repaired but is not being used.

IPMP

Indicates that this is an IPMP IP interface.

LOOPBACK

Indicates that this is the loopback interface.

MULTI_BCAST

Indicates that the broadcast address is used for multicast on this interface.

MULTICAST

The interface supports multicast. IP assumes that any interface that supports hardware broadcast, or that is a point-to-point link, will support multicast.

NOARP

There is no address resolution protocol (ARP) for this interface that corresponds to all interfaces for a device without a broadcast address. This flag is specific to IPv4.

NOFAILOVER

The address associated with this logical interface is available to in.mpathd for probe-based failure detection of the associated physical IP interface.

NOLOCAL

The interface has no address , just an on-link subnet.

NONUD

NUD is disabled on this interface. NUD (neighbor unreachability detection) is used by a node to track the reachability state of its neighbors, to which the node actively sends packets, and to perform any recovery if a neighbor is detected to be unreachable. This flag is specific to IPv6.

NORTEXCH

The interface does not exchange routing information. For RIP-2, routing packets are not sent over this interface. Additionally, messages that appear to come over this interface receive no response. The subnet or address of this interface is not included in advertisements over other interfaces to other routers.

NOXMIT

Indicates that the address does not transmit packets. RIP-2 also does not advertise this address.

OFFLINE

The interface is offline and thus cannot send or receive IP data traffic. This is only set on IP interfaces in an IPMP group. See if_mpadm(1M) and cfgadm(1M).

POINTOPOINT

Indicates that the address is a point-to-point link. This flag and BROADCAST are mutually exclusive

PREFERRED

This address is a preferred IPv6 source address. This address will be used as a source address for IPv6 communication with all IPv6 destinations, unless another address on the system is of more appropriate scope. The DEPRECATED flag takes precedence over the PREFERRED flag.

PRIVATE

Indicates that this address is not advertised. For RIP-2, this interface is used to send advertisements. However, neither the subnet nor this address are included in advertisements to other routers.

PROMISC

A read-only flag indicating that an interface is in promiscuous mode. All addresses associated with an interface in promiscuous mode will display (in response to ifconfig -a, for example) the PROMISC flag.

ROUTER

Indicates that IP packets can be forwarded to and from the interface.

RUNNING

Indicates that the required resources for an interface are allocated. For some interfaces this also indicates that the link is up. For IPMP IP interfaces, RUNNING is set as long as one IP interface in the group is active.

STANDBY

Indicates that this physical interface will not be used for data traffic unless another interface in the IPMP group becomes unusable. The INACTIVE and FAILED flags indicate whether it is actively being used.

TEMPORARY

Indicates that this is a temporary IPv6 address as defined in RFC 3041.

UNNUMBERED

This flag is set when the local IP address on the link matches the local address of some other link in the system

UP

Indicates that the logical interface (and the associated physical interface) is up. The IP module will accept packets destined to UP addresses (unless the address is zero), along with any associated multicast and broadcast IP addresses. Similarly, the IP module will allow packets to be sent with an UP address as a source address.

VIRTUAL

Indicates that the physical interface has no underlying hardware. It is not possible to transmit or receive packets through a virtual interface. These interfaces are useful for configuring local addresses that can be used on multiple interfaces. (See also the usesrc option.)

L3PROTECT

Indicates that Layer-3 protection has been enforced on the physical interface using the allowed-ips link property in dladm(1M).

PROBER

Indicates that the FAILED underlying interface in an IPMP group is probing to discover if it has been repaired. The PROBER flag and its semantics are internal to the Solaris IPMP implementation and subject to change.

Logical Interfaces Solaris TCP/IP allows multiple logical interfaces to be associated with a physical network interface. This allows a single machine to be assigned multiple IP addresses, even though it may have only one network interface. Physical network interfaces have names of the form *driver-name physical-unit-number*, while logical interfaces have names of the form *driver-name physical-unit-number*:*logical-unit-number*. A physical interface is configured into the system using the plumb command. For example:

example% **ifconfig eri0 plumb**

Once a physical interface has been "plumbed", logical interfaces associated with the physical interface can be configured by separate -plumb or -addif options to the ifconfig command.

example% **ifconfig eri0:1 plumb**

allocates a specific logical interface associated with the physical interface eri0. The command

example% **ifconfig eri0 addif 192.168.200.1/24 up**

allocates the next available logical unit number on the eri0 physical interface and assigns an *address* and *prefix_length*.

A logical interface can be configured with parameters (*address*,*prefix_length*, and so on) different from the physical interface with which it is associated. Logical interfaces that are associated with the same physical interface can be given different parameters as well. Each logical interface must be associated with an existing and "up" physical interface. So, for example, the logical interface eri0:1 can only be configured after the physical interface eri0 has been plumbed.

To delete a logical interface, use the unplumb or removeif options. For example,

example% **ifconfig eri0:1 down unplumb**

will delete the logical interface eri0:1.

Ip Multipathing Groups Physical interfaces that share the same link–layer broadcast domain *must* be collected into a single IP Multipathing (IPMP) group using the group subcommand. Each IPMP group has an associated IPMP IP interface, which can either be explicitly created (the preferred method) by using the ipmp subcommand or implicitly created by ifconfig in response to placing an IP interface into a new IPMP group. Implicitly-created IPMP interfaces will be named ipmp*N* where *N* is the lowest integer that does not conflict with an existing IP interface name or IPMP group name.

Each IPMP IP interface is created with a matching IPMP group name, though it can be changed using the group subcommand. Each IPMP IP interface hosts a set of highly-available IP addresses. These addresses will remain reachable so long as at least one interface in the group is active, where "active" is defined as having at least one UP address and having INACTIVE, FAILED, and OFFLINE clear. IP addresses hosted on the IPMP IP interface may either be configured statically or configured through DHCP by means of the dhcp subcommand.

Interfaces assigned to the same IPMP group are treated as equivalent and monitored for failure by in.mpathd. Provided that active interfaces in the group remain, IP interface failures (and any subsequent repairs) are handled transparently to sockets-based applications. IPMP is also integrated with the Dynamic Reconfiguration framework (see cfgadm(1M)), which enables network adapters to be replaced in a way that is invisible to sockets-based applications.

The IP module automatically load-spreads all outbound traffic across all active interfaces in an IPMP group. Similarly, all UP addresses hosted on the IPMP IP interface will be distributed

across the active interfaces to promote inbound load-spreading. The ipmpstat(1M) utility allows many aspects of the IPMP subsystem to be observed, including the current binding of IP data addresses to IP interfaces.

When an interface is placed into an IPMP group, any UP logical interfaces are "migrated" to the IPMP IP interface for use by the group, unless:

- the logical interface is marked NOFAILOVER;
- the logical interface hosts an IPv6 link-local address;
- the logical interface hosts an IPv4 0.0.0.0 address.

Likewise, once an interface is in a group, if changes are made to a logical interface such that it is UP and not exempted by one of the conditions above, it will also migrate to the associated IPMP IP interface. Logical interfaces never migrate back, even if the physical interface that contributed the address is removed from the group.

Each interface placed into an IPMP group may be optionally configured with a "test" address that in.mpathd will use for probe-based failure detection; see in.mpathd(1M). These addresses must be marked NOFAILOVER (using the -failover subcommand) prior to being marked UP. Test addresses may also be acquired through DHCP by means of the dhcp subcommand.

For more background on IPMP, please see the IPMP–related chapters of the *Oracle Solaris Administration: Network Interfaces and Network Virtualization*.

Configuring Ipv6 Interfaces When an IPv6 physical interface is plumbed and configured "up" with ifconfig, it is automatically assigned an IPv6 link-local address for which the last 64 bits are calculated from the MAC address of the interface.

```
example% ifconfig eri0 inet6 plumb up
```

The following example shows that the link-local address has a prefix of fe80::/10.

```
example% ifconfig eri0 inet6
ce0: flags=2000841<UP,RUNNING,MULTICAST,IPv6>
        mtu 1500 index 2
        inet6 fe80::a00:20ff:fe8e:f3ad/10
```

Link-local addresses are only used for communication on the local subnet and are not visible to other subnets.

If an advertising IPv6 router exists on the link advertising prefixes, then the newly plumbed IPv6 interface will autoconfigure logical interface(s) depending on the prefix advertisements. For example, for the prefix advertisement 2001:0db8:3c4d:0:55::/64, the autoconfigured interface will look like:

```
eri0:2: flags=2080841<UP,RUNNING,MULTICAST,ADDRCONF,IPv6>
        mtu 1500 index 2
        inet6 2001:0db8:3c4d:55:a00:20ff:fe8e:f3ad/64
```

Even if there are no prefix advertisements on the link, you can still assign global addresses manually, for example:

```
example% ifconfig eri0 inet6 addif \
2001:0db8:3c4d:55:a00:20ff:fe8e:f3ad/64 up
```

Configuring IP-over-IP Tunnel Interfaces

An IP tunnel is conceptually comprised of two parts: a virtual link between two or more IP nodes, and an IP interface above this link which allows the system to transmit and receive IP packets encapsulated by the underlying link.

The dladm(1M) command is used to configure tunnel links, and ifconfig is used to configure IP interfaces over those tunnel links. An IPv4-over-IPv4 tunnel is created by plumbing an IPv4 interface over an IPv4 tunnel link. An IPv6-over-IPv4 tunnel is created by plumbing an IPv6 interface over an IPv6 tunnel link, and so forth.

When IPv6 interfaces are plumbed over IP tunnel links, their IPv6 addresses are automatically set. For IPv4 and IPv6 tunnels, source and destination link-local addresses of the form fe80::*interface-id* are configured. For IPv4 tunnels, the *interface-id* is the IPv4 tunnel source or destination address. For IPv6 tunnels, the *interface-id* is the last 64 bits of the IPv6 tunnel source or destination address. For example, for an IPv4 tunnel between 10.1.2.3 and 10.4.5.6, the IPv6 link-local source and destination addresses of the IPv6 interface would be fe80::a01:203 and fe80::a04:506. For an IPv6 tunnel between 2000::1234:abcd and 3000::5678:abcd, the IPv6 link-local source and destination addresses of the interface would be fe80::1234:abcd and fe80::5678:abcd. These default link-local addresses can be overridden by specifying the addresses explicitly, as with any other point-to-point interface.

For 6to4 tunnels, a 6to4 global address of the form 2002:*tsrc*::1/16 is configured. The *tsrc* portion is the tunnel source IPv4 address. The prefix length of the 6to4 interface is automatically set to 16, as all 6to4 packets (destinations in the 2002::/16 range) are forwarded to the 6to4 tunnel interface. For example, for a 6to4 link with a tunnel source of 75.1.2.3, the IPv6 interface would have an address of 2002:4b01:203::1/16.

Additional IPv6 addresses can be added using the addif option or by plumbing additional logical interfaces.

For backward compatibility, the plumbing of tunnel IP interfaces with special names will implicitly result in the creation of tunnel links without invoking dladm create-iptun. These tunnel names are:

ip.tun*N*   An IPv4 tunnel

ip6.tun*N*   An IPv6 tunnel

ip.6to4tun*N*   A 6to4 tunnel

These tunnels are "implicit tunnels", denoted with the i flag in dladm show-iptun output. The tunnel links over which these special IP interfaces are plumbed are automatically created, and they are automatically deleted when the last reference is released (that is, when the last IP interface is unplumbed).

The tsrc, tdst, encaplim, and hoplimit options to ifconfig are obsolete and maintained only for backward compatibility. They are equivalent to their dladm(1M) counterparts.

Display of Tunnel Security Settings
The ifconfig output for IP tunnel interfaces indicates whether IPsec policy is configured for the underlying IP tunnel link. For example, a line of the following form will be displayed if IPsec policy is present:

```
tunnel security settings  -->  use 'ipsecconf -ln -i ip.tun1'
```

If you do net set security policy, using either ifconfig or ipsecconf(1M), there is no tunnel security setting displayed.

Examples EXAMPLE 1   Using the ifconfig Command

If your workstation is not attached to an Ethernet, the network interface, for example, eri0, should be marked "down" as follows:

```
example% ifconfig eri0 down
```

EXAMPLE 2   Printing Addressing Information

To print out the addressing information for each interface, use the following command:

```
example% ifconfig -a
```

EXAMPLE 3   Resetting the Broadcast Address

To reset each interface's broadcast address after the netmasks have been correctly set, use the next command:

```
example% ifconfig -a broadcast +
```

EXAMPLE 4   Changing the Ethernet Address

To change the Ethernet address for interface ce0, use the following command:

```
example% ifconfig ce0 ether aa:1:2:3:4:5
```

EXAMPLE 5   Configuring an IP-in-IP Tunnel

To configure an IP-in-IP tunnel, first create an IP tunnel link (tunsrc and tundst are hostnames with corresponding IPv4 entries in /etc/hosts):

```
example% dladm create-iptun -T ipv4 -s tunsrc -d tundst tun0
```

Then plumb a point-to-point interface, supplying the source and destination addresses (mysrc and thedst are hostnames with corresponding IPv4 entries in /etc/hosts):

```
example% ifconfig tun0 plumb mysrc thedst up
```

Use ipsecconf(1M), as described above, to configure tunnel security properties.

EXAMPLE 5 Configuring an IP-in-IP Tunnel   *(Continued)*

Configuring IPv6 tunnels is done by using a tunnel type of `ipv6` with `create-iptun`. IPv6 interfaces can also be plumbed over either type of tunnel.

EXAMPLE 6 Configuring 6to4 Tunnels

To configure 6to4 tunnels, first create a 6to4 tunnel link (`myv4addr` is a hostname with a corresponding IPv4 entry in `/etc/hosts`):

```
example% dladm create-iptun -T 6to4 -s myv4addr my6to4tun0
```

Then an IPv6 interface is plumbed over this link:

```
example% ifconfig my6to4tun0 inet6 plumb up
```

The IPv6 address of the interface is automatically set as described above.

EXAMPLE 7 Configuring IP Forwarding on an Interface

To enable IP forwarding on a single interface, use the following command:

```
example% ifconfig eri0 router
```

To disable IP forwarding on a single interface, use the following command:

```
example% ifconfig eri0 -router
```

EXAMPLE 8 Configuring Source Address Selection Using a Virtual Interface

The following command configures source address selection such that every packet that is locally generated with no bound source address and going out on `qfe2` prefers a source address hosted on `vni0`.

```
example% ifconfig qfe2 usesrc vni0
```

The `ifconfig -a` output for the `qfe2` and `vni0` interfaces displays as follows:

```
qfe2: flags=1100843<UP,BROADCAST,RUNNING,MULTICAST,ROUTER,IPv4> mtu
  1500 index 4
  usesrc vni0
  inet 1.2.3.4 netmask ffffff00 broadcast 1.2.3.255
  ether 0:3:ba:17:4b:e1
vni0: flags=20011100c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL>
  mtu 0 index 5
  srcof qfe2
  inet 3.4.5.6 netmask ffffffff
```

Observe, above, the `usesrc` and `srcof` keywords in the `ifconfig` output. These keywords also appear on the logical instances of the physical interface, even though this is a per-physical

EXAMPLE 8   Configuring Source Address Selection Using a Virtual Interface   *(Continued)*

interface parameter. There is no srcof keyword in ifconfig for configuring interfaces. This information is determined automatically from the set of interfaces that have usesrc set on them.

The following command, using the none keyword, undoes the effect of the preceding ifconfig usesrc command.

example% **ifconfig qfe2 usesrc none**

Following this command, ifconfig -a output displays as follows:

```
qfe2: flags=1100843<UP,BROADCAST,RUNNING,MULTICAST,ROUTER,IPv4> mtu
  1500 index 4
  inet 1.2.3.4 netmask ffffff00 broadcast 1.2.3.255
  ether 0:3:ba:17:4b:e1
vni0: flags=20011100c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL>
  mtu 0 index 5
  inet 3.4.5.6 netmask ffffffff
```

Note the absence of the usesrc and srcof keywords in the output above.

EXAMPLE 9   Configuring Source Address Selection for an IPv6 Address

The following command configures source address selection for an IPv6 address, selecting a source address hosted on vni0.

example% **ifconfig qfe1 inet6 usesrc vni0**

Following this command, ifconfig -a output displays as follows:

```
qfe1: flags=2000841<UP,RUNNING,MULTICAST,IPv6> mtu 1500 index 3
  usesrc vni0
  inet6 fe80::203:baff:fe17:4be0/10
  ether 0:3:ba:17:4b:e0
vni0: flags=2002210041<UP,RUNNING,NOXMIT,NONUD,IPv6,VIRTUAL> mtu 0
  index 5
  srcof qfe1
  inet6 fe80::203:baff:fe17:4444/128
vni0:1: flags=2002210040<RUNNING,NOXMIT,NONUD,IPv6,VIRTUAL> mtu 0
  index 5
  srcof qfe1
  inet6 fec0::203:baff:fe17:4444/128
vni0:2: flags=2002210040<RUNNING,NOXMIT,NONUD,IPv6,VIRTUAL> mtu 0
  index 5
  srcof qfe1
  inet6 2000::203:baff:fe17:4444/128
```

EXAMPLE 9 Configuring Source Address Selection for an IPv6 Address   *(Continued)*

Depending on the scope of the destination of the packet going out on qfe1, the appropriately scoped source address is selected from vni0 and its aliases.

EXAMPLE 10 Using Source Address Selection with Shared-IP Zones

The following is an example of how the usesrc feature can be used with the zones(5) facility in Solaris. The following commands are invoked in the global zone:

```
example% ifconfig hme0 usesrc vni0
example% ifconfig eri0 usesrc vni0
example% ifconfig qfe0 usesrc vni0
```

Following the preceding commands, the ifconfig -a output for the virtual interfaces would display as:

```
vni0: flags=20011100c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL>
   mtu 0 index 23
   srcof hme0 eri0 qfe0
   inet 10.0.0.1 netmask ffffffff
vni0:1:
   flags=20011100c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL> mtu 0
   index 23
   zone test1
   srcof hme0 eri0 qfe0
   inet 10.0.0.2 netmask ffffffff
vni0:2:
   flags=20011100c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL> mtu 0
   index 23
   zone test2
   srcof hme0 eri0 qfe0
   inet 10.0.0.3 netmask ffffffff
vni0:3:
   flags=20011100c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL> mtu 0
   index 23
   zone test3
   srcof hme0 eri0 qfe0
   inet 10.0.0.4 netmask ffffffff
```

There is one virtual interface alias per zone (test1, test2, and test3). A source address from the virtual interface alias in the same zone is selected. The virtual interface aliases were created using zonecfg(1M) as follows:

```
example% zonecfg -z test1
zonecfg:test1> add net
zonecfg:test1:net> set physical=vni0
zonecfg:test1:net> set address=10.0.0.2
```

EXAMPLE 10 Using Source Address Selection with Shared-IP Zones   *(Continued)*

The test2 and test3 zone interfaces and addresses are created in the same way.

EXAMPLE 11 Turning Off DHCPv6

The following example shows how to disable automatic use of DHCPv6 on all interfaces, and immediately shut down DHCPv6 on the interface named hme0. See in.ndpd(1M) and ndpd.conf(4) for more information on the automatic DHCPv6 configuration mechanism.

```
example% echo ifdefault StatefulAddrConf false >> /etc/inet/ndpd.conf
example% pkill -HUP -x in.ndpd
example% ifconfig hme0 dhcp release
```

Files   /etc/netmasks
   Netmask data.

/etc/default/inet_type
   Default Internet protocol type.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability for command-line options	Committed
Interface Stability for command output	Uncommitted

Oracle Solaris Administration: IP Services

Diagnostics   ifconfig sends messages that indicate if:

- the specified interface does not exist
- the requested address is unknown
- the user is not privileged and tried to alter an interface's configuration

Notes   Do not select the names broadcast, down, private, trailers, up or other possible option names when you choose host names. If you choose any one of these names as host names, it can cause unusual problems that are extremely difficult to diagnose.

Name if_mpadm – administer interfaces in an IP multipathing group

Synopsis if_mpadm -d | -r *ifname*

Description The if_mpadm utility administers IP interfaces that are part of an IP Multipathing (IPMP)
group. Currently, administration is limited to offlining IP interfaces and undoing previous
offline operations.

When an IP interface is taken offline, all IP data traffic that was flowing over the IP interface is
moved to another IP interface in the IPMP group. In addition, all UP IP addresses hosted on
the IP interface are brought down, causing in.mpathd(1M) to stop probe-based failure
detection on the IP interface. As a result, an offline IP interface will not be used for any
inbound or outbound IP traffic. Only IP interfaces that are in an IPMP group may be brought
offline. If the IP interface is the last functioning interface in the IPMP group, the offline
operation will fail.

When an offline operation is undone, any IP addresses hosted on that IP interface are brought
UP and will be considered by in.mpathd for probe-based failure detection. In addition,
provided the IP interface is otherwise active (see in.mpathd(1M)), it will again be used to send
and receive IP data traffic for the IPMP group. Note that not all offline operations can be
undone. For instance, in.mpathd may have offlined an IP interface because its hardware
address was not unique within its IPMP group. The ipmpstat utility can be used to determine
why an IP interface is offline, identify which IP interfaces in a group are being used for
inbound and outbound IP traffic, and more; see ipmpstat(1M).

Options The if_mpadm utility supports the following options:

-d *ifname*   Offline the IP interface specified by *ifname*. If *ifname* is not in an IPMP group,
                or the offline would cause the IPMP group to lose network connectivity, the
                operation will fail.

-r *ifname*   Undo a previous offline of the IP interface specified by *ifname*. If *ifname* is not
                offline, the operation will fail.

Examples EXAMPLE 1   Offlining an IP Interface

The following command offlines the IP interface under0, causing any IP packets that were
being sent and received through it to be handled by another IP interface in its group.

example% **if_mpadm -d under0**

EXAMPLE 2   Undoing a Previous Offline Operation

Use the following command to undo the operation in the previous example:

example% **if_mpdadm -r under0**

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Uncommitted

See Also ifconfig(1M), in.mpathd(1M), ipmpstat(1M), attributes(5)

Diagnostics cannot offline: no other functioning interfaces are in its IPMP group.
Description: This message means that offlining the IP interface would leave the IPMP group without network connectivity.

cannot offline: not a physical interface or not in an IPMP group
Description: This means that the IP interface is not an underlying interface in an IPMP group, and therefore is not eligible to be offlined.

Name ifparse – parse ifconfig command line

Synopsis /usr/sbin/ifparse [-fs] *addr_family commands*

Description Use the ifparse command to parse the ifconfig(1M) command line options and output substrings, one per line, as appropriate. If no options are specified, ifparse returns the entire ifconfig command line as a series of substrings, one per line.

Options The ifparse command supports the following options:

-f   Lists only substrings of the ifconfig command line that are relevant to IP network multipath failover

-s   Lists only substrings of the ifconfig command line that are not relevant to IP network multipath failover

Operands The ifparse command *does not* support the *interface* operand of the ifconfig command.

Examples EXAMPLE 1   Parsing Command Line Options Relevant to Failover

The following example shows the use of the ifparse command to parse the command line options relevant to IP network multipath failover:

```
example# ifparse -f inet 1.2.3.4 up group one addif 1.2.3.5 -failover up
set 1.2.3.4 up
```

EXAMPLE 2   Parsing Command Line Options That Are Not Relevant to Failover

The following example shows the use of the ifparse command to parse the command line options that are not relevant to IP network multipath failover:

```
example# ifparse -s inet 1.2.3.4 up group one addif 1.2.3.5 -failover up
group one
addif 1.2.3.5 -failover up
```

EXAMPLE 3   Parsing the Command Line For All Options

The following example shows the use of the ifparse command to parse the command line for all ifconfig options:

```
example# ifparse inet 1.2.3.4 up group one addif 1.2.3.5 -failover up
group one
set 1.2.3.4 up
addif 1.2.3.5 -failover up
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Obsolete

See Also ifconfig(1M), attributes(5)

Diagnostics usage: -fs <addr_family> <commands>
   Description: This message indicates an invalid command line.

   ifparse: Not enough space
   Description: This message indicates insufficient memory.

   ifparse: dhcp not supported for inet6
   Description: DHCP operations are not supported for the inet6 address family.

   ifparse: Operation <operation> not supported for <addr_family>
   Description: Most operations cannot be used with all address families. For example, the
   broadcast operation is not supported on the inet6 address family.

   ifparse: no argument for <operation>
   Description: Some operations, for example broadcast, require an argument.

Notes The ifparse command is classified as an obsolete interface. It will likely be removed in a
   future release. You should not develop applications that depend upon this interface.

Name   iiadm – command–line interface to control Sun StorageTek Availability Suite Point-in-Time Copy operations

Synopsis   iiadm -e {ind | shd} *master_vol shadow_vol bitmap_vol*

iiadm -ne ind *master_vol shadow_vol bitmap_vol*

iiadm [-p] [-n] {-c | -u} {s | m} *volume_set*

iiadm [-adDilR] *volume_set*

iiadm [-p] [-n] -w *volume_set*

iiadm [-hilLv]

iiadm -P *delay units volume_set*

iiadm -P *volume_set*

iiadm -A *overflow_vol volume_set*

iiadm [-OQ] *overflow_vol*

iiadm -E *volume_set*

iiadm [-IJ] *volume_set bitmap*

iiadm -g *group_name* [-aAcdDeEilLmPRuw]

iiadm [-C] *cluster_tag* [*options*]

Description   Point-in-Time Copy software is a point-in-time snapshot feature of the Solaris operating system.

A Point-in-Time Copy snapshot is an instantly-available, time-fixed, replicated view of a momentarily quiesced volume. Once a snapshot is taken, Point-in-Time Copy software allows immediate read/write access to both the master and shadow volume data.

Point-in-Time Copy software tracks the differences between the master and shadow volumes (caused by writes) from the moment that the snapshot was established. This capability allows applications accessing the master volume's data to move forward in time independently of applications accessing the shadow volume's data, and vice-versa.

The Point-in-Time Copy software's tracking of differences between the master and shadow volumes facilitates a fast resynchronization or a full copy at a later time. The volume resynchronization can occur from either shadow to master or master to shadow.

Instantly after the point-in-time is (re-)established (either when the CLI prompt returns or the next shell script command is read), the master volume can be remounted or the applications using them can be resumed. Also, the shadow volume can be mounted and immediately accessed.

The iiadm command line utility performs only one action per command invocation. Because of this, you cannot combine multiple options, except in combination with the following overall command modifiers:

- If no action item is entered, `iiadm` displays the list of Point-in-Time Copy sets (non-suspended) currently configured. If more than one action item, or an incorrectly specified action item is entered, `iiadm` displays the specific error message to stderr, followed by a brief usage summary.

- For the Point-in-Time Copy options ENABLE (`-e`), COPY (`-c`) and UPDATE (`-u`), there are two associated shadow volume selection qualifiers, `{ind|dep}`, that are used to specify the type of Point-in-Time Copy volume set to create.

An independent (`ind`) snapshot causes Point-in-Time Copy software to perform a full volume copy operation from the master to the shadow. When the copy completes, the shadow volume data is identical to the master volume data at the moment that it was established. Create an independent shadow if you require two physical copies of the data. An independent shadow volume must be the same size or greater than the size of the master volume. Sun recommends that the master and shadow volumes be the same size for environments where resynchronization from shadow to master is a consideration.

A dependent (`dep`) snapshot causes Point-in-Time Copy software not to perform a full volume copy. The resulting shadow volume relies on the master volume for all unmodified data blocks, which are not copied until requested. Create a dependent shadow when you do not require two physical copies of the data. A dependent shadow volume can be either the same size or smaller than the master volume. A smaller shadow volume is called a *Compact Dependent Shadow Volume*, and is typically used when the amount of change that occurs to a Point-in-Time Copy volume set is small compared to the entire size of the master volume.

The following syntax allows you to create an exportable independent shadow volume in a Sun Cluster environment:

```
# iiadm -ne ind master shadow bitmap
```

An issue arises when using a Compact Dependent Shadow Volume in that its size is established at the time that the Point-in-Time Copy volume set is enabled. If the amount of change to the entire volume set over the duration of its usage exceeds the space allocated for the shadow volume, the shadow volume is marked as out of space. It is possible to read from the shadow volume even after it is out of space, until a portion of the data for which there was no room is requested. Once that happens, the read fails and the shadow volume is marked offline.

To address this issue, Point-in-Time Copy supports the ability to associate an *overflow* volume to an existing Point-in-Time Copy dependent volume set. Thus, if the size of the Compact Dependent Shadow Volume is too small, or an unscheduled amount of change occurs to the volume set, changed data can be redirected to the associated overflow volume. To facilitate efficient usage of this overflow volume, it can be associated with multiple Point-in-Time Copy volume sets on an as-needed basis.

Considerations Prior to invoking an Point-in-Time Copy `enable`, `copy` or `update` operation, Point-in-Time Copy assures that the shadow volume is not mounted, to prevent a file system panic from occurring. Also, it is suggested that you either unmount or suspend (quiesce) all applications using the master volume, for only the instant when the point-in-time snapshot is taken. This assures that an atomically consistent point-in-time snapshot is taken.

It is suggested that, if the master volume was suspended rather than unmounted, the new point-in-time shadow volume's integrity be validated using volume validation utilities, such as [fsck(1M)](). The reason is that Point-in-Time Copy has made a point-in-time copy of a `mounted` master volume to an `unmounted` shadow volume. During the mounting of the shadow volume, the file system detects that it is in the `mounted` state. Typically this state occurs only when a system crashes, so the file system attempts to validate the integrity of the volume assuming a system failure occurred, not an Point-in-Time Copy.

ENVIRONMENT   The `ii_bitmap` variable in the `/usr/kernel/drv/ii.conf` configuration file determines the
OPTIONS   bitmap volume operational semantics as follows:

0   Indicates that the bitmap is maintained in memory only or resume operation.

1   Indicates that the bitmap is maintained in memory and on disk. This is the default value.

If a system failure occurrs while using `ii_bitmap=0`, the shadow volume might be inconsistent and fast resynchronization would not be possible.

If Point-in-Time Copy is used in conjunction with the Network Storage component Remote Mirror or in a Sun Cluster, set `ii_bitmap=1`.

The `ii_debug` variable in the `/usr/kernel/drv/ii.conf` configuration file determines the amount of information logging that is output to the system console `/dev/console` during Point-in-Time Copy processing.

0   Indicates that no logging is sent to the system console.

1   Indicates that informational logging is sent to the system console.

2   Indicates that developmental logging is sent to the system console.

Options The iiadm utility supports the following options.

-e{ind|dep} *master_vol shadow_vol bitmap_vol*
  Enable Point-in-Time Copy for the specified master, shadow, and bitmap volumes.

  The enable shadow set processing assures that the specified volumes are accessible, that the *shadow_vol* is not mounted, and that the *bitmap_vol* is correctly sized for the type of shadow set being created. Additionally, it assures that the volumes are under control of the SV driver (if they are not, it puts them there), initializes the bitmap volume, and, if the volume set is an independent shadow set, a full copy operation is initiated.

On a successful enable, Point-in-Time Copy stores the specified *master_vol*, *shadow_vol* and *bitmap_vol* names, plus the enabling type (`ind` or `dep`), into the Point-in-Time Copy configuration store. The configuration store contains all currently configured Point-in-Time Copy Volume Sets and their associated configuration attributes. (See discussion above on independent and dependent shadow volume semantics.)

master_vol is the volume from which a point-in-time snapshot is made.

shadow_vol is the volume that contains the point-in-time snapshot.

bitmap_vol is used for tracking differences between the shadow and master volumes. When Point-in-Time Copy shadow operations are suspended or resumed, the bitmap volume (maintained in kernel memory) can be stored in or retrieved from permanent storage. The storage associated with the bitmap volume should be as redundant as that of the shadow volume storage.

The *shadow_vol* name is the name that the Point-in-Time Copy Shadow Set is known by for all `iiadm` options requiring specification of a *volume_set* name.

-d *volume_set*

Disable the Point-in-Time Copy volume set associated with the specified *volume_set*.

If Point-in-Time Copy was running in `independent` mode as specified in the `-e ind` options, above, the shadow volume data contains the same data as it did before it was disabled (assuming no writes have occurred). Users can access the master and shadow volumes, as they are now standalone point-in-time copies.

During the time that the full copy is active, an `independent` volume operates as though it is a `dependent` volume. To assure that the volume is no longer in full copy mode, issue the following command to wait for the full copy to complete:

```
# iiadm -w volume_set
```

[-p] -u s *volume_set*

Update the shadow volume from the master.

Updates a point-in-time copy of the master volume to the shadow volume. *volume_set* is the Point-in-Time Copy shadow set containing the master and shadow volumes. This option provides a fast resynchronization of the shadow volume, creating an incremental copy of the master. This update copies all 32KB segments flagged as different between the master and shadow volumes. It does not copy all master volume data, only changed data. While the data is being copied, the shadow is dependent upon the master volume.

Before using this option, momentarily quiesce the workload to the volumes; stop the host application from writing to the volumes. This ensures that the point-in-time data is consistent. You can visually check the status of this copy or update operation with `iiadm -i` *volume_set*, or interactively (by means of a shell or script) with `iiadm -w` *volume_set*, before using the target volume for any other operations.

This command supports PID (Process IDentifier) locking, by using the option `-p`, `iiadm -p -u s`. Enabling this option prevents other processes from taking a new point-in-time snapshot, thus invalidating prior point-in-time data.

[`-p`] [`-n`] `-u m` *volume_set*
Updates a point-in-time copy of the master volume from the shadow. *volume_set* is the Point-in-Time Copy volume set containing the master and shadow. This option provides a fast resynchronization of the master volume, creating an incremental copy of the shadow. This update copies all 32KB segments flagged as different between the master and shadow volumes. It does not copy all shadow volume data, only changed data. While the data is being copied, the master is dependent upon the shadow volume.

Before using this option, momentarily quiesce the workload to the volumes; stop the host application from writing to the volumes. This ensures that the point-in-time data is consistent. You can visually check the status of this copy or update operation with `iiadm -i` *volume_set*, or interactively (by means of a shell or script) with `iiadm -w` *volume_set*, before using the target volume for any other operations.

This command is query enabled to prevent accidentally overwriting the data on a master volume. When this command option is used in scripts, add the `-n` option to prevent the query from occurring.

This command supports PID (Process IDentifier) locking, by using the option `-p`, `iiadm -p -u m`. Enabling this option prevents other processes from taking a new point-in-time snapshot, thus invalidating prior point-in-time data.

[`-p`] `-c s` *volume_set*
Copy the master volume to the shadow.

Creates a point-in-time copy of the master volume to the shadow volume. *volume_set* is the Point-in-Time Copy volume set containing the master and shadow. This option writes all data in the point-in-time copy of the master volume to the shadow volume. While the data is being copied from master to shadow, the shadow is dependent on the master volume.

This option performs a full volume copy. Use `iiadm -u s` unless the integrity of the data on the independent shadow volume is in doubt. Otherwise, use this option to synchronize the master and shadow volumes; that is, make the data on each volume match.

Before using this option, momentarily quiesce the workload to the volumes; stop the host application from writing to the volumes. This ensures that the point-in-time data is consistent. You can visually check the status of this copy or update operation with `iiadm -i` *volume_set*, or interactively (by means of a shell or script) with `iiadm -w` *volume_set*, before using the target volume for any other operations.

This command supports PID (Process IDentifier) locking, by using the `-p` option, `iiadm -p -c s`. Enabling this option prevents other processes from taking a new point-in-time snapshot, thus invalidating prior point-in-time data.

-c m *volume_set*

Copy the shadow volume to the master.

Creates a point-in-time copy of the shadow volume to the master volume. *volume_set* is the Point-in-Time Copy volume set containing the master and shadow volumes. This option writes all data in the point-in-time copy of the shadow volume to the master volume. While the data is being copied from the shadow to the master, the master is dependent upon the shadow volume.

This option performs a full volume copy. Use iiadm -u m unless the integrity of the data on the independent master is in doubt. Otherwise, use this option to synchronize the master and shadow volumes; that is, make the data on each volume match.

Before using this option, momentarily quiesce the workload to the volumes; stop the host application from writing to the volumes. This ensures that the point-in-time data is consistent. You can visually check the status of this copy or update operation with iiadm -i *volume_set*, or interactively (by means of a shell or script) with iiadm -w *volume_set*, before using the target volume for any other operations.

This command is query-enabled to prevent accidentally overwriting the data on a master volume. When this command option is used in scripts, add the -n option to prevent the query from occurring.

This command supports PID (Process IDentifier) locking, by using the -p option, iiadm -p -c m. Enabling this option prevents other processes from taking a new point-in-time snapshot, thus invalidating prior point-in-time data.

-a *volume_set*

Abort any current copy operation that might be active between the master and shadow volumes. *volume_set* is the Point-in-Time Copy volume set containing the master and shadow volumes. After executing iiadm -a, the update or copy to the target (master or shadow) volume is incomplete. The target volume is now a dependent copy of the source volume. Reissue the update or copy command option to resynchronize the volumes.

[-p] [-n] -w *volume_set*

Wait until any in-progress copy or update operation completes or is aborted. *volume_set* is the Point-in-Time Copy volume set containing the master and shadow volumes.

This option waits until the current Point-in-Time Copy operation is complete, thus preventing a subsequent iiadm command (from a shell or script) from executing. Use this command option when you need to be sure the copy or update operation has completed.

This command supports PID (Process IDentifier) unlocking. If a prior copy or update, using a command iiadm -p {-c|-u} {m|s}, was invoked with the -p option, upon completion of the wait processing, if the current PID was the PID that locked the point-in-time data, this option unlocks the data.

-i *volume_set*

    Display status for the Point-in-Time Copy currently-enabled or -suspended volume set. *volume_set* is the Point-in-Time Copy volume set containing the master and shadow volumes. If no *volume_set* is specified, status is displayed for all Point-in-Time Copy volume sets that are configured.

-l

    List all currently configured Point-in-Time Copy volumes.

-O *overflow_vol*

    This option causes Point-in-Time Copy to initialize the specified *overflow_vol* for subsequent use as an overflow volume in conjunction with Compact Dependent Shadow Volumes. To facilitate efficient, shared usage of this overflow volume, it can be associated with multiple Point-in-Time Copy volume sets on an as-needed basis.

    During initialization of the *overflow_vol*, the initiator of this option, must answer the following question: "Initialize this overflow volume? yes/no" A response of either "yes/no" is required before proceeding.

    This option supports the -n option, so that the requested action is performed without prompting. This option is useful for inclusion in a script. The -n option must be specified first. For example, "iiadm -nO vol" is valid; "iiadm -On vol" is not.

    Make sure you want to initialize the data on the specified *overflow_vol*, especially when using the -n option.

-A *overflow_vol volume_set*

    This option enables the specified *overflow_vol*, for subsequent use as an overflow volume in a situation where the size of the Compact Dependent Shadow Volume is too small, or an unscheduled amount of change occurs to the volume set. Overflow changed data would be redirected to the associated overflow volume. *volume_set* is the Point-in-Time Copy volume set containing the master and shadow volumes.

    If the *overflow_vol* has not been initialized, this option initializes the *overflow_vol* (see -O option), then attaches the *overflow_vol* to the *volume_set*.

    If *overflow_vol* was previously initialized, this option attaches the *overflow_vol* to the *volume_set*.

    This option supports the -n option, so that the requested action is performed without prompting. This option is useful for inclusion in a script. The -n option must be specified first. For example, "iiadm -nA vol" is valid; "iiadm -An vol" is not.

    Make sure you want to initialize the data on the specified *overflow_vol*, especially when using the -n option.

-D *volume_set*

This option removes the overflow volume currently associated with the specified *volume_set*. If the overflow volume is currently in use by the *volume_set*, this operation fails with an "Overflow volume still in use" error message. To resolve this situation, perform one of the operations described below on the *volume_set*. These operations momentarily clear out all overflow writes that are associated with this volume set.

abort(-a)
    Abort copy operation.

disable(-d)
    Dissolve the volume set.

update(-u)
    Update the volume set.

-L

This option lists all overflow volumes which are associated with one or more volume sets.

-Q *overflow_vol*

This option displays the current status of the *overflow_vol*.

-E *volume_set*

Export the independent shadow volume of the Point-in-Time Copy volume set specified by *volume_set*. The shadow volume is to be made available to another host for read/write access, by means of an enabling technology, such as multi-ported devices. This other host is responsible for maintaining a bitmap of differences that is used to merge with locally recorded differences to the master when the shadow volume is rejoined to its master volume. While a shadow volume is exported it must not be subject to an update or copy operation. Perform an iiadm -w *volume_set* command prior to invoking an export command.

-I *volume_set bitmap_vol*

Import the independent shadow volume of the Point-in-Time Copy volume set specified by *volume_set*. The shadow volume must have been previously exported from a host by means of an enabling technology, such as multi-ported devices. The import operation causes this host to start maintaining a bitmap of differences as the volume is modified. The *bitmap_vol* should not be the same as that used when the shadow volume was originally formed into a shadow group.

After the exported/imported independent shadow volume is no longer needed by the other node, you must enter a disable command so that the *bitmap_vol* and its associated *shadow_vol* are consistent, prior to performing a join operation. For example,

    # iiadm -d *volume_set*

-J *volume_set bitmap_vol*

Join the *volume_set*, using the *bitmap_vol*, with the master volume set of the Point-in-Time Copy volume set. The bitmap volume supplied is read and merged with the original

volume to reconstruct the original volume set consisting of the master, shadow, and bitmap volumes. The *bitmap_vol* to be merged is the one obtained on the node that had imported the independent shadow volume. There must be no write activity to the shadow volume on the importing machine from the time the bitmap is copied over until the shadow is once again imported.

-g *group_name* -m *volume_set [volume_set2 ...]*

Add one or more existing Point-in-Time Copy *volume_set(s)* into a user specified *group_name*. This association of one or more Point-in-Time Copy volume sets in a group allows the list of iiadm options shown below to be performed on all volume sets within the *group_name* as a whole.

Only the commands COPY (-c) and UPDATE (-u) are performed atomically across all Point-in-Time Copy sets within the group. All other grouped, iiadm commands are performed sequentially on each member of the group.

The syntax of an iiadm group command is as follows:

iiadm -g *group_name* [*options*]

The *options* are as follows:

-a

Abort copy operation on all sets within *group_name*.

-A

Attach *overflow_vol* to all sets within *group_name*.

-c {s | m}

Copy shadow/master for all sets within *group_name*.

-D

Detach *overflow_vol* from all sets within *group_name*.

-d

Disable all sets within *group_name*.

-E

Export all volume sets within *group_name*.

-i

Status of all volume sets within *group_name*.

-l

List all volume sets within *group_name*.

-L

List all groups.

-n

Do not ask if an update of the master volume is what the user really intended.

-P

   Set parameters on all volume sets within *group_name*.

-R

   Reset all volume sets within *group_name*.

-u {s | m}

   Update shadow/master for all sets within *group_name*.

-w

   Wait for all volume sets within *group_name*.

-g - " " -m *volume_set* [*volume_set2* ...]

   Remove one or more existing Point-in-Time Copy *volume_set(s)* from their currently associated *group_name*. By default, or until moved into a user specified *group_name*, all Point-in-Time Copy *volume_set(s)* are in the blank (" ") group. This association allows all the previously documented iiadm group commands to be performed against the blank (" ") iiadm *group_name*.

-C *cluster_tag*

   This Point-in-Time Copy option is a modifier that limits configuration operations to only those volumes belonging to a Sun Cluster Resource Group, or Disk Group.

   In a Sun Cluster where the volume manager is Sun Cluster-aware, iiadm automatically obtains the correct Disk Group information, therefore this option is typically not required unless the volumes are part of an encompassing Resource Group.

   In a Sun Cluster where the volumes are accessible on the local node only, the special *cluster_tag* of local is used to indicate volumes that are not part of a Sun Cluster Resource Group or Disk Group.

   If "-L" is given as a the *cluster_tag* argument, then iiadm lists all cluster tags associated with Point-in-Time Copy.

   This option is invalid when used on a Solaris system on which the Sun Cluster package has not been installed or configured.

-h

   Prints the iiadm usage summary.

-v

   Display the current version of the Point-in-Time Copy software components.

Contact Sun Enterprise Services for assistance in using the remaining commands in this section.

-P *delay unit volume_set*

   Alter the Point-in-Time Copy volume set tuning parameters for the specified *volume_set* to *delay* ticks, every *unit* I/O's. Delay ranges from 2 to 10000 inclusive; unit ranges from 100 to 60000 inclusive.

-R *volume*

　　After a volume has failed, Point-in-Time Copy places it offline. After replacing the volume, place it back online using this option. Associated dependent volumes in the Point-in-Time Copy volume set are also placed online. After the volume is placed online, this command also starts any necessary point-in-time volume updates.

Exit Status　0　　　　　　Command completed successfully.

　　　　　　　　>0　　　　　An error occurred.

Attributes　See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/avs/avs-point-in-time-copy
Interface Stability	Committed

Name iicpbmp – copy Availability Suite Point-In-Time bitmap volumes

Synopsis iicpbmp [-c] *old_bitmap new_bitmap*...

Description The iicpbmp command copies an Availability Suite Point-in-Time bitmap volume, rewriting the bitmap header so that it is consistent with the new bitmap volume name. The configuration entry for the shadow set is rewritten to reflect the location of the new bitmap.

No checks on the current use of either the old or new bitmap volumes are made. The iicpbmp command should only be run when the Point–In–Time Copy shadow set using the old bitmap is suspended.

Options -c Do not attempt to update the Availability Suite configuration for the Point-in-Time shadow set that uses the bitmap. This option produces a duplicate of the bitmap but does not affect the shadow set using the old bitmap volume.

Operands *old_bitmap new_bitmap*
The old and new Point-In-Time bitmap volumes.

Warnings The iicpbmp should be run only when a system is in single-user mode. iicpbmp makes no attempt to check if an Point–In–Time Copy set is in use at the time the copy is made. Running iicpbmp without the -c flag while Point–In–Time Copy is using the shadow set results in inconsistencies in the shadow set the next time Point–In–Time Copy is started.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/avs/avs-point-in-time-copy
Interface Stability	Committed

See Also iiadm(1M), iicpshd(1M), attributes(5)

Name iicpshd – copy Availability Suite Point-in-Time shadow volume

Synopsis iicpshd [-s] *old_shadow* *new_shadow*...

Description The iicpshd command copies an Availability Suite Instant Image shadow volume, updating the bit map header and Availability Suite configuration to reflect the new shadow volume.

No checks on the current use of either the old or new shadow volumes are made. The iicpshd command should only be run when the Instant Image shadow set using the old shadow volume is suspended.

Options The iicpshd command supports the following option:

-s   Update the StorageTek configuration information for the Point-in-Time shadow set, but do *not* copy data from the old shadow volume to the new shadow volume.

Operands A iicpshd command line has the following operands:

old_shadow new_shadow
    iicpshd copies the data of the old Availability Suite Instant Image shadow volume to the new shadow volume and updates the bit map header and configuration data.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/avs/avs-point-in-time-copy
Interface Stability	Committed

See Also iiadm(1M), iicpbmp(1M), attributes(5)

Warnings iicpshd should be run only when the system is in single-user mode. When you run iicpshd, the command makes no attempt to check if a Point-in-Time set is in use. Running iicpshd with the -s flag while Point-in-Time is using the old shadow volume can result in shadow volume data loss. If you use the -s option, you must manually copy the data on the old shadow volume to the new shadow volume.

Name ikeadm – manipulate Internet Key Exchange (IKE) parameters and state

Synopsis ikeadm [-np]

ikeadm [-np] get [debug | priv | stats | defaults]

ikeadm [-np] set [debug | priv] [level] [file]

ikeadm [-np] [get | del] [p1 | rule | preshared] [id]

ikeadm [-np] add [rule | preshared] { *description* }

ikeadm [-np] token [login | logout] *PKCS#11_Token_Object*

ikeadm [-np] [read | write] [rule | preshared | certcache] *file*

ikeadm [-np] dump [p1 | rule | preshared | certcache | groups
    | encralgs | authalgs]

ikeadm [-np] flush [p1 | certcache]

ikeadm help
    [get | set | add | del | read | write | dump | flush | token]

Description The ikeadm utility retrieves information from and manipulates the configuration of the Internet Key Exchange (IKE) protocol daemon, in.iked(1M).

ikeadm supports a set of operations, which may be performed on one or more of the supported object types. When invoked without arguments, ikeadm enters interactive mode which prints a prompt to the standard output and accepts commands from the standard input until the end-of-file is reached.

Because ikeadm manipulates sensitive keying information, you must be superuser to use this command. Additionally, some of the commands available require that the daemon be running in a privileged mode, which is established when the daemon is started.

For details on how to use this command securely see Security.

Options The following options are supported:

-n

Prevent attempts to print host and network names symbolically when reporting actions. This is useful, for example, when all name servers are down or are otherwise unreachable.

-p

Paranoid. Do not print any keying material, even if saving Security Associations. Instead of an actual hexadecimal digit, print an X when this flag is turned on.

Usage

Commands The following commands are supported:

add

Add the specified object. This option can be used to add a new policy rule or a new preshared key to the current (running) in.iked configuration. When adding a new preshared key, the command cannot be invoked from the command line, as it will contain keying material. The rule or key being added is specified using appropriate id-value pairs as described in the ID FORMATS section.

del

Delete a specific object or objects from in.iked's current configuration. This operation is available for IKE (Phase 1) SAs, policy rules, and preshared keys. The object to be deleted is specified as described in the Id Formats.

dump

Display all objects of the specified type known to in.iked. This option can be used to display all Phase 1 SAs, policy rules, preshared keys, implemented Diffie-Helman groups, encryption and authentication algorithms available for Phase 1, or the certificate cache. A large amount of output might be generated by this command.

flush

Remove all IKE (Phase 1) SAs or cached certificates from in.iked.

Note that flushing the certcache will also (as a side-effect) update IKE with any new certificates added or removed.

get

Lookup and display the specified object. May be used to view the current debug or privilege level, global statistics and default values for the daemon, or a specific IKE (Phase 1) SA, policy rule, or preshared key. The latter three object types require that identifying information be passed in; the appropriate specification for each object type is described below.

help

Print a brief summary of commands, or, when followed by a command, prints information about that command.

read

Update the current in.iked configuration by reading the policy rules or preshared keys from either the default location or from the file specified.

set

Adjust the current debug or privilege level. If the debug level is being modified, an output file may optionally be specified; the output file *must* be specified if the daemon is running in the background and is not currently printing to a file. When changing the privilege level, adjustments may only be made to lower the access level; it cannot be increased using ikeadm.

write

Write the current in.iked policy rule set or preshared key set to the specified file. A destination file must be specified. This command should not be used to overwrite the existing configuration files.

token

Log into a PKCS#11 token object and grant access to keying material or log out and invalidate access to keying material.

token can be run as a normal user with the following authorizations:

- token login: solaris.network.ipsec.ike.token.login
- token logout: solaris.network.ipsec.ike.token.logout

Object Types debug

Specifies the daemon's debug level. This determines the amount and type of output provided by the daemon about its operations. The debug level is actually a bitmask, with individual bits enabling different types of information.

Description	Flag	Nickname
Certificate management	0x0001	cert
Key management	0x0002	key
Operational	0x0004	op
Phase 1 SA creation	0x0008	phase1
Phase 2 SA creation	0x0010	phase2
PF_KEY interface	0x0020	pfkey
Policy management	0x0040	policy
Proposal construction	0x0080	prop
Door interface	0x0100	door
Config file processing	0x0200	config
Label processing	0x0400	label
All debug flags	0x07ff	all

When specifying the debug level, either a number (decimal or hexadecimal) or a string of nicknames may be given. For example, 88, 0x58, and phase1+phase2+policy are all equivalent, and will turn on debug for phase 1 sa creation, phase 2 sa creation, and policy management. A string of nicknames may also be used to remove certain types of information; all-op has the effect of turning on all debug *except* for operational messages; it is equivalent to the numbers 1019 or 0x3fb.

priv

Specifies the daemon's access privilege level. The possible values are:

```
Description                  Level   Nickname
Base level                   0       base
Access to preshared key info 1       modkeys
Access to keying material    2       keymat
```

By default, in.iked is started at the base level. A command-line option can be used to start the daemon at a higher level. ikeadm can be used to lower the level, but it cannot be used to raise the level.

Either the numerical level or the nickname may be used to specify the target privilege level.

In order to get, add, delete, dump, read, or write preshared keys, the privilege level must at least give access to preshared key information. However, when viewing preshared keys (either using the get or dump command), the key itself will only be available if the privilege level gives access to keying material. This is also the case when viewing Phase 1 SAs.

stats

Global statistics from the daemon, covering both successful and failed Phase 1 SA creation.

Reported statistics include:

- Count of current P1 SAs which the local entity initiated
- Count of current P1 SAs where the local entity was the responder
- Count of all P1 SAs which the local entity initiated since boot
- Count of all P1 SAs where the local entity was the responder since boot
- Count of all attempted P1 SAs since boot, where the local entity was the initiator; includes failed attempts
- Count of all attempted P1 SAs since boot, where the local entity was the responder; includes failed attempts
- Count of all failed attempts to initiate a P1 SA, where the failure occurred because the peer did not respond
- Count of all failed attempts to initiate a P1 SA, where the peer responded
- Count of all failed P1 SAs where the peer was the initiator
- Whether a PKCS#11 library is in use, and if applicable, the PKCS#11 library that is loaded. See Example 11.

defaults

Display default values used by the in.iked daemon. Some values can be overriden in the daemon configuration file (see ike.config(4)); for these values, the token name is displayed in the get defaults output. The output will reflect where a configuration token has changed the default.

Default values might be ignored in the event a peer system makes a valid alternative proposal or they can be overriden by per-rule values established in `ike.config`. In such instances, a `get defaults` command continues to display the default values, not the values used to override the defaults.

p1

An IKE Phase 1 SA. A `p1` object is identified by an IP address pair or a cookie pair; identification formats are described below.

rule

An IKE policy rule, defining the acceptable security characteristics for Phase 1 SAs between specified local and remote identities. A rule is identified by its label; identification formats are described below.

preshared

A preshared key, including the local and remote identification and applicable IKE mode. A preshared key is identified by an IP address pair or an identity pair; identification formats are described below.

Id Formats   Commands like `add`, `del`, and `get` require that additional information be specified on the command line. In the case of the delete and get commands, all that is required is to minimally identify a given object; for the add command, the full object must be specified.

Minimal identification is accomplished in most cases by a pair of values. For IP addresses, the local addr and then the remote addr are specified, either in dot-notation for IPv4 addresses, colon-separated hexadecimal format for IPv6 addresses, or a host name present in the host name database. If a host name is given that expands to more than one address, the requested operation will be performed multiple times, once for each possible combination of addresses.

Identity pairs are made up of a local type-value pair, followed by the remote type-value pair. Valid types are:

prefix

An address prefix.

fqdn

A fully-qualified domain name.

domain

Domain name, synonym for fqdn.

user_fqdn

User identity of the form *user*@fqdn.

mailbox

Synonym for `user_fqdn`.

A cookie pair is made up of the two cookies assigned to a Phase 1 Security Association (SA) when it is created; first is the initiator's, followed by the responder's. A cookie is a 64-bit number.

Finally, a label (which is used to identify a policy rule) is a character string assigned to the rule when it is created.

Formatting a rule or preshared key for the add command follows the format rules for the in.iked configuration files. Both are made up of a series of id-value pairs, contained in curly braces ({ and }). See ike.config(4) and ike.preshared(4) for details on the formatting of rules and preshared keys.

Security The ikeadm command allows a privileged user to enter cryptographic keying information. If an adversary gains access to such information, the security of IPsec traffic is compromised. The following issues should be taken into account when using the ikeadm command.

- Is the TTY going over a network (interactive mode)?

  If it is, then the security of the keying material is the security of the network path for this TTY's traffic. Using ikeadm over a clear-text telnet or rlogin session is risky. Even local windows may be vulnerable to attacks where a concealed program that reads window events is present.

- Is the file accessed over the network or readable to the world (read/write commands)?

  A network-mounted file can be sniffed by an adversary as it is being read. A world-readable file with keying material in it is also risky.

If your source address is a host that can be looked up over the network, and your naming system itself is compromised, then any names used will no longer be trustworthy.

Security weaknesses often lie in misapplication of tools, not the tools themselves. It is recommended that administrators are cautious when using the ikeadm command. The safest mode of operation is probably on a console, or other hard-connected TTY.

For additional information regarding this subject, see the afterward by Matt Blaze in Bruce Schneier's *Applied Cryptography: Protocols, Algorithms, and Source Code in C.*

Examples **EXAMPLE 1** Emptying out all Phase 1 Security Associations

The following command empties out all Phase 1 Security Associations:

```
example# ikeadm flush p1
```

EXAMPLE 2 Displaying all Phase 1 Security Associations

The following command displays all Phase 1 Security Associations:

```
example# ikeadm dump p1
```

EXAMPLE 3 Deleting a Specific Phase 1 Security Association

The following command deletes the specified Phase 1 Security Associations:

```
example# ikeadm del p1 local_ip remote_ip
```

EXAMPLE 4 Adding a Rule From a File

The following command adds a rule from a file:

```
example# ikeadm add rule rule_file
```

EXAMPLE 5 Adding a Preshared Key

The following command adds a preshared key:

```
example# ikeadm
     ikeadm> add preshared { localidtype ip localid local_ip
             remoteidtype ip remoteid remote_ip ike_mode main
             key 1234567890abcdef1234567890abcdef }
```

EXAMPLE 6 Saving All Preshared Keys to a File

The following command saves all preshared keys to a file:

```
example# ikeadm write preshared target_file
```

EXAMPLE 7 Viewing a Particular Rule

The following command views a particular rule:

```
example# ikeadm get rule rule_label
```

EXAMPLE 8 Reading in New Rules from ike.config

The following command reads in new rules from the ike.config file:

```
example# ikeadm read rules
```

EXAMPLE 9 Lowering the Privilege Level

The following command lowers the privilege level:

```
example# ikeadm set priv base
```

EXAMPLE 10 Viewing the Debug Level

The following command shows the current debug level

```
example# ikeadm get debug
```

EXAMPLE 11 Using stats to Verify Hardware Accelerator

The following example shows how stats may include an optional line at the end to indicate if
IKE is using a PKCS#11 library to accelerate public-key operations, if applicable.

```
example# ikeadm get stats
Phase 1 SA counts:
Current:  initiator:     0    responder:      0
Total:    initiator:    21    responder:     27
Attempted:initiator:    21    responder:     27
```

EXAMPLE 11 Using stats to Verify Hardware Accelerator   *(Continued)*

```
Failed:  initiator:    0    responder:       0
            initiator fails include 0 time-out(s)
PKCS#11 library linked in from /opt/system/core-osonn/lib/libpkcs11.so
example#
```

EXAMPLE 12 Displaying the Certificate Cache

The following command shows the certificate cache and the status of associated private keys, if applicable:

example# **ikeadm dump certcache**

EXAMPLE 13 Logging into a PKCS#11 Token

The following command shows logging into a PKCS#11 token object and unlocking private keys:

```
example# ikeadm token login "Sun Metaslot"
Enter PIN for PKCS#11 token:
ikeadm: PKCS#11 operation successful
```

Exit Status   The following exit values are returned:

0   Successful completion.

non-zero   An error occurred. Writes an appropriate error message to standard error.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Not an Interface

See Also   in.iked(1M), ike.config(4), ike.preshared(4), attributes(5), ipsec(7P)

Schneier, Bruce, *Applied Cryptography: Protocols, Algorithms, and Source Code in C*, Second Edition, John Wiley & Sons, New York, NY, 1996.

Notes   As in.iked can run only in the global zone and exclusive-IP zones, this command is not useful in shared-IP zones.

Name ikecert – manipulates the machine's on-filesystem public-key certificate databases

Synopsis ikecert certlocal
     [-a | -e | -h | -k | -l | -r | -U | -C | -L]
     [[-p] -T *PKCS#11 token identifier*]
     [*option_specific_arguments*]...

ikecert certdb [-a | -e | -h | -l | -r | -U | -C | -L]
     [[-p] -T *PKCS#11 token identifier*]
     [*option_specific_arguments*]...

ikecert certrldb [-a | -e | -h | -l | -r]
     [*option_specific_arguments*]...

ikecert tokens

Description The ikecert command manipulates the machine's on-filesystem public-key certificate databases. See the "Files" section, below.

ikecert has three subcommands, one for each of the three major repositories, plus one for listing available hardware tokens:

- certlocal deals with the private-key repository,
- certdb deals with the public-key repository, and:
- certrldb deals with the certificate revocation list (CRL) repository.
- tokens shows the available PKCS#11 tokens for a given PKCS#11 library.

The only supported PKCS#11 library and hardware is the Sun Cryptographic Accelerator 4000.

Options Except for tokens, each subcommand requires one option, possibly followed by one or more option-specific arguments.

The tokens subcommand lists all available tokens in the PKCS#11 library specified in /etc/inet/ike/config.

The following options are supported:

-a

     certlocal
          When specified with the certlocal subcommand, this option installs (adds) a private key into the Internet Key Exchange (IKE) local ID database. The key data is read from standard input, and is in either Solaris-only format or unencrypted PKCS#8 DER format. Key format is automatically

detected. PKCS#8 key files in PEM format and files in password protected, encrypted format are not recognized, but can be converted appropriately using tools available in OpenSSL.

This option cannot be used with PKCS#11 hardware objects when the corresponding public certificate is not already present in the IKE database. When importing both a public certificate and a private key, the public portion must be imported first using the `certdb` subcommand.

certdb

When specified with the `certdb` subcommand, this option reads a certificate from standard input and adds it to the IKE certificate database. The certificate must be a `X.509` certificate in `PEM Base64` or `ASN.1 BER` encoding. The certificate adopts the name of its identity.

This option can import a certificate into a PKCS#11 hardware key store one of two ways: Either a matching public key object *and* an existing private key object were created using the `certlocal -kc` option, or if a PKCS#11 token is explicitly specified using the `-T` option.

certrldb

When specified with the `certrldb` subcommand, this option installs (adds) a CRL into the IKE database. The CRL reads from standard input.

-e [-f pkcs8] *slot*

certlocal

When specified with the
certlocal subcommand, this
option extracts a private key from
the IKE local ID database. The key
data are written to standard output.
The slot specifies which private key
to extract. Private keys are only
extracted in binary/ber format.

*Use this option with extreme
caution.* See the "Security" section,
below.

This option will not work with
PKCS#11 hardware objects.

When used in conjunction with "-f
pkcs8", the private key is extracted
in unencrypted PKCS#8 format.

-e [-f *output-format*] certspec

certdb

When specified with the certdb
subcommand, this option extracts
a certificate from the IKE certificate
database which matches the
certspec and writes it to standard
output. The *output-format* option
specifies the encoding format.
Valid options are PEM and BER. This
extracts the first matching identity.
The default output format is PEM.

certrldb

When specified with the certrldb
subcommand, this option extracts
a CRL from the IKE database. The
key data are written to standard
output. The certspec specifies
which CRL that is extracted. The
first one that matches in the
database is extracted. See NOTES,
below, for details on certspec

patterns.

-kc -m *keysize* -t *keytype* -D *dname* -A *altname*[...]
[-S *validity start_time*][-F *validity end_time*]
[-T *PKCS#11 token identifier*]

certlocal

When specified with the
certlocal subcommand, this
option generates a IKE
public/private key pair and adds it
into the local ID database. It also
generates a certificate request and
sends that to standard output. For
details on the above options see
Notes for details on the *dname*
argument and see ALTERNATIVE
NAMES for details on the *altname*
argument(s) to this command.

If -T is specified, the hardware
token will generate the pair of keys.

If -p is specified with -T, the
PKCS#11 token pin is stored in the
clear on-disk, with root-protected
file permissions. If not specified,
one must unlock the token with
ikeadm(1M) once in.iked(1M) is
running.

-ks -m *keysize* -t *keytype* -D *dname* -A *altname*[...]
[-S *validity start_time*][-F *validity end_time*]
[-f *output-format*][[-p] -T *PKCS#11 token identifier*]

certlocal

When specified with the
certlocal subcommand,
generates a public/private key pair
and adds it into the local ID
database. This option also
generates a self-signed certificate
and installs it into the certificate
database. See NOTES, below, for
details on the *dname* and *altname*
arguments to this command.

If -T is specified, the hardware
token will generate the pair of keys,
and the self-signed certificate will
also be stored in the hardware.

-l [-v] [*slot*]

certlocal
    When specified with the
    certlocal subcommand, this
    option lists private keys in the local
    ID database. The -v option
    switches output to a verbose mode
    where the entire certificate is
    printed.

    *Use the -v option with extreme
    caution.* See the "Security" section,
    below. The -v option will not work
    with PKCS#11 hardware objects.

-l [-v] [certspec]

certdb
    When specified with the certdb
    subcommand, this option lists
    certificates in the IKE certificate
    database matching the certspec, if
    any pattern is given. The list
    displays the identity string of the
    certificates, as well as, the private
    key if in the key database. The -v
    switches the output to a verbose
    mode where the entire certificate is
    printed.

    If the matching ceritifcate is on a
    hardware token, the token ID is
    also listed.

certrldb
    When specified with the certrldb
    subcommand, this option lists the
    CRLs in the IKE database along
    with any certificates that reside in
    the database and match the Issuer
    Name. certspec can be used to

specify to list a specific CRL. The -v option switches the output to a verbose mode where the entire certificate is printed. See NOTES, below, for details on certspec patterns.

-r *slot*

certlocal

When specified with the certlocal subcommand, deletes the local ID in the specified slot. If there is a corresponding public key, it is not be deleted. If this slot is deemed as "corrupted" or otherwise unrecognizable, it is deleted as well.

If this is invoked on a PKCS#11 hardware object, it will also delete the PKCS#11 public key and private key objects. If the public key object was already deleted by certdb -r, that is not a problem.

-r certspec

certdb

Removes certificates from the IKE certificate database. Certificates matching the specified certificate pattern are deleted. Any private keys in the certlocal database corresponding to these certificates are not deleted. This removes the first matching identity.

If the pattern specifies a slot and the slot is deemed as "corrupted" or otherwise unrecognizable, it is deleted as well.

If this is invoked on a PKCS#11 hardware object, it will also delete the certificate and the PKCS#11 public key object. If the public key

object was already deleted by
`certlocal -r`, that is not a
problem.

certrldb

When specified with the `certrldb`
subcommand, this option deletes
the CRL with the given `certspec`.

-U slot

certlocal

When specified with the
`certlocal` subcommand and the
`-T` flag, this option unlinks a
PKCS#11 private key object from
the IKE database. There will be no
attempt to access the hardware
keystore or to validate or remove
the on-token private key object.
The object is simply disassociated
from the IKE database.

certdb

When specified with the `certdb`
subcommand and the `-T` flag, this
option unlinks a PKCS#11
certificate object from the IKE
database. There will be no attempt
to access the hardware keystore or
to validate or remove the on-token
certificate or public key objects.
The objects are simply
disassociated from the IKE
database.

-C certspec

certlocal

When specified with the
`certlocal` subcommand, this
option copies both the private key
and its corresponding certificate
and the public key from the
on-disk keystore to the hardware
keystore specified by its PKCS#11
token. This subcommand attempts

to create each of these components, even if one part fails. In all cases, the original on-disk private key and public certificate are still retained and must be deleted separately. Some hardware keystores, such as FIPS-140 compliant devices, may not support migration of private key objects in this manner.

certdb

When specified with the `certdb` subcommand, this option copies the certificate matching the given `certspec` and corresponding public key from the on-disk keystore to the hardware keystore specified by its PKCS#11 token. The original public certificate is still retained and must be deleted separately, if desired.

If `-p` is specified, the PKCS#11 token pin is stored in the clear on-disk, with root-protected file permissions. If not specified, one must unlock the token with ikeadm(1M) once in.iked(1M) is running.

-L pattern

certlocal

When specified with the `certlocal` subcommand, this option links an existing on-token private key object to the IKE database. The object itself remains on the token. This option simply lets the IKE infrastructure know that the object exists, as if it had been originally created on-token with the Solaris IKE utilities.

certdb

When specified with the `certdb` subcommand, this option links an

existing on-token certificate object to the IKE database. The object itself remains on the token. This option simply lets the IKE infrastructure know that the object exists, as if it had been originally created on-token with the Solaris IKE utilities.

If -p is specified, the PKCS#11 token pin is stored in the clear on-disk, with root-protected file permissions. If not specified, one must unlock the token with ikeadm(1M) once in.iked(1M) is running.

Parameters The following parameters are supported:

certspec

Specifies the pattern matching of certificate specifications. Valid certspecs are the Subject Name, Issuer Name, and Subject Alternative Names.

These can be specified as certificates that match the given certspec values and that do not match other certspec values. To signify a certspec value that is not supposed to be present in a certificate, place an ! in front of the tag.

Valid certspecs are:

```
<Subject Names>
SUBJECT=<Subject Names>
ISSUER=<Issuer Names>
SLOT=<Slot Number in the certificate database>

Example:"ISSUER=C=US, O=SUN" IP=1.2.3.4 !DNS=example.com
Example:"C=US,  O=CALIFORNIA" IP=5.4.2.1 DNS=example.com
```

Valid arguments to the alternative names are as follows:

```
IP=<IPv4 address>
DNS=<Domain Name Server address>
EMAIL=<email (RFC 822) address>
URI=<Uniform Resource Indicator value>
DN=<LDAP Directory Name value>
RID=<Registered Identifier value>
```

Valid Slot numbers can be specified without the keyword tag. Alternative name can also be issued with keyword tags.

-A

Subject Alternative Names the certificate. The argument that follows the -A option should be in the form of *tag*=*value*. Valid tags are IP, DNS, EMAIL, URI, DN, and RID (See example below).

-D

X.509 distinguished name for the certificate subject. It typically has the form of: C=country, O=organization, OU=organizational unit, CN=common name. Valid tags are: C, O, OU, and CN.

-f

Encoding output format. pem for PEM Base64 or ber for ASN.1 BER. If -f is not specified, pem is assumed.

-F *validity end_time*

Finish certificate validity time. If the -F flag is not specified, the validity end time is calculated at four years from the validity start time. See NOTES for an explanation for the validity date and time syntax.

-m

Key size. It can be 512, 1024, 2048, 3072, or 4096. Use the following command to determine the key sizes supported by the Solaris Cryptographic Framework:

```
% cryptoadm list -vm
```

The mechanisms displayed by the preceding command are described in pkcs11_softtoken(5). If your system has hardware acceleration, the mechanisms supported by the hardware will be listed in a separate section for each provider. Mechanisms can be any of:

```
CKM_RSA_PKCS_KEY_PAIR_GEN
CKM_DSA_KEY_PAIR_GEN
CKM_DH_PKCS_KEY_PAIR_GEN
```

Note – Some hardware does not support all key sizes. For example, the Sun Cryptographic Accelerator 4000's keystore (when using the -T option, below), supports only up to 2048-bit keys for RSA and 1024-bit keys for DSA.

-S *validity start_time*

Start certificate validity time. If the -S flag is not specified, the current date and time is used for the validity start time. See NOTES, below, for an explanation for the validity date and time syntax.

-t

Key type. It can be rsa-sha1, rsa-md5, or dsa-sha1.

-T

PKCS#11 token identifier for hardware key storage. This specifies a hardware device instance in conformance to the PKCS#11 standard. A PKCS#11 library must be specified in /etc/inet/ike/config. (See ike.config(4).)

A token identifier is a 32-character space-filled string. If the token given is less than 32 characters long, it will be automatically padded with spaces.

If there is more than one PKCS#11 library on a system, keep in mind that only one can be specified at a time in /etc/inet/ike/config. There can be multiple tokens (each with individual key storage) for a single PKCS#11 library instance.

Security This command can save private keys of a public-private key pair into a file. Any exposure of a private key may lead to compromise if the key is somehow obtained by an adversary.

The PKCS#11 hardware object functionality can address some of the shortcomings of on-disk private keys. Because IKE is a system service, user intervention at boot is not desireable. The token's PIN, however, is still needed. The PINfor the PKCS#11 token, therefore, is stored where normally the on-disk cryptographic keys would reside. This design decision is deemed acceptable because, with a hardware key store, *possession* of the key is still unavailable, only *use* of the key is an issue if the host is compromised. Beyond the PIN, the security of ikecert then reduces to the security of the PKCS#11 implementation. The PKCS#11 implementation should be scrutinized also.

Refer to the afterword by Matt Blaze in Bruce Schneier's *Applied Cryptography: Protocols, Algorithms, and Source Code in C* for additional information.

Examples **EXAMPLE 1** Generating a Self-Signed Certificate

The following is an example of a self-signed certificate:

```
example# ikecert certlocal -ks -m 512 -t rsa-md5 -D "C=US, O=SUN" -A
IP=1.2.3.4
Generating, please wait...
Certificate generated.
Certificate added to database.
-----BEGIN X509 CERTIFICATE-----
MIIBRDCB76ADAgECAgEBMA0GCSqGSIb3DQEBBAUAMBsxCzAJBgNVBAYTAlVTMQww
CgYDVQQKEwNTVU4wHhcNMDEwMzE0MDEzMDM1WhcNMDUwMzE4MDEzMDM1WjAbMQsw
CQYDVQQGEwJVUzEMMAoGA1UEChMDU1VOMFowDQYJKoZIhvcNAQEBBQADSQAwRgJB
APDhqpKgjgRoRUr6twTMTtSuNsReEnFoReVer!ztpXpQK6ybYlRH18JIqU/uCV/r
26R/cVXTy5qc5NbMwA40KzcCASOjIDAeMAsGA1UdDwQEAwIFoDAPBgNVHREECDAG
hwQBAgMEMA0GCSqGSIb3DQEBBAUAA0EApTRD23KzN95GMvPD71hwwCluksIKLVg8
f1xm9ZsHLPJLRxHFwsqqjAad4j4wwwriiUmGAHLTGB0lJMl8xsgxag==
-----END X509 CERTIFICATE-----
```

EXAMPLE 2 Generating a CA Request

Generating a CA request appears the same as the self-signed certificate. The only differences between the two is the option -c instead of -s, and the certificate data is a CA request.

```
example# ikecert certlocal -kc -m 512 -t rsa-md5 \
    -D "C=US, O=SUN" -A IP=1.2.3.4
```

EXAMPLE 3 A CA Request Using a Hardware Key Store

The following example illustrates the specification of a token using the -T option.

```
example# # ikecert certlocal -kc -m 1024 -t rsa-md5 -T vca0-keystore \
  -D "C=US, O=SUN" -A IP=1.2.3.4
```

Exit Status The following exit values are returned:

0
    Successful completion.

non-zero
    An error occurred. Writes an appropriate error message to standard error.

Files /etc/inet/secret/ike.privatekeys/*
    Private keys. A private key *must* have a matching public-key certificate with the same filename in /etc/inet/ike/publickeys/.

/etc/inet/ike/publickeys/*
    Public-key certificates. The names are only important with regard to matching private key names.

/etc/inet/ike/crls/*
    Public key certificate revocation lists.

/etc/inet/ike/config
    Consulted for the pathname of a PKCS#11 library.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

Schneier, Bruce. *Applied Cryptography: Protocols, Algorithms, and Source Code in C*. Second Edition. John Wiley & Sons. New York, NY. 1996.

RSA Labs, PKCS#11 v2.11: *Cryptographic Token Interface Standards*, November 2001.

Notes The following is the validity date and time syntax when the -F or -S flags are used:

For relative dates, the syntax is as follows:

{+,-}[Ns][Nm][Nh][Nd][Nw][NM][Ny]

where:

N
   represents an integer

s
   represents seconds

m
   represents minutes

h
   represents hours

d
   represents days

w
   represents weeks

M
   represents months

y
   represents years

These parameters can be given in any order. For example, "+3d12h" is three and a half days from now, and "-3y2M" is three years and 2 months ago.

All parameters with fixed values can be added up in absolute seconds. Months and years, which have variable numbers of seconds, are calculated using calendar time. Months and years, which are not of fixed length, are defined such that adding a year or month means the same day next year or month. For instance, if it is Jan 26, 2005 and the certificate should expire 3 years and 1 month from today, the expiration (end validity time) date will be Feb 26, 2008. Overflows are dealt with accordingly. For example, one month from Jan 31, 2005 is March 3, 2005, since February has only 28 days.

For absolute dates, the syntax of the date formats included in the file /etc/datemsk are accepted (See getdate(3C) for details). Any date string prepended with a "+" or "-" is treated as a time relative to the current time, while others are treated as absolute dates. Sanity checking is also done to ensure that the end validity date is greater than the start validity date. For example, the following command would create a certificate with start date 1 day and 2 hours ago and an end date of Jan 22nd, 2007 at 12:00:00 local time.

```
# ikecert certlocal -ks -t rsa-sha1 -m 1024 \
    -D "CN=mycert, O=Sun, C=US" \
    -S -1d2h -F "01/22/2007 12:00:00"
```

As in.iked(1M) can run only in the global zone and exclusive-IP zones, this command is not useful in shared-IP zones.

Name ilbadm – establish and manipulate load balancing rules

Synopsis ilbadm create-rule [-e] [-p] -i vip=*value*,port=*value*[,protocol=*value*]
        -m lbalg=*value*,type=*value*[,proxy-src=*ip-range*][,pmask=*mask*]
        [-h hc-name=*value*[,hc-port=*value*]]
        [-t [conn-drain=*N*][,nat-timeout=*N*],[persist-timeout=*N*]]
        -o servergroup=*value name*

ilbadm show-rule [-e|-d] [-f |[-p] -o *key*[,*key* ...]] [*name* ...]

ilbadm delete-rule -a | *name* ...

ilbadm enable-rule [*name* ...]

ilbadm disable-rule [*name* ...]

ilbadm show-statistics [-p] -o *field*[,*field*] [-thAdvi]
        [-r *rulename*] | [-s *servername*] [*interval* [*count*]]

ilbadm create-servergroup [-s *server*=*hostspec*[:*portspec*...]] *groupname*

ilbadm delete-servergroup *groupname*

ilbadm show-servergroup [-s|-f|[-p] -o *field*[,*field*]] [[-v] *name*]

ilbadm enable-server *server* ...

ilbadm disable-server *server* ...

ilbadm show-server [[-p] -o *field*[,*field*...]] [*rulename*...]

ilbadm add-server -s *server*=*value*[,*value* ...] *name*

ilbadm remove-server -s *server*=*value*[,*value* ...] *name*

ilbadm create-healthcheck [-n] -h hc-test=*value*
        [,hc-timeout=*value*][,hc-count=*value*][,hc-interval=*value*] *hcname*

ilbadm delete-healthcheck *hcname*

ilbadm show-healthcheck [*hcname* ...]

ilbadm show-hc-result [*rule-name*]

ilbadm show-nat [*count*]

ilbadm show-persist [*count*]

ilbadm export-config *filename*

ilbadm import-config [-p] *filename*

Description The `ilbadm` command manipulates or displays information about Integrated Load Balancer (ILB) rules using the subcommands described below.

Rule names are case insensitive, but case is preserved as it is entered. Rule names are limited in length to 19 characters. Server names cannot exceed 14 characters.

All parseable output (invoked with the -p option) requires that the fields to be printed or displayed be specified with the -o option. Fields will be displayed in the same order they are encountered on the command line. Multiple fields are separated by the colon (:) character. If a colon or backslash (\) occurs in the displayed string itself, it will be preceded by a backslash. No headers will be displayed for parseable output.

Server IDs are generated by the system when a server is added, using either the create-servergroup or the add-server subcommands.

Server IDs are guaranteed to be unique within the server group. A rule can be attached to only one server group, with the result that serverIDs are unique for rules as well. Note that since more than one rule can attach to the same server group, the server ID alone is not sufficient to indicate a rule.

To be able to distinguish server IDs from hostnames, server IDs are prefixed with a leading underscore (_).

As noted below, the server group and heathcheck entities must be defined before they can be used in the create-rule subcommand.

Sub-commands Following are the ilbadm subcommands, along with their related options and operands. Note that subcommands have a normal and a short form; for example, create-rule and create-rl, saving you from having to type a few additional characters.

create-rule|create-rl [-e] [-p] -i *incoming* -m *method_attributes* -o *outgoing_spec* [-h *healthcheck*] [-t *timers*] *name*
Creates a rule *name* with a set of specified characteristics. *incoming* and *method_attributes* are both specified as a set of *key=value* pairs. If *name* already exists, the command will fail. If a given tuple (virtual IP address, port(s), and protocol) matches another rule, the command will also fail. create-rule has the following options that control the overall effect of the command:

-e   Enable the create-rule function. The default is that create-rule is disabled.

-p   Create the rule as persistent (sticky). The default is that the rule exists only for the current session.

Keys and values are introduced by one-letter identifiers. These identifiers and their related keys and acceptable values are as follows.

-i
   Introduces the matching criteria for incoming packets.

   vip
      (Virtual) destination IP address

port[-port]

Port number or name, for example, telnet or dns. A port can be specified by port number or symbolic name (as in /etc/services). Port number ranges are also supported.

protocol

TCP (the default) or UDP (see /etc/services).

-m

Specifies the keys describing how to handle a packet.

lbalg

The default is roundrobin, or its short form, rr. Other alternatives are: hash-ip (short form: hip), hash-ip-port (short form: hipp), hash-ip-vip (short form: hipv).

type

Refers to topology of network. Can be DSR (or dsr or d), NAT (or n or nat), HALF-NAT (or h or half-nat).

proxy-src

Required for full NAT only. Specifies the IP address range to use as the proxy source address range. The range is limited to ten IP addresses.

pmask

Optional. Has an alias of: stickiness. Specifies that this rule is to be persistent. The argument is a prefix length in CIDR notation; that is, 0–32 for IPv4 and 0–128 for IPv6. Use the -p option to specify this keyword.

-o

Specifies destination(s) for packets that match the criteria specified by the -i "clause". This identifier has one well-known argument:

servergroup   Specify a single server group as target. The server group must already have been created.

-h

The health check option has two arguments:

hc-name

Specifies the name of a predefined health check method

hc-port

Specifies the port(s) for the HC test program to check. The value can be keywords ALL or ANY, or a specific port number within the port range of the server group.

-t

Specifies customized timers, in seconds. A value of 0 means to use the system default value. The following are valid modifiers for -t:

conn-drain

If a server's type is NAT or HALF-TYPE, conn-drain is the timeout after which the server's connection state is deleted following the server's removal from a rule. This deletion occurs even if the server is not idle.

The default for TCP is that the connection state remains stable until the connection is gracefully shutdown. The default for UDP is that the connection state remains stable until the connection has been idle for the period nat-timeout.

nat-timeout

Applies only to NAT and half-NAT type connections. If such a connection is idle for the nat-timeout period, the connection state will be removed. The default is 120 for TCP and 60 UDP.

persist-timeout

When persistent mapping is enabled, if a numeric-only mapping has not been used for persist-timeout seconds, the mapping will be removed. The default is 60.

Note that server group and health check must be defined before they can be used in create-rule.

delete-rule|delete-rl -a *name*[...]
Remove all information pertaining to rule *name*. If *name* does not exist, command will fail. delete-rule has one option:

-a

Delete all rules. (*name* is ignored.)

enable-rule|enable-rl *name*[...]
Enables a named rule, or all rules, if no name is specified). Enabling rules that are already enabled has no effect.

disable-rule|disable-rl *name*[...]
Disables a named rule, or all rules, if no name is specified. Disabling rules that are already disabled has no effect.

show-statistics|show-stats [[-p] -o *field*[,...]] [-tv] [-A | -d] [[-i] -r *rulename* | -s *servername*] [*interval* [*count*]]
Displays statistics, the output of which is subject to the use of the options described below. The syntax and semantics of this subcommand are modeled on vmstat(1M).

-t

Prepend a timestamp with every sample.

-d

Display the delta over entire interval. The default is changes per second. Cannot be used with the -a option.

-A

Display absolute numbers. That is, numbers since module initialization, rule creation, and server addition. Cannot be used with the -d option.

-r *rulename*

Display statistics only for the specified *rulename*. In combination with the -i option, display a line for each server.

-s *servername*

Display statistics only for *server*. In combination with the -i option, display a line for each rule.

-i

Itemize the information displayed by the -r and -s options. These are the only options with which -i is valid. Does not work with the -v option.

-v

Display additional details for droppages. Note that, when the rule name is specified, drops are counted per rule and not per server. Does not work with the -i option.

-p

Display parseable format. Requires use of -o option.

-o *field*

Can be one or more from the list below. *field* can be uppercase or lowercase.

PKT_P	Packets processed.
BYTES_P	Bytes processed.
PKT_U	Unprocessed packets.
BYTES_U	Unprocessed bytes.
PKT_D	Packets dropped.
BYTES_D	Bytes dropped.
ICMP_P	ICMP echo requests processed.
ICMP_D	ICMP echo requests dropped.
ICMP2BIG_P	ICMP fragmentation needed; message processed.
ICMP2BIG_D	Fragmentation needed; message dropped.
NOMEMP_D	Packets dropped because of out-of-memory condition.
NOPORTP_D	Packets dropped in NAT mode because no source port was available.

Note that when a question mark (?) is displayed as a column entry, it indicates that the proper value cannot be determined, most often because a rule or server was added or deleted.

Note that headers are displayed once for each ten samples. The timestamp format follows the date(1) format for the C locale. Neither the addition nor removal of a rule is detected.

show-rule|show-rl [-d|-e] [-f|[-p] -o *field*[,...]] [*name*...]
Displays characteristics of the specified rules, or all, if no rule is specified. The subcommand has the following options:

-d
   Display only disabled rules.

-e
   Display only enabled rules.

-f
   Display a full list.

-o *field*[,...]
   Display output for *field*(s). Cannot be used with -f option.

-p
   Display parsable output in the format described in "Description". Requires the -o option.

Note that the -o (with or without -p) and -f options are mutually exclusive.

show-nat *count*
Displays NAT table information. If *count* is specified, displays *count* entries from the NAT table. If no count is specified, displays the entire NAT table.

count

No assumptions should be made about the relative positions of elements in consecutive runs of this command. For example, executing show-nat 10 twice is not guaranteed to display the same ten items twice, especially on a busy system.

Display format:

T: IP1 > IP2 >>> IP3 > IP4

These items are described as follows:

T   The transport protocol used in this entry.

IP1   The client's IP address and port.

IP2   The VIP and port.

IP3   If half NAT mode, the client's IP address and port. If full NAT mode, the NAT'ed client's IP address and port.

IP4   The backend server's IP address and port.

show-persist|show-pt *count*
    Displays persistence table information. If *count* is specified, displays *count* entries from the table. If no count is specified, displays the entire persistence table.

    No assumptions should be made about the relative positions of elements in consecutive runs of this command. For example, executing show-persist 10 twice is not guaranteed to display the same ten items twice, especially on a busy system.

    Display format:

    R: IP1 --> IP2

    These items are described as follows:

    R
        The rule this persistence entry is tied to.

    IP1
        The client's IP address and port.

    IP2
        The backend server's IP address.

export-config|export-cf [*filename*]
    Exports the current configuration in a format suitable for re-import using ilbadm import. If no filename is specified, the subcommand writes to stdout.

import-config|import-cf [-p] [*filename*]
    Reads configuration contents of a file. By default, this overrides any existing configuration. If no filename is specified, the subcommand reads from stdin. This subcommand has the following option:

    -p
        Preserve existing configuration and do incremental import.

create-servergroup|create-sg [-s *server=hostspec*[:*portspec*...]] *groupname*
    Creates a server group. Additional servers can be added later using the add-server subcommand. Server groups are the only entity that can be used during rule creation to indicate back-end servers. If the specified server group is associated with one or more rules, the server is enabled when it is added. This subcommand has the following option and operands:

    -s *server=hostspec*[:*portspec*...]
        Specifies a list of servers to be added to the server group.

        hostspec is a hostname or IP address. IPv6 addresses must be enclosed in brackets ([]) to distinguish them from ":*portspec*"

        portspec is a service name or port number. If the port number is not specified, a number in the range 1–65535 is used.

disable-server|disable-srv *server*
　　Disable one or more server(s). That is, tell the kernel not to forward traffic to this server.
　　disable-server applies to all rules that are attached to the server group this server is part
　　of.

　　server is a server ID.

enable-server|enable-srv *server*...
　　Reenables disabled servers.

show-server|show-srv [[-p] -o *field*[,*field*...]] [*rulename*...]
　　Displays servers associated with named rules, or all servers if no rulename is specified. The
　　subcommand has the following options.

　　-o *field*[,*field*...]
　　　　Display only the specified fields.

　　-p
　　　　Display fields in parsable format. Requires the -o option.

delete-servergroup|delete-sg *groupname*
　　Deletes a server group.

show-servergroup|show-sg [[-p] -o *field*[,...]] [*name*]
　　Lists a server group, or all server groups, if no *name* is specified. The subcommand has the
　　following options:

　　-o *field*[,...]
　　　　Display output for *field*(s).

　　-p
　　　　Display parsable output in the format described in "Description". Requires the -o
　　　　option.

add-server|add-srv -s *server=value*[, *value*...] *servergroup*
　　Add specified server(s) to *servergroup*. See description of create-servergroup for
　　definition of *value*.

　　-s
　　　　See create-servergroup.

　　Performing an add-server to a server group immediately after performing a
　　remove-server on that server group might fail because of incomplete connection draining.
　　Refer to the description of the remove-server subcommand for instructions on how to
　　avoid this failure.

remove-server|remove-srv -s *server=value*[, *value*...] *servergroup*
　　Remove specified server(s) from *servergroup*.

　　-s
　　　　One or more of a server ID.

If a server is being used by a NAT/half-NAT rule, it is recommended that the server be disabled (using disable-server) before removal. By disabling a server, the server enters the connection-draining state. After all of the connections are drained, the server can then be removed by remove-server. If the conn-drain timeout value is set, the connection-draining state will be finished upon conclusion of the timeout period. Note that the default conn-drain timeout is 0, meaning it will keep waiting until a connection is gracefully shut down.

create-healthcheck|create-hc [-n] -h hc-test=*value*,hc-timeout=*value*, hc-count=*num_value*,hc-interval=*value hcname*

Sets up a health check object for rules to use. All servers associated with a rule are checked using the same test. A health check event of a server consists of one to hc-count number of hc-test executions. If an hc-test's result shows a server to be unresponsive, further hc-test checks are made, up to hc-count invocations, before a server is considered to be down.

-h

The hc-test is performed hc-count times until it succeeds or hc-timeout has expired. For a given rule, all servers are checked using the same test. The tests are as follows:

hc-test

PING, TCP, external method (script or binary). An external method should be specified with a full path name.

hc-timeout

Threshold at which a test is considered failed following interim failures of hc-test. If you kill an hc-test test, the result is considered a failure. The default value is five seconds.

hc-count

Maximum number of attempts to run hc-test before marking a server as down. The default value is three iterations.

hc-interval

Interval between invocations of hc-test. This value must be greater than hc-timeout times hc-count. The default value is 30 seconds.

The following arguments are passed to external methods:

$1

VIP (literal IPv4 or IPv6 address).

$2

Server IP (literal IPv4 or IPv6 address).

$3

Protocol (UDP, TCP as a string).

$4

The load balance mode, DSR, NAT, HALF_NAT.

$5

Numeric port.

$6

Maximum time (in seconds) the method should wait before returning failure. If the method runs for longer, it can be killed, and the test considered failed.

External methods should return `0` (or the round-trip time to the back end server, in microseconds) for success and `-1` if the server is considered down.

Before higher layer health check(s), TCP, UDP, and external tests start, a default `ping` test is performed first. The higher layer test will not be performed if `ping` fails. You can turn off the default `ping` check for these high layer health checks by through use of `-n`.

-n

Disable default `ping` test for high layer health check tests.

delete-healthcheck|delete-hc *hcname*...

Delete the named health check object(s) (*hcname*). If the given health check object is associated with enabled rule(s), deletion of the object will fail.

show-healthcheck|show-hc [*hcname*...]

List the health check information for the specified health check (*hcname*). If no health check is specified, list information for all existing health checks.

show-hc-result|show-hc-res [*rule-name*]

List the health check result for the servers that are associated with *rule-name*. If *rule-name* is not given, the health check results for all servers are displayed.

Examples   EXAMPLE 1   Configuring NAT Mode

The following commands create a rule with health check and timers set (port range shifting and session persistence).

```
# ilbadm create-healthcheck -h hc-test=tcp,hc-timeout=2,hc-count=3, \
    hc-interval=10 hc1
# ilbadm create-servergroup -s \
    server=60.0.0.10:6000-6009,60.0.0.11:7000-7009 sg1
# ilbadm create-rule -e -i vip=81.0.0.10,port=5000-5009,protocol=tcp \
-m lbalg=rr,type=NAT,proxy-src=60.0.0.101-60.0.0.104, \
    pmask=24 \
-h hc-name=hc1 \
-t conn-drain=180,nat-timeout=180,persist-timeout=180 \
-o servergroup=sg1 rule1
```

The following command creates a rule with the default timer values and without health check.

```
# ilbadm create-servergroup -s server=60.0.0.10 sg1
 # lbadm create-rule -e -i vip=81.0.0.10,port=5000 \
    -m lbalg=rr,type=NAT,proxy-src=60.0.0.105 \
```

EXAMPLE 1 Configuring NAT Mode   *(Continued)*

```
    -o servergroup=sg1 rule1
# ilbadm add-server -e -s server=60.0.0.11sg1
# ilbadm enable-rule rule1
```

EXAMPLE 2 Configuring Half-NAT Mode

The following command configures half-NAT mode and exemplifies port range collapsing.

```
# ilbadm create-servergroup sg1
# ilbadm create-rule -e -i vip=81.0.0.10,port=5000-5009 \
    -m lbalg=rr,type=h -o servergroup=sg1 rule1
# ilbadm add-server -s server=60.0.0.10:6000,60.0.0.11:7000 sg1
```

EXAMPLE 3 Configuring DSR Mode and Preparing Two Sets of Rules

The following command establishes two sets of rules to enable load balancing between HTTP and FTP traffic. Note both types of traffic traverse interface 60.0.0.10.

```
# ilbadm create-servergroup -s servers=60.0.0.9,60.0.0.10 websg
# ilbadm create-servergroup -s servers=60.0.0.10,60.0.0.11 ftpgroup

# ilbadm create-rule -e -i vip=81.0.0.10,port=80 \
    -m lbalg=hash-ip-port,type=DSR \
    -o servergroup=websg webrule
# ilbadm create-rule -e -i vip=81.0.0.10,port=ftp \
    -m lbalg=hash-ip-port,type=DSR,pmask=24 \
    -o servergroup=ftpgroup ftprule
# ilbadm create-rule -e -p -i vip=81.0.0.10,port=ftp-data \
    -m lbalg=hash-ip-port,type=DSR,pmask=24 \
    -o servergroup=ftpgroup ftpdatarule
```

EXAMPLE 4 Deleting Rule, Server Group, and Health Check

The following commands delete the rule, server group, and health check established in the first example.

```
# ilbadm ilbadm delete-rule -a
# ilbadm delete-servergroup sg1
# ilbadm delete-healthcheck hc1
```

EXAMPLE 5 Display a List of Rules

The following command displays a list of rules.

```
# ilbadm show-rule
RULENAME        STATUS LBALG    TYPE    PROTOCOL VIP  PORT
r2              E      hash-ip  NAT     TCP 45.0.0.10 81
r1              E      hash-ip  NAT     TCP 45.0.0.10 80
```

EXAMPLE 5 Display a List of Rules   *(Continued)*

```
# ilbadm show-rule -f
        RULENAME: rule1
          STATUS: E
            PORT: 80
        PROTOCOL: TCP
           LBALG: roundrobin
            TYPE: HALF-NAT
       PROXY-SRC: --
         PERSIST: --
         HC-NAME: hc1
         HC-PORT: ANY
      CONN-DRAIN: 0
     NAT-TIMEOUT: 120
 PERSIST-TIMEOUT: 60
     SERVERGROUP: sg1
             VIP: 80.0.0.2
         SERVERS: _sg1.0,_sg1.1
```

EXAMPLE 6 Exporting and Importing Rules

The following commands show how to export rules to and import rules from stdout, and to/from a file.

```
# ilbadm export-config
```

```
create-servergroup ftpgroup
add-server -s server=10.1.1.3:21 ftpgroup
add-server -s server=10.1.1.4:21 ftpgroup
create-servergroup webgroup_v6
add-server -s server=[2000::ff]:80 webgroup_v6
create-rule -e protocol=tcp,VIP=1.2.3.4,port=ftp \
        -m lbalg=roundrobin,type=DSR \
        -o servergroup=ftpgroup rule4
create-rule protocol=tcp,VIP=2003::1,port=ftp \
        -m lbalg=roundrobin,type=DSR \
        -o servergroup=ftpgroup6 rule3
create-rule -e protocol=tcp,VIP=2002::1,port=http \
        -m lbalg=roundrobin,type=DSR \
        -o serverrgroup=webgrp_v6 RULE-all
```

The following command exports rules to a file.

```
# ilbadm export-config /tmp/ilbrules
```

Following this command, /tmp/ilbrules contains the output displayed in the previous command.

The following command imports rules from a file.

EXAMPLE 6 Exporting and Importing Rules *(Continued)*

```
# ilbadm import-config /tmp/ilbrules
```

This command replaces whatever rules were in place with the contents of /tmp/ilbrules.

The following command imports rules from stdin.

```
# cat /tmp/ilbrules | ilbadm import-config
```

The effect of this command is identical to the effect of the preceding command.

EXAMPLE 7 Creating a Single Health Check

The following command creates a single health check.

```
# ilbadm create-healthcheck -h hc-timeout=3,hc-count=2,hc-interval=8,\
    hc-test=tcp hc1
```

EXAMPLE 8 Listing All Healthchecks

The following command lists all extant health checks.

```
# ilbadm show-healthcheck
HCNAME      TIMEOUT COUNT   INTERVAL DEF_PING TEST
hc1         2       1       10       Y        tcp
hc2         2       1       10       N        /usr/local/bin/probe
```

EXAMPLE 9 Deleting a Single Health Check

The following command deletes a single health check.

```
# ilbadm delete-healthcheck hc1
```

EXAMPLE 10 Displaying Statistics

The following command displays statistics at an interval of one seconds, for three iterations.

```
# ilbadm show-stats -A 1 3
 PKT_P   BYTES_P   PKT_U   BYTES_U   PKT_D   BYTES_D
0        0         0       0         4       196
0        0         0       0         4       196
0        0         0       0         4       196
```

The following is the command you would use to display statistics in verbose mode at intervals of one second. Output is too wide to fit within the page boundary.

```
# ilbadm show-stats -v 1
```

The following command displays statistics for rule r1 at an interval of one second for three iterations.

EXAMPLE 10 Displaying Statistics   *(Continued)*

```
# ilbadm show-stats -A -r r1 1 3
PKT_P   BYTES_P   PKT_U   BYTES_U   PKT_D   BYTES_D
0       0         0       0         4       196
0       0         0       0         4       196
0       0         0       0         4       196
```

The following command displays statistics for rule r1 for each of its servers, for an interval of one second and a count of 3.

```
# ilbadm show-stats -A -r r1 -i 1 3
SERVERNAME        PKT_P    BYTES_P
_sg1.0            0        0
_sg1.1            0        0
_sg1.2            0        0
_sg1.0            0        0
_sg1.1            0        0
_sg1.2            0        0
_sg1.0            0        0
_sg1.1            0        0
_sg1.2            0        0
```

The following command displays itemized statistics, with timestamps, for server _sg1.0, at an interval of one second and a count of 3.

```
# ilbadm show-stats -A -s _sg1.0 -it 1 3
RULENAME          PKT_P    BYTES_P    TIME
r1                0        0          2009-07-20:16.10.20
r1                0        0          2009-07-20:16.10.21
r1                0        0          2009-07-20:16.10.22
```

The following command displays statistics with specific option fields, at an interval of one second and a count of 3.

```
# ilbadm show-stats -o BYTES_D,TIME 1 3
BYTES_D   TIME
196       2009-07-20:16.14.25
0         2009-07-20:16.14.26
0         2009-07-20:16.14.27
```

EXAMPLE 11 Displaying Health Check Results

The following command displays the results of a health check.

```
# ilbadm show-hc-result rule1
RULENAME   HCNAME    SERVERID    STATUS    FAIL LAST       NEXT       RTT
rule1      hc1       _sg1.0      dead      6    04:45:17 04:45:30 698
rule1      hc1       _sg1.1      alive     0    04:45:11 04:45:25 260
rule1      hc1       _sg1.2      unreach   6    04:45:17 04:45:30 0
```

EXAMPLE 12 Displaying the NAT Table

The following command displays the NAT table.

```
# ilbadm show-nat 5
UDP: 124.106.235.150.53688>85.0.0.1.1024>>>82.0.0.39.4127>82.0.0.56.1024
UDP: 71.159.95.31.61528> 85.0.0.1.1024>>> 82.0.0.39.4146> 82.0.0.55.1024
UDP: 9.213.106.54.19787> 85.0.0.1.1024>>> 82.0.0.40.4114> 82.0.0.55.1024
UDP: 118.148.25.17.26676> 85.0.0.1.1024>>>82.0.0.40.4112> 82.0.0.56.1024
UDP: 69.219.132.153.56132>85.0.0.1.1024>>>82.0.0.39.4134> 82.0.0.55.1024
```

In actual ilbadm output, spaces are interspersed for greater readability.

EXAMPLE 13 Displaying the Persistence Table

The following command displays the persistence table.

```
# ilbadm show-persist 5
rule2: 124.106.235.150 --> 82.0.0.56
rule3: 71.159.95.31 --> 82.0.0.55
rule3: 9.213.106.54 --> 82.0.0.55
rule1: 118.148.25.17 --> 82.0.0.56
rule2: 69.219.132.153 --> 82.0.0.55
```

EXAMPLE 14 Displaying Server Groups

The following command displays basic information about server groups.

```
# ilbadm show-servergroup
sg1: id:sg1.2 35.0.0.4:80
sg1: id:sg1.1 35.0.0.3:80
sg1: id:sg1.0 35.0.0.2:80
sg2: id:sg2.3 35.0.0.5:81
sg2: id:sg2.2 35.0.0.4:81
sg2: id:sg2.1 35.0.0.3:81
sg2: id:sg2.0 35.0.0.2:81
```

The following command displays all available information about server groups.

```
# ilbadm show-servergroup -o all
sgname          serverID          minport maxport IP_address
sg1             _sg1.0            --      --       1.1.1.1
sg2             _sg2.1            --      --       1.1.1.6
sg3             _sg3.0            9001    9001     1.1.1.1
sg3             _sg3.1            9001    9001     1.1.1.2
sg3             _sg3.2            9001    9001     1.1.1.3
sg3             _sg3.3            9001    9001     1.1.1.4
sg3             _sg3.4            9001    9001     1.1.1.5
sg3             _sg3.5            9001    9001     1.1.1.6
sg3             _sg3.6            9001    9001     1.1.1.11
sg3             _sg3.7            9001    9001     1.1.1.12
sg3             _sg3.8            9001    9001     1.1.1.13
```

EXAMPLE 14   Displaying Server Groups   *(Continued)*

```
sg3             _sg3.9          9001  9001      1.1.1.14
sg3             _sg3.10         9001  9001      1.1.1.15
sg3             _sg3.11         9001  9001      1.1.1.16
sg4             _sg4.0          9001  9006      1.1.1.1
sg4             _sg4.1          9001  9006      1.1.1.6
```

EXAMPLE 15   List Servers Associated with a Rule

The following command lists the servers that are associated with a rule.

```
# ilbadm show-server r1
SERVERID          ADDRESS      PORT RULENAME    STATUS SERVERGROUP
_sg1.0            35.0.0.10    80   rule1       E      sg1
_sg1.1            35.0.0.11    80   rule1       E      sg1
_sg1.2            35.0.0.12    80   rule1       D      sg1
```

Attributes   See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/load-balancer/ilb
Interface Stability	Committed

See Also   `ilbd(1M)`, `vmstat(1M)`, `attributes(5)`

Name ilbd – ILB daemon

Synopsis /usr/lib/inet/ilbd

Description The Integrated Load Balancer (ILB) daemon, ilbd, provides user-level services for the ILB. It is a system daemon started by the Service Management Facility (see smf(5)). Its fault management resource identifier (FMRI) is:

svc:/network/loadbalancer/ilb:default

Note that ilbd is a Consolidation Private interface. See attributes(5).

ilbd provides no administrative interface. All ILB administration should be done through ilbadm(1M) or the programming library libilb(3LIB).

Options The ilbd daemon has no options.

Examples EXAMPLE 1 Enabling the ILB Service

The following command enables the ILB service:

svcadm enable svc:/network/loadbalancer/ilb:default

EXAMPLE 2 Disabling the ILB Service

The following command disables the ILB service:

svcadm disable svc:/network/loadbalancer/ilb:default

Errors The ilbd daemon uses syslog(3C) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_INFO priority. The default entries in the /etc/syslog.conf file log all of the ilbd daemon error messages to the /var/adm/messages log.

Files /usr/lib/inet/ilbd
   ILB daemon binary

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/load-balancer/ilb
Interface Stability	Project Private

See Also svcs(1), ilbadm(1M), svcadm(1M), syslog(3C), libilb(3LIB), syslog.conf(4), attributes(5), smf(5)

Notes   The ilbd service is managed by the service management facility, smf(5), under the fault
management resource identifier (FMRI):

svc:/network/loadbalancer/ilb:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can
be performed using svcadm(1M). The service's status can be queried using the svcs(1)
command. To administer the service, the authorization solaris.smf.manage.ilb must be
granted. Alternatively, the rights profile "ILB Management" can be granted.

The ILB service must be enabled for the ilbadm(1M) command and any other libilb(3LIB)
client applications to function properly.

Name ilomconfig – ILOM LAN configuration utility

Synopsis ilomconfig list *subcommand* [*options*]

ilomconfig modify *subcommand* [*options*]

ilomconfig enable *subcommand* [*options*]

ilomconfig disable *subcommand* [*options*]

Description ilomconfig is an Oracle Integrated Lights Out Management (ILOM) configuration utility that allows an administrator to configure the LAN interface between the Service Processor (SP) and host. The administrator can view the LAN configuration settings by means of the list command and configure the interface using the enable, disable, and modify commands.

Sub-commands The following subcommands are available under the list command:

system-summary
    List product summary information and ILOM version.

interconnect
    List Host-to-ILOM interconnect settings.

The following subcommands are available under the modify command:

interconnect
    Modifies Host-to-ILOM interconnect settings.

The following subcommand is available under the enable command:

interconnect
    Enables the Host-to-ILOM interconnect.

The following subcommand is available under the disable command:

interconnect
    Disables the Host-to-ILOM interconnect.

Options The following options are available for the enable and modify commands:

-ipaddress=*ipaddress*
    Set the IP address for the SP side of the LAN interconnect.

-hostipaddress=*ipaddress*
    Set the IP address for the host side of the LAN interconnect.

-netmask=*netmask*
    Set the network mask for the IP addresses used for the LAN.

The following are general options:

-?, -h, --help
    Display a brief usage message and then exit.

-q, --quiet
   Suppress informational message output and return only error codes.

-V, --version
   Display version information for ilomconfig and then exit.

Files /var/log/ilomconfig/ilomconfig.log
   ilomconfig-specific log file.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/management/ilomconfig
Interface Stability	Committed

Name imqadmin – launch the Message Queue administration console

Synopsis /usr/bin/imqadmin [-javahome *path*]

/usr/bin/imqadmin -h

/usr/bin/imqadmin -v

Description imqadmin launches the graphical user interface application that performs most Message Queue administration tasks. These tasks include managing broker instances (including physical destinations) and administered objects.

Options The following options are supported:

-h   Display usage help. The application is not launched.

-javahome *path*   Specify a path to an alternate Java 2 compatible runtime.

-v   Display version information.

Environment Variables The following environment variables affect the execution of this command:

IMQ_JAVAHOME   Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to /usr/j2se.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Files $HOME/.imq/admin/brokerlist.properties
  Contains user settings, a list of broker instances being managed.

$HOME/.imq/admin/objectstorelist.properties
  Contains user settings, a list of object stores being managed.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWiq

Sun Java System Message Queue Administrator's Guide

Name imqbrokerd – start a Message Queue broker instance

Synopsis `/usr/bin/imqbrokerd [`*option*`...]`

`/usr/bin/imqbrokerd -h`

Description `imqbrokerd` starts an instance of the Message Queue broker. The Message Queue broker is the main component of a Message Queue message server. The broker performs reliable delivery of messages to and from Java Message Service (JMS) clients.

`imqbrokerd` uses command line options to specify broker configuration properties.

Options The following options are supported:

`-backup` *fileName*	Back up a Master Broker's configuration change record to *fileName*. This option only applies to broker clusters.
`-cluster` *brokerList*	Specify the list of broker instances which are connected in a cluster. This list is merged with the list in the imq.cluster.brokerlist property. This option only applies to broker clusters.
	brokerList is a comma-separated list of broker instances, each specified by *hostName:port* (the host on which the broker instance is running and the port number it is using) If you don't specify a value for *hostName*, `localhost` is used. If you don't specify a value for *port*, the value of 7676 is used. For example: `host1:8899,host2,:7878`.
`-dbpassword` *password*	Specify the password for a plugged-in JDBC-compliant database used as a Message Queue data store.
`-dbuser` *userName*	Specify the user name for a plugged-in JDBC-compliant data store.
`-D`*property*`-=`*value*	Set the specified broker configuration property to the *value*. The system does not validate either the configuration property or *value*. Therefore, spelling, formatting, and case is important. Message Queue can not set incorrect values passed using the `-D` option.
`-force`	Perform action without user confirmation. This option only applies when you use the `-remove` *instance* option, which normally requires confirmation.

-h	Display usage help. Execute nothing else on the command line.
-javahome *path*	Specify the path to an alternate Java 2-compatible Java Development Kit (JDK) or Java Runtime Environment (JRE) The default is to use the runtime bundled with the operating system.
-ldappassword *password*	Specify the password for accessing an LDAP user repository when using an LDAP server (as opposed to a built-in flat-file repository) to authenticate users of a Message Queue message server.
-license [*name*]	Specify the license to load, if different from the default for your Message Queue product edition. If you don't specify a license name, this lists all licenses installed on the system. Depending on the installed Message Queue edition, the values for *name* are pe (Platform Edition-basic features), try (Platform Edition-90-day trial enterprise features), and unl (Enterprise Edition).
-loglevel *level*	Specify the logging level. Valid values for *level* are NONE, ERROR, WARNING, or INFO. The default value is INFO.
-metrics *int*	Report metrics at a specific interval. Specify *int* as the number of seconds.
-name *brokerName*	Specify the instance name of this broker and use the corresponding instance configuration file. If you do not specify a broker name, the name of the file is set to imqbroker. If you run more than one instance of a broker on the same host, each must have a unique name.
-passfile *filename*	Specify the name of the file from which to read the passwords for the SSL keystore, LDAP user repository, or JDBC-compliant database.
-password *keypassword*	Specify the password for the SSL certificate keystore.
-port *number*	Specify the broker's Port Mapper port number. By default, this is set to 7676. To run two instances of a broker on the same server, each broker's Port

	Mapper must have a different port number. JMS clients connect to the broker instance using this port number.
-remove *instance*	Remove the broker instance. Delete the instance configuration file, log files, data store, and other files and directories associated with the broker instance. This option requires user confirmation unless you also specify the -force option.
-reset store|messages|durables|props	Reset the data store (or a subset of the store) or resets the configuration properties of the broker instance when the broker instance is started. The action depends on the argument provided.

	store	Clear all persistent data in the data store, including messages, durable subscriptions, and transaction information store.
	messages	Clear all persistent messages durable.
	durables	Clear all durable subscriptions.
	props	Clear all configuration information in the config.props instance configuration file. All properties assume default values.

-restore *filename*	Replace the Master Broker's configuration change record with the specified backup file. This file must have been previously created using the -backup option. This option only applies to broker clusters.
-shared	Specify that the jms connection service be implemented using the shared threadpool model, in which threads are shared among connections to increase the number of connections supported by a broker instance.
-silent	Turn off logging to the console.
-tty	Display all messages be to the console. WARNING and ERROR level messages are displayed on the console by default.

-upgrade-store-nobackup	Specify that an earlier, incompatible version Message Queue data store is automatically removed when migrating to Message Queue 3.5 format.
	If you do not use this option, you must manually delete the earlier data store. This applies to both built-in (flat-file) persistence and plugged-in (JDBC-compliant) persistence. Migration of the earlier data store to a Message Queue 3.5 data store takes place the first time you start a Message Queue 3.5 broker instance on an earlier version data store.
-version	Display the version number of the installed product.
-vmargs *are* [[*arg*]…]	Specify arguments to pass to the Java VM. Separate arguments with spaces. If you want to pass more than one argument or if an argument contains a space, use enclosing quotation marks. For example:

```
imqbrokerd -tty -vmargs " -Xmx128m -Xincgc"
```

Environment Variables The following environment variables affect the execution of this command:

IMQ_JAVAHOME   Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to /usr/j2se.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Files /etc/init.d/imq
Shell script for starting imqbrokerd. This file looks at the /etc/imq/imqbrokerd.conf file.

/etc/imq/imqbrokerd.conf
Configuration file which controls the behavior of the broker startup script.

/etc/imq/passwd
Flat file user repository for authenticating users.

/etc/imq/accesscontrol.properties
Controls client access to broker functionality.

/etc/imq/passfile.sample
Sample passfile used by the -passfile option.

/var/imq/instances/brokerName/props/config.properties
   Broker instance configuration file.

Attributes   See attributes(5) for descriptions of the following attributes:

Sun Java System Message Queue Administrator's Guide

Name imqcmd – manage Message Queue brokers

Synopsis /usr/bin/imqcmd *subcommand argument* [*option*...]

/usr/bin/imqcmd [-h | -H]

/usr/bin/imqcmd -v

Description imqcmd manages the Message Queue broker, including resources such as connection services, physical destinations, durable subscriptions, and transactions. The utility provides a number of subcommands for managing these resources.

imqcmd supports many subcommands. Basic connection and authentication is required for the execution of every imqcmd subcommand. Use the -secure option to specify secure connections. Subcommands and their corresponding arguments and options follow the imqcmd command on the command line. See USAGE and OPTIONS.

Options The following options are supported:

-b *hostName*:*port*	Specify the name of the host on which the broker instance is running and the port number it is using.
	The default value is localhost:7676. If you do not specify the -b option, imqcmd uses the default.
	To specify port only, use: -b :7878. This is equivalent to -b localhost:7878
	To specify name only, use: -b somehost. This is equivalent to -b somehost:7676.
-c *clientID*	Specify the ID of the durable subscriber to a topic.
-d *topicName*	Specify the name of the topic.
	Use this option with the list dur and destroy dur subcommands.
-f	Perform action without user confirmation.
	Use this option with any subcommand.
-h	Display usage help. Execute nothing else on the command line.
-H	Display usage help, attribute list, and examples. Execute nothing else on the command line.
-int *interval*	Specify the interval, in seconds, at which the metrics bkr, metrics dst, and metrics svc subcommands display metrics output.
	Use this option with the metrics subcommand.
-javahome	Specify an alternate Java 2 compatible runtime to use.

-m *metricType*	Specify the type of metric information to diplay.	

Use this option with the `metrics bkr`, `metrics dst`, and `metrics svc` subcommands. The value of *metricType* depends on whether the metrics are generated for a destination, a service, or a broker.

Use one of the following values to specify *metricType*:

ttl   Total of messages in and out of the broker (default)

rts   Provides the same information as `ttl`, but specifies the number of messages per second

cxn   Connections, virtual memory heap, threads

The following command displays connection, VM heap, and threads metric information for the default broker instance (`localhost:7676`) every five seconds:

```
imqcmd metrics bkr -m cxn -int 5
```

-msp *numSamples*	Specify the number of samples the `metrics bkr`, `metrics dst`, and `metrics svc` subcommands display in the metrics output.
-n *argumentName*	Specify the name of the subcommand argument. Depending on the subcommand, this might be the name of a service, a physical destination, a durable subscription, or a transaction ID.
-o *attribute=value*	Specify the value of an attribute. Depending on the subcommand argument, this might be the attribute of a broker, service, or destination.
-p *password*	Specify the administrator password.

This option is deprecated. Use the `-passfile` option instead.

-passfile	Specify the administrator password.
-pst *pauseType*	Specify whether producers, consumers, or both are paused when pausing a destination.

Use this option with the `pause dst` subcommand. Use one of the following values:

CONSUMERS	Pause delivery of messages to consumers.
PRODUCERS	Pause delivery of messages from producers.
ALL	Pause delivery of messages to consumers and from producers.

<table>
<tr><td></td><td>If the -pst option is not specified, pauses both consumers and producers (the equivalent of -pst ALL).</td></tr>
<tr><td>-rtm timeout</td><td>Specify the timeout period in seconds of an imqcmd subcommand. The default value is 10.</td></tr>
<tr><td>-rtr numRetries</td><td>Specify the number of retries attempted after an imqcmd subcommand times out.</td></tr>
<tr><td></td><td>The default value is 5.</td></tr>
<tr><td>-s</td><td>Silent mode. No output is displayed.</td></tr>
<tr><td></td><td>Use this option with any subcommand.</td></tr>
<tr><td>-secure</td><td>Specify a secure administration connection to the broker instance. You must first configure the broker to enable a secure connection service.</td></tr>
<tr><td></td><td>Use this option whenever you want a secure communication with the broker.</td></tr>
<tr><td>-svn serviceName</td><td>Specify the service for which the connections are listed.</td></tr>
<tr><td></td><td>Use this option with the list cxn subcommand.</td></tr>
<tr><td>-t destinationType</td><td>Specify the type of a destination: t (topic) or q (queue).</td></tr>
<tr><td>-tmp</td><td>Include temporary destinations when listing destinations using the list dst subcommand.</td></tr>
<tr><td>-u name</td><td>Specify the administrator user name.</td></tr>
<tr><td></td><td>If you omit this value, you are prompted for it.</td></tr>
<tr><td>-v</td><td>Display version information. Execute nothing else on the command line.</td></tr>
</table>

Usage

Subcommands and Options
The following subcommands and associated arguments and options are supported:

compact dst [-t *type* -n *destName*]
  Compact the flat-file data store for the destination of the specified type and name. If no type and name are specified, all destinations are compacted. Destinations must be paused before they can be compacted.

commit txn -n *transaction_id*
  Commit the specified transaction

create dst -t *destinationType* -n *destName* [-o *attribute=value*] [-o *attribute=value1*]...
    Create a destination of the specified type, with the specified name, and the specified
    attributes. Destination names must contain only alphanumeric characters (no spaces) and
    can begin with an alphabetic character or the underscore character (_).

destroy dst -t *destinationType* -n *destName*
    Destroy the destination of the specified type and name.

destroy dur -n *subscrName* -c *client_id*
    Destroy the specified durable subscription for the specified Client Identifier.

list cxn [-svn *serviceName*] [-b *hostName:port*]
    List all connections of the specified service name on the default broker or on a broker at the
    specified host and port. If the service name is not specified, all connections are listed.

list dst [-tmp]
    List all destinations, with option of listing temporary destinations as well .

list dur -d *destination*
    List all durable subscriptions for the specified destination.

list svc
    List all connection services on the broker instance.

list txn
    List all transactions, being tracked by the broker.

metrics bkr [-m *metricType*] [-int *interval*] [-msp *numSamples*]
    Display broker metrics for the broker instance.

    Use the -m option to specify the type of metric to display. Use one of the following values to
    specify *metricType*:

    ttl   Specifies the total of messages in and out of the broker (default) .

    rts   Provides the same information as ttl, but specifies the number of messages per
            second.

    cxn   Connections, virtual memory heap, threads.

    Use the -int option to specify the interval (in seconds) at which to display the metrics. The
    default is 5 seconds.

    Use the -msp option to specify the number of samples displayed in the output. A value of -1
    means an unlimited number. The default value is -1.

metrics dst -t *type* -n *destName* [-m *metricType*] [-int *interval*] [-msp *numSamples*]
    Displays metrics information for the destination of the specified type and name.

    Use the -m option to specify the type of metrics to display. Use one of the following values
    to specify *metricType*:

ttl   Specifies the number of messages flowing in and out of the broker and residing in memory.

rts   Provides the same information as `ttl`, but specifies the number of messages per second.

con   Displays consumer related metrics.

dsk   Displays disk usage metrics.

Use the `-int` option to specify the interval (in seconds) at which to display the metrics. The default is 5 seconds.

Use the `-msp` option to specify the number of samples displayed in the output. A value of -1 means an unlimited number. The default value is 5.

metrics svc -n *serviceName* [-m *metricType*] [-int *interval*] [-msp *numSamples*]
> List metrics for the specified service on the broker instance. Use the `-m` option to specify the type of metric to display. Use one of the following values to specify *metricType*:

ttl   Total of messages in and out of the broker (default)

rts   Provides the same information as `ttl`, but specifies the number of messages per second

cxn   Connections, virtual memory heap, threads

Use the `-int` option to specify the interval (in seconds) at which to display the metrics. The default is 5 seconds.

Use the `-msp` option to specify the number of samples displayed in the output. A value of -1 means an unlimited number. The default value is -1.

pause bkr
> Pause the broker instance.

pause dst [-t *type* -n *destName*] [-pst *pauseType*]
> Pause the delivery of messages to consumers (-pst CONSUMERS), or from producers (-pst PRODUCERS), or both (-pst ALL), for the destination of the specified type and name. If no destination type or name are specified, all destinations are paused.

pause svc -n *serviceName*
> Pause the specified service running on the broker instance. You cannot pause the administative service.

purge dst -t *destinationType* -n *destName*
> Purge messages at the destination with the specified type and name.

purge dur -n *subscrName* -c *client_id*
> Purge all messages for the specified client identifier.

query bkr
> List the current settings of properties of the broker instance. Show the list of running brokers (in a multi-broker cluster) that are connected to the specified broker.

query dst -t *destinationType* -n *destName*
> List information about the destination of the specified type and name.

query svc -n *serviceName*
> Display information about the specified service running on the broker instance.

query txn -n *transaction_id*
> List information about the specified transaction.

reload cls
> Forces all the brokers in a cluster to reload the `imq.cluster.brokerlist` property and update cluster information. This subcommand only applies to broker clusters.

restart bkr
> Shut down and restart the broker instance. This command restarts the broker using the options specified when the broker was first started. If you want different options to be in effect, you must shut down the broker and then start it again, specifying the options you want.

resume bkr
> Resume the broker instance.

resume dst [-t *type*] [-n -destName]
> Resumes the delivery of messages for the paused destination of the specified type and name. If no destination type and name are specified, all destinations are resumed.

resume svc -n *serviceName*
> Resume the specified service running on the broker instance.

rollback txn -n *transaction_id*
> Roll back the specified transaction.

shutdown bkr
> Shut down the broker instance

update bkr -o *attribute=value* [-o *attribute=value*]...
> Change the specified attributes for the broker instance.

update dst -t *destinationType* -n *destName* -o *attribute=value* [-o *attribute=value1*]...
> Update the value of the specified attributes at the specified destination..

update svc -n *serviceName* -o *attribute=value* [-o *attribute=value1*]...
> Update the specified attribute of the specified service running on the broker instance.

Attribute Value Pairs   You can specify attributes with the create and update subcommands. Applicable attributes depend on the subcommand arguments.

The following attributes are supported:

Queue (dst):

maxTotalMsgBytes   Value: Integer (maximum total size of messages, in bytes)

                      Default: 0 (unlimited)

maxBytesPerMsg   Value: Integer (maximum size of a single message, in bytes)

                      Default: 0 (unlimited)

maxNumMsgs   Value: Integer (maximum total number of messages)

                      Default: 0 (unlimited)

consumerFlowLimit   Value: Integer Initial number of queued messages sent to active
                      consumers before load-balancing starts A value of -1 means an
                      unlimited number.

                      Default: 1000

isLocalOnly   Value: Boolean (destination limited to delivering messages to local
                      consumers only) Default: false

limitBehavior   Value: Specify how broker responds when memory-limit is
                      reached. Use one of the following values:

                      FLOW_CONTROL   Slows down producers

                      REMOVE_OLDEST   Purges oldest messages

                      REJECT_NEWEST   Rejects the newest messages

                      Default: REJECT_NEWEST

localDeliveryPreferred Value: Boolean Specify messages be delivered to remote
                      consumers only if there are no consumers on the local broker.
                      Requires that the destination not be restricted to local-only
                      delivery (isLocalOnly = false)

                      Default: false

maxNumActiveConsumers Value: Integer (maximum number of active consumers in
                      load-balanced delivery) A value of -1 means an unlimited number.

                      Default: 1

maxNumBackupConsumers Value: Integer (maximum number of backup consumers in
                      load-balanced delivery) A value of -1 means an unlimited number.

                      Default: 0

maxNumProducers	Value: (maximum total number of producers) A value of -1 means an unlimited number.
	Default: -1
useDMQ	Specify whether a destination's dead messages are discarded or put on the dead message queue.
	Default: true

Topic (dst):

consumerFlowLimit	Value: Integer Maximum number of messages delivered to a consumer in a single batch. A value of -1 means an unlimited number.
	Default: 1000
isLocalOnly	Value: Boolean (destination limited to delivering messages to local consumers only)
	Default: false
limitBehavior	Value: Specify how broker responds when memory-limit is reached. Use one of the following values:

FLOW_CONTROL	Slows down producers
REMOVE_OLDEST	Purges the oldest messages
REJECT_NEWEST	Rejects the newest messages

Default: REJECT_NEWEST

maxBytesPerMsg	Value: Integer (maximum size of a single message, in bytes)
	Default: 0 (unlimited)
maxNumMsgs	Value: Integer (maximum total number of messages) A value of -1 means an unlimited number.
	Default: -1
maxNumProducers	Value: (maximum total number of producers)
	Default: 0 (unlimited)
maxTotalMsgBytes	Value: Integer (maximum total size of messages, in bytes) A value of -1 means an unlimited number.
	Default: -1

useDMQ	Specify whether a destination's dead messages are discarded or put on the dead message queue.
	Default: `true`

Broker (bkr):

imq.autocreate.destination.useDMQ	Value: Boolean. Set the `useDMQ` attribute to `true` to enable all autocreated physical destinations on a broker to use the dead message queue. Set the `useDMQ` attribute to `false` to disable all autocreated physical destinations on a broker from using the dead message queue.
	Default: `true`
imq.autocreate.queue	Value: Boolean
	Default: `true`
imq.autocreate.queue.maxNumActiveConsumers	Value: Integer (maximum number of consumers that can be active in load-balanced delivery from an autocreated queue destination) A value of `-1` means an unlimited number.
	Default: `1`
imq.autocreate.queue.maxNumBackupConsumers	Value: Integer (maximum number of backup consumers that can take the place of active consumers) A value of `-1` means an unlimited number.
	Default: `0`
imq.autocreate.topic	Value: Boolean
	Default: `true`
imq.cluster.url	Value: String (location of cluster configuration file)
	Default: none
imq.log.file.rolloverbytes	Value: Integer (maximum size of a log file, in bytes)

		Default: 0 (no rollover based on size)
	imq.log.file.rolloversecs	Value: Integer (maximum age of a log file, in seconds)
		Default: 0 (no rollover based on age)
	imq.log.level	Value: String (NONE, ERROR, WARNING, INFO)
		Default: INFO
	imq.message.max_size	Value: Integer (maximum size of a single message, in bytes)
		Default: 70m
	imq.portmapper.port	Value: Integer
		Default: 7676
	imq.system.max_count	Value: Integer (maximum total number of messages)
		Default: 0 (no limit)
	imq.system.max_size	Value: Integer (maximum total size of messages, in bytes)
		Default: 0 (no limit)

Service (svc):

maxThreads	Value: Integer (maximum threads assigned)
	Default: Depends on service
minThreads	Value: Integer (minimum threads assigned)
	Default: Depends on service
port	Value: Integer
	Default: 0 (dynamically allocated)

Examples EXAMPLE 1   Shutting Down a Broker

The following command shuts down a broker for hostname myserver on port 7676:

```
mqcmd shutdown bkr -b myserver:7676
```

EXAMPLE 2 Restarting a Broker

The following command restarts a broker for hostname `myserver`:

```
imqcmd restart bkr -b myserver
```

EXAMPLE 3 Pausing a Service

The following command pauses a broker for hostname `localhost` on port 7676, with a
serviceName of `jms`:

```
imqcmd pause svc -n jms -b :7676
```

EXAMPLE 4 Resuming a Service

The following command resumes a service for hostname `localhost` on port 7676, with a
serviceName of `jms`:

```
imqcmd resume svc -n jms -b myserver:7676
```

EXAMPLE 5 Creating a Queue Destination

The following command creates a queue destination for hostname `myserver` on port 7676,
with a *destName* of `myFQ`, a *queueDeliveryPolicy* of `Failover`, and a *maxBytesPerMsg* of 10000:

```
imqcmd create dst -n myFQ -t q -o "queueDeliveryPolicy=f" \
    -o "maxBytesPerMsg=10000" -b myserver:7676
```

EXAMPLE 6 Purging a Queue Destination

The following command purges a queue destination for hostname `myserver` on port 7676,
with a *destName* of `myFQ`:

```
imqcmd purge dst -n myFQ -t q -b myserver:7676
```

EXAMPLE 7 Listing Destinations on a Broker

The following command lists destinations for hostname `myserver` on port 7676:

```
imqcmd list dst -b myserver:7676
```

EXAMPLE 8 Updating a Portmapper Port

The following command updates a portmapper port on hostname `myserver` from port 7676 to
7878:

```
imqcmd update bkr -o "imq.portmapper.port=7878"
```

EXAMPLE 9 Updating the Maximum Number of Messages in the Queue

The following command updates the maximum number of messages in the queue to 2000 for
`myserver` on port 8080 with a *destName* of `TestQueue`:

```
imqcmd update dst -b myserver:8080 -n TestQueue -t q -o "maxNumMsgs=2000"
```

EXAMPLE 10 Updating the Maximum Threads

The following command updates the maximum threads jms connection service to 200 for hostname localhost on port 7676:

```
imqcmd update svc -n jms -o "minThreads=200"
```

EXAMPLE 11 Listing Durable Subscriptions

The following command lists durable subscriptions for a topic with hostname localhost on port 7676 with a *destName* of myTopic:

```
imqcmd list dur -d myTopic
```

EXAMPLE 12 Destroying Durable Subscriptions

The following command destroys subscriptions for hostname localhost on port 7676 with a *dursubName* of myDurSub and a *client_ID* of 111.222.333.444:

```
imqcmd destroy dur -n myDurSub -c "111.222.333.444"
```

EXAMPLE 13 Listing All Transactions

The following command lists all transactions on a broker with hostname localhost on port 7676:

```
imqcmd list txn
```

EXAMPLE 14 Displaying Information About a Transaction

The following command displays information about a transaction with hostname localhost on port 7676, and a *transactionID* of 1234567890

```
imqcmd query txn -n 1234567890
```

EXAMPLE 15 Committing a Transaction

The following command commits a transaction with hostname localhost on port 7676, and a *transactionID* of 1234567890:

```
imqcmd commit txn -n 1234567890
```

Environment Variables   The following environment variables affect the execution of this command:

IMQ_JAVAHOME   Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to /usr/j2se.

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Sun Java System Message Queue Administrator's Guide

Name   imqdbmgr – manage a plugged-in JDBC-compliant Message Queue data store

Synopsis   /usr/bin/imqdbmgr *subcommand argument* [[*option*...]]

/usr/bin/imqdbmgr -h | -help

/usr/bin/imqdbmgr -v | -version

Description   The imqdbmgr utility creates and manages a Java DataBase Connectivity (JDBC) compliant database used for Message Queue persistent storage.

The database can be either embedded or external. To use a JDBC-compliant database (and the imdbmgr utility), you need to first set a number of JDBC-related properties in the broker instance configuration file. See the *Sun Java System Message Queue Administrator's Guide* for additional information.

imqdbmgr supports four management subcommands. These *subcommand*s, and their corresponding *argument*s and *option*s follow the imqdbmgr command on the command line. See USAGE and OPTIONS.

The following subcommands are supported:

create   Create a Message Queue database schema.

delete   Delete Message Queue database tables in the current data store.

recreate   Delete Message Queue database tables and recreate Message Queue database schema in the curent data store.

reset   Reset the database table lock to allow other processes to access database tables.

The imqdbmgr subcommands support the following arguments:

all   Indicates the subcommand applies to the data store, as well as the database tables.

lck   Indicates the subcommand applies to the database table lock.

oldtbl   Indicates the subcommand applies to an older version of the database tables.

tbl   Indicates the subcommand applies to the database tables only.

Options   The following options are supported:

-b *brokerName*   Specify the broker instance name and corresponding instance configuration properties. If this option is not specified, the default broker instance is assumed.

Use this option with the create, delete, recreate, or reset subcommands.

-D *property=value*   Set system property *property* to *value*.

	Use this option with the create, delete, recreate, or reset subcommands.
-h | -help	Display usage help. Execute nothing else on the command line.
-p *password*	Specify the database password.
	Use this option with the create, delete, recreate, or reset subcommands.
-u *userName*	Specify the database user name.
	Use this option with the create, delete, recreate, or reset subcommands.
-v | -version	Display version information. Execute nothing else on the command line.

Usage   The following subcommands and associated arguments are supported:

create all	Create a new embedded data store and Message Queue database schema for a specified or default broker instance.
create tbl [-u *userName*] [-p *password*]	Create Message Queue database schema in an existing data store for a specified or default broker instance.
delete tbl [-u *userName*] [-p *password*]	Delete Message Queue database tables in the current data store for a specified or default broker instance.
delete oldtbl [-u *userName*] [-p *password*]	Delete the earlier version of Message Queue database tables. Used after the data store has been automatically migrated to the current version of Message Queue.
recreate tbl [-u *userName*] [-p *password*]	Delete Message Queue database tables and recreate Message Queue database schema in the current data store for a specified or default broker instance.
reset lck	Reset the database table lock to allow other processes to access database tables.

Environment Variables   The following environment variables affect the execution of this command:

IMQ_JAVAHOME   Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to /usr/j2se.

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Files   /var/imq/instances/*brokerName*/dbstore   Recommended directory in which to create
                                                        an embedded database.

Sun Java System Message Queue Administrator's Guide

Name imqkeytool – generate a self-signed certificate for secure communication

Synopsis /usr/bin/imqkeytool [-broker] [-servlet *keystore_location*]

/usr/bin/imqkeytool -h

Description The imqkeytool utility generates a self-signed certificate for secure communication. The certificate can be used by a broker instance to establish a secure connection with a client, or by a Message Queue-supplied HTTPS servlet to establish a secure connection with a broker instance. An HTTPS servlet is an SSL-enabled varient of the HyperText Transfer Protocol that establishes a secure connection with a broker instance.

Without an option, imqkeytool generates a self-signed certificate for a broker instance.

imqkeytool uses command line options to specify whether the certificate is used by a broker instance or by a servlet.

Options The following options are supported:

-broker   Generate a self-signed certificate for the broker and places it in the Message Queue keystore. All broker instances running on a system must use the same certificate.

-h   Display usage help. Do not execute anything else on the command line.

-servlet *keystore_location*   Generate a self-signed certificate for an HTTPS servlet and places it in *keystore_location*.

                                   keystore_location refers to the location of the keystore. You should move this keystore to a location where it is accessible and readable by the Message Queue HTTPS servlet to establish a secure connection with a broker.

Environment Variables The following environment variables affect the execution of this command:

IMQ_JAVAHOME   Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to /usr/j2se.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Files /etc/imq/keystore   Contains Message Queue keystore in which imqkeytool stores a self-signed certificate for brokers.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWiq

Sun Java System Message Queue Administrator's Guide

Name imqobjmgr – manage Message Queue administered objects

Synopsis /usr/bin/imqobjmgr *subcommand* [[*option*]...]

/usr/bin/imqobjmgr -i *fileName*

/usr/bin/imqobjmgr -h | [-H] | -help | -Help

/usr/bin/imqobjmgr -v

Description imqobjmgr manages Message Queue administered objects in an object store accessible using JNDI. Administered objects allow JMS clients to be provider-independent by insulating them from provider-specific naming and configuration formats.

imqobjmgr supports five management subcommands. These *subcommand*s, and their corresponding *option*s follow the imqobjmgr command on the command line. See USAGE and OPTIONS.

The following subcommands are supported:

add   Add a new administered object

delete   Delete an administered object

list   Display a list of administered objects

query   Display information about administered objects

update   Update administered objects

You can use the -i option to specify the name of an input file that uses java property file syntax to represent all or part of any imqobjmgr subcommand clause. The -f, -s, and -pre options can be used with any imqobjmgr subcommand.

Options The following options are supported:

-f	Perform action without user confirmation.
-h | -help	Display usage help. Execute nothing else on the command line.
-H | -Help	Display usage help, attribute list, and examples. Execute nothing else on the command line.
-i *fileName*	Specify the name of an input file containing all or part of the subcommand clause, specifying object type, lookup name, object attributes, object store attributes, or other options. Use this option for repetitive information, such as object store attributes.
-j *attribute=value*	Specify attributes necessary to identify and access a JNDI object store.
-javahome	Specify an alternate Java 2 compatible runtime to use. imqobjmgr uses the runtime bundled with the operating system by default.

-l *lookupName*	Specify the JNDI lookup name of an administered object. This name must be unique in the object store's context.
-o *attribute=value*	Specify the attributes of an administered object.
-pre	Run command in preview mode. Preview mode indicates what will be done without performing the command.
-r *read-only_state*	Specify if an administered object is a read-only object. A value of true indicates the administered object is a read-only object. JMS clients cannot modify the attributes of read-only administered objects. The read-only state is set to false by default.
-s	Silent mode. No output is displayed.
-t *type*	Specify the type of an administered object:

```
q = queue
t = topic
cf = ConnectionFactory
qf = queueConnectionFactory
tf = topicConnectionFactory
xcf = XA ConnectionFactory (distributed transactions)
xqf = XA queueConnectionFactory (distributed transactions)
xtf = XA topicConnectionFactory (distributed transactions)
e = SOAP endpoint (used to support SOAP messaging)
```

-v	Display version information. Execute nothing else on the command line.

Usage This section provides information on subcommands, options, and attribute value pairs.

Subcommands and Options

The following subcommands and corresponding options are supported:

add -t *type* -l *lookupName* [-o *attribute=value*]... -j *attribute=value*...
Add a new administered object of the specified type, lookup name , and object attributes to an object store.

delete -t *type* -l *lookupName* -j *attribute=value*...
Delete an administered object, of the specified type and lookup name from an object store.

list [-t *type*] -j *attribute=value*...
Display a list of administered objects of a specified type, or all administered objects, in an object store.

query -l *lookupName* -j *attribute=value*...
Display information about an administered object of a specified lookup name in an object store.

update -l *lookupName* [-o *attribute=value*]... -j *attribute=value*...
Update the specified attribute values of an administered object of the specified lookup name in an object store.

Attribute Value Pairs   The following attribute value pairs are supported for the specified administered object types:

Type = ConnectionFactories: ConnectionFactory, TopicConnectionFactory, QueueConnectionFactory, XAConnectionFactory, XATopicConnectionFactory, and XAQueueConnectionFactory

imqAckOnAcknowledge
Value: String (`true`, `false`, not specified)

Default: not specified

imqAckOnProduce
Value: String (`true`, `false`, not specified)

Default: not specified

imqAckTimeout
Value: String (time in milliseconds)

Default: `0` (no timeout)

imqAddressList
Value: String

Default: not specified

imqAddressListBehavior
Value: String

Default: Priority

imqAddressListIterations
Value: Integer

Default: 1

imqBrokerHostName
Used if imqConnectionType is `TCP` or `TLS`. This attribute type is only supported in Message Queue 3.0.

Value: String

Default:`localhost`

imqBrokerHostPort
Used if imqConnectionType is `TCP` or `TLS`. This attribute type is only supported in Message Queue 3.0.

Value: Integer

Default: 7676

imqBrokerServicePort
Used if imqConnectionType is TCP or TLS. This attribute type is only supported in Message
Queue 3.0.

Value: Integer

Default: 0

imqConfiguredClientID
Value: String (ID number)

Default: no ID specified

imqConnectionFlowCount
Value: Integer

Default: 100

imqConnectionFlowLimit
Value: Integer

Default: 1000

imqConnectionFlowLimitEnabled
Value: Boolean

Default: false

imqConnectionType
This attribute type is only supported in Message Queue 3.0.

Value: String (TCP, TLS, HTTP).

Default: TCP

imqConnectionURL
Used if imqConnectionType is HTTP. This attribute type is only supported in Message
Queue 3.0.

Value: String

Default: http://*localhost*/imq/tunnel

imqConsumerFlowLimit
Value: Integer

Default: 1000

imqConsumerFlowThreshold
Value: Integer

Default: 50

imqDefaultPassword
Value: String

Default: guest

imqDefaultUsername
Value: String

Default: guest

imqDisableSetClientID
Value: Boolean

Default: false

imqJMSDeliveryMode
Value: Integer (1=non-persistent, 2=persistent)

Default: 2

imqJMSExpiration
Value: Long (time in milliseconds)

Default: 0 (does not expire)

imqJMSPriority
Value: Integer (0 to 9)

Default: 4

imqLoadMaxToServerSession
Value: Boolean

Default: true

imqOverrideJMSDeliveryMode
Value: Boolean

Default: false

imqOverrideJMSExpiration
Value: Boolean

Default: false

imqOverrideJMSHeadersToTemporaryDestinations
Value: Boolean

Default: false

imqOverrideJMSPriority
    Value: Boolean

    Default: false

imqQueueBrowserMaxMessagesPerRetrieve
    Value: Integer

    Default: 1000

imqBrowserRetrieveTimeout
    Value: Long (time in milliseconds)

    Default: 60,000

imqReconnectAttempts
    Value: Integer

    Default: 0

imqReconnectEnabled
    Value: Boolean

    Default: false

imqReconnectInterval
    Value: Long (time in milliseconds)

    Default: 3000

imqSetJMSXAppID
    Value: Boolean

    Default: false

imqSetJMSXConsumerTXID
    Value: Boolean

    Default: false

imqSetJMSXProducerTXID
    Value: Boolean

    Default: false

imqSetJMSXRcvTimestamp
    Value: Boolean

    Default: false

imqSetJMSXUserID
    Value: Boolean

    Default: false

imqSSLIsHostTrusted
   Used if imqConnectionType is TLS. This attribute type is only supported in Message Queue 3.0.

   Value: Boolean

   Default: true

Type = Destinations: Topic and Queue

imqDestinationDescription	Value: String
	Default: no description
imqDestinationName	Value: String
	Default: Untitled_Destination_Object

Type = Endpoint (SOAP Endpoint)

imqEndpointDescription	Value: String
	Default: A description for the endpoint object
imqEndpointName	Value: String
	Default: Untitled_Endpoint_Object
imqSOAPEndpointList	Value: String (one or more space-separated URLs)
	Default: no url

Examples EXAMPLE 1 Adding a Topic Administered Object to an Object Store

Where JNDI lookup name=myTopic and imqDestinationName=MyTestTopic, the following command adds to an LDAP server object store:

```
imqobjmgr add -t t -l "cn=myTopic"\
-o "imqDestinationName=MyTestTopic"\
-j "java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory"\
-j "java.naming.provider.url=ldap://mydomain.com:389/o=imq"
```

Where JNDI lookup name=myTopic and imqDestinationName=MyTestTopic, the following command adds to a file system object store:

```
imqobjmgr add -t -l "cn=myTopic"\
-o "imqDestinationName=MyTestTopic"\
-j \
  "java.naming.factory.initial=com.sun.jndi.fscontext.RefFSContextFactory"\
-j "java.naming.provider.url=file:/home/foo/imq_admin_objects"
```

EXAMPLE 1 Adding a Topic Administered Object to an Object Store   *(Continued)*

Where JNDI lookup name=myTopic and imqDestinationName=MyTestTopic, the following
command adds to a file system object store, using an input file:

```
imqobjmgr -i inputfile
```

The associated input file consists of the following:

```
cmdtype=add
obj.type=t
obj.lookupName=cn=myTopic
obj.attrs.imqDestinationName=MyTestTopic
objstore.attrs.java.naming.factory.initial=com.sun.jndi.fscontext.\
  RefFSContextFactory
objstore.attrs.java.naming.provider.url=file:/home/foo/imq_admin_objects
```

EXAMPLE 2 Adding a QueueConnectionFactory Administered Object to an Object Store

Where JNDI lookup name=myQCF, read-only state=true,
imqAddressList=mq://foohost:777/jms, the following command adds to an LDAP server
object store:

```
imqobjmgr add -t qf -l "cn=myQCF" -r true\

-o "imqAddressList=mq://foohost:777/jms"\
-j "java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory"\
-j "java.naming.provider.url=ldap://mydomain.com:389/o=imq"\
```

Where JNDI lookup name=myQCF, read-only state=true,
imqAddressList=mq://foohost:777/jms, the following command adds to an LDAP server
object store using an input file:

```
imqobjmgr -i inputfile
```

The associated input file consists of the following:

```
cmdtype=add
obj.type=qf
obj.lookupName=cn=myQCF
obj.readOnly=true
obj.attrs.imqAddressList=mq://foohost:777/jms
objstore.attrs.java.naming.factory.initial=com.sun.jndi.\
  ldap.LdapCtxFactory
objstore.attrs.java.naming.provider.url=ldap://mydomain.com:389/o=imq
```

Where JNDI lookup name=myQCF, read-only state=true,
imqAddressList=mq://foohost:777/jms, the following command adds to an LDAP server
object store, using both an input file and command options:

EXAMPLE 2 Adding a `QueueConnectionFactory` Administered Object to an Object Store
(Continued)

```
imqobjmgr add -t qf -l "cn=myQCF"\
-o "imqAddressList=mq://foohost:777/jms"\
-i inputfile
```

The associated input file consists of the following:

```
objstore.attrs.java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory
objstore.attrs.java.naming.provider.url=ldap://mydomain.com:389/o=imq
```

EXAMPLE 3 Deleting a Topic Administered Object from an Object Store

Where JNDI lookup name=myTopic and no confirmation is requested, the following
command deletes from an LDAP server object store:

```
imqobjmgr delete -f -l "cn=myTopic"\
-j "java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory"\
-j "java.naming.provider.url=ldap://mydomain.com:389/o=imq"
```

EXAMPLE 4 Querying Information About a Topic Administered Object

Where JNDI lookup name=myTopic, the following command queries from an LDAP server
object store using simple authentication scheme:

```
imqobjmgr query -l "cn=myTopic"\
-j "java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory"\
-j "java.naming.provider.url=ldap://mydomain.com:389/o=imq"\
-j "java.naming.security.authentication=simple"\
-j "java.naming.security.principal=uid=foo,ou=imqobjmgr,o=imq"\
-j "java.naming.security.credentials=foo"
```

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

Sun Java System Message Queue Administrator's Guide

Name imqusermgr – command utility for managing a Message Queue user repository

Synopsis /usr/bin/imqusermgr *subcommand* [[*option*]...]

/usr/bin/imqusermgr -h

/usr/bin/imqusermgr -v

Description The imqusermgr utility manages a file-based user repository to authenticate and authorize users of a Message Queue message server.

imqusermgr provides subcommands for adding, deleting, updating, and listing user entries in the repository.

imqusermgr supports four management subcommands. These *subcommand*s, and their corresponding *option*s follow the imqusermgr command on the command line. See USAGE and OPTIONS.

The following subcommands are supported:

add   Add a new user and associated password to the repository.

delete   Delete a user from the repository.

list   Display information users in the repository.

update   Update the password or state of a user in the repository.

Options The following options are supported:

-a *active_state*   Specify if user's state is active or inactive. An inactive user cannot create connections to the Message Queue message server.

Valid values for *active_state* are true or false. Specify true for active or false for inactive. the default is true.

Use this option with the update subcommmand.

-f   Perform action without user confirmation.

Use this option with the delete and update subcommmands.

-g *group*   Specify the group of the user.

Valid values for group are admin, user, and anonymous.

Use this option with the add subcommmand.

-h   Display usage help. Exceute nothing else on the command line.

-i *brokerName*   Specify the broker instance user repository to which the command applied. If you do not specify *brokerName*, the default *brokerName* is assumed.

Use this option with the add, delete, list, and update subcommmands.

-p *password*   Specify user password.

Use this option with the add and update subcommmands.

-s   Silent mode. Display no output

Use this option with the add, delete, and update subcommands.

-u *userName*   Specify user name.

userName cannot contain the following characters: asterisk (*), colon (:),
NEWLINE, or RETURN.

Use this option with the add, delete, update and list subcommands.

-v   Display version information. Exceute nothing else on the command line.

Usage   The following subcommands and corresponding options are supported:

add -u *userName* -p *password* [-g *group*] [-s] [-i *brokerName*]
Add a new user and associated password to the repository, and optionally specify the user's group.

delete -u *userName* [-s] [-f] [-i *brokerName*]
Delete a user from the repository.

list [-u *user_name*] [-i *brokerName*]
Display information about the specified user in the repository. If no user is specified, all users are displayed.

update -u *userName* -p *password* [-a *state*] [-s] [-f] [-i *brokerName*]
update -u *userName* -a *state* [-p *password*] [-s] [-f] [-i *brokerName*]
Update the password or state (or both) of a user.

Environment Variables   The following environment variables affect the execution of this command:

IMQ_JAVAHOME   Specify the Java 2 compatible runtime. When this environment variable is not set, it defaults to /usr/j2se.

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Files   /etc/imq/passwd   Flat-file user repository.

Attributes   See `attributes`(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWiq

Sun Java System Message Queue Administrator's Guide

Name   in.chargend – UDP or TCP character generator service daemon

Synopsis   in.chargend

   FMRI *svc*:/internet/chargen:default

Description   FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See fmd(1M) and smf(5).

   The in.chargend service provides the server-side of the character-generator protocol. This protocol is used for debugging and bandwidth measurement and is available on both TCP and UDP transports, through port 19.

   The in.chargend service is an inetd(1M) smf(5) delegated service. The in.chargend detects which transport is requested by examining the socket it is passed by the inetd daemon.

   TCP-based service   Once a connection is established, the in.chargend generates a stream of data. Any data received is discarded. The server generates data until the client program terminates the connection. Note that the data flow is limited by TCP flow control mechanisms.

   UDP-based service   The in.chargend listens for UDP datagrams. When a datagram is received, the server generates a UDP datagram in response containing a random number of ASCII characters (ranging from 0 to 512 characters). Any received data is ignored.

   The in.chargend data consists of a pattern of 72 character lines containing the printable, 7–bit ASCII characters. Each line is terminated with a carriage return and a line feed character.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/legacy-network-services
Interface Stability	Committed

See Also   inetd(1M), attributes(5), smf(5)

   RFC 864

Name in.comsat, comsat – biff server

Synopsis /usr/sbin/in.comsat

Description comsat is the server process which listens for reports of incoming mail and notifies users who have requested to be told when mail arrives. It is invoked as needed by inetd(1M), and times out if inactive for a few minutes.

comsat listens on a datagram port associated with the biff service specification (see services(4)) for one line messages of the form

user@mailbox-offset

If the *user* specified is logged in to the system and the associated terminal has the owner execute bit turned on (by a biff y), the *offset* is used as a seek offset into the appropriate mailbox file, and the first 7 lines or 560 characters of the message are printed on the user's terminal. Lines which appear to be part of the message header other than the From, To, Date, or Subject lines are not printed when displaying the message.

Files /var/adm/utmpx   user access and administration information

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

See Also svcs(1), inetadm(1M), inetd(1M), svcadm(1M),services(4), attributes(5), smf(5)

Notes The message header filtering is prone to error.

The in.comsat service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/comsat:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name in.daytimed – UDP or TCP daytime protocol service daemon

Synopsis `in.daytimed`

FMRI *svc*:/internet/daytime:default

Description FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See `fmd(1M)` and `smf(5)`.

The `in.daytimed` service provides the server-side of the daytime protocol. This protocol is used for debugging and bandwidth measurement and is available on both TCP and UDP transports, through port 13.

The `in.daytimed` service is an `inetd(1M) smf(5)` delegated service. The `in.daytimed` detects which transport is requested by examining the socket it is passed by the `inetd` daemon.

TCP-based service Once a connection is established, the `in.daytimed` generates the current date and time in `ctime(3C)` format as 7-bit ASCII and sends it through the connection. The server then closes the connection. Any data received from the client side of the connection is discarded.

UDP-based service The `in.daytimed` listens for UDP datagrams. When a datagram is received, the server generates the current date and time in `ctime(3C)` format as 7-bit ASCII and inserts it in a UDP datagram sent in response to the client's request. Any received data is ignored.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/legacy-network-services
Interface Stability	Committed

See Also `inetd(1M)`, `attributes(5)`, `smf(5)`

RFC 867

Name   in.dhcpd – Dynamic Host Configuration Protocol server

Synopsis   /usr/lib/inet/in.dhcpd [-denv] [-h *relay_hops*] [-i *interface, ...*]
 [-l *syslog_local_facility*] [-b automatic | manual]
 [-o *DHCP_offer_time*] [-t *dhcptab_rescan_interval*]

 /usr/lib/inet/in.dhcpd [-dv] [-h *relay_hops*] [-i *interface,*]...
 [-l *syslog_local_facility*] -r *IP_address* | *hostname, ...*

Description   in.dhcpd is a daemon that responds to Dynamic Host Configuration Protocol (DHCP)
requests and optionally to BOOTP protocol requests. The daemon forks a copy of itself that
runs as a background process. It must be run as root. The daemon has two run modes, DHCP
server (with optional BOOTP compatibility mode) and BOOTP relay agent mode.

The first line in the SYNOPSIS section illustrates the options available in the DHCP/BOOTP
server mode. The second line in the SYNOPSIS section illustrates the options available when
the daemon is run in BOOTP relay agent mode.

The DHCP and BOOTP protocols are used to provide configuration parameters to Internet
hosts. Client machines are allocated their IP addresses as well as other host configuration
parameters through this mechanism.

The DHCP/BOOTP daemon manages two types of DHCP data tables: the dhcptab
configuration table and the DHCP network tables.

See dhcptab(4) regarding the dhcptab configuration table and dhcp_network(4) regarding the
DHCP network tables.

The dhcptab contains macro definitions defined using a termcap-like syntax which permits
network administrators to define groups of DHCP configuration parameters to be returned to
clients. However, a DHCP/BOOTP server always returns hostname, network broadcast
address, network subnet mask, and IP maximum transfer unit (MTU) if requested by a client
attached to the same network as the server machine. If those options have not been explicitly
configured in the dhcptab, in.dhcpd returns reasonable default values.

The dhcptab is read at startup, upon receipt of a SIGHUP signal, or periodically as specified by
the -t option. A SIGHUP (sent using the command svcadm refresh network/dhcp-server)
causes the DHCP/BOOTP daemon to reread the dhcptab within an interval from 0-60
seconds (depending on where the DHCP daemon is in its polling cycle). For busy servers,
users should run svcadm restart network/dhcp-server to force the dhcptab to be reread.

The DHCP network tables contain mappings of client identifiers to IP addresses. These tables
are named after the network they support and the datastore used to maintain them.

The DHCP network tables are consulted during runtime. A client request received from a
network for which no DHCP network table exists is ignored.

This daemon is obsolete and is subject to removal in a future release of Oracle Solaris. Scripts,
programs, or procedures that use this command will likely need modification when upgrading
to future Solaris software releases.The command line options provided with the in.dhcpd

daemon are used only for the current session, and include only some of the server options you can set. The dhcpsvc.conf(4) contains all the server default settings, and can be modified by using the dhcpmgr utility. See dhcpsvc.conf(4) for more details.

Options   The following options are supported:

-b automatic | manual   This option enables BOOTP compatibility mode, allowing the DHCP server to respond to BOOTP clients. The option argument specifies whether the DHCP server should automatically allocate permanent lease IP addresses to requesting BOOTP clients if the clients are not registered in the DHCP network tables (automatic) or respond only to BOOTP clients who have been manually registered in the DHCP network tables (manual). This option only affects DHCP server mode.

-d   Debugging mode. The daemon remains as a foreground process, and displays verbose messages as it processes DHCP and/or BOOTP datagrams. Messages are displayed on the current TTY. This option can be used in both DHCP/BOOTP server mode and BOOTP relay agent mode.

-h *relay_hops*   Specifies the maximum number of relay agent hops that can occur before the daemon drops the DHCP/BOOTP datagram. The default number of relay agent hops is 4. This option affects both DHCP/BOOTP server mode and BOOTP relay agent mode.

-i *interface,* . . .   Selects the network interfaces that the daemon should monitor for DHCP/BOOTP datagrams. The daemon ignores DHCP/BOOTP datagrams on network interfaces not specified in this list. This option is only useful on machines that have multiple network interfaces. If this option is not specified, then the daemon listens for DHCP/BOOTP datagrams on all network interfaces. The option argument consists of a comma-separated list of interface names. It affects both DHCP/BOOTP server and BOOTP relay agent run modes.

-l *syslog_local_facility*   The presence of this option turns on transaction logging for the DHCP server or BOOTP relay agent. The value specifies the syslog local facility (an integer from 0 to 7 inclusive) the DHCP daemon should use for tagging the transactions. Using a facility separate from the LOG_DAEMON facility allows the network administrator to capture these transactions separately from other DHCP daemon events for such

purposes as generating transaction reports. See syslog(3C), for details about local facilities. Transactions are logged using a record with 9 space-separated fields as follows:

1. Protocol:

   ```
   Relay mode:      "BOOTP"
   Server mode:     "BOOTP" or "DHCP" based upon client
                         type.
   ```

2. Type:

   ```
Relay mode:     "RELAY-CLNT", "RELAY-SRVR"
Server mode:    "ASSIGN", "EXTEND", "RELEASE",
                   "DECLINE", "INFORM", "NAK" "ICMP-ECHO."
   ```

3. Transaction time: absolute time in seconds (unix time)

4. Lease time:

   ```
Relay mode:    Always 0.
Server mode:   0 for ICMP-ECHO events, absolute time in
                  seconds (unix time)  otherwise
   ```

5. Source IP address: Dotted Internet form

   Relay mode: Relay interface IP on RELAY-CLNT,
                   INADDR_ANY on RELAY-SRVR.
   Server mode: Client IP.

6. Destination IP address: Dotted Internet form

   Relay mode: Client IP on RELAY-CLNT, Server IP on
                   RELAY-SRVR.
   Server mode: Server IP.

7. Client Identifier: Hex representation (0-9, A-F)

   Relay mode: MAC address
   Server mode: BOOTP - MAC address; DHCP - client id

8. Vendor Class identifier (white space converted to periods (.)).

   Relay mode: Always "N/A"
   Server mode: Vendor class ID tokenized by
                   converting white space characters
                   to periods (.)

9. MAC address: Hex representation (0-9, A-F)

	Relay mode:	MAC address
	Server mode:	MAC address

The format of this record is subject to change between releases.

Transactions are logged to the console if daemon is in debug mode (-d).

Logging transactions impact daemon performance.

It is suggested that you periodically rotate the DHCP transaction log file to keep it from growing until it fills the filesystem. This can be done in a fashion similar to that used for the general system message log /var/adm/messages and is best accomplished using the facilities provided by logadm(1M).

-n
Disable automatic duplicate IP address detection. When this option is specified, the DHCP server does not attempt to verify that an IP address it is about to offer a client is not in use. By default, the DHCP server pings an IP address before offering it to a DHCP/BOOTP client, to verify that the address is not in use by another machine.

-o *DHCP_offer_time*
Specifies the number of seconds the DHCP server should cache the offers it has extended to discovering DHCP clients. The default setting is 10 seconds. On slow network media, this value can be increased to compensate for slow network performance. This option affects only DHCP server mode.

-r *IP_address* | *hostname, . . .*
This option enables BOOTP relay agent mode. The option argument specifies a comma-separated list of IP addresses or hostnames of DHCP or BOOTP servers to which the relay agent is to forward BOOTP requests. When the daemon is started in this mode, any DHCP tables are ignored, and the daemon simply acts as a BOOTP relay agent.

A BOOTP relay agent listens to UDP port 68, and forwards BOOTP request packets received on this port to the destinations specified on the command line. It supports the BROADCAST flag described in RFC 1542. A BOOTP relay

agent can run on any machine that has knowledge of local routers, and thus does not have to be an Internet gateway machine.

Note that the proper entries must be made to the netmasks database so that the DHCP server being served by the BOOTP relay agents can identify the subnet mask of the foreign BOOTP/DHCP client's network. See netmasks(4) for the format and use of this database.

-t *dhcptab_rescan_interval*   Specifies the interval in minutes that the DHCP server should use to schedule the automatic rereading of the dhcptab information. Typically, you would use this option if the changes to the dhcptab are relatively frequent. Once the contents of the dhcptab have stabilized, you can turn off this option to avoid needless reinitialization of the server.

-v   Verbose mode. The daemon displays more messages than in the default mode. Note that verbose mode can reduce daemon efficiency due to the time taken to display messages. Messages are displayed to the current TTY if the debugging option is used; otherwise, messages are logged to the syslogd facility. This option can be used in both DHCP/BOOTP server mode and BOOTP relay agent mode.

Examples   EXAMPLE 1   Starting a DHCP Server in BOOTP Compatibility Mode

The following command starts a DHCP server in BOOTP compatibility mode, permitting the server to automatically allocate permanent IP addresses to BOOTP clients which are not registered in the server's table; limits the server's attention to incoming datagrams on network devices le2 and tr0; drops BOOTP packets whose hop count exceeds 2; configures the DHCP server to cache extended DHCP offers for 15 seconds; and schedules dhcptab rescans to occur every 10 minutes:

```
# in.dhcpd -i le2,tr0 -h 2 -o 15 -t 10 -b automatic
```

EXAMPLE 2   Starting the Daemon in BOOTP Relay Agent Mode

The following command starts the daemon in BOOTP relay agent mode, registering the hosts bladerunner and 10.0.0.5 as relay destinations, with debugging and verbose modes enabled, and drops BOOTP packets whose hop count exceeds 5:

```
# in.dhcpd -d -v -h 5 -r bladerunner,10.0.0.5
```

Notes   The `in.dhcpd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/dhcp-server
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

Name   in.discardd – UDP or TCP discard protocol service

Synopsis `in.discardd`

FMRI *svc*:/internet/discard:default

Description FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See `fmd(1M)` and `smf(5)`.

The `in.discardd` service provides the server-side of the discard protocol. This protocol is used for debugging and bandwidth measurement and is available on both TCP and UDP transports through port 9.

The `in.discardd` service is an `inetd(1M)` `smf(5)` delegated service. The `in.discardd` detects which transport is requested by examining the socket it is passed by the `inetd` daemon.

The discard service simply throws away any data it receives from the client.

TCP-based service   Once a connection is established, the `in.discardd` discards any data received. No response is generated. The connection remains open until the client terminates it.

UDP-based service   The `in.discardd` listens for UDP datagrams. When a datagram is received, the server discards it. No response is sent.

Attributes See `attributes(5)` for descriptions of the following attributes:

RFC 863

Name in.echod – UDP or TCP echo protocol service daemon

Synopsis `in.echod`

   FMRI *svc*:`/internet/echo:default`

Description FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See fmd(1M) and smf(5).

The `in.echod` service provides the server-side of the echo protocol. This protocol is used for debugging and bandwidth measurement and is available on both TCP and UDP transports, through port 7.

The `in.echod` service is an inetd(1M) smf(5) delegated service. The `in.echod` detects which transport is requested by examining the socket it is passed by the `inetd` daemon.

TCP-based service	Once a connection is established, the `in.echod` echoes any data received from the client back to the client. The server echoes data until the client program terminates the connection.
UDP-based service	The `in.echod` listens for UDP datagrams. When a datagram is received, the server creates a UDP datagram containing the data it received and sends it to the client.

RFC 862

Name inetadm – observe or configure inetd-controlled services

Synopsis inetadm

inetadm -?

inetadm -p

inetadm -l {*FMRI* | *pattern*}

inetadm -e {*FMRI* | *pattern*}

inetadm -d {*FMRI* | *pattern*}

inetadm -m {*FMRI* | *pattern*}... {*name=value*}...

inetadm -M {*name=value*}...

Description The inetadm utility provides the following capabilities for inetd-managed SMF services:

- Provides a list of all such services installed.
- Lists the services' properties and values.
- Allows enabling and disabling of services.
- Allows modification of the services' property values, as well as the default values provided by inetd.

See smf(5) for a description of an SMF service.

With no arguments, inetadm lists all services under inetd(1M) control, including such attributes as their current run state and whether or not they are enabled.

Options For options taking one or more FMRI operands (see smf(5) for a description of an FMRI), if the operand specifies a service (instead of a service instance), and that service has only a single instance, inetadm operates on that instance.

If a service name is supplied and it contains more than one instances or a pattern is supplied and and it matches more than one instance, a warning message is displayed and that operand is ignored.

For those options taking *name=value* parameters, a description of each of the possible names and the allowed values is found in the inetd(1M) man page.

The following options are supported:

-?	Display a usage message.
-p	Lists all default inet service property values provided by inetd in the form of *name=value* pairs. If the value is of boolean type, it is listed as TRUE or FALSE.

-l {*FMRI* | *pattern*}...		List all properties for the specified service instances as *name=value* pairs. In addition, if the property value is inherited from the default value provided by inetd, the *name=value* pair is identified by the token (default). Property inheritance occurs when properties do not have a specified service instance default.
-e {*FMRI* | *pattern*}...		Enable the specified service instances.
-d {*FMRI* | *pattern*}...		Disable the specified service instances.
-m {*FMRI* | *pattern*}...{*name=value*}...		Change the values of the specified properties of the identified service instances. Properties are specified as whitespace-separated *name=value* pairs. To remove an instance-specific value and accept the default value for a property, simply specify the property without a value, for example, name= .
-M {*name=value*}...		Change the values of the specified inetd default properties. Properties are specified as whitespace-separated *name=value* pairs.

Examples **EXAMPLE 1**   Displaying Properties for a Service

The following command displays the properties for the spray service.

```
# inetadm -l network/rpc/spray:default
SCOPE     NAME=VALUE
          name="sprayd"
          endpoint_type="tli"
          proto="datagram_v"
          isrpc=TRUE
          rpc_low_version=1
          rpc_high_version=1
          wait=TRUE
          exec="/usr/lib/netsvc/spray/rpc.sprayd"
          user="root"
default   bind_addr=""
default   bind_fail_max=-1
default   bind_fail_interval=-1
default   max_con_rate=-1
default   max_copies=-1
default   con_rate_offline=-1
default   failrate_cnt=40
default   failrate_interval=60
default   inherit_env=TRUE
default   tcp_trace=FALSE
```

EXAMPLE 1 Displaying Properties for a Service   *(Continued)*

```
default  tcp_wrappers=FALSE
default  connection_backlog=10
```

EXAMPLE 2 Displaying Default Properties

The following command displays default properties.

```
# inetadm -p
NAME=VALUE
bind_addr=""
bind_fail_max=-1
bind_fail_interval=-1
max_con_rate=-1
max_copies=-1
con_rate_offline=-1
failrate_cnt=40
failrate_interval=60
inherit_env=TRUE
tcp_trace=FALSE
tcp_wrappers=FALSE
default  connection_backlog=10
```

EXAMPLE 3 Changing Property Values for a Service

The following command changes rpc_high_version to 3 and tcp_trace to TRUE for the
spray service.

```
# inetadm -m network/rpc/spray:default \
         rpc_high_version=3 tcp_trace=TRUE
# inetadm -l network/rpc/spray:default
SCOPE    NAME=VALUE
         name="sprayd"
         endpoint_type="tli"
         proto="datagram_v"
         isrpc=TRUE
         rpc_low_version=1
         rpc_high_version=3
         wait=TRUE
         exec="/usr/lib/netsvc/spray/rpc.sprayd"
         user="root"
default  bind_addr=""
default  bind_fail_max=-1
default  bind_fail_interval=-1
default  max_con_rate=-1
default  max_copies=-1
default  con_rate_offline=-1
default  failrate_cnt=40
```

EXAMPLE 3 Changing Property Values for a Service *(Continued)*

```
default  failrate_interval=60
default  inherit_env=TRUE
         tcp_trace=TRUE
default  tcp_wrappers=FALSE
default  connection_backlog=10
```

Exit Status The following exit values are returned:

0   Operation completed successfully.

1   A fatal error occurred. An accompanying error message will provide further information.

2   Invalid arguments were supplied, such as an ambiguous service FMRI or pattern.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also inetd(1M), svccfg(1M), attributes(5), smf(5)

Name   inetconv – convert `inetd.conf` entries into smf service manifests, import them into smf repository

Synopsis   `inetconv -?`

`inetconv [-f] [-n] [-i srcfile] [-o destdir]`

`inetconv -e [-n] [-i srcfile]`

Description   The `inetconv` utility converts a file containing records of `inetd.conf(4)` into `smf(5)` service manifests, and then import those manifests into the `smf` repository. Once the `inetd.conf` file has been converted, the only way to change aspects of an inet service is to use the `inetadm(1M)` utility.

There is a one-to-one correspondence between a service line in the input file and the manifest generated. By default, the manifests are named using the following template:

<svcname>-*<proto>*.xml

The *<svcname>* token is replaced by the service's name and the *<proto>* token by the service's protocol. Any slash (/) characters that exist in the source line for the service name or protocol are replaced with underscores (_).

The service line is recorded as a property of the converted service.

During the conversion process, if a service line is found to be malformed or to be for an internal `inetd` service, no manifest is generated and that service line is skipped.

The input file is left untouched by the conversion process.

Options   The following options are supported:

-?   Display a usage message.

-e   Enable `smf` services which are listed in the input file.

-f   If a service manifest of the same name as the one to be generated is found in the destination directory, `inetconv` will overwrite that manifest if this option is specified. Otherwise, an error message is generated and the conversion of that service is not performed.

-i *srcfile*   Permits the specification of an alternate input file *srcfile*. If this option is not specified, then the `inetd.conf(4)` file is used as input.

-n   Turns off the auto-import of the manifests generated during the conversion process. Later, if you want to import a generated manifest into the `smf(5)` repository, you can do so through the use of the `svccfg(1M)` utility.

If the -e option is specified, the -n option only displays the `smf` services that would be enabled.

-o   Permits the specification of an alternate destination directory *destdir* for the
              generated manifests. If this option is not specified, then the manifests are placed
              in /lib/svc/manifest/network/rpc, if the service is a RPC service, or
              /lib/svc/manifest/network otherwise.

Examples **EXAMPLE 1** Generating smf Manifests from inetd.conf

The following command generates smf(5) manifests from inetd.conf(4) and places them in
/var/tmp, overwriting any preexisting manifests of the same name, and then imports them
into the smf repository.

```
# inetconv -f -o /var/tmp
100232/10 -> /var/tmp/100232_10-rpc_udp.xml
Importing 100232_10-rpc_udp.xml ...Done
telnet -> /var/tmp/telnet-tcp6.xml
Importing telnet-tcp6.xml ...Done
```

EXAMPLE 2 Generating Manifests from an Alternate Input File

The following command specifies a different input file and does not load the resulting
manifests into the smf repository.

```
# inetconv -n -i /export/test/inet.svcs -o /var/tmp
100232/10 -> /var/tmp/100232_10-rpc_udp.xml
telnet -> /var/tmp/telnet-tcp6.xml
```

Exit Status The following exit values are returned:

0   Operation completed successfully (no errors).

1   Invalid options specified.

2   One or more service lines are malformed, and thus no manifest(s) were generated for
     them.

3   An error occurred importing one or more of the generated manifests.

4   A system error occurred.

Files /lib/svc/manifest/network/{rpc}/*<svcname>*-*<proto>*.xml
       Default output manifest file name.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also inetadm(1M), inetd(1M), svccfg(1M), inetd.conf(4), attributes(5), smf(5)

Name inetd – Solaris Management Facility delegated restarter for inet services

Synopsis inetd [*configuration-file*] start | stop | refresh

svc:/network/inetd:default

Description inetd is the delegated restarter for internet services for the Service Management Facility (SMF). Its basic responsibilities are to manage service states in response to administrative requests, system failures, and service failures; and, when appropriate, to listen for network requests for services.

Services are no longer managed by editing the inetd configuration file, inetd.conf(4). Instead, you use inetconv(1M) to convert the configuration file content into SMF format services, then manage these services using inetadm(1M) and svcadm(1M). Once a service has been converted by inetconv, any changes to the legacy data in the inetd config file will not become effective. However, inetd does alert the administrator when it notices change in the configuration file. See the start description under the "inetd Methods" section for further information.

Also note that the current inetd cannot be run from outside the SMF. This means it cannot be run from the command line, as was supported by the previous inetd. If you attempt to do this, a message is sent to stderr displaying mappings between the options supported by the previous inetd to the SMF version of inetd.

inetd listens for connections on behalf of all services that are in either the online or degraded state. A service enters one of these states when the service is enabled by the user and inetd manages to listen on its behalf. A listen attempt can fail if another server (whether standalone or a third-party internet service) is already listening on the same port. When this occurs, inetd logs this condition and continues trying to bind to the port at configured intervals a configured number of times. See the property bind_fail_max under "Service Properties," below, for more details.

The configuration of all inetd's managed SMF services is read when it is started. It is reread when inetd is refreshed, which occurs in response to an SMF request, or when it receives a SIGHUP signal. See the refresh description under "inetd Methods" for the behavior on configuration refresh.

You can use the inetadm(1M) or svccfg(1M) utilities to make configuration changes to Internet services within the SMF repository. inetadm has the advantage over svccfg in that it provides an Internet/RPC service context.

Service States As part of its service management duties, inetd implements a state machine for each of its managed services. The states in this machine are made up of the smf(5) set of states. The semantics of these states are as follows:

uninitialized
    inetd has yet to process this service.

online

The service is handling new network requests and might have existing connections active.

degraded

The service has entered this state because it was able to listen and process requests for some, but not all, of the protocols specified for the service, having exhausted its listen retries. Existing network connections might be active.

offline

Connections might be active, but no new requests are being handled. This is a transient state. A service might be offline for any of the following reasons:

- The service's dependencies are unmet. When its dependencies become met the service's state will be re-evaluated.

- The service has exceeded its configured connection rate limit, max_con_rate. The service's state is re-evaluated when its connection offline timer, con_rate_offline, expires.

- The service has reached its allowed number of active connections, max_copies. The service's state is re-evaluated when the number of active connections drops below max_copies.

- inetd failed to listen on behalf of the service on all its protocols. As mentioned above, inetd retries up to a configured maximum number of times, at configured intervals.The service's state is re-evaluated when either a listen attempt is successful or the retry limit is reached.

disabled

The service has been turned off by an administrator, is not accepting new connections, and has none active. Administrator intervention is required to exit this state.

maintenance

A service is in this state because it is either malfunctioning and needs adminstrator attention or because an administrator has requested it.

Events constituting malfunctioning include: inetd's inability to listen on behalf on any of the service's protocols before exceeding the service's bind retry limit, non-start methods returning with non-success return values, and the service exceeding its failure rate.

You request the maintenance state to perform maintenance on the service, such as applying a patch. No new requests are handled in this state, but existing connections might be active. Administrator intervention is required to exit this state.

Use inetadm(1M) to obtain the current state of a managed service.

Service Methods   As part of certain state transitions inetd will execute, if supplied, one of a set of methods provided by the service. The set of supported methods are:

inetd_start

Executed to handle a request for an online or degraded service. Since there is no separate state to distinguish a service with active connections, this method is not executed as part of a state transition.

inetd_offline

Executed when a service is taken from the online or degraded state to the offline state. For a wait-type service that at the time of execution is performing its own listening, this method should result in it ceasing listening. This method will be executed before the disable method in the case an online/degraded service is disabled. This method is required to be implemented for a wait-type service.

inetd_online

Executed when a service transitions from the offline state to the online state. This method allows a service author to carry out some preparation prior to a service starting to handle requests.

inetd_disable

Executed when a service transitions from the offline state to the disabled state. It should result in any active connections for a service being terminated.

inetd_refresh

Executed when both of the following conditions are met:

- inetd is refreshed, by means of the framework or a SIGHUP, or a request comes in to refresh the service, and

- the service is currently in the online state and there are no configuration changes that would result in the service needing to be taken offline and brought back again.

The only compulsory method is the inetd_start method. In the absence of any of the others, inetd runs no method but behaves as if one was run successfully.

Service Properties   Configuration for SMF–managed services is stored in the SMF repository. The configuration is made up of the basic configuration of a service, the configuration for each of the service's methods, and the default configuration applicable to all inetd-managed services.

For details on viewing and modifying the configuration of a service and the defaults, refer to inetadm(1M).

The basic configuration of a service is stored in a property group named inetd in the service. The properties comprising the basic configuration are as follows:

bind_addr

The address of the network interface to which the service should be bound. An empty string value causes the service to accept connections on any network interface.

bind_fail_interval

The time interval in seconds between a failed bind attempt and a retry. The values 0 and -1 specify that no retries are attempted and the first failure is handled the same as exceeding bind_fail_max.

bind_fail_max

The maximum number of times inetd retries binding to a service's associated port before giving up. The value -1 specifies that no retry limit is imposed. If none of the service's protocols were bound to before any imposed limit is reached, the service goes to the maintenance state; otherwise, if not all of the protocols were bound to, the service goes to the degraded state.

con_rate_offline

The time in seconds a service will remain offline if it exceeds its configured maximum connection rate, max_con_rate. The values 0 and -1 specify that connection rate limiting is disabled.

connection_backlog

The backlog queue size. Represents a limit on the number of incoming client requests that can be queued at the listening endpoints for servers.

endpoint_type

The type of the socket used by the service or the value tli to signify a TLI-based service. Valid socket type values are: stream, dgram, raw, seqpacket.

failrate_cnt

The count portion of the service's failure rate limit. The failure rate limit applies to wait-type services and is reached when *count* instances of the service are started within a given time. Exceeding the rate results in the service being transitioned to the maintenance state. This is different from the behavior of the previous inetd, which continued to retry every 10 minutes, indefinitely. The failrate_cnt check accounts for badly behaving servers that fail before consuming the service request and which would otherwise be continually restarted, taxing system resources. Failure rate is equivalent to the -r option of the previous inetd. The values 0 and -1 specify that this feature is disabled.

failrate_interval

The time portion in seconds of the service's failure rate. The values 0 and -1 specify that the failure rate limit feature is disabled.

inherit_env

If true, pass inetd's environment on to the service's start method. Regardless of this setting, inetd will set the variables SMF_FMRI, SMF_METHOD, and SMF_RESTARTER in the start method's environment, as well as any environment variables set in the method context. These variables are described in smf_method(5).

isrpc

If true, this is an RPC service.

max_con_rate

The maximum allowed connection rate, in connections per second, for a nowait-type service. The values 0 and -1 specify that that connection rate limiting is disabled.

max_copies

The maximum number of copies of a nowait service that can run concurrently. The values 0 and -1 specify that copies limiting is disabled.

name

Can be set to one of the following values:

- a service name understood by getservbyname(3SOCKET);
- if isrpc is set to true, a service name understood by getrpcbyname(3NSL);
- if isrpc is set to true, a valid RPC program number.

proto

In the case of socket-based services, this is a list of protocols supported by the service. Valid protocols are: tcp, tcp6, tcp6only, udp, udp6, and udp6only. In the case of TLI services, this is a list of netids recognized by getnetconfigent(3NSL) supported by the service, plus the values tcp6only and udp6only. RPC/TLI services also support nettypes in this list, and inetd first tries to interpret the list member as a nettype for these service types. The values tcp6only and udp6only are new to inetd; these values request that inetd listen only for and pass on true IPv6 requests (not IPv4 mapped ones). See "Configuring Protocols for Sockets-Based Services," below.

rpc_low_version

Lowest supported RPC version. Required when isrpc is set to true.

rpc_high_version

Highest supported RPC version. Required when isrpc is set to true.

tcp_keepalive

If true, enable the periodic transmission of messages on a connected socket. If the connected party fails to respond to these messages, the connection is considered broken. This applies only to services with endpoint_type set to streams and wait set to false.

tcp_trace

If true, and this is a nowait-type service, inetd logs the client's IP address and TCP port number, along with the name of the service, for each incoming connection, using the syslog(3C) facility. inetd uses the syslog facility code daemon and notice priority level. See syslog.conf(4) for a description of syslog codes and severity levels. This logging is separate from the logging done by the TCP wrappers facility.

tcp_trace is equivalent to the previous inetd's -t option (and the /etc/default/inetd property ENABLE_CONNECTION_LOGGING).

tcp_wrappers

If true, enable TCP wrappers access control. This applies only to services with endpoint_type set to streams and wait set to false. The syslog facility code daemon is used to log allowed connections (using the notice severity level) and denied traffic (using

the warning severity level). See syslog.conf(4) for a description of syslog codes and severity levels. The Interface Stability of the TCP wrappers facility and its configuration files is Volatile. As the TCP wrappers facility is not controlled by Sun, intra-release incompatibilities are not uncommon. See attributes(5).

For more information about configuring TCP wrappers, you can refer to the tcpd(1M) and hosts_access(4) man pages, which are delivered as part of the Solaris operating system at /usr/sfw/man. These pages are not part of the standard Solaris man pages, available at /usr/man.

tcp_wrappers is equivalent to the previous inetd's /etc/default/inetd property ENABLE_TCPWRAPPERS.

wait

If true this is a wait-type service, otherwise it is a nowait-type service. A wait-type service has the following characteristics:

- Its inetd_start method will take over listening duties on the service's bound endpoint when it is executed.

- inetd will wait for it to exit after it is executed before it resumes listening duties.

Datagram servers must be configured as being of type wait, as they are always invoked with the original datagram endpoint that will participate in delivering the service bound to the specified service. They do not have separate "listening" and "accepting" sockets. Connection-oriented services, such as TCP stream services can be designed to be either of type wait or nowait.

A number of the basic properties are optional for a service. In their absence, their values are taken from the set of default values present in the defaults property group in the inetd service. These properties, with their seed values, are listed below. Note that these values are configurable through inetadm(1M).

```
bind_fail_interval   -1
bind_fail_max        -1
con_rate_offline     -1
connection_backlog   10
failrate_count       40
failrate_time        60
inherit_env          true
max_con_rate         -1
max_copies           -1
tcp_keepalive        false
tcp_trace            false
tcp_wrappers         false
```

Each method specified for a service will have its configuration stored in the SMF repository, within a property group of the same name as the method. The set of properties allowable for

these methods includes those specified for the services managed by svc.startd(1M). (See svc.startd(1M) for further details.) Additionally, for the inetd_start method, you can set the arg0 property.

The arg0 property allows external wrapper programs to be used with inetd services. Specifically, it allows the first argument, argv[0], of the service's start method to be something other than the path of the server program.

In the case where you want to use an external wrapper program and pass arguments to the service's daemon, the arguments should be incorporated as arguments to the wrapper program in the exec property. For example:

```
exec='/path/to/wrapper/prog service_daemon_args'
arg0='/path/to/service/daemon'
```

In addition to the special method tokens mentioned in smf_method(5), inetd also supports the :kill_process token for wait-type services. This results in behavior identical to that if the :kill token were supplied, except that the kill signal is sent only to the parent process of the wait-type service's start method, not to all members of its encompassing process contract (see process(4)).

Configuring Protocols for Sockets-Based Services

When configuring inetd for a sockets-based service, you have the choice, depending on what is supported by the service, of the alternatives described under the proto property, above. The following are guidelines for which proto values to use:

- For a service that supports only IPv4: tcp and udp

- For a service that supports only IPv6: tcp6only and udp6only

- For a service that supports both IPv4 and IPv6:

    - Obsolete and not recommended: tcp6 and udp6

    - Recommended: use two separate entries that differ only in the proto field. One entry has tcp and the other has tcp6only, or udp plus udp6only.

See EXAMPLES for an example of a configuration of a service that supports both IPv4 and IPv6.

inetd Methods   inetd provides the methods listed below for consumption by the master restarter, svc.startd(1M).

start

Causes inetd to start providing service. This results in inetd beginning to handle smf requests for its managed services and network requests for those services that are in either the online or degraded state.

In addition, inetd also checks if the inetd.conf(4)–format configuration file it is monitoring has changed since the last inetconv(1M) conversion was carried out. If it has, then a message telling the administrator to re-run inetconv to effect the changes made is logged in syslog.

stop

Causes inetd to stop providing service. At this point, inetd transitions each of its services that are not in either the maintenance or disabled states to the offline state, running any appropriate methods in the process.

refresh

Results in a refresh being performed for each of its managed services and the inetd.conf(4) format configuration file being checked for change, as in the start method. When a service is refreshed, its behavior depends on its current state:

- if it is in the maintenance or disabled states, no action is performed because the configuration will be read and consumed when the service leaves the state;

- if it is in the offline state, the configuration will be read and any changes consumed immediately;

- if it is in the online or degraded state and the configuration has changed such that a re-binding is necessary to conform to it, then the service will be transitioned to the offline state and back again, using the new configuration for the bind;

- if it is in the online state and a re-binding is not necessary, then the inetd_refresh method of the service, if provided, will be run to allow online wait-type services to consume any other changes.

Options No options are supported.

Operands *configuration-file*

Specifies an alternate location for the legacy service file (inetd.conf(4)).

start|stop|refresh

Specifies which of inetd's methods should be run.

Examples EXAMPLE 1   Configuring a Service that Supports Both IPv4 and IPv6

The following commands illustrate the existence of services that support both IPv4 and IPv6 and assign proto properties to those services.

```
example# svcs -a | grep mysvc
online         15:48:29 svc:/network/mysvc:dgram4
online         15:48:29 svc:/network/mysvc:dgram6
online         15:51:47 svc:/network/mysvc:stream4
online         15:52:10 svc:/network/mysvc:stream6

# inetadm -M network/rpc/mysvc:dgram4 proto=udp
# inetadm -M network/rpc/mysvc:dgram6 proto=udp6only
# inetadm -M network/rpc/mysvc:stream4 proto=tcp
# inetadm -M network/rpc/mysvc:stream6 proto=tcp6only
```

See svcs(1) and inetadm(1M) for descriptions of those commands.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also fmd(1M), inetadm(1M), inetconv(1M), svcadm(1M), svccfg(1M), svcs(1), svc.startd(1M), syslog(3C), getnetconfigent(3NSL), getrpcbyname(3NSL), getservbyname(3SOCKET), inetd.conf(4), process(4), syslog.conf(4), attributes(5), smf(5), smf_method(5)

Notes The inetd daemon performs the same function as, but is implemented significantly differently from, the daemon of the same name in Solaris 9 and prior Solaris operating system releases. In the current Solaris release, inetd is part of the Solaris Management Facility (see smf(5)) and will run only within that facility.

The /etc/default/inetd file has been deprecated. The functionality represented by the properties ENABLE_CONNECTION_LOGGING and ENABLE_TCP_WRAPPERS are now available as the tcp_trace and tcp_wrappers properties, respectively. These properties are described above, under "Service Properties".

Name   in.fingerd, fingerd – remote user information server

Synopsis   `/usr/sbin/in.fingerd [-s]`

Description   fingerd implements the server side of the Name/Finger protocol, specified in *RFC 742*. The Name/Finger protocol provides a remote interface to programs which display information on system status and individual users. The protocol imposes little structure on the format of the exchange between client and server. The client provides a single command line to the finger server which returns a printable reply.

fingerd waits for connections on TCP port 79. Once connected, it reads a single command line terminated by RETURN-LINEFEED and passes the arguments to finger(1), prepended with -s. fingerd closes its connections as soon as the output is finished.

Options   fingerd supports the following option.

-s   Enable secure mode. Deny forwarding of queries to other remote hosts.

Files   /var/adm/utmpx   User and accounting information.

/etc/passwd   System password file.

/var/adm/lastlog   Last login times.

$HOME/.plan   User's plans.

$HOME/.project   User's projects.

Usage   fingerd and in.fingerd are IPv6–enabled. See ip6(7P).

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

See Also   finger(1), svcs(1), inetadm(1M), inetd(1M), svcadm(1M), attributes(5), smf(5), ip6(7P)

Harrenstien, Ken, *RFC 742, NAME/FINGER*, Network Information Center, SRI International, Menlo Park, Calif., December 1977.

Notes   Connecting directly to the server from a TIP or an equally narrow-minded TELNET-protocol user program can result in meaningless attempts at option negotiation being sent to the server, which foul up the command line interpretation. fingerd should be taught to filter out IAC's and perhaps even respond negatively (IAC does not) to all option commands received.

The in.fingerd service is managed by the service management facility, smf(5), under the service identifier:

`svc:/network/finger:default`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name infocmp – compare or print out terminfo descriptions

Synopsis /usr/bin/infocmp [-d] [-c] [-n] [-I] [-L] [-C] [-r] [-u]
        [-s | d | i | l | c] [-v] [-V] [-1] [-w *width*]
        [-A *directory*] [-B *directory*] [*termname*]...

Description infocmp compares a binary terminfo entry with other terminfo entries, rewrites a terminfo
description to take advantage of the use= terminfo field, or prints out a terminfo description
from the binary file (term) in a variety of formats. It displays boolean fields first, then numeric
fields, followed by the string fields. If no options are specified and zero, or one *termname* is
specified, the -I option is assumed. If more than one *termname* is specified, the -d option is
assumed.

Options The -d , -c , and -n options can be used for comparisons. infocmp compares the terminfo
description of the first terminal *termname* with each of the descriptions given by the entries
for the other terminal's *termname*. If a capability is defined for only one of the terminals, the
value returned will depend on the type of the capability: F for boolean variables, −1 for integer
variables, and NULL for string variables.

-d   Produce a list of each capability that is different between two entries. This option is
      useful to show the difference between two entries, created by different people, for the
      same or similar terminals.

-c   Produce a list of each capability that is common between two entries. Capabilities that
      are not set are ignored. This option can be used as a quick check to see if the -u option is
      worth using.

-n   Produce a list of each capability that is in neither entry. If no *termname* is given, the
      environment variable TERM will be used for both of the *termname*s. This can be used as
      a quick check to see if anything was left out of a description.

The -I , -L , and -C options will produce a source listing for each terminal named.

-I   Use the terminfo names.

-L   Use the long C variable name listed in < term.h >.

-C   Use the termcap names. The source produced by the -C option may be used directly as
      a termcap entry, but not all of the parameterized strings may be changed to the
      termcap format. infocmp will attempt to convert most of the parameterized
      information, but anything not converted will be plainly marked in the output and
      commented out. These should be edited by hand.

-r   When using -C , put out all capabilities in termcap form.

If no *termname* is given, the environment variable TERM will be used for the terminal name.

All padding information for strings will be collected together and placed at the beginning of
the string where termcap expects it. Mandatory padding (padding information with a trailing
'/') will become optional.

All `termcap` variables no longer supported by `terminfo` , but are derivable from other `terminfo` variables, will be displayed. Not all `terminfo` capabilities will be translated; only those variables which were part of `termcap` will normally be displayed. Specifying the `-r` option will take off this restriction, allowing all capabilities to be displayed in `termcap` form.

Note that because padding is collected to the beginning of the capability, not all capabilities are displayed. Mandatory padding is not supported. Because `termcap` strings are not as flexible, it is not always possible to convert a `terminfo` string capability into an equivalent `termcap` format. A subsequent conversion of the `termcap` file back into `terminfo` format will not necessarily reproduce the original `terminfo` source.

Some common `terminfo` parameter sequences, their `termcap` equivalents, and some terminal types which commonly have such sequences, are:

```
terminfo      termcap       Representative Terminals
%p1%c    %.    adm
%p1%d    %d    hp, ANSI standard, vt100
%p1%'x'%+%c    %+x    concept
%i    %i    ANSI standard, vt100
%p1%?%'x'%>%t%p1%'y'%+%;    %>xy    concept
%p2 is printed before %p1    %r    hp
```

-u   Produce a `terminfo` source description of the first terminal *termname* which is relative to the sum of the descriptions given by the entries for the other terminals' *termname*s. It does this by analyzing the differences between the first *termname* and the other *termnames* and producing a description with `use=` fields for the other terminals. In this manner, it is possible to retrofit generic `terminfo` entries into a terminal's description. Or, if two similar terminals exist, but were coded at different times, or by different people so that each description is a full description, using `infocmp` will show what can be done to change one description to be relative to the other.

A capability is displayed with an at-sign (@) if it no longer exists in the first *termname*, but one of the other *termname* entries contains a value for it. A capability's value is displayed if the value in the first *termname* is not found in any of the other *termname* entries, or if the first of the other *termname* entries that has this capability gives a different value for that capability.

The order of the other *termname* entries is significant. Since the `terminfo` compiler `tic` does a left-to-right scan of the capabilities, specifying two `use=` entries that contain differing entries for the same capabilities will produce different results, depending on the order in which the entries are given. `infocmp` will flag any such inconsistencies between the other *termname* entries as they are found.

Alternatively, specifying a capability *after* a `use=` entry that contains, it will cause the second specification to be ignored. Using `infocmp` to recreate a description can be a useful check to make sure that everything was specified correctly in the original source description.

Another error that does not cause incorrect compiled files, but will slow down the compilation time, is specifying superfluous use= fields. infocmp will flag any superfluous use= fields.

-s   Sorts the fields within each type according to the argument below:

d   Leave fields in the order that they are stored in the terminfo database.

i   Sort by terminfo name.

l   Sort by the long C variable name.

c   Sort by the termcap name.

If the -s option is not given, the fields are sorted alphabetically by the terminfo name within each type, except in the case of the -C or the -L options, which cause the sorting to be done by the termcap name or the long C variable name, respectively.

-v   Print out tracing information on standard error as the program runs.

-V   Print out the version of the program in use on standard error and exit.

−1   Print the fields one to a line. Otherwise, the fields are printed several to a line to a maximum width of 60 characters.

-w*width*   Changes the output to *width* characters.

The location of the compiled terminfo database is taken from the environment variable TERMINFO . If the variable is not defined, or the terminal is not found in that location, the system terminfo database, usually in /usr/share/lib/terminfo, is used. The options -A and -B may be used to override this location.

-A *directory*   Set TERMINFO for the first *termname*.

-B *directory*   Set TERMINFO for the other *termname*s. With this, it is possible to compare descriptions for a terminal with the same name located in two different databases. This is useful for comparing descriptions for the same terminal created by different people.

Files   /usr/share/lib/terminfo/?/*   Compiled terminal description database.

Attributes   See attributes(5) for descriptions of the following attributes:

Name in.iked – daemon for the Internet Key Exchange (IKE)

Synopsis /usr/lib/inet/in.iked [-d] [-f *filename*] [-p *level*]

/usr/lib/inet/in.iked -c [-f *filename*]

Description in.iked performs automated key management for IPsec using the Internet Key Exchange (IKE) protocol.

in.iked implements the following:

- IKE authentication with either pre-shared keys, DSS signatures, RSA signatures, or RSA encryption.

- Diffie-Hellman key derivation using either 768, 1024, 1536, 2048, 3072, or 4096-bit public key moduli, or 256, 384, or 521-bit elliptic curve moduli.

- Authentication protection with cipher choices of AES, DES, Blowfish, or 3DES, and hash choices of either HMAC-MD5 or HMAC-SHA-1. Encryption in in.iked is limited to the IKE authentication and key exchange. See ipsecesp(7P) for information regarding IPsec protection choices.

in.iked is managed by the following smf(5) service:

svc:/network/ipsec/ike

This service is delivered disabled because the configuration file needs to be created before the service can be enabled. See ike.config(4) for the format of this file.

See "Service Management Facility" for information on managing the smf(5) service.

in.iked listens for incoming IKE requests from the network and for requests for outbound traffic using the PF_KEY socket. See pf_key(7P).

in.iked has two support programs that are used for IKE administration and diagnosis: ikeadm(1M) and ikecert(1M).

The ikeadm(1M) command can read the /etc/inet/ike/config file as a rule, then pass the configuration information to the running in.iked daemon using a doors interface.

example# **ikeadm read rule /etc/inet/ike/config**

Refreshing the ike smf(5) service provided to manage the in.iked daemon sends a SIGHUP signal to the in.iked daemon, which will (re)read /etc/inet/ike/config and reload the certificate database.

The preceding two commands have the same effect, that is, to update the running IKE daemon with the latest configuration. See "Service Management Facility" for more details on managing the in.iked daemon.

When Trusted Extensions are enabled (see labeld(1M)), in.iked can be used in the global zone to negotiate labeled security associations. On labeled systems using in.iked, UDP ports 500 and 4500 must be configured as multi-level ports for the global zone in the tnzonecfg file (see tnzonecfg(4), part of the *Solaris Trusted Extensions Reference Manual*). See ike.config(4) for more information on configuring in.iked to be label-aware.

Service Management Facility

The IKE daemon (in.iked) is managed by the service management facility, smf(5). The following group of services manage the components of IPsec:

```
svc:/network/ipsec/ipsecalgs    (See ipsecalgs(1M))
svc:/network/ipsec/policy       (See ipsecconf(1M))
svc:/network/ipsec/manual-key   (See ipseckey(1M))
svc:/network/ipsec/ike          (see ike.config(4))
```

The manual-key and ike services are delivered disabled because the system administrator must create configuration files for each service, as described in the respective man pages listed above.

The correct administrative procedure is to create the configuration file for each service, then enable each service using svcadm(1M).

The ike service has a dependency on the ipsecalgs and policy services. These services should be enabled before the ike service. Failure to do so results in the ike service entering maintenance mode.

If the configuration needs to be changed, edit the configuration file then refresh the service, as follows:

example# **svcadm refresh ike**

The following properties are defined for the ike service:

config/admin_privilege
Defines the level that ikeadm(1M) invocations can change or observe the running in.iked. The acceptable values for this property are the same as those for the -p option. See the description of -p in OPTIONS.

config/config_file
Defines the configuration file to use. The default value is /etc/inet/ike/config. See ike.config(4) for the format of this file. This property has the same effect as the -f flag. See the description of -f in OPTIONS.

config/debug_level
Defines the amount of debug output that is written to the debug_logfile file, described below. The default value for this is op or operator. This property controls the recording of information on events such as re-reading the configuration file. Acceptable value for debug_level are listed in the ikeadm(1M) man page. The value all is equivalent to the -d flag. See the description of -d in OPTIONS.

config/debug_logfile

Defines where debug output should be written. The messages written here are from debug code within in.iked. Startup error messages are recorded by the smf(5) framework and recorded in a service-specific log file. Use any of the following commands to examine the logfile property:

```
example# svcs -l ike
example# svcprop ike
example# svccfg -s ike listprop
```

The values for these log file properties might be different, in which case both files should be inspected for errors.

config/ignore_errors

A boolean value that controls in.iked's behavior should the configuration file have syntax errors. The default value is false, which causes in.iked to enter maintenance mode if the configuration is invalid.

Setting this value to true causes the IKE service to stay online, but correct operation requires the administrator to configure the running daemon with ikeadm(1M). This option is provided for compatibility with previous releases.

These properties can be modified using svccfg(1M) by users who have been assigned the following authorization:

solaris.smf.value.ipsec

PKCS#11 token objects can be unlocked or locked by using ikeadm token login and ikeadm token logout, respectively. Availability of private keying material stored on these PKCS#11 token objects can be observed with: ikeadm dump certcache. The following authorizations allow users to log into and out of PKCS#11 token objects:

solaris.network.ipsec.ike.token.login
solaris.network.ipsec.ike.token.logout

See auths(1), ikeadm(1M), user_attr(4), rbac(5).

The service needs to be refreshed using svcadm(1M) before a new property value is effective. General, non-modifiable properties can be viewed with the svcprop(1) command.

```
# svccfg -s ipsec/ike setprop config/config_file = \
/new/config_file
# svcadm refresh ike
```

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using svcadm(1M). A user who has been assigned the authorization shown below can perform these actions:

solaris.smf.manage.ipsec

The service's status can be queried using the svcs(1) command.

The in.iked daemon is designed to be run under smf(5) management. While the in.iked command can be run from the command line, this is discouraged. If the in.iked command is to be run from the command line, the ike smf(5) service should be disabled first. See svcadm(1M).

Options   The following options are supported:

-c   Check the syntax of a configuration file.

-d   Use debug mode. The process stays attached to the controlling terminal and produces large amounts of debugging output. This option is deprecated. See "Service Management Facility" for more details.

-f *filename*   Use *filename* instead of /etc/inet/ike/config. See ike.config(4) for the format of this file. This option is deprecated. See "Service Management Facility" for more details.

-p *level*   Specify privilege level (*level*). This option sets how much ikeadm(1M) invocations can change or observe about the running in.iked.

                Valid *levels* are:

                0   Base level

                1   Access to preshared key info

                2   Access to keying material

                If -p is not specified, *level* defaults to 0.

                This option is deprecated. See "Service Management Facility" for more details.

Security   This program has sensitive private keying information in its image. Care should be taken with any core dumps or system dumps of a running in.iked daemon, as these files contain sensitive keying information. Use the coreadm(1M) command to limit any corefiles produced by in.iked.

Files /etc/inet/ike/config   Default configuration file.

           /etc/inet/secret/ike.privatekeys/*   Private keys. A private key *must* have a matching public-key certificate with the same filename in /etc/inet/ike/publickeys/.

           /etc/inet/ike/publickeys/*   Public-key certificates. The names are only important with regard to matching private key names.

           /etc/inet/ike/crls/*   Public key certificate revocation lists.

           /etc/inet/secret/ike.preshared   IKE pre-shared secrets for Phase I authentication.

Attributes   See attributes(5) for descriptions of the following attributes:

Name   init – process control initialization

Synopsis   /usr/sbin/init [0123456abcQqSs]

Description   init is the default primordial user process. (Options given to the kernel during boot may result in the invocation of an alternative primordial user process, as described on kernel(1M)). init initiates the core components of the service management facility, svc.configd(1M) and svc.startd(1M), and restarts these components if they fail. For backwards compatibility, init also starts and restarts general processes according to /etc/inittab, as desribed below.

The run levels and system booting descriptions given below are provided for compatibility purposes only, and otherwise made obsolete by the service management facility, smf(5).

init Failure   If init exits for any reason other than system shutdown, it will be restarted with process-ID 1.

Run Level Defined   At any given time, the system is in one of eight possible run levels. A run level is a software configuration under which only a selected group of processes exists. Processes spawned by init for each of these run levels are defined in /etc/inittab. init can be in one of eight run levels, 0–6 and S or s (S and s are identical). The run level changes when a privileged user runs /usr/sbin/init.

init and System Booting   When the system is booted, init is invoked and the following occurs. First, it reads the properties for the svc:/system/environment:init service. Among these properties are values for locale-related environments, such as LANG or LC_CTYPE. init then looks in /etc/inittab for the initdefault entry (see inittab(4)). If the initdefault entry:

exists
    init usually uses the run level specified in that entry as the initial run level to enter only if the options/milestone property has not been specified for svc.startd(1M).

does not exist
    The service management facility, smf(5), examines its configuration specified in svc.startd(1M), and enters the milestone specified by the options/milestone property.

The initdefault entry in /etc/inittab corresponds to the following run levels:

S or s
    init goes to the single-user state. In this state, the system console device (/dev/console) is opened for reading and writing and the command /usr/sbin/su, (see su(1M)), is invoked. Use init to change the run level of the system. Note that if the shell is terminated (using an end-of-file), init only re-initializes to the single-user state if /etc/inittab does not exist.

0-6
    init enters the corresponding run level. Run levels 0, 5, and 6 are reserved states for shutting the system down. Run levels 2, 3, and 4 are available as multi-user operating states.

If this is the first time since power up that init has entered a run level other than single-user state, init first scans /etc/inittab for boot and bootwait entries (see inittab(4)). These entries are performed before any other processing of /etc/inittab takes place, providing

that the run level entered matches that of the entry. In this way any special initialization of the operating system, such as mounting file systems, can take place before users are allowed onto the system. init then scans /etc/inittab and executes all other entries that are to be processed for that run level.

To spawn each process in /etc/inittab, init reads each entry and for each entry that should be respawned, it forks a child process. After it has spawned all of the processes specified by /etc/inittab, init waits for one of its descendant processes to die, a powerfail signal, or a signal from another init process to change the system's run level. When one of these conditions occurs, init re-examines /etc/inittab.

inittab Additions   New entries can be added to /etc/inittab at any time; however, init still waits for one of the above three conditions to occur before re-examining /etc/inittab. To get around this, init Q or init q command wakes init to re-examine /etc/inittab immediately.

When init comes up at boot time and whenever the system changes from the single-user state to another run state, init sets the ioctl(2) states of the console to those modes saved in the file /etc/ioctl.syscon. init writes this file whenever the single-user state is entered.

Run Level Changes   When a run level change request is made, init or a designate sends the warning signal (SIGTERM) to all processes that are undefined in the target run level. A minimum interval of five seconds is observed before init or its designate forcibly terminates these processes by sending a kill signal (SIGKILL). Additionally, init informs svc.startd(1M) that the run level is changing. svc.startd(1M) then restricts the system to the set of services which the milestone corresponding to the run-level change depends on.

When init receives a signal telling it that a process it spawned has died, it records the fact and the reason it died in /var/adm/utmpx and /var/adm/wtmpx if it exists (see who(1)). A history of the processes spawned is kept in /var/adm/wtmpx.

If init receives a powerfail signal (SIGPWR) it scans /etc/inittab for special entries of the type powerfail and powerwait. These entries are invoked (if the run levels permit) before any further processing takes place. In this way init can perform various cleanup and recording functions during the powerdown of the operating system.

Setting Environment   You can set default values for environment variables, for such items as timezone and character
Variables   formatting, in the list of properties for the svc:/system/environment:init service.

Security   init uses pam(3PAM) for session management. The PAM configuration policy, listed through /etc/pam.conf, specifies the session management module to be used for init. Here is a partial pam.conf file with entries for init using the UNIX session management module.

```
init    session    required    pam_unix_session.so.1
```

If there are no entries for the init service, then the entries for the "other" service will be used.

Options   **0**

Go into firmware.

1

Put the system in system administrator mode. All local file systems are mounted. Only a small set of essential kernel processes are left running. This mode is for administrative tasks such as installing optional utility packages. All files are accessible and no users are logged in on the system.

This request corresponds to a request for smf(5) to restrict the system milestone to svc:/milestone/single-user:default.

2

Put the system in multi-user mode. All multi-user environment terminal processes and daemons are spawned. This state is commonly referred to as the multi-user state.

This request corresponds to a request for smf(5) to restrict the system milestone to svc:/milestone/multi-user:default.

3

Extend multi-user mode by making local resources available over the network.

This request corresponds to a request for smf(5) to restrict the system milestone to svc:/milestone/multi-user-server:default.

4

Is available to be defined as an alternative multi-user environment configuration. It is not necessary for system operation and is usually not used.

5

Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible.

6

Stop the operating system and reboot to the state defined by the initdefault entry in /etc/inittab.

The service svc:/system/boot-config:default is enabled by default. When the config/fastreboot_default property is set to true, init 6 will bypass certain firmware initialization and test steps, depending on the specific capabilities of the system.

a,b,c

Process only those /etc/inittab entries having the a, b, or c run level set. These are pseudo-states, which may be defined to run certain commands, but which do not cause the current run level to change.

Q,q

Re-examine /etc/inittab.

S, s

Enter single-user mode. This is the only run level that doesn't require the existence of a properly formatted /etc/inittab file. If this file does not exist, then by default, the only legal run level that init can enter is the single-user mode. When in single-user mode, the filesystems required for basic system operation will be mounted. When the system comes down to single-user mode, these file systems will remain mounted (even if provided by a remote file server), and any other local filesystems will also be left mounted. During the transition down to single-user mode, all processes started by init or init.d scripts that should only be running in multi-user mode are killed. In addition, any process that has a utmpx entry will be killed. This last condition insures that all port monitors started by the SAC are killed and all services started by these port monitors, including ttymon login services, are killed.

This request corresponds to a request for smf(5) to restrict the system milestone to svc:/milestone/single-user:default.

Files /dev/console

System console device.

/etc/default/init

This file is Obsolete and might be removed in a future release. Instead of obtaining values from this file, the init process reads properties for the svc:/system/environment:init service. To make changes that were formerly made by editing /etc/default/init, an administrator with the System Administrator or System Configuration Rights Profile can set the corresponding properties of the init service instance and refresh the instance.

This read-only file contains environment variables and their default values. The variables are:

TZ

Always set to localtime. To set the system timezone, an administrator must set the timezone/localtime property in timezone:default SMF service.

CMASK

The mask (see umask(1)) that init uses and that every process inherits from the init process. If not set, init uses the mask it inherits from the kernel. Note that init always attempts to apply a umask of 022 before creating a file, regardless of the setting of CMASK

LC_CTYPE

Character characterization information

LC_MESSAGES

Message translation

LC_MONETARY

Monetary formatting information

LC_NUMERIC

Numeric formatting information

LC_TIME

Time formatting information

LC_ALL

If set, all other LC_* environmental variables take-on this value.

LANG

If LC_ALL is not set, and any particular LC_* is also not set, the value of LANG is used for that particular environmental variable.

/etc/inittab

Controls process dispatching by init.

/etc/ioctl.syscon

ioctl states of the console, as saved by init when single-user state is entered.

/etc/svc/volatile/init.state

init state necessary to recover from failure.

/var/adm/utmpx

User access and administration information.

/var/adm/wtmpx

History of user access and administration information.

/var/run/initpipe

A named pipe used for internal communication.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also login(1), sh(1), stty(1), who(1), kernel(1M), shutdown(1M), su(1M), svc.configd(1M), svc.startd(1M), ttymon(1M), ioctl(2), kill(2), ctime(3C), pam(3PAM), init.d(4), inittab(4), pam.conf(4), TIMEZONE(4), utmpx(4), attributes(5), pam_unix_session(5), smf(5), termio(7I)

Diagnostics If init finds that it is respawning an entry from /etc/inittab more than ten times in two minutes, it assumes that there is an error in the command string in the entry and generates an error message on the system console. It then refuses to respawn this entry until either five minutes has elapsed or it receives a signal from a user-spawned init command. This prevents init from eating up system resources when someone makes a typographical error in the inittab file, or a program is removed that is referenced in /etc/inittab.

Notes init can be run only by a privileged user.

The S or s state must not be used indiscriminately in /etc/inittab. When modifying this file, it is best to avoid adding this state to any line other than initdefault.

If a default state is not specified in the initdefault entry in /etc/inittab, state 6 is entered. Consequently, the system will loop by going to firmware and rebooting continuously.

If the utmpx file cannot be created when booting the system, the system will boot to state "s" regardless of the state specified in the initdefault entry in /etc/inittab. This can occur if the /var file system is not accessible.

When a system transitions down to the S or s state, the /etc/nologin file (see nologin(4)) is created. Upon subsequent transition to run level 2, this file is removed.

init uses /var/run/initpipe, a named pipe, for internal communication.

Name   init.sma – start and stop the snmpd daemon

Synopsis   /etc/init.d/init.sma start | stop | restart | status

Description   The init.sma utility is run automatically during installation and each time the system is rebooted. This utility manages the snmpd.

Options   The following options are supported:

start   Starts the snmpd daemon.

stop   Stops the snmpd daemon.

restart   Stops then starts the snmpd daemon.

status   Reports the snmpd daemon's status.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmagt
Interface Stability	Uncommitted

Name init.wbem – start and stop the CIM Boot Manager

Synopsis `svccfg svc:/application/management/wbem start | stop`

Description The `init.wbem` utility is run automatically during installation, each time the system is rebooted, and by means of the `svccfg(1M)` command. This method manipulates the CIM Object Manager (CIMOM). `init.wbem` can be used to start, stop, or retrieve status from the server.

CIM Object Manager The CIM Object Manager manages CIM objects on a WBEM-enabled system. A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects are stored internally as Java classes.

When a WBEM client application accesses information about a CIM object, the CIM Object Manager contacts either the appropriate provider for that object or the CIM Object Manager Repository. Providers are classes that communicate with managed objects to access data.

When a WBEM client application requests data from a managed resource that is not available from the CIM Object Manager Repository, the CIM Object Manager forwards the request to the provider for that managed resource. The provider dynamically retrieves the information.

At startup, the CIM Object Manager performs the following functions:

- Listens for RMI connections on RMI port 5987 and for XML/HTTP connections on HTTP port 5988.
- Sets up a connection to the CIM Object Manager Repository.
- Waits for incoming requests.

During normal operations, the CIM Object Manager performs the following functions:

- Performs security checks to authenticate user login and authorization to access namespaces.
- Performs syntactical and semantic checking of CIM data operations to ensure that they comply with the latest CIM Specification.
- Routes requests to the appropriate provider or to the CIM Object Manager Repository.
- Delivers data from providers and from the CIM Object Manager Repository to WBEM client applications.

A WBEM client application contacts the CIM Object Manager to establish a connection when it needs to perform WBEM operations, such as creating a CIM class or updating a CIM instance. When a WBEM client application connects to a CIM Object Manager, it gets a reference to the CIM Object Manager, which it then uses to request services and operations.

System Booting The `init.wbem` script is installed in the `/etc/init.d` directory.

Options The init.wbem function is implemented as a service management facility (SMF) method and is controlled by means of the svcadm(1M) command using the fault management resource identifier (FMRI) svc:/application/management/wbem.

The following options are supported through svcadm(1M):

start   Starts the CIMOM on the local host.

stop   Stops the CIMOM.

status   Gets the status of the CIMOM.

The SMF property options/tcp_listen is used to control whether CIMOM and the Solaris Management console server will respond to requests from remote systems.

The specification:

svc:/application/management/wbem/options/tcp_listen = true

...allows remote access and false disallows remote access. false is the default value.

Examples EXAMPLE 1 Allowing Access to Remote Systems

The following commands enable CIMOM to allow access from remote systems.

```
# svccfg -s \
svc:/application/management/wbem setprop options/tcp_listen = true
# svcadm refresh svc:/application/management/wbem
```

Notes When the init.wbem script is invoked by SMF, it does not run the CIMOM directly. The server process is in Java and is too heavyweight to be run immediately at system boot time. Instead, three lightweight processes listen on three different ports that the CIMOM normally uses. This acts similarly to inetd(1M).

Because Java programs cannot inherit file descriptors as other programs can, there is a small time period from when the first connection is made until the server is fully operational where client connections may be dropped. WBEM clients are immune to this, as they will retry until the server comes online.

Attributes See attributes(5) for descriptions of the following attributes:

Name inityp2l – create NIS (YP) to LDAP configuration files

Synopsis /usr/lib/netsvc/yp/inityp2l [-m *mapping_file_name*]
[-c *config_file_name*]

Description The inityp2l utility assists with creation of the NISLDAPmapping and ypserv files. See
NISLDAPmapping(4) andypserv(4). inityp2l examines the NIS maps on a system. and
through a dialogue with the user, determines which NIS to (and from) LDAP mappings are
required. A NISLDAPmapping file is then created based on this information. The utility asks
users about their LDAP server configuration and a ypserv file is created based on this
information.

The inityp2l utility handles mappings for standard NIS maps and the auto.* series of maps.
If requested, it creates default mappings for custom maps, with each map entry represented as
a single DIT string. inityp2l does not handle full custom mapping, but if requested,
inityp2l will insert comments into the NISLDAPmapping file that indicate where these should
be added.

To write to the NISLDAPmapping or ypserv files is potentially dangerous. inityp2l warns the
user and asks for confirmation before:

1. it overwrites either file

2. it writes to the default NISLDAPmapping file location, if this file did not previously exist.
   This is important because the existence of a file in this location causes NIS components to
   work NIS to LDAP (N2L) mode when next restarted, rather than to traditional NIS mode.

inityp2l assists with rapid creation of a simple N2L configuration files. It is not a general
purpose tool for the management of these files. An advanced user who would like to maintain
the files or use custom mappings should examine the output of inityp2l and customize it by
using a standard text editor.

Options inityp2l supports the following options:

-c Specify the name of the generated ypserv file. The default location is described in Files.

-m Specify the name of the generated NISLDAPmapping file. The default is described in
Files.

Files /var/yp   The directory to be searched for candidate domains
                                         (/var/yp/*) and NIS maps (/var/yp/*/*)

/var/yp/NISLDAPmapping   The default location for the generated NISLDAPmapping file

/etc/default/ypserv   The default location for the generated ypserv file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/nis
Interface Stability	Obsolete

See Also   NISLDAPmapping(4), ypserv(4), attributes(5)

Name in.lpd – BSD print protocol adaptor

Synopsis /usr/lib/print/in.lpd

Description in.lpd implements the network listening service for the BSD print protocol specified in RFC 1179. The BSD print protocol provides a remote interface for systems to interact with a local spooling system. The protocol defines five standard requests from the client to the server: starting queue processing, transferring print jobs, retrieving terse status, retrieving verbose status, and canceling print jobs.

The in.lpd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/lp

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

in.lpd uses the config/log_from_remote property to allow or disallow remote access. The default value of this property, localhost, disallows remote access.

inetd waits for connections on TCP port 515. Upon receipt of a connect request, in.lpd is started to service the connection. Once the request has been filled, in.lpd closes the connection and exits.

Examples EXAMPLE 1 Allowing Remote Access

The following command allows remote access to in.lpd.

inetadm -m svc:/application/print/rfc1179:default bind_addr=""

Exit Status The following exit values are returned:

0   Successful completion.

non-zero   An error occurred.

Files /usr/lib/print/bsd-adaptor/bsd_*.so*   Spooler translation modules.

Attributes See attributes(5) for descriptions of the following attributes:

Name in.mpathd – IP multipathing daemon

Synopsis /usr/lib/inet/in.mpathd

Description The in.mpathd daemon performs failure and repair detection for IP interfaces that have been placed into an IPMP group (or optionally, for all IP interfaces on the system). It also controls which IP interfaces in an IPMP group are "active" (being used by the system to send or receive IP data traffic) in a manner that is consistent with the administrator's configured policy. Functioning interfaces that are not active are referred to as *alternate* interfaces.

The in.mpathd daemon can detect IP interface failure and repair through three methods: by monitoring the IFF_RUNNING flag for each IP interface (link-state based failure detection), by sending and receiving ICMP probes on each IP interface (ICMP probe-based failure detection), or by transitive probing. Failure detection by transitive probing is done by sending and receiving ICMP probes on active interfaces, while determining the liveness of alternate interfaces through their ability to send and receive link-layer (that is, transitive) probes to an active interface.

By default, only link-state based failure detection is enabled. This requires the driver to support link-status notification. ICMP probe-based failure detection must be enabled through the configuration of one or more test addresses, which are described below. Transitive probing can be enabled by modifying the value of the SMF property (shown below) to true:

svc:/network/ipmp/config/transitive-probing

See EXAMPLES for more information on how to modify the value of the transitive-probing property.

Both ICMP and transitive probe-based failure detection methods test the entire IP interface send and receive path. The ipmpstat(1M) utility can be used to check which failure detection methods are enabled.

If transitive-probing is set to true, and no test addresses are configured for a given IPMP group, then transitive probing will be used. If it is set to false (default value), then transitive probing will not be used under any circumstance.

If only link-state based failure detection is enabled, then the health of the interface is determined solely from the state of the IFF_RUNNING flag. If probes have been enabled, the interface is considered failed if either link-state or probes indicate a failure, and repaired once the failure detection method has indicated the failure has been corrected. Although all interfaces in a group need not be configured with the same failure detection methods, transitive probing will be disabled on any interface of a group that has at least one IP test address.

As mentioned above, to perform ICMP probe-based failure detection, in.mpathd requires a test address on each IP interface for the purpose of sending and receiving probes. Each address must be marked NOFAILOVER (see ifconfig(1M)) and in.mpathd will be limited to probing targets on the same subnet. Each address may be configured statically or acquired by means of

DHCP. To find targets, in.mpathd first consults the routing table for routes on the same subnet, and uses the specified next-hop. If no routes match, it sends all-hosts ICMP probes and selects a subset of the systems that respond. Thus, for probe-based failure detection to operate, there must be at least one neighbor on each subnet that responds to ICMP echo request probes. The ipmpstat(1M) utility can be used to display both the current probe target information and the status of sent probes.

Both IPv4 and IPv6 are supported. If an IP interface is plumbed for IPv4 and an IPv4 test address is configured then in.mpathd will start sending ICMPv4 probes over that IP interface. Similarly, if an IP interface is plumbed for IPv6 and an IPv6 test address is configured, then in.mpathd will start sending ICMPv6 probes over that IP interface. However, note that in.mpathd will ignore IPv6 test addresses that are not link-local. If both IPv4 and IPv6 are plumbed, it is sufficient to configure only one of the two, that is, either an IPv4 test address or an IPv6 test address. If both IPv4 and IPv6 test addresses are configured, in.mpathd probes using both ICMPv4 and ICMPv6.

As mentioned above, in.mpathd also controls which IP interfaces in an IPMP group are "active" (used by the system to send and receive IP data traffic). Specifically, in.mpathd tracks the administrative configuration of each IPMP group and attempts to keep the number of active IP interfaces in each group consistent with that configuration. Therefore, if an active IP interface fails, in.mpathd will activate an INACTIVE interface in the group, provided one exists (it will prefer INACTIVE interfaces that are also marked STANDBY). Likewise, if an IP interface repairs and the resulting repair leaves the IPMP group with more active interfaces than the administrative configuration specifies, in.mpathd will deactivate one of the interfaces (preferably one marked STANDBY), except when the FAILBACK variable is used, as described below. Similar adjustments will be made by in.mpathd when offlining IP interfaces (for instance, in response to if_mpadm(1M)).

The in.mpathd daemon accesses three variable values in /etc/default/mpathd: FAILURE_DETECTION_TIME, FAILBACK and TRACK_INTERFACES_ONLY_WITH_GROUPS.

The FAILURE_DETECTION_TIME variable specifies the probe-based failure detection time. The shorter the failure detection time, the more probe traffic. The default value of FAILURE_DETECTION_TIME is 10 seconds. This means that IP interface failure will be detected by in.mpathd within 10 seconds. The IP interface repair detection time is always twice the value of FAILURE_DETECTION_TIME. Note that failures and repairs detected by link-based failure detection are acted on immediately, though in.mpathd may ignore link state changes if it suspects that the link state is flapping due to defective hardware; see DIAGNOSTICS.

By default, in.mpathd limits failure and repair detection to IP interfaces that are configured as part of a named IPMP group. Setting TRACK_INTERFACES_ONLY_WITH_GROUPS to no enables failure and repair detection on all IP interfaces, even if they are not part of a named IPMP group. IP interfaces that are tracked but not part of a named IPMP group are considered to be part of the "anonymous" IPMP group. In addition to having no name, this IPMP group is special in that its IP interfaces are not equivalent and thus cannot take over for one another in

the event of an IP interface failure. That is, the anonymous IPMP group can only be used for failure and repair detection, and provides no high-availability or load-spreading.

As described above, when in.mpathd detects that an IP interface has repaired, it activates it so that it will again be used to send and receive IP data traffic. However, if FAILBACK is set to no, then the IP interface will only be activated if no other active IP interfaces in the group remain. However, the interface may subsequently be activated if another IP interface in the group fails.

SMF Management The in.mpathd daemon service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/ipmp:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M).

Examples EXAMPLE 1   Enabling Fault Detection by Transitive Probing

The following example shows the sequence of SMF commands used to enable fault detection by transitive probing.

```
# svccfg -s svc:/network/ipmp setprop config/transitive-probing=true
# svcadm refresh  svc:/network/ipmp:default
```

Files /etc/default/mpathd   Contains default values used by the in.mpathd daemon.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

Oracle Solaris Administration: IP Services

Diagnostics IP interface *interface_name* has a hardware address which is not unique in group *group_name*; offlining
    Description: For probe-based failure detection, load-spreading, and other code IPMP features to work properly, each IP interface in an IPMP group must have a unique hardware address. If this requirement is not met, in.mpathd will automatically offline all but one of the IP interfaces with duplicate hardware addresses.

IP interface *interface_name* now has a unique hardware address in group *group_name*; onlining
    Description: The previously-detected duplicate hardware address is now unique, and therefore in.mpathd has brought *interface_name* back online.

Test address *address* is not unique in group; disabling probe-based failure
detection on *interface_name*
>   **Description:** For in.mpathd to perform probe-based failure detection, each test address in
>   the group must be unique.

No test address configured on interface *interface_name* disabling probe-based
failure detection on it
>   **Description:** For in.mpathd to perform probe-based failure detection on an IP interface, it
>   must be configured with a test address: IPv4, IPv6, or both.

IP *interface_name* in group *group_name* is not plumbed for IPv[4|6], affecting
IPv[4|6] connectivity
>   **Description:** All IP interfaces in a multipathing group must be homogeneously plumbed.
>   For example, if one IP interface is plumbed for IPv4, then all IP interfaces in the group
>   must be plumbed for IPv4, or IPv4 packets will not be able to be reliably sent and received.
>   The STREAMS modules pushed on all IP interfaces must also be identical.

The link has come up on *interface_name* more than 2 times in the last minute;
disabling repair until it stabilizes.
>   **Description:** To limit the impact of interfaces with intermittent hardware (such as a bad
>   cable), in.mpathd will not consider an IP interface with a frequently changing link state as
>   repaired until the link state stabilizes.

Invalid failure detection time of *time*, assuming default 10000 ms
>   **Description:** An invalid value was encountered for FAILURE_DETECTION_TIME in the
>   /etc/default/mpathd file.

Too small failure detection time of *time*, assuming minimum of 100 ms
>   **Description:** The minimum value that can be specified for FAILURE_DETECTION_TIME is
>   currently 100 milliseconds.

Invalid value for FAILBACK *value*
>   **Description:** Valid values for the boolean variable FAILBACK are yes or no.

Invalid value for TRACK_INTERFACES_ONLY_WITH_GROUPS *value*
>   **Description:** Valid values for the boolean variable TRACK_INTERFACES_ONLY_WITH_GROUPS
>   are yes or no.

Cannot meet requested failure detection time of *time* ms on (inet[6]
interface_name) new failure detection time for group *group_name* is *time* ms
>   **Description:** The round trip time for ICMP probes is higher than necessary to maintain the
>   current failure detection time. The network is probably congested or the probe targets are
>   loaded. in.mpathd automatically increases the failure detection time to whatever it can
>   achieve under these conditions.

Improved failure detection time *time* ms on (inet[6] *interface_name*) for group
group_name
>   **Description:** The round trip time for ICMP probes has now decreased and in.mpathd has
>   lowered the failure detection time correspondingly.

IP interface failure detected on *interface_name*
>   **Description:** in.mpathd has detected a failure on *interface_name*, and has set the
>   IFF_FAILED flag on *interface_name*, ensuring that it will not be used for IP data traffic.

IP interface repair detected on *interface_name*
>   **Description:** in.mpathd has detected a repair on *interface_name*, and has cleared the
>   IFF_FAILED flag. Depending on the administrative configuration, the *interface_name* may
>   again be used for IP data traffic.

All IP interfaces in group *group* are now unusable
>   **Description:** in.mpathd has determined that none of the IP interfaces in *group* can be used
>   for IP data traffic, breaking network connectivity for the group.

At least 1 IP interface (*interface_name*) in group *group* is now usable
>   **Description:** in.mpathd has determined that at least one of the IP interfaces in *group* can
>   again be used for IP data traffic, restoring network connectivity for the group.

The link has gone down on *interface_name*
>   **Description:** in.mpathd has detected that the IFF_RUNNING flag for *interface_name* has been
>   cleared, indicating that the link has gone down.

The link has come up on *interface_name*
>   **Description:** in.mpathd has detected that the IFF_RUNNING flag for *interface_name* has been
>   set, indicating that the link has come up.

Name in.ndpd – daemon for IPv6 autoconfiguration

Synopsis /usr/lib/inet/in.ndpd [-adt] [-f *config_file*]

Description in.ndpd provides both the host and router autoconfiguration components of Neighbor Discovery for IPv6 and Stateless and Stateful Address Autoconfiguration for IPv6. In particular, in.ndpd implements:

- router discovery;
- prefix discovery;
- parameter discovery;
- invocation of stateful address autoconfiguration;
- stateless address autoconfiguration; and
- privacy extensions for stateless address autoconfiguration.

Other aspects of Neighbor Discovery are implemented by ip6(7P), including:

- address resolution;
- neighbor unreachability detection; and
- redirect.

The duplicate address detection function is implemented by the system kernel.

in.ndpd is managed by the service management facility (SMF), by means of the service identifier:

svc:/network/routing/ndp:default

If the /etc/inet/ndpd.conf file does not exist or does not set the variable AdvSendAdvertisements to true for a network interface, then in.ndpd will make the node a host for that interface, that is, sending router solicitation messages and then using router advertisement messages it receives to autoconfigure the node. Note that in.ndpd only autoconfigures the addresses of global or site-local scope from the prefix advertisement.

If AdvSendAdvertisements is set to true for an interface, then in.ndpd will perform router functions on that interface, that is, sending router advertisement messages to autoconfigure the attached hosts, but not use any advertisements it receives for autoconfiguration. However, when sending advertisements, in.ndpd will use the advertisements it sends itself to autoconfigure its prefixes.

Stateless autoconfiguration requires no manual configuration of hosts, minimal (if any) configuration of routers, and no additional servers. The stateless mechanism enables a host to generate its own addresses and uses local information as well as non-local information that is advertised by routers to generate the addresses. in.ndpd will plumb logical interfaces for each of these addresses.

Stateful autoconfiguration involves the dhcpagent(1M) daemon and the use of the DHCPv6 protocol. The dhcpagent daemon is responsible for plumbing the logical interfaces for the acquired addresses, maintaining the leases, and handling duplicate addresses. in.ndpd starts

the dhcpagent daemon automatically and signals when DHCPv6 should be started. in.ndpd also detects when dhcpagent configures the logical interfaces, and sets the appropriate prefix length on each according to received Routing Advertisement messages. in.ndpd will not stop dhcpagent; use ifconfig(1M) to control dhcpagent if necessary.

Temporary addresses that are autoconfigured for an interface can also be implemented. A temporary address token is enabled for one or more interfaces on a host. However, unlike standard, autoconfigured IPv6 addresses, a temporary address consists of the site prefix and a randomly generated 64 bit number. This random number becomes the interface ID segment of the IPv6 address. A link-local address is not generated with the temporary address as the interface ID.

If the kernel detects a duplicate temporary address, in.ndpd will automatically choose another.

Routers advertise all prefixes that have been assigned on the link. IPv6 hosts use Neighbor Discovery to obtain a subnet prefix from a local router. Hosts automatically create IPv6 addresses by combining the subnet prefix with an interface IDs that is generated from an interface's MAC address. In the absence of routers, a host can generate only link-local addresses. Link-local addresses can only be used for communication with nodes on the same link.

For information on how to enable IPv6 address autoconfiguration, see *Oracle Solaris Administration: IP Services*

Options   Supported options and equivalent SMF service properties are listed below. SMF service properties are set using a command of the form:

routeadm -m ndp:default *key*=*value*

-a

Turn off stateless and stateful address auto configuration. When set, the daemon does not autoconfigure any addresses and does not renumber any addresses. This option does the same thing as the following lines in ndpd.conf(4):

```
ifdefault StatefulAddrConf off
ifdefault StatelessAddrConf off
```

Use of this option is equivalent to setting the stateless_addr_conf property to false.

-d

Turn on large amounts of debugging output on stdout. When set, the program runs in the foreground and stays attached to the controlling terminal. Use of this option is equivalent to setting the debug property to true.

-f *config_file*

Use *config_file* for configuration information instead of the default /etc/inet/ndpd.conf. Use of this option is equivalent to setting the config_file property to the configuration file to be used.

-t

Turn on tracing (printing) of all sent and received packets to stdout. When set, the
program runs in the foreground and stays attached to the controlling terminal. As such,
this option cannot be run under the SMF.

Files   /etc/inet/ndpd.conf   Configuration file. This file is not necessary on a host, but it is
required on a router to enable in.ndpd to advertise
autoconfiguration information to the hosts.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   dhcpagent(1M), ifconfig(1M), routeadm(1M), svcadm(1M), ndpd.conf(4), attributes(5),

Society. December 1998.

Narten, T., and Draves, R. RFC 3041, Privacy Extensions for Stateless Address
Autoconfiguration in IPv6. The Internet Society. January 2001.

Diagnostics   Receipt of a SIGHUP signal will make in.ndpd restart and reread /etc/inet/ndpd.conf.

Notes   The in.ndpd daemon service is managed by the service management facility, smf(5), under
the service identifier:

svc:/network/routing/ndp:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can
be performed using svcadm(1M) or routeadm(1M).

Name in.rarpd, rarpd – DARPA Reverse Address Resolution Protocol server

Synopsis /usr/sbin/in.rarpd [-d] -a

/usr/sbin/in.rarpd [-d] *device unit*

Description in.rarpd starts a daemon that responds to Reverse Address Resolution Protocol (RARP) requests. The daemon forks a copy of itself that runs in background. It must be run as root.

RARP is used by machines at boot time to discover their Internet Protocol (IP) address. The booting machine provides its Ethernet address in a RARP request message. Using the ethers and hosts databases, in.rarpd maps this Ethernet address into the corresponding IP address which it returns to the booting machine in an RARP reply message. The booting machine must be listed in both databases for in.rarpd to locate its IP address. in.rarpd issues no reply when it fails to locate an IP address.

in.rarpd uses the STREAMS-based Data Link Provider Interface (DLPI) message set to communicate directly with the datalink device driver.

Options The following options are supported:

-a   Get the list of available network interfaces from IP using the SIOCGIFADDR ioctl and start a RARP daemon process on each interface returned.

-d   Print assorted debugging messages while executing.

Examples EXAMPLE 1 Starting An in.rarpd Daemon For Each Network Interface Name Returned From /dev/ip:

The following command starts an in.rarpd for each network interface name returned from /dev/ip:

example# /usr/sbin/in.rarpd -a

EXAMPLE 2 Starting An in.rarpd Daemon On The Device /dev/le With The Device Instance Number 0

The following command starts one in.rarpd on the device /dev/le with the device instance number 0.

example# /usr/sbin/in.rarpd le 0

Files /etc/ethers   File or other source, as specified by nsswitch.conf(4).

/etc/hosts   File or other source, as specified by nsswitch.conf(4).

/tftpboot

/dev/ip

/dev/arp

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/boot/network

See Also svcs(1), boot(1M), ifconfig(1M), svcadm(1M), ethers(4), hosts(4), netconfig(4), nsswitch.conf(4),attributes(5), smf(5), dlpi(7P)

Finlayson, R., Mann, T., Mogul, J., and Theimer, M., *RFC 903, A Reverse Address Resolution Protocol*, Network Information Center, SRI International, June 1984.

Notes The in.rarpd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rarp

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name in.rdisc, rdisc – network router discovery daemon

Synopsis /usr/sbin/in.rdisc [-a] [-f] [-s] [*send-address*] [*receive-address*]

/usr/sbin/in.rdisc -r [-p *preference*] [-T *interval*]
 [*send-address*] [*receive-address*]

Description in.rdisc remains part of the software distribution of the Solaris Operating Environment. It is, however, not used by default. in.routed(1M) includes the functionality provided by in.rdisc. See routeadm(1M) for details of how to specify the IPV4 routing daemon.

in.rdisc implements the ICMP router discovery protocol. The first form of the command is used on hosts and the second form is used on routers.

in.rdisc can be invoked in either the first form (host mode) or second form (router mode).

On a host, in.rdisc populates the network routing tables with default routes. On a router, advertises the router to all the hosts.

in.rdisc is managed by the service management facility (SMF), by means of the service identifier:

svc:/network/routing/rdisc:default

Host (First Form) On a host, in.rdisc listens on the ALL_HOSTS (224.0.0.1) multicast address for ROUTER_ADVERTISE messages from routers. The received messages are handled by first ignoring those listed router addresses with which the host does not share a network. Among the remaining addresses, the ones with the highest preference are selected as default routers and a default route is entered in the kernel routing table for each one of them.

Optionally, in.rdisc can avoid waiting for routers to announce themselves by sending out a few ROUTER_SOLICITATION messages to the ALL_ROUTERS (224.0.0.2) multicast address when it is started.

A timer is associated with each router address. The address will no longer be considered for inclusion in the routing tables if the timer expires before a new *advertise* message is received from the router. The address will also be excluded from consideration if the host receives an *advertise* message with the preference being maximally negative or with a lifetime of zero.

Router (Second Form) When in.rdisc is started on a router, it uses the SIOCGIFCONF ioctl(2) to find the interfaces configured into the system and it starts listening on the ALL_ROUTERS multicast address on all the interfaces that support multicast. It sends out *advertise* messages to the ALL_HOSTS multicast address advertising all its IP addresses. A few initial *advertise* messages are sent out during the first 30 seconds and after that it will transmit *advertise* messages approximately every 600 seconds.

When in.rdisc receives a *solicitation* message, it sends an *advertise* message to the host that sent the *solicitation* message.

When in.rdisc is terminated by a signal, it sends out an *advertise* message with the preference being maximally negative.

Options Supported options and equivalent SMF service properties are listed below. SMF service properties are set using a command of the form:

```
# routeadm -m rdisc:default key=value
```

-a   Accept all routers independent of the preference they have in their *advertise* messages. Normally, in.rdisc only accepts (and enters in the kernel routing tables) the router or routers with the highest preference. Use of this option is equivalent to setting the accept_all property to true.

-f   Run in.rdisc forever even if no routers are found. Normally, in.rdisc gives up if it has not received any *advertise* message after soliciting three times, in which case it exits with a non-zero exit code. If -f is not specified in the first form then -s must be specified. For SMF execution, this option is required.

-r   Act as a router, rather than a host. Use of this option is equivalent to setting the act_as_router property to true.

-s   Send three *solicitation* messages initially to quickly discover the routers when the system is booted. When -s is specified, in.rdisc exits with a non-zero exit code if it can not find any routers. This can be overridden with the -f option. This option is not compatible with SMF execution and is not supported for the rdisc service.

-p *preference*   Set the preference transmitted in the *solicitation* messages. The default is zero. Use of this option is equivalent to setting the preference property.

-T *interval*   Set the interval between transmitting the *advertise* messages. The default time is 600 seconds. Use of this option is equivalent to setting the transmit_interval property.

The send-address and receive-address daemon options can be set by means of the send_address and receive_address properties.

Attributes See attributes(5) for descriptions of the following attributes:

Name in.rexecd, rexecd – remote execution server

Synopsis in.rexecd

Description in.rexecd is the server for the rexec(3SOCKET) routine. The server provides remote execution facilities with authentication based on user names and passwords. It is invoked automatically as needed by inetd(1M), and then executes the following protocol:

1. The server reads characters from the socket up to a null (\0) byte. The resultant string is interpreted as an ASCII number, base 10.

2. If the number received in step 1 is non-zero, it is interpreted as the port number of a secondary stream to be used for the stderr. A second connection is then created to the specified port on the client's machine.

3. A null terminated user name of at most 16 characters is retrieved on the initial socket.

4. A null terminated password of at most 16 characters is retrieved on the initial socket.

5. A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the system's argument list.

6. rexecd then validates the user as is done at login time and, if the authentication was successful, changes to the user's home directory, and establishes the user and group protections of the user. If any of these steps fail the connection is aborted and a diagnostic message is returned.

7. A null byte is returned on the connection associated with the stderr and the command line is passed to the normal login shell of the user. The shell inherits the network connections established by rexecd.

Usage in.rexecd and rexecd are IPv6–enabled. See ip6(7P).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

See Also svcs(1), inetd(1M), inetadm(1M), svcadm(1M), rexec(3SOCKET), attributes(5), smf(5), ip6(7P)

Diagnostics All diagnostic messages are returned on the connection associated with the stderr, after which any network connections are closed. An error is indicated by a leading byte with a value of 1 (0 is returned in step 7 above upon successful completion of all the steps prior to the command execution).

username too long   The name is longer than 16 characters.

password too long   The password is longer than 16 characters.

`command too long`	The command line passed exceeds the size of the argument list (as configured into the system).
`Login incorrect.`	No password file entry for the user name existed.
`Password incorrect.`	The wrong password was supplied.
`No remote directory.`	The `chdir` command to the home directory failed.
`Try again.`	A `fork` by the server failed.
`/usr/bin/sh: ...`	The user's login shell could not be started.

Notes The `in.rexecd` service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/rexec:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name in.ripngd – network routing daemon for IPv6

Synopsis /usr/sbin/in.ripngd [-s] [-q] [-t] [-p *n*] [-P] [-v]
[*logfile*]

Description in.ripngd is the IPv6 equivalent of in.routed(1M). It is invoked at boot time to manage the
network routing tables. The routing daemon uses the Routing Information Protocol for IPv6.

in.ripngd is managed by the service management facility (SMF), by means of the service
identifier:

svc:/network/routing/ripng:default

In normal operation, in.ripngd listens on the udp(7P) socket port 521 for routing
information packets. If the host is an internetwork router, it periodically supplies copies of its
routing tables to any directly connected hosts and networks.

When in.ripngd is started, it uses the SIOCGLIFCONF ioctl(2) to find those directly
connected IPv6 interfaces configured into the system and marked "up"; the software loopback
interface is ignored. If multiple interfaces are present, it is assumed the host will forward
packets between networks. in.ripngd then multicasts a request packet on each IPv6 interface
and enters a loop, listening for request and response packets from other hosts.

When a request packet is received, in.ripngd formulates a reply based on the information
maintained in its internal tables. The response packet contains a list of known routes. With
each route is a number specifying the number of bits in the prefix. The prefix is the number of
bits in the high order part of an address that indicate the subnet or network that the route
describes. Each route reported also has a "*hop count*" metric. A count of 16 or greater is
considered "infinity." The metric associated with each route returned provides a metric
relative to the sender.

The request packets received by in.ripngd are used to update the routing tables if one of the
following conditions is satisfied:

- No routing table entry exists for the destination network or host, and the metric indicates
  the destination is "reachable", that is, the *hop count* is not infinite.

- The source host of the packet is the same as the router in the existing routing table entry.
  That is, updated information is being received from the very internetwork router through
  which packets for the destination are being routed.

- The existing entry in the routing table has not been updated for a period of time, defined to
  be 90 seconds, and the route is at least as cost-effective as the current route.

- The new route describes a shorter route to the destination than the one currently stored in
  the routing tables; this is determined by comparing the metric of the new route against the
  one stored in the table.

When an update is applied, in.ripngd records the change in its internal tables and generates a response packet to all directly connected hosts and networks. To allow possible unstable situations to settle, in.ripngd waits a short period of time (no more than 30 seconds) before modifying the kernel's routing tables.

In addition to processing incoming packets, in.ripngd also periodically checks the routing table entries. If an entry has not been updated for 3 minutes, the entry's metric is set to infinity and marked for deletion. Deletions are delayed an additional 60 seconds to insure the invalidation is propagated throughout the internet.

Hosts acting as internetwork routers gratuitously supply their routing tables every 30 seconds to all directly connected hosts and networks.

Options in.ripngd supports the options listed below. Listed with the options are the equivalent SMF property values. These are set for the ripng:default service with a command of the form:

routeadm -m ripng:default *key=value*

-p *n*   Send and receive the routing packets from other routers using the UDP port number
            n. Use of this option is equivalent to setting the udp_port property.

-P   Do not use poison reverse. Use of this option is equivalent to setting the
            poison_reverse property to false.

-q   Do not supply routing information. Use of this option is equivalent to setting the
            quiet_mode property to true.

-s   Force in.ripngd to supply routing information whether it is acting as an
            internetwork router or not. Use of this option is equivalent to setting the
            supply_routes property to true.

-t   Print all packets sent or received to standard output. in.ripngd will not divorce itself
            from the controlling terminal. Accordingly, interrupts from the keyboard will kill the
            process. Not supported by the ripng service.

-v   Print all changes made to the routing tables to standard output with a timestamp. Use
            of this option is equivalent to setting the verbose property to true.

            Any other argument supplied to this option is interpreted as the name of the file in
            which the actions of in.ripngd, as specified by this option or by -t, should be logged
            instead of being sent to standard output.

            The logfile can be specified for the ripng service by means of the log_file property.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/routing

See Also in.routed(1M), routeadm(1M), svcadm(1M), ioctl(2), attributes(5), smf(5), udp(7P)

G. Malkin, R. Minnear, *RFC 2080, RIPng for IPv6*, January 1997.

Notes The kernel's routing tables may not correspond to those of in.ripngd for short periods of time while processes that utilize existing routes exit; the only remedy for this is to place the routing process in the kernel.

in.ripngd currently does not support all of the functionality of in.routed(1M). Future releases may support more if appropriate.

in.ripngd initially obtains a routing table by examining the interfaces configured on a machine. It then sends a request on all directly connected networks for more routing information. in.ripngd does not recognize or use any routing information already established on the machine prior to startup. With the exception of interface changes, in.ripngd does not see any routing table changes that have been done by other programs on the machine, for example, routes added, deleted or flushed by means of the route(1M) command. Therefore, these types of changes should not be done while in.ripngd is running. Rather, shut down in.ripngd, make the changes required, and then restart in.ripngd.

Name   in.rlogind, rlogind – remote login server

Synopsis   /usr/sbin/in.rlogind [-k5eExXciPp] [-s *tos*] [-S *keytab*]
            [-M *realm*]

Description   in.rlogind is the server for the rlogin(1) program. The server provides a remote login
facility with authentication based on Kerberos V5 or privileged port numbers.

in.rlogind is invoked by inetd(1M) when a remote login connection is established. When
Kerberos V5 authentication is required (see option -k below), the authentication sequence is
as follows:

- Check Kerberos V5 authentication.
- Check authorization according to the rules in krb5_auth_rules(5).
- Prompt for a password if any checks fail and /etc/pam.conf is configured to do so.

In order for Kerberos authentication to work, a host/<*FQDN*> Kerberos principal must exist
for each Fully Qualified Domain Name associated with the in.rlogind server. Each of these
host/<*FQDN*> principals must have a keytab entry in the /etc/krb5/krb5.keytab file on
the in.rlogind server. An example principal might be:

host/bigmachine.eng.example.com

See kadmin(1M) or gkadmin(1M) for instructions on adding a principal to a krb5.keytab file.
See *Oracle Solaris Administration: Security Services* for a discussion of Kerberos
authentication.

If Kerberos V5 authentication is not enabled, then the authentication procedure follows the
standard rlogin protocol:

- The server checks the client's source port. If the port is not in the range 512-1023, the
  server aborts the connection.
- The server checks the client's source address. If an entry for the client exists in both
  /etc/hosts and /etc/hosts.equiv, a user logging in from the client is not prompted for
  a password. If the address is associated with a host for which no corresponding entry exists
  in /etc/hosts, the user is prompted for a password, regardless of whether or not an entry
  for the client is present in /etc/hosts.equiv. See hosts(4) and hosts.equiv(4).

Once the source port and address have been checked, in.rlogind allocates a pseudo-terminal
and manipulates file descriptors so that the slave half of the pseudo-terminal becomes the
stdin, stdout, and stderr for a login process. The login process is an instance of the login(1)
program, invoked with the -r.

The login process then proceeds with the pam(3PAM) authentication process. See SECURITY
below. If automatic authentication fails, it reprompts the user to login.

The parent of the login process manipulates the master side of the pseudo-terminal, operating as an intermediary between the login process and the client instance of the rlogin program. In normal operation, a packet protocol is invoked to provide Ctrl-S and Ctrl-Q type facilities and propagate interrupt signals to the remote programs. The login process propagates the client terminal's baud rate and terminal type, as found in the environment variable, TERM.

Options The following options are supported:

-5 Same as -k, for backwards compatibility.

-c Requires Kerberos V5 clients to present a cryptographic checksum of initial connection information like the name of the user that the client is trying to access in the initial authenticator. This checksum provides additionl security by preventing an attacker from changing the initial connection information. This option is mutually exclusive with the -i option.

-e Creates an encrypted session.

-E Same as -e, for backwards compatibility.

-i Ignores authenticator checksums if provided. This option ignores authenticator checksums presented by current Kerberos clients to protect initial connection information. Option -i is the opposite of option -c.

-k Allows Kerberos V5 authentication with the .k5login access control file to be trusted. If this authentication system is used by the client and the authorization check is passed, then the user is allowed to log in.

-M *realm* Uses the indicated Kerberos V5 realm. By default, the daemon will determine its realm from the settings in the krb5.conf(4) file.

-p Prompts for authentication only if other authentication checks fail.

-P Prompts for a password in addition to other authentication methods.

-s *tos* Sets the IP TOS option.

-S *keytab* Sets the KRB5 keytab file to use. The /etc/krb5/krb5.keytab file is used by default.

-x Same as -e, for backwards compatibility.

-X Same as -e, for backwards compatibility.

Usage rlogind and in.rlogind are IPv6–enabled. See ip6(7P). IPv6 is not currently supported with Kerberos V5 authentication.

Typically, Kerberized rlogin service runs on port 543 (klogin) and Kerberized, encrypted rlogin service runs on port 2105 (eklogin). The corresponding FMRI entries are:

```
svc:/network/login:klogin (rlogin with kerberos)
svc:/network/login:eklogin (rlogin with kerberos and encryption)
```

Security in.rlogind uses pam(3PAM) for authentication, account management, and session management. The PAM configuration policy, listed through /etc/pam.conf, specifies the modules to be used for in.rlogind. Here is a partial pam.conf file with entries for the rlogin command using the "rhosts" and UNIX authentication modules, and the UNIX account, session management, and password management modules.

rlogin	auth sufficient	pam_rhosts_auth.so.1
rlogin	auth requisite	pam_authtok_get.so.1
rlogin	auth required	pam_dhkeys.so.1
rlogin	auth required	pam_unix_auth.so.1
rlogin	account required	pam_unix_roles.so.1
rlogin	account required	pam_unix_projects.so.1
rlogin	account required	pam_unix_account.so.1
rlogin	session required	pam_unix_session.so.1

With this configuration, the server checks the client's source address. If an entry for the client exists in both /etc/hosts and /etc/hosts.equiv, a user logging in from the client is not prompted for a password. If the address is associated with a host for which no corresponding entry exists in /etc/hosts, the user is prompted for a password, regardless of whether or not an entry for the client is present in /etc/hosts.equiv. See hosts(4) and hosts.equiv(4).

When running a Kerberized rlogin service (with or without the encryption option), the pam service name that should be used is "krlogin".

If there are no entries for the rlogin service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords. Removing the pam_rhosts_auth.so.1 entry will disable the /etc/hosts.equiv and ~/.rhosts authentication protocol and the user would always be forced to type the password. The *sufficient* flag indicates that authentication through the pam_rhosts_auth.so.1 module is sufficient to authenticate the user. Only if this authentication fails is the next authentication module used.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

See Also login(1), svcs(1), rlogin(1), gkadmin(1M), in.rshd(1M), inetadm(1M), inetd(1M), kadmin(1M), svcadm(1M), pam(3PAM), hosts(4), hosts.equiv(4), krb5.conf(4), pam.conf(4), attributes(5), environ(5), krb5_auth_rules(5), pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), pam_unix_session(5), smf(5)

Oracle Solaris Administration: Security Services

Diagnostics All diagnostic messages are returned on the connection associated with the stderr, after which any network connections are closed. An error is indicated by a leading byte with a value of 1.

Hostname for your address unknown.	No entry in the host name database existed for the client's machine.
Try again.	A *fork* by the server failed.
/usr/bin/sh:...	The user's login shell could not be started.

Notes The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but it is useful in an "open" environment.

A facility to allow all data exchanges to be encrypted should be present.

The in.rlogind service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/login:rlogin (rlogin)
svc:/network/login:klogin (rlogin with kerberos)
svc:/network/login:eklogin (rlogin with kerberos and encryption)
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name   in.routed, routed – network routing daemon

Synopsis   /usr/sbin/in.routed [-AdghmnqsStVz] [-T *tracefile* [-v]]
 [-F *net*[/mask][,metric]] [-P *params*]

Description   The daemon in.routed, often referred to as routed, is invoked at boot time to manage the
network routing tables. It uses Routing Information Protocol, RIPv1 (RFC 1058), RIPv2 (RFC
2453), and Internet Router Discovery Protocol (RFC 1256) to maintain the kernel routing
table. The RIPv1 protocol is based on the reference 4.3BSD daemon.

in.routed is managed by means of the service management facility (SMF), using the fault
management resource identifier (FMRI):

svc:/network/routing/route:default

The daemon listens on a udp socket for the route service (see services(4)) for Routing
Information Protocol packets. It also sends and receives multicast Router Discovery ICMP
messages. If the host is a router, in.routed periodically supplies copies of its routing tables to
any directly connected hosts and networks. It also advertises or solicits default routes using
Router Discovery ICMP messages.

When started (or when a network interface is later turned on), in.routed uses an AF_ROUTE
address family facility to find those directly connected interfaces configured into the system
and marked "up". It adds necessary routes for the interfaces to the kernel routing table. Soon
after being first started, and provided there is at least one interface on which RIP has not been
disabled, in.routed deletes all pre-existing non-static routes in the kernel table. Static routes
in the kernel table are preserved and included in RIP responses if they have a valid RIP metric
(see route(1M)).

If more than one interface is present (not counting the loopback interface), it is assumed that
the host should forward packets among the connected networks. After transmitting a RIP
request and Router Discovery Advertisements or Solicitations on a new interface, the daemon
enters a loop, listening for RIP request and response and Router Discovery packets from other
hosts.

When a request packet is received, in.routed formulates a reply based on the information
maintained in its internal tables. The response packet generated contains a list of known
routes, each marked with a "hop count" metric (a count of 16 or greater is considered
"infinite"). Advertised metrics reflect the metric associated with an interface (see
ifconfig(1M)), so setting the metric on an interface is an effective way to steer traffic.

Responses do not include routes with a first hop on the requesting network, to implement in
part split-horizon. Requests from query programs such as rtquery(1M) are answered with the
complete table.

The routing table maintained by the daemon includes space for several gateways for each
destination to speed recovery from a failing router. RIP response packets received are used to

update the routing tables, provided they are from one of the several currently recognized gateways or advertise a better metric than at least one of the existing gateways.

When an update is applied, in.routed records the change in its own tables and updates the kernel routing table if the best route to the destination changes. The change in the kernel routing table is reflected in the next batch of response packets sent. If the next response is not scheduled for a while, a flash update response containing only recently changed routes is sent.

In addition to processing incoming packets, in.routed also periodically checks the routing table entries. If an entry has not been updated for 3 minutes, the entry's metric is set to infinity and marked for deletion. Deletions are delayed until the route has been advertised with an infnite metric to insure the invalidation is propagated throughout the local internet. This is a form of poison reverse.

Routes in the kernel table that are added or changed as a result of ICMP Redirect messages are deleted after a while to minimize black-holes. When a TCP connection suffers a timeout, the kernel tells in.routed, which deletes all redirected routes through the gateway involved, advances the age of all RIP routes through the gateway to allow an alternate to be chosen, and advances of the age of any relevant Router Discovery Protocol default routes.

Hosts acting as internetwork routers gratuitously supply their routing tables every 30 seconds to all directly connected hosts and networks. These RIP responses are sent to the broadcast address on nets that support broadcasting, to the destination address on point-to-point links, and to the router's own address on other networks. If RIPv2 is enabled, multicast packets are sent on interfaces that support multicasting.

If no response is received on a remote interface, if there are errors while sending responses, or if there are more errors than input or output (see netstat(1M)), then the cable or some other part of the interface is assumed to be disconnected or broken, and routes are adjusted appropriately.

The Internet Router Discovery Protocol is handled similarly. When the daemon is supplying RIP routes, it also listens for Router Discovery Solicitations and sends Advertisements. When it is quiet and listening to other RIP routers, it sends Solicitations and listens for Advertisements. If it receives a good Advertisement and it is not multi-homed, it stops listening for broadcast or multicast RIP responses. It tracks several advertising routers to speed recovery when the currently chosen router dies. If all discovered routers disappear, the daemon resumes listening to RIP responses. It continues listening to RIP while using Router Discovery if multi-homed to ensure all interfaces are used.

The Router Discovery standard requires that advertisements have a default "lifetime" of 30 minutes. That means should something happen, a client can be without a good route for 30 minutes. It is a good idea to reduce the default to 45 seconds using -P rdisc_interval=45 on the command line or rdisc_interval=45 in the /etc/gateways file. See gateways(4).

While using Router Discovery (which happens by default when the system has a single network interface and a Router Discover Advertisement is received), there is a single default route and a variable number of redirected host routes in the kernel table. On a host with more than one network interface, this default route will be via only one of the interfaces. Thus, multi-homed hosts running with -q might need the no_rdisc argument described below.

To support "legacy" systems that can handle neither RIPv2 nor Router Discovery, you can use the pm_rdisc parameter in the /etc/gateways. See gateways(4).

By default, neither Router Discovery advertisements nor solicitations are sent over point-to-point links (for example, PPP). The Solaris OE uses a netmask of all ones (255.255.255.255) on point-to-point links.

in.routed supports the notion of "distant" passive or active gateways. When the daemon is started, it reads the file /etc/gateways to find such distant gateways that cannot be located using only information from a routing socket, to discover if some of the local gateways are passive, and to obtain other parameters. Gateways specified in this manner should be marked passive if they are not expected to exchange routing information, while gateways marked active should be willing to exchange RIP packets. Routes through passive gateways are installed in the kernel's routing tables once upon startup and are not included in transmitted RIP responses.

Distant active gateways are treated like network interfaces. RIP responses are sent to the distant active gateway. If no responses are received, the associated route is deleted from the kernel table and RIP responses are advertised via other interfaces. If the distant gateway resumes sending RIP responses, the associated route is restored.

Distant active gateways can be useful on media that do not support broadcasts or multicasts but otherwise act like classic shared media, such as some ATM networks. One can list all RIP routers reachable on the HIPPI or ATM network in /etc/gateways with a series of "host" lines. Note that it is usually desirable to use RIPv2 in such situations to avoid generating lists of inferred host routes.

Gateways marked external are also passive, but are not placed in the kernel routing table, nor are they included in routing updates. The function of external entries is to indicate that another routing process will install such a route if necessary, and that other routes to that destination should not be installed by in.routed. Such entries are required only when both routers might learn of routes to the same destination.

Options Listed below are available options. Any other argument supplied is interpreted as the name of a file in which the actions of in.routed should be logged. It is better to use -T (described below) instead of appending the name of the trace file to the command. Associated SMF properties for these options are described, and can be set by means of a command of the form:

```
# routeadm -m route:default name=value
```

-A

Do not ignore RIPv2 authentication if we do not care about RIPv2 authentication. This option is required for conformance with RFC 2453. However, it makes no sense and breaks using RIP as a discovery protocol to ignore all RIPv2 packets that carry authentication when this machine does not care about authentication. This option is equivalent to setting the ignore_auth property value to false.

-d

Do not run in the background. This option is meant for interactive use and is not usable under the SMF.

-F net[/*mask*][,*metric*]

Minimize routes in transmissions via interfaces with addresses that match *net* (network number)/*mask* (netmask), and synthesizes a default route to this machine with the *metric*. The intent is to reduce RIP traffic on slow, point-to-point links, such as PPP links, by replacing many large UDP packets of RIP information with a single, small packet containing a "fake" default route. If *metric* is absent, a value of 14 is assumed to limit the spread of the "fake" default route. This is a dangerous feature that, when used carelessly, can cause routing loops. Notice also that more than one interface can match the specified network number and mask. See also -g. Use of this option is equivalent to setting the minimize_routes property.

-g

Used on internetwork routers to offer a route to the "default" destination. It is equivalent to -F 0/0,1 and is present mostly for historical reasons. A better choice is -P pm_rdisc on the command line or pm_rdisc in the /etc/gateways file. A larger metric will be used with the latter alternatives, reducing the spread of the potentially dangerous default route. The -g (or -P) option is typically used on a gateway to the Internet, or on a gateway that uses another routing protocol whose routes are not reported to other local routers. Note that because a metric of 1 is used, this feature is dangerous. Its use more often creates chaos with a routing loop than solves problems. Use of this option is equivalent to setting the offer_default_route property to true.

-h

Causes host or point-to-point routes not to be advertised, provided there is a network route going the same direction. That is a limited kind of aggregation. This option is useful on gateways to LANs that have other gateway machines connected with point-to-point links such as SLIP. Use of this option is equivalent to setting the advertise_host_routes property to false.

-m

Cause the machine to advertise a host or point-to-point route to its primary interface. It is useful on multi-homed machines such as NFS servers. This option should not be used except when the cost of the host routes it generates is justified by the popularity of the server. It is effective only when the machine is supplying routing information, because there is more than one interface. The -m option overrides the -q option to the limited extent

of advertising the host route. Use of this option is equivalent to setting the
advertise_host_routes_primary property to true.

-n

Do not install routes in kernel. By default, routes are installed in the kernel. Use of this
option is equivalent to setting the install_routes property to false.

-P *params*

Equivalent to adding the parameter line *params* to the /etc/gateways file. Can also be set
by means of the parameters property.

-q

Opposite of the -s option. This is the default when only one interface is present. With this
explicit option, the daemon is always in "quiet mode" for RIP and does not supply routing
information to other computers. Use of this option is equivalent to setting the quiet_mode
property to true.

-s

Force in.routed to supply routing information. This is the default if multiple network
interfaces are present on which RIP or Router Discovery have not been disabled, and if
global IPv4 forwarding is turned on (by means of ipadm(1M)). Use of this option is
equivalent to setting the supply_routes property to true.

-S

If in.routed is not acting as an internetwork router, instead of entering the whole routing
table in the kernel, it enters only a default route for each internetwork router. This reduces
the memory requirements without losing any routing reliability. This option is provided
for compatibility with the previous, RIPv1–only in.routed. Use of this option is generally
discouraged. Use of this option is equivalent to setting the default_routes_only property
to true.

-t

Runs in the foreground (as with -d) and logs the contents of the packets received (as with
-zz). This is for compatibility with prior versions of Solaris and has no SMF equivalent.

-T *tracefile*

Increases the debugging level to at least 1 and causes debugging information to be
appended to the trace file. Because of security concerns, do not to run in.routed routinely
with tracing directed to a file. Use of this option is equivalent to setting the log_file
property to trace file path.

-v

Enables debug. Similar to -z, except, where -z increments trace_level, -v sets
trace_level to 1. Also, -v requires the -T option. Use of this option is equivalent to setting
the debug property to true.

-V

Displays the version of the daemon.

-z

Increase the debugging level, which causes more information to be logged on the tracefile
specified with -T or stdout. The debugging level can be increased or decreased with the
SIGUSR1 or SIGUSR2 signals or with the rtquery(1M) command.

Files /etc/defaultrouter   If this file is present and contains the address of a default router, the
system startup script does not run in.routed. See
defaultrouter(4).

/etc/gateways   List of distant gateways and general configuration options for
in.routed. See gateways(4).

Internet Transport Protocols, XSIS 028112, Xerox System Integration Standard

Routing Information Protocol, v2 (RFC 2453, STD 0056, November 1998)

RIP-v2 MD5 Authentication (RFC 2082, January 1997)

Routing Information Protocol, v1 (RFC 1058, June 1988)

ICMP Router Discovery Messages (RFC 1256, September 1991)

Notes In keeping with its intended design, this daemon deviates from RFC 2453 in two notable ways:

- By default, in.routed does not discard authenticated RIPv2 messages when RIP
  authentication is not configured. There is little to gain from dropping authenticated
  packets when RIPv1 listeners will gladly process them. Using the -A option causes
  in.routed to conform to the RFC in this case.

- Unauthenticated RIP requests are never discarded, even when RIP authentication is
  configured. Forwarding tables are not secret and can be inferred through other means such
  as test traffic. RIP is also the most common router-discovery protocol, and hosts need to
  send queries that will be answered.

in.routed does not always detect unidirectional failures in network interfaces, for example,
when the output side fails.

Name   in.rshd, rshd – remote shell server

Synopsis   in.rshd [-k5eciU] [-s *tos*] [-S *keytab*] [-M *realm*]
               [-L *env_var*] *host.port*

Description   in.rshd is the server for the rsh(1) program. The server provides remote execution facilities with authentication based on Kerberos V5 or privileged port numbers.

in.rshd is invoked by inetd(1M) each time a shell service is requested.

When Kerberos V5 authentication is required (this can be set with Kerberos-specific options listed below), the following protocol is initiated:

1. Check Kerberos V5 authentication.

2. Check authorization according to rules in krb5_auth_rules(5).

3. A null byte is returned on the initial socket and the command line is passed to the normal login shell of the user. (The PATH variable is set to /usr/bin.) The shell inherits the network connections established by in.rshd.

In order for Kerberos authentication to work, a host/<*FQDN*> Kerberos principal must exist for each Fully Qualified Domain Name associated with the in.rshd server. Each of these host/<*FQDN*> principals must have a keytab entry in the /etc/krb5/krb5.keytab file on the in.rshd server. An example principal might be:

host/bigmachine.eng.example.com

See kadmin(1M) or gkadmin(1M) for instructions on adding a principal to a krb5.keytab file. See *Oracle Solaris Administration: Security Services* for a discussion of Kerberos authentication.

If Kerberos V5 authentication is not enabled, then in.rshd executes the following protocol:

1. The server checks the client's source port. If the port is not in the range 512-1023, the server aborts the connection. The client's host address (in hex) and port number (in decimal) are the arguments passed to in.rshd.

2. The server reads characters from the socket up to a null (\\0) byte. The resultant string is interpreted as an ASCII number, base 10.

3. If the number received in step 2 is non-zero, it is interpreted as the port number of a secondary stream to be used for the stderr. A second connection is then created to the specified port on the client's machine. The source port of this second connection is also in the range 512-1023.

4. A null-terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as the user identity on the *client*'s machine.

5. A null terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as a user identity to use on the *server*'s machine.

6. A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the system's argument list.

7. `in.rshd` then validates the user according to the following steps. The remote user name is looked up in the password file and a `chdir` is performed to the user's home directory. If the lookup fails, the connection is terminated. If the `chdir` fails, it does a `chdir` to / (root). If the user is not the superuser, (user ID 0), and if the pam_rhosts_auth PAM module is configured for authentication, the file `/etc/hosts.equiv` is consulted for a list of hosts considered "equivalent". If the client's host name is present in this file, the authentication is considered successful. See the SECURITY section below for a discussion of PAM authentication.

If the lookup fails, or the user is the superuser, then the file `.rhosts` in the home directory of the remote user is checked for the machine name and identity of the user on the client's machine. If this lookup fails, the connection is terminated

8. A null byte is returned on the initial connection and the command line is passed to the normal login shell of the user. The `PATH` variable is set to `/usr/bin`. The shell inherits the network connections established by `in.rshd`.

Options The following options are supported:

-5   Same as `-k`, for backwards compatibility

-c   Requires Kerberos V5 clients to present a cryptographic checksum of initial connection information like the name of the user that the client is trying to access in the initial authenticator. This checksum provides additionl security by preventing an attacker from changing the initial connection information. This option is mutually exclusive with the `-i` option.

-e   Requires the client to encrypt the connection.

-i   Ignores authenticator checksums if provided. This option ignores authenticator checksums presented by current Kerberos clients to protect initial connection information. Option `-i` is the opposite of option `-c`.

-k   Allows Kerberos V5 authentication with the `.k5login` access control file to be trusted. If this authentication system is used by the client and the authorization check is passed, then the user is allowed to log in.

-L *env_var*   List of environment variables that need to be saved and passed along.

-M *realm*   Uses the indicated Kerberos V5 realm. By default, the daemon will determine its realm from the settings in the `krb5.conf(4)` file.

-s *tos*   Sets the `IP TOS` option.

-S *keytab*   Sets the `KRB5` keytab file to use. The `/etc/krb5/krb5.keytab` file is used by default.

-U	Refuses connections that cannot be mapped to a name through the getnameinfo(3SOCKET) function.	

Usage rshd and in.rshd are IPv6–enabled. See ip6(7P). IPv6 is not currently supported with Kerberos V5 authentication.

The Kerberized rshd service runs on port 544 (kshell). The corresponding FMRI entry is: :

```
svc:/network/shell:kshell (rshd with kerberos (ipv4 only))
```

Security in.rshd uses pam(3PAM) for authentication, account management, and session management. The PAM configuration policy, listed through /etc/pam.conf, specifies the modules to be used for in.rshd. Here is a partial pam.conf file with entries for the rsh command using rhosts authentication, UNIX account management, and session management module.

rsh	auth	required	pam_rhosts_auth.so.1
rsh	account	required	pam_unix_roles.so.1
rsh	session	required	pam_unix_projects.so.1
rsh	session	required	pam_unix_account.so.1
rsh	session	required	pam_unix_session.so.1

If there are no entries for the rsh service, then the entries for the "other" service are used. To maintain the authentication requirement for in.rshd, the rsh entry must always be configured with the pam_rhosts_auth.so.1 module.

in.rshd can authenticate using Kerberos V5 authentication or pam(3PAM). For Kerberized rsh service, the appropriate PAM service name is krsh.

Files /etc/hosts.equiv

$HOME/.k5login   File containing Kerberos principals that are allowed access.

/etc/krb5/krb5.conf   Kerberos configuration file.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

See Also   rsh(1), svcs(1), gkadmin(1M), inetadm(1M), inetd(1M), kadmin(1M), svcadm(1M), pam(3PAM), getnameinfo(3SOCKET), hosts(4), krb5.conf(4), pam.conf(4), attributes(5), environ(5), krb5_auth_rules(5), pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_rhosts_auth(5), pam_unix_account(5), pam_unix_auth(5), pam_unix_session(5), smf(5), ip6(7P)

Oracle Solaris Administration: Security Services

Diagnostics   The following diagnostic messages are returned on the connection associated with stderr, after which any network connections are closed. An error is indicated by a leading byte with a value of 1 in step 8 above (0 is returned above upon successful completion of all the steps prior to the command execution).

`locuser too long`	The name of the user on the client's machine is longer than 16 characters.
`remuser too long`	The name of the user on the remote machine is longer than 16 characters.
`command too long`	The command line passed exceeds the size of the argument list (as configured into the system).
`Hostname for your address unknown.`	No entry in the host name database existed for the client's machine.
`Login incorrect.`	No password file entry for the user name existed.
`Permission denied.`	The authentication procedure described above failed.
`Can't make pipe.`	The pipe needed for the stderr was not created.
`Try again.`	A *fork* by the server failed.

Notes   The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but it is useful in an "open" environment.

A facility to allow all data exchanges to be encrypted should be present.

The in.rshd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/shell:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name   in.rwhod, rwhod – system status server

Synopsis   /usr/sbin/in.rwhod [-m [*ttl*]]

Description   in.rwhod is the server which maintains the database used by the rwho(1) and ruptime(1) programs. Its operation is predicated on the ability to broadcast or multicast messages on a network.

in.rwhod operates as both a producer and consumer of status information. As a producer of information it periodically queries the state of the system and constructs status messages which are broadcast or multicast on a network. As a consumer of information, it listens for other in.rwhod servers' status messages, validating them, then recording them in a collection of files located in the directory /var/spool/rwho.

The rwho server transmits and receives messages at the port indicated in the rwho service specification, see services(4). The messages sent and received are defined in /usr/include/protocols/rwhod.h and are of the form:

```
struct  outmp {
        char    out_line[8];   /* tty name */
        char    out_name[8];   /* user id */
        long    out_time;      /* time on */
};
struct  whod {
        char    wd_vers;
        char    wd_type;
        char    wd_fill[2];
        int     wd_sendtime;
        int     wd_recvtime;
        char    wd_hostname[32];
        int     wd_loadav[3];
        int     wd_boottime;
        struct  whoent {
                struct  outmp we_utmp;
                int     we_idle;
        } wd_we[1024 / sizeof (struct whoent)];
 };
```

All fields are converted to network byte order prior to transmission. The load averages are as calculated by the w(1) program, and represent load averages over the 1, 5, and 15 minute intervals prior to a server's transmission. The host name included is that returned by the uname(2) system call. The array at the end of the message contains information about the users who are logged in to the sending machine. This information includes the contents of the utmpx(4) entry for each non-idle terminal line and a value indicating the time since a character was last received on the terminal line.

Messages received by the rwho server are discarded unless they originated at a rwho server's port. In addition, if the host's name, as specified in the message, contains any unprintable ASCII characters, the message is discarded. Valid messages received by in.rwhod are placed in files named whod.hostname in the directory /var/spool/rwho. These files contain only the most recent message, in the format described above.

Status messages are generated approximately once every 3 minutes.

Options The following options are supported:

-m [*ttl*]   Use the rwho IP multicast address (224.0.1.3) when transmitting. Receive announcements both on this multicast address and on the IP broadcast address. If *ttl* is not specified in.rwhod multicasts on all interfaces but with the IP TimeToLive set to 1 (that is, packets are not forwarded by multicast routers.) If *ttl* is specified in.rwhod only transmits packets on one interface and setting the IP TimeToLive to the specified *ttl*.

Files /var/spool/rwho/whod.*   information about other machines

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

See Also ruptime(1), rwho(1), w(1), uname(2), services(4), utmpx(4), attributes(5)

Warnings This service can cause network performance problems when used by several hosts on the network. It is not run at most sites by default. If used, include the -m multicast option.

Notes This service takes up progressively more network bandwidth as the number of hosts on the local net increases. For large networks, the cost becomes prohibitive.

in.rwhod should relay status information between networks. People often interpret the server dying as a machine going down.

Name install – install commands

Synopsis /usr/sbin/install -c *dira* [-m *mode*] [-u *user*] [-g *group*]
        [-o] [-s] *file*

/usr/sbin/install -f *dirb* [-m *mode*] [-u *user*] [-g *group*]
        [-o] [-s] *file*

/usr/sbin/install -n *dirc* [-m *mode*] [-u *user*] [-g *group*]
        [-o] [-s] *file*

/usr/sbin/install -d | -i [-m *mode*] [-u *user*] [-g *group*]
        [-o] [-s] *dirx*...

/usr/sbin/install [-m *mode*] [-u *user*] [-g *group*] [-o] [-s] *file*
        [*dirx*]...

Description install is most commonly used in "makefiles" (see make(1S)) to install a file in specific
locations, or to create directories within a file system. Each file is installed by copying it into
the appropriate directory.

install uses no special privileges to copy files from one place to another. The implications of
this are:

- You must have permission to read the files to be installed.

- You must have permission to copy into the destination directory.

- You must have permission to change the modes on the final copy of the file if you want to
  use the -m option.

- You must be super-user if you want to specify the ownership of the installed file with the -u
  or -g options. If you are not the super-user, the installed file is owned by you, regardless of
  who owns the original.

Note that if the ROOT environment variable is set, each of the default directory paths are
prefixed by its value (for example, $ROOT/bin and so on).

install prints messages telling the user exactly what files it is replacing or creating and where
they are going.

If no options or directories (*dirx*...) are given, install searches a set of default directories (
/bin, /usr/bin, /etc, /lib, and /usr/lib, in that order) for a file with the same name as
file. When the first occurrence is found, install issues a message saying that it is
overwriting that file with file, and proceeds to do so. If the file is not found, the program
states this and exits.

If one or more directories (*dirx*...) are specified after file, those directories are searched
before the default directories.

This version of install (/usr/sbin/install) is not compatible with the install binaries in
many versions of Unix other than Solaris. For a higher degree of compatibility with other Unix
versions, use /usr/ucb/install, which is described in the install(1B) man page.

Options The following options are supported:

-c *dira*   Install file in the directory specified by *dira*, if file does not yet exist. If it is found, install issues a message saying that the file already exists, and exits without overwriting it.

-f *dirb*   Force file to be installed in given directory, even if the file already exists. If the file being installed does not already exist, the mode and owner of the new file is set to 755 and bin , respectively. If the file already exists, the mode and owner is that of the already existing file.

-n *dirc*   If file is not found in any of the searched directories, it is put in the directory specified in *dirc*. The mode and owner of the new file is set to 755 and bin, respectively.

-d   Create a directory. Missing parent directories are created as required as in mkdir -p. If the directory already exists, the owner, group and mode is set to the values given on the command line.

-i   Ignore default directory list, searching only through the given directories (*dirx* . . .).

-m *mode*   The mode of the new file is set to *mode*. Set to 0755 by default.

-u *user*   The owner of the new file is set to *user*. Only available to the super-user. Set to bin by default.

-g *group* The group id of the new file is set to *group*. Only available to the super-user. Set to bin by default.

-o   If file is found, save the "found" file by copying it to OLDfile in the directory in which it was found. This option is useful when installing a frequently used file such as /bin/sh or /lib/saf/ttymon, where the existing file cannot be removed.

-s   Suppress printing of messages other than error messages.

Usage See largefile(5) for the description of the behavior of install when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also chgrp(1), chmod(1), chown(1), cp(1), install(1B), make(1S), mkdir(1), attributes(5), largefile(5)

Name installboot – install bootblocks in a disk partition

Synopsis `installboot [-F zfs|ufs|hsfs] *bootblk* *raw-disk-device*`

Description The boot(1M) program, `ufsboot`, is loaded from disk by the bootblock program which resides in the boot area of a disk partition. This program is filesystem-specific, and must match the type of filesystem on the disk to be booted.

The boot objects are platform-dependent and reside in the `/usr/platform/*platform-name*/lib/fs/*file-system*` directory. The platform name can be found using the `-i` option of uname(1). The filesystem type can be found using:

`% fstyp *raw-disk-device*`

See fstyp(1M).

The `installboot` utility is a SPARC only program. It is not supported on the x86 architecture. x86 users should use installgrub(1M) instead.

Options The following option is supported:

`-F zfs|ufs|hsfs`
Specifies the file system type of the boot block to be installed. Required if you wish to specify `zfs` or `hsfs`. The default is `ufs`.

Operands *bootblk*
The name of the bootblock code.

raw-disk-device
The name of the disk device onto which the bootblock code is to be installed; it must be a character device which is readable and writable. Naming conventions for a SCSI or IPI drive are `c?t?d?s?` and `c?d?s?` for an IDE drive.

Examples EXAMPLE 1   Installing UFS Boot Block

To install a `ufs` boot block on slice 0 of target 0 on controller 1 of the platform where the command is being run, use:

```
# installboot /usr/platform/'uname -i'/lib/fs/ufs/bootblk \
    /dev/rdsk/c1t0d0s0
```

EXAMPLE 2   Installing ZFS Boot Block

To install a ZFS boot block on slice 0 of target 0 on controller 1 of the platform where the command is being run, use syntax such as the following:

```
# installboot -F zfs /usr/platform/'uname -i'/lib/fs/zfs/bootblk \
    /dev/rdsk/c1t1d0s0
```

Files /usr/platform/*platform-name*/lib/fs/   Directory where boot objects reside.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also kmdb(1), od(1), uname(1), boot(1M), fstyp(1M), init(1M), kernel(1M), monitor(1M), reboot(1M), rpc.bootparamd(1M), init.d(4), attributes(5)

Installing Oracle Solaris 11 Systems

Warnings The installboot utility fails if the *bootblk* or *openfirmware* files do not exist or if the raw disk device is not a character device.

Name installf – add a file to the software installation database

Synopsis installf [-c *class*] [[-M] -R *root_path*] [-V *fs_file*] *pkginst pathname*
            [*ftype* [*major minor*] [*mode owner group*]]

installf [-c *class*] [[-M] -R *root_path*] [-V *fs_file*] *pkginst* –

installf -f [-c *class*] [[-M] -R *root_path*] [-V *fs_file*] *pkginst*

Description installf informs the system that a pathname not listed in the pkgmap(4) file is being created
or modified. It should be invoked before any file modifications have occurred.

When the second synopsis is used, the pathname descriptions will be read from standard
input. These descriptions are the same as would be given in the first synopsis but the
information is given in the form of a list. The descriptions should be in the form:

pathname [*ftype* [*major minor*] [*mode owner group*]]

After all files have been appropriately created and/or modified, installf should be invoked
with the -f synopsis to indicate that installation is final. Links will be created at this time and,
if attribute information for a pathname was not specified during the original invocation of
installf, or was not already stored on the system, the current attribute values for the
pathname will be stored. Otherwise, installf verifies that attribute values match those given
on the command line, making corrections as necessary. In all cases, the current content
information is calculated and stored appropriately.

Package commands are largefile(5)-aware. They handle files larger than 2 GB in the same
way they handle smaller files. In their current implementations, pkgadd(1M), pkgtrans(1)
and other package commands can process a datastream of up to 4 GB.

Options   -c *class*   Class to which installed objects should be associated. Default class is none.

        -f   Indicates that installation is complete. This option is used with the final
                    invocation of installf (for all files of a given class).

        -M   Instruct installf not to use the $*root_path*/etc/vfstab file for
                    determining the client's mount points. This option assumes the mount
                    points are correct on the server and it behaves consistently with Solaris 2.5
                    and earlier releases.

        -R *root_path*   Define the full path name of a directory to use as the *root_path*. All files,
                    including package system information files, are relocated to a directory tree
                    starting in the specified *root_path*. The *root_path* can be specified when
                    installing to a client from a server (for example, /export/root/client1).

                    installf inherits the value of the PKG_INSTALL_ROOT environment variable.
                    (See ENVIRONMENT VARIABLES, below.) If PKG_INSTALL_ROOT is set,
                    such as when the -R option is used with pkgadd(1M) or pkgrm(1M)

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-V *fs_file*   Specify an alternative *fs_file* to map the client's file systems. For example, used in situations where the $*root_path*/etc/vfstab file is non-existent or unreliable.

Operands   *pkginst*   Name of package instance with which the pathname should be associated.

pathname   Pathname that is being created or modified.

ftype   A one-character field that indicates the file type. Possible file types include:

b   block special device

c   character special device

d   directory

e   a file to be edited upon installation or removal

f   a standard executable or data file

l   linked file

p   named pipe

s   symbolic link

v   volatile file (one whose contents are expected to change)

x   an exclusive directory

major   The major device number. The field is only specified for block or character special devices.

minor   The minor device number. The field is only specified for block or character special devices.

mode   The octal mode of the file (for example, 0664). A question mark (?) indicates that the mode will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.

owner   The owner of the file (for example, bin or root). The field is limited to 14 characters in length. A question mark (?) indicates that the owner will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.

group   The group to which the file belongs (for example, bin or sys). The field is limited to 14 characters in length. A question mark (?) indicates that the group will be left unchanged, implying that the file already exists on the target

machine. This field is not used for linked or symbolically linked files.

Examples EXAMPLE 1 Basic Usage

The following example shows the use of `installf`, invoked from an optional pre-install or post-install script:

```
# create /dev/xt directory
# (needs to be done before drvinstall)
installf $PKGINST /dev/xt d 755 root sys ||
    exit 2
majno='/usr/sbin/drvinstall -m /etc/master.d/xt
    -d $BASEDIR/data/xt.o -v1.0' ||
    exit 2
i=00
while [ $i —lt $limit ]
do
    for j in 0 1 2 3 4 5 6 7
    do
        echo /dev/xt$i$j c $majno 'expr $i ? 8 + $j'
                644 root sys |
        echo /dev/xt$i$j=/dev/xt/$i$j
    done
    i='expr $i + 1'
    [ $i —le 9 ] && i="0$i" #add leading zero
done | installf $PKGINST — || exit 2
# finalized installation, create links
installf -f $PKGINST || exit 2
```

Environment Variables `installf` inherits the value of the following environment variable. This variable is set when pkgadd(1M) or pkgrm(1M) is invoked with the `-R` option.

PKG_INSTALL_ROOT   If present, defines the full path name of a directory to use as the system's PKG_INSTALL_ROOT path. All product and package information files are then looked for in the directory tree, starting with the specified PKG_INSTALL_ROOT path. If not present, the default system path of / is used.

Exit Status 0   Successful operation.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also pkginfo(1), pkgmk(1), pkgparam(1), pkgproto(1), pkgtrans(1), pkgadd(1M), pkgask(1M), pkgchk(1M), pkgrm(1M), removef(1M), pkgmap(4), space(4), attributes(5), largefile(5)

Application Packaging Developer's Guide

Notes When *ftype* is specified, all applicable fields, as shown below, must be defined:

ftype	Required Fields
p, x, d, f, v, or e	mode owner group
c or b	major minor mode owner group

The installf command will create directories, named pipes and special devices on the original invocation. Links are created when installf is invoked with the -f option to indicate installation is complete.

Links should be specified as *path1=path2*. *path1* indicates the destination and *path2* indicates the source file.

Files installed with installf will be placed in the class none, unless a class is defined with the command. Subsequently, they will be removed when the associated package is deleted. If this file should not be deleted at the same time as the package, be certain to assign it to a class which is ignored at removal time. If special action is required for the file before removal, a class must be defined with the command and an appropriate class action script delivered with the package.

When classes are used, installf must be used in one of the following forms:

```
installf -c class1 . . .
installf -f -c class1 . . .
installf -c class2 . . .
installf -f -c class2 . . .
```

Name   installgrub – install GRUB in a disk partition

Synopsis `/usr/sbin/installgrub [-fm]` *stage1 stage2 raw-device*

Description The `installgrub` command is an x86–only program. GRUB stands for GRand Unified
Bootloader.

installgrub installs GRUB stage 1 and stage 2 files on the boot area of a disk partition. If you
specify the -m option, installgrub installs the stage 1 file on the master boot sector of the
disk.

Options The installgrub command accepts the following options:

-f   Suppresses interaction when overwriting the master boot sector.

-m   Installs GRUB *stage1* on the master boot sector interactively. You must use this option
       if Solaris is installed on an extended partition.

Operands The installgrub command accepts the following operands:

stage1   The name of the GRUB stage 1 file.

stage2   The name of the GRUB stage 2 file.

raw-device   The name of the device onto which GRUB code is to be installed. It must be a
               character device that is readable and writable. For disk devices, specify the slice
               where the GRUB menu file is located. (For Solaris it is the root slice.)

Examples EXAMPLE 1   Installing GRUB on a Hard Disk Slice

The following command installs GRUB on a system where the root slice is c0d0s0:

```
example# /usr/sbin/installgrub /boot/grub/stage1 \
         /boot/grub/stage2 /dev/rdsk/c0d0s0
```

Files /boot/grub   Directory where GRUB files reside.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Uncommitted

See Also boot(1M), fdisk(1M), fmthard(1M), kernel(1M), attributes(5)

Warnings Installing GRUB on the master boot sector (-m option) overrides any boot manager currently
installed on the machine. The system will always boot the GRUB in the Solaris partition
regardless of which fdisk partition is active.

Name in.stdiscover – Service Tag Discovery Daemon

Synopsis /usr/lib/inet/in.stdiscover

Description The in.stdiscover daemon allows a mechanism for discovering the location of the Service Tag Listener. By default, the in.stdiscover daemon listens for discovery probes (using a minimal built-in protocol) on UDP port 6481.

The daemon is under control of the service management facility, smf(5), under its inetd framework. It only runs upon demand and exits when no longer in use.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/management/service-tag
Interface Stability	Private

See Also in.stlisten(1M), stclient(1M)

Name in.stlisten – Service Tag Listener

Synopsis /usr/lib/inet/in.stlisten

Description The in.stlisten daemon allows a mechanism for discovering the location of the Service Tag. By default, the in.stlisten daemon listens for discovery probes (using a minimal built-in protocol) on TCP port 6481.

The daemon is under control of the service management facility, smf(5), under its inetd framework. It only runs upon demand and exits when no longer in use.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/management/service-tag
Interface Stability	Private

See Also in.stdiscover(1M), stclient(1M), svccfg(1M), attributes(5), environ(5), smf(5)

Notes In open networks where the participants may not always be trusted, it is recommended that you deploy this daemon with the passphrase-encryption option. In smf(5) environments, the following command can be used to set the *passphrase*:

```
< prepare a text file "passfile" containing the passphrase >
# chown svctag:daemon passfile
# chmod 600 passfile
svccfg -s svc:/network/stlisten \
        setprop servicetag/passphrase=passfile
```

where *passfile* is the path of a file containing the intended *passphrase*.

This *passphrase* can be subsequently cleared as follows:

```
svccfg -s svc:/network/stlisten \
        setprop servicetag/passphrase=""
```

Name   in.talkd, talkd – server for talk program

Synopsis   in.talkd

Description   talkd is a server used by the talk(1) program. It listens at the UDP port indicated in the "talk" service description; see services(4). The actual conversation takes place on a TCP connection that is established by negotiation between the two machines involved.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

See Also   svcs(1), talk(1), inetadm(1M), inetd(1M), svcadm(1M), services(4), attributes(5), smf(5)

Notes   The protocol is architecture dependent.

The in.talkd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/talk

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name   in.telnetd, telnetd – DARPA TELNET protocol server

Synopsis   /usr/sbin/in.telnetd [-a *authmode*] [-EXUh] [-s *tos*]
          [-S *keytab*] [-M *realm*]

Description   in.telnetd is a server that supports the DARPA standard TELNET virtual terminal protocol.
in.telnetd is normally invoked in the internet server (see inetd(1M)), for requests to
connect to the TELNET port as indicated by the /etc/services file (see services(4)).

in.telnetd operates by allocating a pseudo-terminal device for a client, then creating a login
process which has the slave side of the pseudo-terminal as its standard input, output, and
error. in.telnetd manipulates the master side of the pseudo-terminal, implementing the
TELNET protocol and passing characters between the remote client and the login process.

When a TELNET session starts up, in.telnetd sends TELNET options to the client side
indicating a willingness to do *remote* echo of characters, and to *suppress go ahead*. The
pseudo-terminal allocated to the client is configured to operate in "cooked" mode, and with
XTABS, ICRNL and ONLCR enabled. See termio(7I).

in.telnetd is willing to do: *echo*, *binary*, *suppress go ahead*, and *timing mark*. in.telnetd is
willing to have the remote client do: *binary*, *terminal type*, *terminal size*, *logout option*, and
suppress go ahead.

in.telnetd also allows environment variables to be passed, provided that the client negotiates
this during the initial option negotiation. The DISPLAY environment variable may be sent
this way, either by the TELNET general environment passing methods, or by means of the
XDISPLOC TELNET option. DISPLAY can be passed in the environment option during the
same negotiation where XDISPLOC is used. Note that if you use both methods, use the same
value for both. Otherwise, the results may be unpredictable.

These options are specified in Internet standards *RFC 1096*, *RFC 1408*, *RFC 1510*, *RFC 1571*,
RFC 2941, *RFC 2942*, *RFC 2946*, and *RFC 1572*. The following Informational draft is also
supported: *RFC 2952*.

The banner printed by in.telnetd is configurable. The default is (more or less) equivalent to
'uname -sr' and will be used if no banner is set in /etc/default/telnetd. To set the banner,
add a line of the form

BANNER="..."

to /etc/default/telnetd. Nonempty banner strings are fed to shells for evaluation. The
default banner may be obtained by

BANNER="\\r\\n\\r\\n'uname -s' 'uname -r'\\r\\n\\r\\n"

and no banner will be printed if /etc/default/telnetd contains

BANNER=""

Options The following options are supported:

-a *authmode*   This option may be used for specifying what mode should be used for authentication. There are several valid values for *authmode*:

valid   Only allows connections when the remote user can provide valid authentication information to identify the remote user, and is allowed access to the specified account without providing a password.

user   Only allows connections when the remote user can provide valid authentication information to identify the remote user. The login(1) command will provide any additional user verification needed if the remote user is not allowed automatic access to the specified account.

none   This is the default state. Authentication information is not required. If no or insufficient authentication information is provided, then the login(1) program provides the necessary user verification.

off   This disables the authentication code. All user verification happens through the login(1) program.

-E   Disables encryption support negotiation.

-h   Disables displaying host specific information before login has been completed.

-M *realm*   Uses the indicated Kerberos V5 realm. By default, the daemon will determine its realm from the settings in the krb5.conf(4) file.

-s *tos*   Sets the IP TOS option.

-S *keytab* Sets the KRB5 keytab file to use. The/etc/krb5/krb5.keytab file is used by default.

-U   Refuses connections that cannot be mapped to a name through the getnameinfo(3SOCKET) function.

-X   Disables Kerberos V5 authentication support negotiation.

Usage telnetd and in.telnetd are IPv6–enabled. See ip6(7P).

Security in.telnetd can authenticate using Kerberos V5 authentication, pam(3PAM), or both. By default, the telnet server will accept valid Kerberos V5 authentication credentials from a telnet client that supports Kerberos. in.telnetd can also support an encrypted session from such a client if the client requests it.

The `telnet` protocol only uses single DES for session protection—clients request service tickets with single DES session keys. The KDC must know that host service principals that offer the `telnet` service support single DES, which, in practice, means that such principals must have single DES keys in the KDC database.

In order for Kerberos authentication to work, a `host/<FQDN>` Kerberos principal must exist for each Fully Qualified Domain Name associated with the `telnetd` server. Each of these `host/<FQDN>` principals must have a keytab entry in the `/etc/krb5/krb5.keytab` file on the `telnetd` server. An example principal might be:

```
host/bigmachine.eng.example.com
```

See kadmin(1M) or gkadmin(1M) for instructions on adding a principal to a `krb5.keytab` file. See *Oracle Solaris Administration: Security Services* for a discussion of Kerberos authentication.

`in.telnetd` uses pam(3PAM) for authentication, account management, session management, and password management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `in.telnetd`. Here is a partial `pam.conf` file with entries for the `telnet` command using the UNIX authentication, account management, session management, and password management modules.

```
telnet  auth requisite          pam_authtok_get.so.1
telent  auth required           pam_dhkeys.so.1
telent  auth required           pam_unix_auth.so.1

telnet  account requisite       pam_roles.so.1
telnet  account required        pam_projects.so.1
telnet  account required        pam_unix_account.so.1

telnet  session required        pam_unix_session.so.1

telnet  password required       pam_dhkeys.so.1
telent  password requisite      pam_authtok_get.so.1
telnet  password requisite      pam_authtok_check.so.1
telnet  password required       pam_authtok_store.so.1
```

If there are no entries for the `telnet` service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.

For a Kerberized telnet service, the correct PAM service name is `ktelnet`.

Files ▪ `/etc/default/telnetd`

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/telnet

See Also   login(1), svcs(1), telnet(1), gkadmin(1M), inetadm(1M), inetd(1M), kadmin(1M), svcadm(1M), pam(3PAM), getnameinfo(3SOCKET), issue(4), krb5.conf(4), pam.conf(4), services(4), attributes(5), pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), pam_unix_session(5), smf(5), ip6(7P), termio(7I)

Ts'o, T., *Telnet Encryption: DES 64 bit Cipher Feedback, RFC 2952*. September 2000.

Notes   Some TELNET commands are only partially implemented.

Binary mode has no common interpretation except between similar operating systems.

The terminal type name received from the remote client is converted to lower case.

The *packet* interface to the pseudo-terminal should be used for more intelligent flushing of input and output queues.

in.telnetd never sends TELNET *go ahead* commands.

The in.telnetd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/telnet

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name in.tftpd, tftpd – Internet Trivial File Transfer Protocol server

Synopsis in.tftpd [-d] [-T *rexmtval*] [-s] [*homedir*]

Description tftpd is a server that supports the Internet Trivial File Transfer Protocol (TFTP).

Before responding to a request, the server attempts to change its current directory to *homedir*; the default directory is /tftpboot.

The use of tftp does not require an account or password on the remote system. Due to the lack of authentication information, in.tftpd will allow only publicly readable files to be accessed. Files may be written only if they already exist and are publicly writable. Note that this extends the concept of "public" to include all users on all hosts that can be reached through the network. This may not be appropriate on all systems, and its implications should be considered before enabling this service.

in.tftpd runs with the user ID and group ID set to [GU]ID_NOBODY under the assumption that no files exist with that owner or group. However, nothing checks this assumption or enforces this restriction.

Options -d   Debug. When specified it sets the SO_DEBUG socket option.

-s   Secure. When specified, the directory change to *homedir* must succeed. The daemon also changes its root directory to *homedir*.

-T *rexmtval*   Specifies the value of the retransmission timeout in seconds. This also affects the maximum session timeout in that the latter is set to five times the retransmission timeout value.

Usage The in.tftpd server is IPv6–enabled. See ip6(7P).

in.tftpd supports transfers of greater than 32 MB, per RFC 2348.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/tftp

See Also svcs(1), tftp(1), inetadm(1M), inetd(1M), svcadm(1M), netconfig(4), attributes(5), smf(5), ip6(7P)

Malkin, G. and Harkin, A. *RFC 2347, TFTP Option Extension*. The Internet Society. May 1998

Malkin, G. and Harkin, A. *RFC 2348, TFTP Blocksize Option*. The Internet Society. May 1998

Malkin, G. and Harkin, A. *RFC 2349, TFTP Timeout Interval and Transfer Size Options*. The Internet Society. May 1998

Sollins, K.R. *RFC 1350, The TFTP Protocol (Revision 2)*. Network Working Group. July 1992.

Notes   The tftpd server only acknowledges the transfer size option that is sent with a read request when the octet transfer mode is specified.

The in.tftpd.1m service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/tftp/udp6:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Unlike most smf(5) services, a manifest for the tftp service is not included in the system. To create one and enable this service, the administrator should:

1. Edit /etc/inet/inetd.conf and uncomment the tftp entry.
2. Run /usr/sbin/inetconv.

After you run inetconv, the svc:/network/tftp/udp6:default service is created and enabled.

Name in.timed – UDP or TCP time protocol service daemon

Synopsis in.timed

FMRI *svc*:/internet/time:default

Description FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See fmd(1M) and smf(5).

The in.timed service provides the server-side of the time protocol. The time server sends to requestors the time in seconds since midnight, January 1, 1900. The time protocol is available on both TCP and UDP transports through port 37.

The in.timed service is an inetd(1M) smf(5) delegated service. The in.timed detects which transport is requested by examining the socket it is passed by the inetd daemon.

TCP-based service	Once a connection is established, the in.timed sends the time as a 32-bit binary number and closes the connection. Any received data is ignored.
UDP-based service	The in.timed listens for UDP datagrams. When a datagram is received, the server generates a UDP datagram containing the time as a 32–bit binary number and sends it to the client. Any received data is ignored.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/legacy-network-services
Interface Stability	Committed

See Also inetd(1M), attributes(5), smf(5)

RFC 868

Name   intrd – interrupt distribution daemon

Synopsis   intrd

Description   The intrd daemon is started at boot time to monitor the assignments between interrupts and CPUs. If intrd decides that the current assignments are imbalanced and harmful to system performance, it will generate and implement new assignments.

Any notifications will be delivered via syslogd(1M).

Because intrd dynamically monitors a system for optimal performance, it consumes a small amount of CPU time, even on an otherwise idle system. This behavior is normal.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/kernel/power
Interface Stability	Uncommitted

See Also   svcs(1), svcadm(1M), syslogd(1M), attributes(5), smf(5)

Notes   The interrupt distribution daemon is managed by the service management facility, smf(5), under the service identifier:

svc:/system/intrd:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name   intrstat – report interrupt statistics

Synopsis   /usr/sbin/intrstat [-c *cpulist* | -C *processor_set_id*] [-T u | d]
                   [-x *opt*[=*val*]] [*interval* [*count*]]

Description   The intrstat utility gathers and displays run-time interrupt statistics. The output is a table of
device names and CPU IDs, where each row of the table denotes a device, and each column of
the table denotes a CPU. Each cell in the table contains both the raw number of interrupts for
the given device on the given CPU, and the percentage of absolute time spent in that device's
interrupt handler on that CPU.

The device name is given in the form of {*name*}#{*instance*}. The name is the normalized
driver name, and typically corresponds to the name of the module implementing the driver.
See ddi_driver_name(9F). Many Sun-delivered drivers have their own manual pages. See
Intro(7).

If standard output is a terminal, the table contains as many columns of data as can fit within
the terminal width. If standard output is not a terminal, the table contains at most four
columns of data. By default, data is gathered and displayed for all CPUs. If the data cannot fit
in a single table, it is printed across multiple tables. The set of CPUs for which data is displayed
can be optionally specified with the -c or -C option.

By default, intrstat displays data once per second and runs indefinitely. Both of these
behaviors can be optionally controlled with the interval and count parameters, respectively.
See OPERANDS.

Because intrstat uses dynamic discovery, it reports only on devices that raise interrupts
while the command is running. Any devices that are silent while intrstat is running are not
displayed.

intrstat induces a small system-wide performance degradation. As a result, only the
super-user can run intrstat by default. The *Solaris Dynamic Tracing Guide* explains how
administrators can grant privileges to other users to permit them to run intrstat.

Options   The following options are supported:

-c *cpulist*
   Displays data for the CPUs specified by *cpulist*.

   cpulist can be a single processor ID (for example, 4), a range of processor IDs (for example,
   4-6), or a comma separated list of processor IDs or processor ID ranges (for example,
   4,5,6 or 4,6-8).

-C *processor_set_id*
   Displays data for the CPUs in the processor set specified by *processor_set_id*.

intrstat modifies its output to always reflect the CPUs in the specified processor set. If a CPU is added to the set, intrstat modifies its output to include the added CPU. If a CPU is removed from the set, intrstat modifies its output to exclude the removed CPU. At most one processor set can be specified.

-T u | d

Display a time stamp.

Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See date(1).

-x *opt*[=*val*]

Enable or modify a DTrace runtime option or D compiler option. The list of options is found in the *Solaris Dynamic Tracing Guide*. A boolean option is enabled by specifying its name. Options with values are set by separating the option name and value with an equal sign (=)

Operands The following operands are supported:

count

Indicates the number of times intrstat will display its output before exiting.

interval

Indicates the number of seconds between displays of intrstat output.

Examples EXAMPLE 1 Using intrstat Without Options

Without options, intrstat displays a table of trap types and CPUs. At most, four columns can fit in the default terminal width. If there are more than four CPUs, multiple tables are displayed.

The following example runs intrstat on a uniprocessor Intel IA/32-based laptop:

```
example# intrstat
           device |     cpu0 %tim
  ----------------+---------------
            ata#0 |      166  0.4
            ata#1 |        0  0.0
      audioi810#0 |        6  0.0
           i8042#0 |      281  0.7
            iprb#0 |        6  0.0
            uhci#1 |        6  0.0
            uhci#2 |        6  0.0

           device |     cpu0 %tim
  ----------------+---------------
            ata#0 |      161  0.5
            ata#1 |        0  0.0
      audioi810#0 |        6  0.0
           i8042#0 |      303  0.6
```

EXAMPLE 1 Using intrstat Without Options   *(Continued)*

```
           iprb#0 |     6  0.0
           uhci#1 |     6  0.0
           uhci#2 |     6  0.0
...
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/dtrace
Interface Stability	See below.

The command-line syntax is Committed. The human-readable output is Uncommitted.

See Also dtrace(1M), trapstat(1M), attributes(5), Intro(7), ddi_driver_name(9F)

Solaris Dynamic Tracing Guide

Name   in.uucpd, uucpd – UUCP server

Synopsis   /usr/sbin/in.uucpd [-n]

Description   in.uucpd is the server for supporting UUCP connections over networks.

in.uucpd is invoked by inetd(1M) when a UUCP connection is established, that is, a connection to the port indicated in the "uucp" service specification, and executes the following protocol. See services(4):

1. The server prompts with login:. The uucico(1M) process at the other end must supply a username.

2. Unless the username refers to an account without a password, the server then prompts with Password:. The uucico process at the other end must supply the password for that account.

If the username is not valid, or is valid but refers to an account that does not have /usr/lib/uucp/uucico as its login shell, or if the password is not the correct password for that account, the connection is dropped. Otherwise, uucico is run, with the user ID, group ID, group set, and home directory for that account, with the environment variables USER and LOGNAME set to the specified username, and with a -u flag specifying the username. Unless the -n flag is specified, entries are made in /var/adm/utmpx, /var/adm/wtmpx, and /var/adm/lastlog for the username. in.uucpd must be invoked by a user with appropriate privilege (usually root) in order to be able to verify that the password is correct.

Security   in.uucpd uses pam(3PAM) for authentication, account management, and session management. The PAM configuration policy, listed through /etc/pam.conf, specifies the modules to be used for in.uucpd. Here is a partial pam.conf file with entries for uucp using the UNIX authentication, account management, and session management module.

```
uucp      auth requisite          pam_authtok_get.so.1
uucp      auth required           pam_dhkeys.so.1
uucp      auth required           pam_unix_auth.so.1

uucp      account requisite       pam_roles.so.1
uucp      account required        pam_projects.so.1
uucp      account required        pam_unix_account.so.1

uucp       session required       pam_unix_session.so.1
```

If there are no entries for the uucp service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the peer may be prompted for multiple passwords.

Files   /var/adm/utmpx   accounting

/var/adm/wtmpx   accounting

/var/adm/lastlog   time of last login

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/uucp

See Also svcs(1), inetadm(1M), inetd(1M), svcadm(1M), uucico(1M), pam(3PAM), pam.conf(4), services(4), attributes(5), pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), pam_unix_session(5), smf(5)

Diagnostics All diagnostic messages are returned on the connection, after which the connection is closed.

user read   An error occurred while reading the username.

passwd read   An error occurred while reading the password.

Login incorrect.   The username is invalid or refers to an account with a login shell other than /usr/lib/uucp/uucico, or the password is not the correct password for the account.

Notes The in.uucpd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/uucp

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name   iostat – report I/O statistics

Synopsis   `/usr/bin/iostat` `[-cCdDeEiImMnpPrstxXYz]` `[-l` *n*`]` `[-T u | d]`
`[`*disk*`]...` `[`*interval* `[`*count*`]]`

Description   The `iostat` utility iteratively reports terminal, disk, and tape I/O activity, as well as CPU utilization. The first line of output is for all time since boot; each subsequent line is for the prior interval only.

To compute this information, the kernel maintains a number of counters. For each disk, the kernel counts reads, writes, bytes read, and bytes written. The kernel also takes hi-res time stamps at queue entry and exit points, which allows it to keep track of the residence time and cumulative residence-length product for each queue. Using these values, `iostat` produces highly accurate measures of throughput, utilization, queue lengths, transaction rates and service time. For terminals collectively, the kernel simply counts the number of input and output characters.

During execution of the kernel status command, the `state` of the system can change. If relevant, a state change message is included in the `iostat` output, in one of the following forms:

```
<<device added: sd0>>
<<device removed: sd0>>
<<partition added: sd0,a>>
<<partition removed: sd0,a>>
<<NFS mounted: nfs1>>
<<NFS unmounted: nfs1>>
<<multi-path added: ssd4>>
<<multi-path removed: ssd4>>
<<controller added: c1>>
<<controller removed: c1>>
<<processors added: 1, 3>>
<<processors removed: 1, 3>>
```

Note that the `names` printed in these state change messages are affected by the `-n` and `-m` options as appropriate.

For more general system statistics, use sar(1), sar(1M), or vmstat(1M).

Output   The output of the `iostat` utility includes the following information.

device   name of the disk

r/s   reads per second

w/s   writes per second

kr/s   kilobytes read per second

The average I/O size during the interval can be computed from kr/s divided by r/s.

kw/s   kilobytes written per second

The average I/O size during the interval can be computed from kw/s divided by w/s.

wait   average number of transactions waiting for service (queue length)

This is the number of I/O operations held in the device driver queue waiting for acceptance by the device.

actv   average number of transactions actively being serviced (removed from the queue but not yet completed)

This is the number of I/O operations accepted, but not yet serviced, by the device.

svc_t   average response time of transactions, in milliseconds

The svc_t output reports the overall *response* time, rather than the *service* time, of a device. The overall time includes the time that transactions are in queue and the time that transactions are being serviced. The time spent in queue is shown with the -x option in the wsvc_t output column. The time spent servicing transactions is the true service time. Service time is also shown with the -x option and appears in the asvc_t output column of the same report.

%w   percent of time there are transactions waiting for service (queue non-empty)

%b   percent of time the disk is busy (transactions in progress)

wsvc_t   average service time in wait queue, in milliseconds

asvc_t   average service time of active transactions, in milliseconds

wt   the I/O wait time is no longer calculated as a percentage of CPU time, and this statistic will always return zero.

Options   The following options are supported:

-c   Report the percentage of time the system has spent in user mode, in system mode, waiting for I/O, and idling. See the NOTES section for more information.

-C   When the -x option is also selected, report extended disk statistics aggregated by *controller id*.

-d   For each disk, report the number of kilobytes transferred per second, the number of transfers per second, and the average service time in milliseconds.

-D   For each disk, report the reads per second, writes per second, and percentage disk utilization.

-e	Display device error summary statistics. The total errors, hard errors, soft errors, and transport errors are displayed.
-E	Display all device error statistics.
-i	In -E output, display the Device ID instead of the Serial No. The Device Id is a unique identifier registered by a driver through ddi_devid_register(9F).
-I	Report the counts in each interval, rather than rates (where applicable).
-l *n*	Limit the number of disks included in the report to *n*; the disk limit defaults to 4 for -d and -D, and unlimited for -x. Note: disks explicitly requested (see *disk* below) are not subject to this disk limit.
-m	Report file system mount points. This option is most useful if the -P or -p option is also specified or used in conjunction with -Xn or -en. The -m option is useful only if the mount point is actually listed in the output. This option can only be used in conjunction with the -n option.
-M	Display data throughput in MB/sec instead of KB/sec.
-n	Display names in descriptive format. For example, cXtYdZ, rmt/N, server:/export/path.
	By default, disks are identified by instance names such as ssd23 or md301. Combining the -n option with the -x option causes disk names to display in the cXtYdZsN format which is more easily associated with physical hardware characteristics. The cXtYdZsN format is particularly useful in FibreChannel (FC) environments where the FC World Wide Name appears in the t field.
-p	For each disk, report per-partition statistics in addition to per-device statistics.
-P	For each disk, report per-partition statistics only, no per-device statistics.
-r	Display data in a comma-separated format.
-s	Suppress messages related to state changes.
-t	Report the number of characters read and written to terminals per second.
-T u | d	Display a time stamp.
	Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See date(1).
-X	For disks under scsi_vhci(7D) control, in addition to disk *lun* statistics, also report statistics for *lun.controller*.
-x	Report extended disk statistics. By default, disks are identified by instance names such as ssd23 or md301. Combining the x option with the -n option causes disk names to display in the cXtYdZsN format, more easily associated with physical

hardware characteristics. Using the cXtYdZsN format is particularly helpful in the FibreChannel environments where the FC World Wide Name appears in the t field.

If no output display is requested (no -x, -e, -E), -x is implied.

-Y   For disks under scsi_vhci(7D) control, in addition to disk *lun* statistics, also report statistics for *lun.targetport* and *lun.targetport.controller*.

In -n (descriptive) mode the *targetport* is shown in using the target-port property of the path. Without -n the *targetport* is shown using the shorter port-id. All target ports with the same target-port property value share the same port-id. The target-port-to-port-id association does not persist across reboot.

If no output display is requested (no -x, -e, -E), -x is implied.

-z   Do not print lines whose underlying data values are all zeros.

The option set -xcnCXTdz *interval* is particularly useful for determining whether disk I/O problems exist and for identifying problems.

Operands   The following operands are supported:

count   Display only *count* reports.

disk   Explicitly specify the disks to be reported; in addition to any explicit disks, any active disks up to the disk limit (see -l above) will also be reported.

interval   Report once each *interval* seconds.

Examples   **EXAMPLE 1**   Using iostat to Generate User and System Operation Statistics

The following command displays two reports of extended device statistics, aggregated by *controller id*, for user (us) and system (sy) operations. Because the -n option is used with the -x option, devices are identified by controller names.

```
example% iostat -xcnCXTdz 5

```

EXAMPLE 3   Using iostat to Generate Partition and Device Statistics

The following command generates partition and device statistics for each disk. Because the -n option is used with the -x option, disks are identified by controller names.

example% **iostat -xnp**

```
                extended device statistics
r/s  w/s  kr/s kw/s wait actv wsvc_t asvc_t %w %b device
0.4  0.3  10.4 7.9  0.0  0.0    0.0   36.9  0  1 c0t0d0
0.3  0.3   9.0 7.3  0.0  0.0    0.0   37.2  0  1 c0t0d0s0
0.0  0.0   0.1 0.5  0.0  0.0    0.0   34.0  0  0 c0t0d0s1
```

EXAMPLE 3 Using iostat to Generate Partition and Device Statistics   *(Continued)*

```
0.0  0.0   0.0  0.1  0.0  0.0   0.6   35.0  0   0 fuji:/export/home/user3
```

EXAMPLE 4 Show Translation from Instance Name to Descriptive Name

The following example illustrates the use of iostat to translate a specific instance name to a descriptive name.

```
example% iostat -xn sd1
                     extended device statistics
r/s    w/s   kr/s   kw/s wait actv wsvc_t asvc_t  %w  %b device
0.0    0.0   0.0    0.0 0.0 0.0   0.0    0.0  0   0 c8t1d0
```

EXAMPLE 5 Show Target Port and Controller Activity for a Specific Disk

In the following example, there are four controllers, all connected to the same target port.

```
# iostat -Y ssd22
                  extended device statistics
device        r/s    w/s    kr/s   kw/s wait actv  svc_t  %w  %b

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

Invocation is evolving. Human readable output is unstable.

See Also   date(1), sar(1), sar(1M), mpstat(1M), vmstat(1M), time(2), attributes(5), scsi_vhci(7D)

Notes   The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

The svc_t response time is not particularly significant when the I/0 (r/s+w/s) rates are under 0.5 per second. Harmless spikes are fairly normal in such cases.

The mpstat utility reports the same wt, usr, and sys statistics. See mpstat(1M) for more information.

When executed in a zone and if the pools facility is active, iostat(1M) will only provide information for those processors in the processor set of the pool to which the zone is bound.

Name ipaddrsel – configure IPv6 default address selection

Synopsis /usr/sbin/ipaddrsel

/usr/sbin/ipaddrsel -f *file*

/usr/sbin/ipaddrsel -d

Description Use the ipaddrsel utility to configure the IPv6 default address selection policy table. The policy table is a longest-matching-prefix lookup table that is used for IPv6 source address selection and for destination address ordering when resolving names to AF_INET6 addresses. For a description of how the policy table is used for source address selection, see inet6(7P). For a description of how the policy table is used for destination address ordering, see getaddrinfo(3SOCKET).

The unmodified policy table is valid for all typical IPv6 deployments. Modify the table only if a circumstance exists for which the default behavior of the IPv6 source address selection or destination address ordering mechanism is unsatisfactory. See the Examples section for examples of such circumstances. You should carefully consider your addressing strategy before you change the table from the provided default.

When the ipaddrsel command is issued without any arguments, the address selection policy currently in use is printed. The format of the output is compatible with the format of the configuration file that the -f option accepts.

Note – If the usesrc subcommand to ifconfig(1M) is applied to a particular physical interface, the selection policy specified by usesrc overrides the source address selection policies specified by ipaddrsel. This is true for packets that are locally generated and for applications that do not choose a non-zero source address using bind(3SOCKET).

The Configuration File The configuration file that the -f option accepts can contain either comment lines or policy entries. Comment lines have a '#' character as the first non-blank character. and they are ignored by the ipaddrsel utility. Policy entry lines have the following format:

prefix/prefix_length precedence label [# *comment*]

The *prefix* must be an IPv6 prefix in a format consistent with inet(3SOCKET). The *prefix_length* is an integer ranging from 0 to 128. The IPv6 source address selection and destination address ordering algorithms determine the precedence or label of an address by doing a longest-prefix-match lookup using the prefixes in this table, much like next-hop determination for a destination is done by doing a longest-prefix-match lookup using an IP routing table.

The precedence is a non-negative integer that represents how the destination address ordering mechanism will sort addresses returned from name lookups. In general, addresses with a higher precedence will be in front of addresses with a lower precedence. Other factors, such as destinations with undesirable source addresses can, however, override these precedence values.

The label is a string of at most fifteen characters, not including the NULL terminator. The label allows particular source address prefixes to be used with destination prefixes of the same label. Specifically, for a particular destination address, the IPv6 source address selection algorithm prefers source addresses whose label is equal that of the destination.

The label may be followed by an optional comment.

The file must contain a default policy entry, which is an entry with ::0/0 as its *prefix* and *prefix_length*. This is to ensure that all possible addresses match a policy.

Options   The ippadrsel utility supports the following options:

-f *file*   Replace the address selection policy table with the policy specified in the *file*.

-d   Revert the kernel's address selection policy table back to the default table. Invoking ipaddrsel in this way only changes the currently running kernel's policy table, and does not alter the configuration file /etc/inet/ipaddrsel.conf. To revert the configuration file back to its default settings, use ipaddrsel -d, then dump the contents of the table to the configuration file by redirecting the output of ipaddrsel to /etc/inet/ipaddrsel.conf.

```
example# ipaddrsel -d
example# ipaddrsel > /etc/inet/ipaddrsel.conf
```

Examples   **EXAMPLE 1**   The Default Policy in /etc/inet/ipaddrsel.conf

The following example is the default policy that is located in /etc/inet/ipaddrsel.conf:

```
# Prefix                       Precedence Label
::1/128                        50 Loopback
::/96                          20 IPv4_Compatible
::ffff:0.0.0.0/96              10 IPv4
2002::/16                      30 6to4
::/0                           40 Default
```

EXAMPLE 2   Assigning a Lower Precedence to Link-local and Site-local Addresses

By default, the destination address ordering rules sort addresses of smaller scope before those of larger scope. For example, if a name resolves to a global and a site-local address, the site local address would be ordered before the global address. An administrator can override this ordering rule by assigning a lower precedence to addresses of smaller scope, as the following table demonstrates.

```
# Prefix                       Precedence Label
::1/128                        50 Loopback
::/0                           40 Default
2002::/16                      30 6to4
fec0::/10                      27 Site-Local
fe80::/10                      23 Link-Local
::/96                          20 IPv4_Compatible
```

EXAMPLE 2 Assigning a Lower Precedence to Link-local and Site-local Addresses *(Continued)*

```
::ffff:0.0.0.0/96              10 IPv4
```

EXAMPLE 3 Assigning Higher Precedence to IPv4 Destinations

By default, IPv6 addresses are ordered in front of IPv4 addresses in name lookups.
`::ffff:0.0.0.0/96` has the lowest precedence in the default table. In the following example,
IPv4 addresses are assigned higher precedence and are ordered in front of IPv6 destinations:

```
# Prefix                       Precedence Label
::1/128                        50 Loopback
::/0                           40 Default
2002::/16                      30 6to4
::/96                          20 IPv4_Compatible
::ffff:0.0.0.0/96              60 IPv4
```

EXAMPLE 4 Ensuring that a Particular Source Address is Used

This example ensures that a particular source address is used only when communicating with
destinations in a particular network.

The following policy table assigns a label of 5 to a particular source address on the local
system, `2001:1111:1111::1`. The table assigns the same label to a network,
`2001:2222:2222::/48`. The result of this policy is that the `2001:1111:1111::1` source
address will only be used when communicating with destinations contained in the
`2001:2222:2222::/48` network. For this example, this network is the `ClientNet`, which could
represent a particular client's network.

```
# Prefix                       Precedence Label
::1/128                        50 Loopback
2001:1111:1111::1/128          40 ClientNet
2001:2222:2222::/48            40 ClientNet
::/0                           40 Default
2002::/16                      30 6to4
::/96                          20 IPv4_Compatible
::ffff:0.0.0.0/96              10 IPv4
```

This example assumes that the local system has one physical interface, and that all global
prefixes are assigned to that physical interface.

Exit Status   ipaddrsel returns the following exit values:

0   ipaddrsel successfully completed.

>0   An error occurred. If a failure is encountered, the kernel's current policy table is
         unchanged.

Files   /etc/inet/ipaddrsel.conf   The file that contains the IPv6 default address selection
policy to be installed at boot time. This file is loaded before
any Internet services are started.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also   nscd(1M), inet(3SOCKET), getaddrinfo(3SOCKET), ipaddrsel.conf(4), attributes(5),
inet6(7P)

Notes   The ipnodes cache kept by nscd(1M) contains addresses that are ordered using the destination
address ordering algorithm, which is one of the reasons why ipaddrsel is called before nscd
in the boot sequence. If ipaddrsel is used to change the address selection policy after nscd has
started, you should invalidate the nscd ipnodes cache invalidated by invoking the following
command:

example# **/usr/sbin/nscd -i ipnodes**

Name ipadm – configure Internet Protocol network interfaces and TCP/IP tunables

Synopsis
```
ipadm create-ip [-t] IP-interface
ipadm delete-ip IP-interface

ipadm create-vni [-t] VNI-interface
ipadm delete-vni VNI-interface

ipadm create-ipmp [-t] [-i interface,[...]...] IPMP-interface
ipadm delete-ipmp [-f] IPMP-interface
ipadm add-ipmp [-t] -i interface,[...] [-i interface,[...]...]
     IPMP-interface
ipadm remove-ipmp [-t] -i interface,[...] [-i interface,[...]...]
     IPMP-interface

ipadm show-if [[-p] -o field[,...]] [interface]
ipadm disable-if -t interface
ipadm enable-if -t interface

ipadm set-ifprop [-t] -m protocol -p prop=value[,...] interface
ipadm reset-ifprop [-t] -m protocol -p prop interface
ipadm show-ifprop [[-c] -o field[,...]] [-p prop,...]
     [-m protocol] [interface]

ipadm create-addr [-t] -T static [-d]
     -a {local|remote}=addr[/prefixlen],... addrobj
ipadm create-addr [-t] -T dhcp [-w seconds | forever]
     [-h hostname] addrobj
ipadm create-addr [-t] -T addrconf [-i {local|remote}=interface-id]
     [-p {stateful|stateless}={yes|no},..] addrobj

ipadm delete-addr [-r] addrobj
ipadm show-addr [[-p] -o field[,...]] [-d] [addrobj | interface/]

ipadm reset-prop [-t] -p prop protocol
ipadm show-prop [[-c] -o field[,...]] [-p prop[,...] protocol | protocol]
```

Description The ipadmcommand provides a set of subcommands that can be used to:

manage interfaces:

- create and delete interfaces of interface classes ip, ipmp, and vni
- modify interface properties

- display interface configuration

manage addresses:

- create and delete addresses
- modify address properties
- display address configuration

manage TCP/IP protocol properties:

- modify TCP/IP properties
- display TCP/IP properties

The various operands to ipadm subcommands are described in the "Operands" section, which follows "Subcommands".

Required Authorization and Privilege   The following subcommands require solaris.network.interface.config authorization and PRIV_SYS_IP_CONFIG privilege.

create-ip	create-addr
delete-ip	up-addr
create-vni	down-addr
delete-vni	refresh-addr
create-ipmp	disable-addr
delete-ipmp	enable-addr
add-ipmp	set-addrprop
remove-ipmp	reset-addrprop
disable-if	set-prop
enable-if	reset-prop
set-ifprop	
reset-ifprop	

In addition to the authorization and privilege specified above, the ipadm subcommands create-ip, create-vni, create-ipmp, and enable-if need PRIV_NET_RAWACCESS privilege.

Sub-commands   The following subcommands are supported:

create-ip [-t] *IP-interface*
    Create an IP interface that handles both IPv4 and IPv6 packets. The address of the IPv4 interface will be set to 0.0.0.0 and the address of the IPv6 interface will be set to ::. This subcommand, by default, causes the information to persist, so that on the next reboot this interface will be instantiated.

    An interface is implicitly enabled for IPv4 and IPv6 when it is created. See the disable-if and enable-if subcommands below, to disable or enable an interface.

    Note that lo0 is a special interface, called the loopback interface. It is a virtual IP interface and is not associated with any physical hardware. It is one of the first IP interfaces to be created on the system, with IPv4 address of 127.0.0.1 and IPv6 address of ::/128.

-t, --temporary
> Specifies that the operation is temporary and must not persist. The operation affects only the active configuration.

delete-ip *IP-interface*
> Deletes the IP interface from active configuration. All addresses configured on the interface will be torn down. Further, all the persistent information related to the interface will be removed from the persistent data store and, for this reason, *interface* will not be instantiated upon reboot. To disable an interface from active configuration (rather than delete the interface), use the disable-if subcommand.

create-vni [-t] *VNI-interface*
> Create a VNI interface that handles both IPv4 and IPv6 packets. The address of the IPv4 interface will be set to 0.0.0.0 and the address of the IPv6 interface will be set to ::. This subcommand, by default, causes the information to persist, so that on the next reboot this interface will be instantiated.

> The interface is implicitly enabled for IPv4 and IPv6 when it is created. See the disable-if and enable-if subcommands below, to disable or enable an interface.

> Note that vni is a special interface, in that it is a virtual interface and does not have any hardware associated with it. See vni(7d).

> -t, --temporary
>> Specifies that the operation is temporary and must not persist. The operation affects only the active configuration.

delete-vni *VNI-interface*
> Deletes the VNI interface from active configuration. All addresses configured on the interface will be torn down. Further, all the persistent information related to the IP interface will be removed from the persistent data store and, for this reason, interface will not be instantiated upon reboot. To disable the interface from active configuration (rather than delete the interface), use the disable-if subcommand.

create-ipmp [-t] [-i *interface*,[...]...] *IPMP-interface*
> Create a IPMP interface that handles both IPv4 and IPv6 packets. The address of the IPv4 interface will be set to 0.0.0.0 and the address of the IPv6 interface will be set to ::. This subcommand, by default, causes the information to persist, so that on the next reboot this interface will be instantiated.

> The interface is implicitly enabled for IPv4 and IPv6 when it is created. See the disable-if and enable-if subcommands below, to disable or enable an IPMP interface.

> -t, --temporary
>> Specifies that the operation is temporary and must not persist. The operation affects only the active configuration.

-i, -–interface *interface*,[...]

A comma-separated list of interfaces to be added as underlying interfaces to the IPMP interface. The specified interfaces must exist in the active configuration to be successfully added to the IPMP group and must not be present in any other IPMP group. More than one -i option is allowed. The command returns with partial success if the IPMP interface was created but none of the given underlying interfaces were added successfully.

delete-ipmp [-f] *IPMP-interface*

Deletes the IPMP interface from active configuration. All addresses configured on the interface will be torn down. The command fails if the IPMP interface has any underlying interfaces, unless the -f option is specified. Further, all the persistent information related to the IPMP interface will be removed from the persistent data store and, for this reason, interface will not be instantiated upon reboot. To disable the interface from active configuration only (rather than delete the interface), use the disable-if subcommand.

-f, --force

If the IPMP interface has any underlying interfaces, specifying this option removes all the underlying interfaces from the group first, before deleting the IPMP interface.

add-ipmp [-t] -i *interface*,[...] [-i *interface*,[...]...] *IPMP-interface*

Adds one or more underlying IP interfaces to the given IPMP interface.

-t, -–temporary

Specifies that the operation is temporary and must not persist. The operation affects only the active configuration.

-i, -–interface *interface*,[...]

A comma-separated list of interfaces to be added as underlying interfaces to the IPMP interface. The specified interfaces must exist in the active configuration to be successfully added to the IPMP group and must not be present in any other IPMP group. The command returns with partial success if at least one interface was added and adding the remaining interfaces failed. More than one -i option is allowed.

remove-ipmp [-t] -i *interface*,[...] [-i *interface*,[...]...] *IPMP-interface*

Removes one or more underlying IP interfaces from the IPMP interface.

-t, -–temporary

Specifies that the operation is temporary and must not persist. The operation affects only the active configuration.

-i, -–interface *interface*,[...]

A comma-separated list of underlying interfaces to be removed from the IPMP interface. The specified interfaces must already be underlying interfaces for the given IPMP group. More than one -i option is allowed. The command returns with partial success if at least one interface was removed and removing the remaining interfaces failed.

show-if [[-p] -o *field*[,...]] [*interface*]
    Show network interface configuration information, either for all the network interfaces
    configured on the system, including the ones that are only in the persistent configuration,
    or for the specified network interface.

-o *field*[,...], --output *field*[,...]
    A case-insensitive, comma-separated list of output fields to display. The *field* name must
    be one of the fields listed below, or the special value all to display all fields. For each
    network interface, the following fields can be displayed:

    IFNAME
        The name of the IP interface.

    CLASS
        Indicates one of the following:

    ip
        An interface that is plumbed over an underlying datalink.

    ipmp
        An IPMP interface that is created over one or more underlying IP interfaces.

    loopback
        A loopback interface.

    vni
        A virtual IP interface. See vni(7d).

    STATE
        Indicates one of the following for the displayed interface.

    ok
        Indicates that the required resources for an interface are allocated. For some
        interfaces this also indicates that the link is up.

    offline
        The interface is offline and thus cannot send or receive IP data traffic. See
        if_mpadm(1M).

    failed
        Indicates that the datalink is down. If the interface is part of an IPMP group it could
        also mean that the interface has failed (that is, IFF_FAILED is set). Failed interfaces
        will not be used to send or receive IP data traffic. If this is set on a physical IP interface
        in an IPMP group, IP data traffic will continue to flow over other usable IP interfaces
        in the IPMP group. If this is set on an IPMP IP interface, the entire group has failed
        and no data traffic can be sent or received over any interfaces in that group. See
        in.ndpd(1M).

    down
        Indicates that the interface is administratively down, preventing any IP packets from
        being sent or received through it.

Indicates that the interface has been disabled from the active configuration using the
disable-if subcommand.

ACTIVE

Either yes or no, depending on whether the IP interface is being used by the system
for IP data traffic.

CURRENT

For interface objects, in active configuration, it indicates any of the following flags.

b

interface supports broadcast

m

interface supports multicast

p

interface is a point-to-point link

v

interface is a virtual interface (for example, vni(7d), loopback), that is, the physical
interface has no underlying hardware.

s

IPMP interface is marked standby administratively. See in.ndpd(1M).

l

interface is an underlying interface for an IPMP interface. See in.ndpd(1M).

i

Underlying interface is inactive. See in.ndpd(1M).

V

interface is a VRRP interface

a

VRRP interface is in accept mode (~IFF_NOACCEPT)

Z

Layer-3 protection of IP addresses for the interface has been administratively
enforced.

4

interface can handle IPv4 packets

6

interface can handle IPv6 packets

Note that b and p are mutually exclusive.

PERSISTENT
Specifies the configuration that will be applied when the interface object is instantiated on reboot or re-enabled using the `enable-if` subcommand. It can be any or all of s, l, 4, and 6 (see above). This field is not shown by default and will be shown only when `all` or `persistent` is specified with `-o`.

OVER
The underlying interface(s) over which the IPMP interface is created. This does not apply to other interface classes.

-p, --parsable
Display using a stable machine-parsable format. The `-o` option is required with this option. See "Parsable Output Format", below.

disable-if -t *interface*
Disables the specified *interface* by removing it from the active configuration. All the addresses configured on the interface will be disabled. If the interface object was created persistently to begin with, then the persistent configuration is unchanged. To re-enable this interface, one should use `enable-if`.

-t, --temporary
Specifies that the disable is temporary and changes apply only to the active configuration.

enable-if -t *interface*
Enables the given interface by reading the configuration from the persistent store. All the persistent interface properties, if any, are applied and all the persistent addresses, if any, on the given interface will be enabled.

-t, --temporary
Specifies that the enable is temporary and changes apply only to the active configuration.

set-ifprop [-t] -m *protocol* -p prop=*value*[,...] *interface*
Modifies an interface property to the value specified by the user. If the property takes multiple values then the values should be specified with a comma as the delimiter. Only one property can be specified at a time. The properties supported on an interface and the property's possible values can be retrieved using `show-ifprop` subcommand. Only one property at a time can be modified.

-t, --temporary
Specifies that the changes are temporary and changes apply only to the active configuration.

-m *protocol*, --module *protocol*
Identifies whether property should be applied for IPv4 or IPv6 packets.

-p prop=*value*[,...], -prop prop=*value*[,...]
A property to set to the specified values.

reset-ifprop [-t] -m *protocol* -p *prop interface*
> Resets a property of the specified interface to its default value. If -t is not used, any persisted value of the property will be deleted. Only one property can be modified at a time.
>
> -t, --temporary
> > Specifies that the resets are temporary and changes apply only to the active configuration.
>
> -m *protocol*, --module *protocol*
> > Identifies whether the property being reset affects either IPv4 or IPv6 packets.
>
> -p *prop*, -prop *prop*
> > A property to set to the specified values.

show-ifprop [[-c] -o *field*[,...]] [-p *prop*,...] [-m *protocol*] [*interface*]
> Show the current and persistent values of one or more properties, either for all the created interfaces or for the specified interface. Several properties of interest can be retrieved at one time by providing comma-separated property names to -p option. If the -p option is not specified, all available interface properties are displayed.
>
> -o *field*[,...], --output *field*[,...]
> > A case-insensitive, comma-separated list of output fields to display. The *field* name must be one of the fields listed below, or the special value all to display all fields. For each interface, the following fields can be displayed:
> >
> > IFNAME
> > > The name of the interface.
> >
> > PROPERTY
> > > The name of the property.
> >
> > PROTO
> > > The name of the protocol the property belongs to. The protocols currently supported are IPv4 and IPv6.
> >
> > PERM
> > > The read/write permissions of the property. The value shown will be r (read-only), w (write-only) or rw (read-and-write).
> >
> > CURRENT
> > > The current value of the property. For disabled interfaces, because a value is not set, it will be shown as --.
> >
> > PERSISTENT
> > > The persistent value of the property. Persistent values are the values that will be reapplied on reboot.
> >
> > DEFAULT
> > > The default value of the property. If the property has no default value, -- is displayed.

POSSIBLE
A comma-separated list of the values the property can have. If the values span a numeric range, *min - max* might be displayed as shorthand. If the possible values are unknown, ? is displayed or if they are unbounded, - - is displayed.

-c, --parsable
Display using a stable machine-parsable format. The -o option is required with this option. See "Parsable Output Format", below.

-p *prop*,..., -–prop=*prop*
A comma-separated list of properties to display. See the sections on interface properties following subcommand descriptions.

-m *protocol*, --module *protocol*
Displays properties matching the given protocol. Valid values are ipv4 and ipv6.

For the supported list of interface properties, see "Interface Properties" below.

create-addr [-t] -T static [-d] -a {local | remote}=*addr*[/*prefixlen*],... *addrobj*
Creates a static IPv4 or IPv6 address on the interface specified in *addrobj*. The interface on which the *addrobj* is being created must already exist. The created static address will be identified by *addrobj*.

By default, a configured address will be marked up, so that it can be used as a source or destination of or for outbound and inbound packets.

All address objects are enabled when they are created. See the disable-addr and enable-addr subcommands for instructions on disabling or enabling an address object.

A persistent operation cannot be performed on a temporary object. That is, if the interface is temporarily created, then one cannot create the address object persistently.

If the interface specified in the *addrobj* name is an IPMP interface, a static data address is created on the IPMP interface. If the interface specifed in the *addrobj* name is an underlying interface for an IPMP group, a static test address is created on the underlying interface.

-t, --temporary
Specifies that the configured address is temporary and changes apply only to the active configuration.

-d, --down
Specifies that the configured address should be marked down, that is, the address will not be used as a source or destination of IP packets.

-a {local | remote}=*addr*[/*prefixlen*],...
--address {local | remote}=*addr*[/*prefixlen*],...
addr indicates a literal IP address or a hostname corresponding to the local or remote end-point (for point-to-point interfaces).

If a hostname is specified its numeric value is uniquely obtained using the entry in /etc/hosts. If no numeric IP address is defined in the file, then the numeric value is uniquely obtained using the resolver order specifed for hosts or ipnodes in nsswitch.conf(4). If there are multiple entries for a given hostname, an error will be generated. Because IP addresses are created before naming services have been brought online during the boot process, it is important that any hostname used be included in /etc/hosts.

If the *prefixlen* is not explicitly specified in the command-line, the netmask for the address is obtained by following the search in the order listed below:

1. using the order specified for netmasks in nsswitch.conf(4)

2. interpreting IPv4 address using Classful subnetting semantics defined in RFC 791, and interpreting IPv6 addresses using the definitions in RFC 4291.

For point-to-point interfaces, along with the address of the local end-point the address of the remote end-point must be specified (for example, -a local=*laddr*,remote=*raddr*). If *prefixlen* for the remote end-point is specified, an error will be returned.

Note that if the interface requires only a local address, specify it directly with the -a option as follows: -a *addr*[/*prefixlen*]. The address will automatically be considered a local address.

create-addr [-t] -T dhcp [-w *seconds* | forever] -h *hostname addrobj*
Creates a DHCP-controlled IPv4 address on an interface specified in *addrobj*. The created IPv4 address will be identified by *addrobj*. When the *addrobj* contains an underlying interface, this command creates a test address; when it contains an IPMP interface, it creates a data address.

All the address objects are enabled when they are created. See the disable-addr and enable-addr subcommands for instructions on disabling and enabling an address object.

A persistent operation cannot be performed on a temporary object. That is, if the interface is temporarily created, one cannot create the address object persistently.

If the interface specified in the *addrobj* name is an IPMP interface, the address obtained through DHCP is created as a data address on the IPMP interface.

-h *hostname*
Specifies the hostname to which the client would like the DHCP server to map the client's leased IPv4 address. There is no guarantee that the DHCP server will be able to fulfill the hostname request.

-t, --temporary
Specifies that the configured address is temporary and changes apply only to the active configuration.

-w *seconds* | forever, --wait *seconds* | forever
  Specifies the amount of time, in seconds, to wait until the operation completes. If no wait interval is given, and the operation is one that cannot complete immediately, ipadm will, by default, wait 120 seconds for the requested operation to complete. Note that the default wait time is subject to change in future releases. The symbolic value forever can be used as well, with obvious meaning.

create-addr [-t] -T addrconf [-i {local | remote}=*interface-id*] [-p {stateful | stateless}={yes | no},..] *addrobj*
  Creates an auto-configured IPv6 address on an interface specified in *addrobj*. The created IPv6 addresses will be identified by *addrobj*.

  The system uses the default interface ID (for the media-type Ethernet, the Interface ID is the MAC address of the interface) to generate auto-configured addresses. This behavior can be overridden using -i option.

  By default:

  - IPv6 addresses will be auto-configured based on prefixes advertised by routers as described in RFC 4862 and...

  - IPv6 addresses will be auto-configured on the specified interface using the IPv6 address offered by DHCPv6 server as described in RFC 3315. (That is, -p stateful=yes,stateless=yes is the default option.)

  All the address objects are enabled when they are created. See the disable-addr and enable-addr subcommands for instructions on disabling and enabling an address object.

  A persistent operation cannot be performed on a temporary object. That is, if the interface is temporarily created, then one cannot create the address object persistently.

  If the interface specified in the *addrobj* name is an IPMP interface, the addresses obtained through IPv6 autoconfiguration are created as data addresses on the IPMP interface.

  -t, --temporary
    Specifies that the configured address is temporary and changes apply only to the active configuration.

  -i {local | remote}=*interface-id*, --interface-id {local | remote}=*interface-id*
    Specifies the interface ID to be used for generating auto-configured addresses.

    For point-to-point interfaces, the interface id of the remote end-point can be specified (for example, -i local=*lid*,remote=*rid*).

    Note that if the interface requires only a local interface id, specify it directly with the -i option as follows: -i *lid*. The interface id will automatically be considered a local interface id.

  -p {stateful | stateless}={yes | no},..
  --prop {stateful | stateless}={yes | no},..

Specifies if stateful or stateless or both methods of auto-configuration should be enabled or not.

If `-p stateful=no` is specified, then stateful auto-configuration based on DHCPv6–specified IPv6 addresses will not be performed.

If `-p stateless=no` is specified, then stateless auto-configuration based on the router-advertised prefixes will not be performed.

If `-p stateful=no,stateless=no` is specified, then both the methods of auto-configuration will not be performed.

With the `-T addrconf` option, `-p stateful=yes,stateless=yes` is used by default.

delete-addr [`-r`] *addrobj*
Deletes all the addresses identified by *addrobj* on the interface specified in the *addrobj*. It also removes these addresses from the persistent data-store; thus, these addresses will not be instantiated on reboot.

If the address object is a DHCP-controlled address, `delete-addr` removes the address from the system without notifying the DHCP server, and records the current lease for later use.

`-r, --release`
If the *addrobj* is a DHCP-controlled address, this option brings about the relinquishing of the DHCP-controlled IP addresses on the interface by notifying the server and the discarding of the current lease.

show-addr [[`-p`] `-o` *field*[,...]] [`-d`] [*addrobj* | *interface*/]
Show address information, either for the given *addrobj* or all the address objects configured on the specified interface, including the address objects that are only in the persistent configuration.

`-p, --parsable`
Display using a stable machine-parsable format. The `-o` option is required with this option. See "Parsable Output Format", below.

`-o` *field*[,...], `--output` *field*[,...]
A case-insensitive, comma-separated list of output fields to display. The *field* name must be one of the fields listed below, or the special value `all` to display all fields. For each interface, the following fields can be displayed:

ADDROBJ
The name of the address object.

TYPE
Type of the address object. It will be one of: `from-gz`, `static`, `dhcp`, or `addrconf`. The `static`, `dhcp`, and `addrconf` types correspond to the type of the address object specified by the `-T` option of `create-addr`. The `from-gz` type will only be displayed

in non-global zones, and indicates that the address was configured based on the `allowed-address` property configured for the non-global exclusive-IP zone from the global zone.

STATE

State of the address object. This field is shown only when `all` is specified with `-o`. This indicates one of the following values:

disabled

Address is not part of the active configuration (see `disable-addr` and `disable-if`).

down

Address is administratively down (see `down-addr`).

duplicate

Address was found to conflict with another system's IP address by duplicate address detection (DAD) and cannot be used until the conflict is resolved. The system will periodically rerun DAD to determine if the conflict has been resolved. Alternatively, `refresh-addr` can be used to immediately rerun DAD.

inaccessible

Address cannot be used because the IP interface it is configured on has failed.

ok

Address is enabled, up, and functioning properly. The system will accept IP packets destined to this address, and will originate IP packets with this address in accordance with the configured IP source address selection policy.

tentative

Address is currently undergoing duplicate address detection (for example, as part of `up-addr` or `refresh-addr`).

CURRENT

For address objects in active configuration, it indicates any of the following flags. This field is not shown by default and will be shown only when `all` or `current` is specified with `-o`.

d (deprecated)

Will not be used as source address for outbound packets unless either there are no other addresses available on the interface or the application has explicitly bound to this address.

p (private)

Address not advertised by the routing daemon.

t (temporary)

Temporary IPv6 address as defined in RFC 3041.

U (up)

Address is marked up for use as a source/destination of outbound/inbound packets.

u (unnumbered)
Address matches the local address of some other link in the system.

PERSISTENT
Specifies the configuration that will be applied when the address object is instantiated on reboot or re-enabled using the enable-addr subcommand. It can be any or all of U, p, and d (see above).

ADDR
Numeric IPv4 or IPv6 address. In the case of point-to- point interfaces, the addresses of both the endpoints, are displayed (*laddr-->raddr*). For an address object of type dhcp, if the state of the address object is disabled, or if the address is 0.0.0.0 for IPv4 or :: for IPv6, then a question mark (?) is displayed.

CID-TYPE
The type of the Client ID used by the dhcpagent(1M), if the address is being obtained using DHCP. For IPv4, this shows the type of the DUID used in constructing the RFC 4361 Client ID. The type is one of DUID-LLT, DUID-EN, DUID-LL, other, or default. This field is not shown in the default output. It can be shown using -d or using cid-type or all with -o.

DUID-LLT
Type 1 RFC 3315 DUID is used in constructing CID-VALUE (for example, 1,1,63463777,0a:0b:0c:0d:0e:0f). Refer to the RFC for more details.

DUID-EN
Type 2 RFC 3315 DUID is used in constructing CID-VALUE (for example, 1,1,63463777,0a:0b:0c:0d:0e:0f). Refer to the RFC for more details.

DUID-LL
Type 3 RFC 3315 DUID is used in constructing CID-VALUE (for example, 1,1,63463777,0a:0b:0c:0d:0e:0f). Refer to the RFC for more details.

other
An RFC 3315 DUID of a Type in {0,4-65535} is used to derive the Client ID (for example, 4,0x734633) or the CID-VALUE is a raw Client ID (for example, Sun, 0xab3146) that does not conform to RFC 3315.

default
Indicates that the RFC 3315 DUID is not being used to construct the Client ID. Instead, Client ID is derived using the MAC address of the interface as per RFC 2132. CID-VALUE will contain the string 0x01 followed by the MAC address hex string. This is applicable only for IPv4.

CID-VALUE
Value of the Client ID used by the dhcpagent(1M), if the address is being obtained using DHCP. Format used follows that of the configuration parameter CLIENT_ID in file /etc/default/dhcpagent. Refer to the description of CLIENT_ID in dhcpagent(1M). When the CID-TYPE is default, the CID-VALUE contains the legacy

CLIENT-ID, constructed as per RFC 2132. This field is not shown in the default output. It can be shown using -d or using cid-type or all with -o.

BEGIN

The time at which the lease began, if one is available, for the addresses obtained using DHCP. The time is displayed in the format dictated by the LC_TIME locale environment variable. For addresses not configured using DHCP or for DHCP addresses that do not have a lease yet, - - (two hyphens) will be displayed. This field is not shown in the default output. It can be shown using -d or using cid-type or all with -o.

EXPIRE

The time at which the lease expires, if one is available, for the addresses obtained using DHCP. The time is displayed in the format dictated by the LC_TIME locale environment variable. For addresses not configured using DHCP or for DHCP addresses that do not have a lease yet, - - (two hyphens) will be displayed. This field is not shown in the default output. It can be shown using -d or using cid-type or all with -o.

RENEW

The time at which the lease was last renewed for the addresses obtained using DHCP. The time is displayed in the format dictated by the LC_TIME locale environment variable. For addresses not configured using DHCP or for DHCP addresses that do not have a lease yet, - - (two hyphens) will be displayed. This field is not shown in the default output. It can be shown using -d or using cid-type or all with -o.

-d, --dhcp

Display the dhcp status fields for addresses acquired using DHCP. The fields displayed are ADDROBJ, STATE, ADDR, CID-TYPE, CID-VALUE, BEGIN, EXPIRE, and RENEW. This option displays only the human-readable output and cannot be used in conjunction with -p.

Note – In some cases the name of the address object starts with an underbar (_), as in e1000g1/_a or e1000g1/_b. These names were automatically generated for applications that used the ipadm programming library. You will also see addresses that have a question mark (?) in the address object name. This means that those addresses were created outside the ipadm library and therefore not known to ipadm.

down-addr [-t] *addrobj*

The address identified by *addrobj* is marked down, so that it cannot be used as a source/destination of outbound/inbound packets. This command has no effect if the address object was already marked down prior to the down-addr invocation. If the address object is of type addrconf, the command returns an error.

-t, --temporary

Specifies that the configured address is temporary and changes apply only to the active configuration. This option is mandatory if the address object type is dhcp.

up-addr [-t] *addrobj*

The address identified by *addrobj* is marked up, so that it can be used as a source/destination of outbound/inbound packets. This subcommand has no effect if the address object has been marked down by the system because it is a duplicate address, or if the address was marked up prior to the up-addr invocation. If the address object is of type addrconf, the command returns an error.

-t, --temporary

Specifies that the configured address is temporary and changes apply only to the active configuration. This option is mandatory if the address object type is dhcp.

refresh-addr [-i] *addrobj*

If the *addrobj* is of the type static then DAD (Duplicate Address Detection) will be restarted (if necessary) on the address identified by the address object.

If the *addrobj* is of the type dhcp, then the lease duration obtained on the address will be extended by the DHCP client daemon.

If the *addrobj* is of the type addrconf then the command returns an error.

-i, --inform

For a specified IP address, obtains network configuration parameters from DHCP without obtaining a lease on it. This is useful in situations where an IP address is obtained through mechanisms other than DHCP.

disable-addr -t *addrobj*

Disables the address by removing it from the active configuration. If the address object was originally created persistently, then the persistent configuration is unchanged. To re-enable this *addrobj*, one should use enable-addr.

-t, --temporary

Specifies that the disabling is temporary and changes apply only to the active configuration.

enable-addr -t *addrobj*

Enables the given *addrobj* by reading the configuration from the persistent store. All the persistent address properties are applied to the address object. This subcommand requires that the interface on which the address object is being enabled be present. If the interface itself is missing in active configuration and is present in persistent store, that is, if the interface is disabled, then the user has to run enable-if before invoking enable-addr.

-t, --temporary

Specifies that the enabling is temporary and changes apply only to the active configuration.

set-addrprop [-t] -p prop=*value*[,...] *addrobj*

Sets the value of a property on the *addrobj* specified. If the *addrobj* maps to several addresses, then property changes applies to all the addresses referenced by the *addrobj*. Only one property can be specified at a time. The properties supported on the *addrobj* and

the property's possible values can be retrieved using show-addrprop subcommand. If the *addrobj* is of type addrconf, the command returns an error.

-t, --temporary

Specifies that the changes are temporary and changes apply only to the active configuration.

-p prop=*value*[,...], --prop prop=*value*[,...]

A property to set to the specified values.

reset-addrprop [-t] -p *prop addrobj*

Resets the given address property to its default value. If -t is not used, any persistent value of the property will be deleted. Only one property can be modified at a time. If the *addrobj* is of type addrconf, the command returns an error.

-t, --temporary

Specifies that the resets are temporary and changes apply only to the active configuration.

-p *prop*, --prop *prop*

A property to be reset.

show-addrprop [[-c] -o *field*[,...]] [-p *prop*,...] [*addrobj*]

Show the current and persistent values of one or more properties, either for all the configured address objects or for the specified *addrobj*. Several properties of interest can be retrieved at one time by providing comma-separated property names to -p option. If the -p option is not specified, all available properties are displayed. If the *addrobj* is of type addrconf, the command returns an error.

-o *field*[,...], --output *field*[,...]

A case-insensitive, comma-separated list of output fields to display. The *field* name must be one of the fields listed below, or the special value all to display all fields. For each *addrobj*, the following fields can be displayed:

ADDROBJ

The name of the address object.

PROPERTY

The name of the property.

PERM

The read/write permissions of the property. The value shown will be r (read only), w (write only) or rw (read/write).

CURRENT

The current value of the property. For the disabled addresses, because the value is not set, the value displays as a double hyphen (--).

PERSISTENT

The persistent value of a property. Persistent values are the values that will be reapplied on reboot.

DEFAULT
The default value of the property. If the property has no default value, double hyphen
(--) is shown.

POSSIBLE
A comma-separated list of the values a property can have. If the values span a
numeric range, *min - max* might be shown as shorthand. If the possible values are
unknown, a question mark (?) is displayed or if they are unbounded, double hyphen
(--) will be shown.

-c, --parsable
Display using a stable machine-parsable format. The -o option is required with this
option. See "Parsable Output Format", below.

-p *prop*,..., --prop=*prop*
A comma-separated list of properties to display. See the sections on address object
properties following subcommand descriptions.

set-prop [-t] -p prop[+ | –]=*value*[,...] *protocol*
Modifies the value of a protocol property to the *value* specified. If the property takes
multiple values, the values should be specified with a comma as the delimiter. Only one
property can be specified at a time. By default, the value is persistent and will be reapplied
on reboot. The properties supported on a protocol and the property's possible values can be
retrieved using the show-prop subcommand

The following protocols are supported: ip, ipv4, ipv6, icmp, tcp, udp and sctp.

Note that for some properties, it might be possible to set the value of the property both
globally, and on a per-interface basis. The per-interface value can be set using the
set-ifprop subcommand. In such cases, if the administrator chooses to customize the
per-interface value of the property to be distinct from the global value, the per-interface
value overrides the global setting for that interface.

-t, --temporary
Specifies that the changes to properties are temporary and changes apply only to the
active configuration.

-p prop[+|-]=*value*[,...], --prop prop[+|-]=*value*[,...]
A property to set to the specified values. It also provides the following "qualifiers" to
perform add and delete operations in addition to assignment.

+
Adds the given value to the current list of value(s).

-
Removes the given value from the current list of value(s).

=
Makes a new assignment and removes all the current value(s).

See EXAMPLES for more information on how to use the qualifiers.

reset-prop [-t] -p *prop protocol*
> Resets a property of the specified protocol to the default value of the property. If -t is not used, any persistent value of the property will be deleted. Only one property can be modified at a time.
>
> -t, --temporary
>> Specifies that the resets are temporary and changes apply only to the active configuration.
>
> -p *prop*, --prop *prop*
>> A property to be reset.

show-prop [[-c] -o *field*[,...]] [-p *prop*[,...] *protocol* | *protocol*]
> Show the current and persistent values of one or more properties, either for all supported protocols or for the specified protocol. Several properties of interest can be retrieved at a time by providing comma-separated property names to -p option. If the -p option is not specified, all available properties are displayed.
>
> -o *field*[,...], --output *field*[,...]
>> A case-insensitive, comma-separated list of output fields to display. The *field* name must be one of the fields listed below, or the special value all to display all fields. For each *protocol*, the following fields can be displayed:
>>
>> PROTO
>>> The name of the protocol.
>>
>> PROPERTY
>>> The name of the property.
>>
>> PERM
>>> The read/write permissions of the property. The value shown will be r (read only), w (write only) or rw (read/write).
>>
>> CURRENT
>>> The current value of the property. For the disabled addresses, because the value is not set, the value displays as a double hyphen (--). If the value is unknown, it is displayed as a question mark (?). If the current value of the property is not in the set of listed POSSIBLE values, the keyword custom is displayed.
>>
>> PERSISTENT
>>> The persistent value of a property. Persistent values are the values that will be reapplied on reboot.
>>
>> DEFAULT
>>> The default value of the property. If the property has no default value, double hyphen (--) is shown.

POSSIBLE
A comma-separated list of the values for the property setting to be used with the
set-prop subcommand. If the values span a numeric range, *min - max* might be
shown as shorthand. If the possible values are unknown, a question mark (?) is
displayed or if they are unbounded, double hyphen (- -) will be shown.

-c, --parsable
Display using a stable machine-parsable format. The -o option is required with this
option. See "Parsable Output Format", below.

-p *prop*,..., -—prop=*prop*
A comma-separated list of properties to display. See the sections on protocol properties
following subcommand descriptions.

For the supported list of properties for every protocol, see "Protocol Properties" below.

Parsable Output Format
The ipadm "show" subcommands have an -o option that displays output in a
machine-parsable format. The output format is one or more lines of colon (:) delimited fields.
The fields displayed are specific to the subcommand used and are listed under the entry for the
-o option for a given subcommand. Output includes only those fields requested by means of
the -o option, in the order requested. Note that the -o all option, which displays all the fields
for a given subcommand, cannot be used with parsable output option.

When you request multiple fields, any literal colon characters are escaped by a backslash (\)
before being output. Similarly, literal backslash characters are also escaped (\\). This escape
format is parsable by using shell read(1) functions with the environment variable set as IFS=:
Note that escaping is not done when you request only a single field.

Protocol Properties
The following protocol properties are supported:

Note – There are protocol properties, specific to a protocol, that begin with "_" (underbar).
These properties are subject to change or removal and by default, are not displayed in ipadm
show-prop output. See *Oracle Solaris Tunable Parameters Reference Manual* for details.

cong_default (TCP, SCTP)
Specify the default congestion control algorithm used by the protocol when new
connections are created. Applications can opt to choose a different algorithm at a later
point in the connnection's lifetime. Only enabled algorithms can be set as default (see
cong_enabled).

cong_enabled (TCP, SCTP)
This option can be used to enable or disable congestion control algorithms. By default, all
algorithms installed on the systems are enabled. Disabled algorithms cannot be set as
default (see cong_default) or used by applications.

Algorithms can be added or removed using the set-prop subcommand and the modifiers
+ and -.

ecn (TCP)

Explicit Congestion Control (see RFC 3168 for more information). Possible values are the same as above: `never`, `passive`, and `active`.

extra_priv_ports (TCP, SCTP, UDP)

This option define additional privileged ports outside of the 1-1023 range. Any program that attempts to bind the ports listed here must run as root. This prevents normal users from starting server processes on specific ports.

These ports can be added, removed, or assigned using the `set-prop` subcommand and the modifiers `+`, `-`, and `=`. See EXAMPLES below on usage.

forwarding (IPv4), forwarding (IPv6)

Enable/disable global IPv4 or IPv6 forwarding. All the configured interfaces will start/stop forwarding packets. Individual interfaces can override the global option using `set-ifprop`.

hostmodel (IPv4), hostmodel (IPv6)

Control send/receive behavior for IP packets on a multi-homed system. The value of `hostmodel` can be set to `strong` or `weak`, corresponding to the equivalent end-system model definitions of RFC 1122. In addition, a third value of `src-priority` is also supported. In the `src-priority` hostmodel scenario, a packet will be accepted on any interface, as long as the packet's destination IP address is configured and marked UP on one of the host's interfaces. When transmitting a packet, if multiple routes for the IP destination in the packet are available, the system will prefer routes where the IP source address in the packet is configured on the outgoing interface. If no such route is available, the system will fall back to selecting the "best" route, as with the weak ES case.

max_buf (TCP, SCTP, UDP, ICMP)

Maximum size of the send or receive socket buffer. The current value of this property limits the maximum value of `recv_buf` and `send_buf`.

recv_buf (TCP, SCTP, UDP, ICMP)
send_buf (TCP, SCTP, UDP, ICMP)

Modifies the receive or send buffer sizes for the specified protocol. The maximum value of these properties is bound by the current value of the `max_buf` property.

sack (TCP)

Selective acknowledgment (SACK) allows recipients to selectively acknowledge out-of-sequence data and is intended to increase performance for data transfers over lossy links. See RFC 2018 for information on the SACK. Possible values and meanings:

never

Will neither accept SACK nor send out SACK information.

passive

Will accept SACK but not send out.

active

Will both accept SACK and send out SACK information.

smallest_anon_port (TCP, SCTP, UDP)
largest_anon_port (TCP, SCTP, UDP)
    These options define the upper and lower bounds on ephemeral ports. Ephemeral (means
    short-lived) ports are used when establishing outbound network connections. Note that
    the current value of the smallest_anon_port should be always less than or equal to the
    current value of largest_anon_port.

smallest_nonpriv_port (TCP, SCTP, UDP)
    This option define the start of non-privileged ports. The non-privileged port range
    normally starts at 1024. Any program that attempts to bind a non-privileged port does not
    have to run as root.

ttl (IPv4), hoplimit (IPv6)
    Specifies the value that will be set for ttl/hoplimit field of an IPv4 or IPv6 header. Can be
    used to prevent the system from reaching other systems more than *N* hops away where *N*
    was the value specified.

Interface Properties   The following interface properties are supported:

arp
    Enables/disables the use of the Address Resolution Protocol (ARP) on an interface. ARP is
    used in mapping between network level addresses and link level addresses. This is currently
    implemented for mapping between IPv4 addresses and MAC addresses. Possible values are
    on or off. Default is on.

exchange_routes
    Enables/disables exchanging of routing information on this interface. Possible values are
    on or off. Default is off.

group
    Specifies the group name of the IPMP interface for which this interface is an underlying
    interface. If the interface is of class IPMP, this specifies the name of the IPMP group. It is a
    read-write property only on IPMP interfaces. For other interface classes, this property is
    read-only.

forwarding
    Enables/disables IP forwarding on an interface. When enabled, the IP packets can be
    forwarded to and from the interface. Possible values are on or off. Default is off.

metric
    Set the routing metric of the interface to *n*; if no value is specified, the default is 0. The
    routing metric is used by the routing protocol. Higher metrics have the effect of making a
    route less favorable. Metrics are counted as additional hops to the destination network or
    host.

mtu
    Set the maximum transmission unit of the interface to *n*. For many types of networks, the
    MTU has an upper limit, for example, 1500 for Ethernet.

nud

Enables/disables the neighbor unreachability detection mechanism on a point-to-point physical interface. Possible values are on or off. Default is on.

standby

Specifies whether the interface is configured as a standby interface for an IPMP group. This property is not applicable to IPMP interfaces.

usesrc

Specifies a physical or virtual interface to be used for source address selection. If the keyword none is used, then any previous selection is cleared. Default is none.

Address Properties   The address properties listed below are supported. Note that modifying address properties for addrconf address objects is not supported.

deprecated

The address should no longer used as a source address in new communications, but packets addressed to this address are processed as expected. Possible values are on or off. Default is off. This property is not supported on an address object of type dhcp.

prefixlen

Specifies the number of left-most contiguous bits of the address that comprise the IPv6 prefix or IPv4 netmask of the address. The remaining low-order bits define the host part of the address. When prefixlen is converted to a text representation of the address, the address contain 1's for the bit positions that are to be used for the network part, and 0's for the host part. The prefixlen must be specified as a single decimal number. This property is not supported on an address object of type dhcp.

private

Specifies that the addresses should not be advertised by the in.routed routing daemon. Possible values are on or off. Default is off.

reqhost

The hostname to which the client would like the DHCP server to map the client's leased IPv4. A hostname request is not guaranteed to be fulfilled.

transmit

Enables packets to be transmitted using the addresses referenced by the address object. This is the default behavior when the address is up. Possible values are on or off. Default is on.

zone

Specifies the zone in which all the addresses referenced by the address object should be placed. The named zone must be active in the kernel in the ready or running state. The interface is unplumbed when the zone is halted or rebooted. The zone must be configured to be an shared-IP zone. zonecfg(1M) is used to assign network interface names to exclusive-IP zones. To modify the zone assignment such that it persists across reboots, please use zonecfg(1M). Possible values are the list of all the zones configured on the system. Default is global.

Operands   Each `ipadm` subcommand operates on one of the following objects:

addrobj
   An address configured on a network interface is identified by an *addrobj*. An *addrobj*
   consists of two parts. The first part is the name of the network interface on which the
   address is configured. The second part is a user-specified string that can use any of the
   alphanumeric characters and can be at-most 32 characters in length and must begin with a
   letter. The two parts of the *addrobj* are delimited by a slash (`/`). An address object always
   represents a unique set of address(es) in a system.

interface
   Name of the network interface on which network address is configured. In general, the
   name can use any alphanumeric characters, plus the underscore (`_`) and the period (`.`), but
   must start with an alphabetic character and end with a number.

protocol
   Name of the TCP/IP Internet protocol family for which a property is to be configured.
   Following protocols are supported: `ip`, `ipv4`, `ipv6`, `icmp`, `tcp`, `sctp` and `udp`.

Examples   EXAMPLE 1   Creating IPv4 Static Addresses

The following command creates the address 10.2.3.4/24 on interface bge1 (linkname `net1`)
and marks the address up, for use.

```
# ipadm create-ip net1
# ipadm create-addr -T static -a local=10.2.3.4/24 net1/v4static1
```

The following command creates another address 10.2.3.5/24 on interface `net1` but marks the
address down until explicitly marked up.

```
# ipadm create-addr -T static -d -a 10.2.3.5/24 net1/v4static2
```

Note that 10.2.3.5/24 is assumed to be the local address, because local was not used and there
was only one address.

The following command marks the address object `net1/v4static2` up that was previously
marked down.

```
# ipadm up-addr net1/v4static2
```

If the DUPLICATE flag was set on the address object, then `refresh-addr` will verify that the
address is still a duplicate on the network. If it is not, the address will be marked up.

```
# ipadm refresh-addr net1/v4static2
```

The following command lists the addresses that were configured. This shows that the address
`net1/v4static2` is not a duplicate.

```
# ipadm show-addr
ADDROBJ         TYPE    STATE     ADDR
lo0/v4          static  ok        127.0.0.1/8
```

EXAMPLE 1 Creating IPv4 Static Addresses   *(Continued)*

```
lo0/v6          static  ok        ::/128
net1/v4static1  static  ok        10.2.3.4/24
net1/v4static2  static  ok        10.2.3.10/24
```

EXAMPLE 2 Creating DHCPv4-controlled Addresses

The following command obtains a DHCPv4 address on interface bge1 (linkname net1).

```
# ipadm create-ip net1
# ipadm create-addr -T dhcp net1/dhaddr
# ipadm show-addr net1/dhaddr
ADDROBJ         TYPE    STATE     ADDR
net1/dhaddr     dhcp    ok        10.8.48.173/25
```

The following command extends the lease duration for the DHCPv4 address object
net1/dhaddr.

```
# ipadm refresh-addr net1/dhaddr
```

EXAMPLE 3 Creating IPv6 Addresses

The following sequence of commands auto-configures IPv6 addresses on bge1 (linkname
net1) using in.ndpd with the default interface ID. A link-local address is configured first,
followed by in.ndpd adding the stateless and stateful auto-configured addresses.

```
# ipadm create-ip net1
# ipadm create-addr -T addrconf net1/v6addr
```

The following command creates a IPv6 static address. To be able to configure an IPv6 address
that is not a link-local address, the interface should already have a link-local address
configured on it. It was accomplished by the previous step with -T addrconf.

```
# ipadm create-addr -T static -a local=2ff0::f3ad/64 net1/v6static
```

The following command changes the prefix length of an IPv6 address.

```
# ipadm set-addrprop -p prefixlen=80 net1/v6static
```

All the auto-configured addresses and the updated prefix length can be viewed by listing the
addresses:

```
# ipadm show-addr
ADDROBJ         TYPE    STATE   ADDR
lo0/v4      static  ok      127.0.0.1/8
lo0/v6      static  ok      ::/128
net1/v6addr addrconf ok      fe80::203:baff:fe94:2f01/10
net1/v6addr addrconf ok      2002:a08:39f0:1:203:baff:\
                                  fe94:2f00/64
net1/v6addr addrconf ok      2001:db8:1:2::402f/128
```

EXAMPLE 3   Creating IPv6 Addresses   *(Continued)*

```
net1/v6static static   ok        2ff0::f3ad/80
```

EXAMPLE 4   Configuring an IPv4 Tunnel

The first command below (ipadm) creates the tunnel source address. Then, a dladm command creates the tunnel link. The final ipadm commands configure the IPv4 and IPv6 addresses on the tunnel IP interface.

```
# ipadm create-ip net1
# ipadm create-addr -T static -a local=10.2.3.4/24 net1/v4static
# dladm create-iptun -T ipv4 -a local=10.2.3.4,remote=10.2.3.5 tun0
# ipadm create-ip tun0
# ipadm create-addr -T static \
       -a local=173.129.134.1,remote=173.129.134.2 tun0/v4tunaddr
# ipadm create-addr -T static \
       -a local=2ff1::3344,remote=2ff1::3345 tun0/v6tunaddr
# ipadm show-addr
ADDROBJ         TYPE    STATE     ADDR
lo0/v4          static ok        127.0.0.1/8
lo0/v6          static ok        ::/128
net1/v4static   static ok        10.2.3.4/24
tun0/v4tunaddr static ok        173.129.134.1-->173.129.134.2
tun0/v6tunaddr static ok        2ff1::3344-->2ff1::3345
```

EXAMPLE 5   Viewing All of the Interfaces

The following command enables you to view all interfaces.

```
# ipadm show-if -o all
IFNAME  CLASS       STATE     ACTIVE CURRENT       PERSISTENT OVER
lo0     loopback ok       yes    -m-v------46  --46        --
net0    ip          ok       yes    bm--------46  --46        --
e1000g0 ip          ok       yes    bm---l----46  -l46        --
e1000g1 ip          ok       yes    bm---l----46  -l46        --
ipmp0   ipmp     down      yes    bm--------46  --46        e1000g0 e1000g1
tun0    ip          failed   no     -mp-------46  --46        --
vni0    vni      disabled no     bm-v--------  --46        --
```

EXAMPLE 6   Displaying Interface Properties

The following command displays all interface properties for a specified interface.

```
# ipadm show-ifprop net0
IFNAME PROPERTY       PROTO PERM CURRENT PERSISTENT DEFAULT  POSSIBLE
net0   arp            ipv4 rw   on      --         on       on,off
net0   forwarding     ipv4 rw   off     on         off      on,off
net0   metric         ipv4 rw   2       2          0        --
net0   mtu            ipv4 rw   1500    --         1500     68-1500
```

EXAMPLE 6 Displaying Interface Properties   *(Continued)*

```
net0   exchange_routes ipv4 rw   off     --        off    on,off
net0   usesrc          ipv4 rw   none    --        none   --
net0   forwarding      ipv6 rw   off     --        off    on,off
net0   metric          ipv6 rw   2       2         0      --
net0   mtu             ipv6 rw   1500    --        1500   1280-1500
net0   nud             ipv6 rw   on      --        on     on,off
net0   exchange_routes ipv6 rw   off     on        off    on,off
net0   usesrc          ipv6 rw   none    --        none   --
net0   group           ip   rw   grp0    --        --     --
net0   standby         ip   r-   off     --        off    on,off
```

EXAMPLE 7 Configuring per-Interface Properties

The following command sets the IPv4 MTU of the interface net0 to 900.

```
# ipadm set-ifprop -m ipv4 -p mtu=900 net0
```

The following command sets the IPv6 MTU of the interface net0 to 1400.

```
# ipadm set-ifprop -m ipv6 -p mtu 1400 net0
```

View the results:

```
# ipadm show-ifprop -p mtu net0
IFNAME PROPERTY         PROTO PERM CURRENT PERSISTENT DEFAULT  POSSIBLE
net0   mtu              ipv4  rw   900     900        1500     68-1500
net0   mtu              ipv6  rw   1400    1400       1500     1280-1500

# ipadm show-ifprop -m ipv6 -p mtu net0
IFNAME PROPERTY         PROTO PERM CURRENT PERSISTENT DEFAULT  POSSIBLE
net0   mtu              ipv6  rw   1400    1400       1500     1280-1500
```

EXAMPLE 8 Displaying Supported Properties

The following command displays the properties supported on TCP.

```
# ipadm show-prop tcp
PROTO PROPERTY            PERM CURRENT PERSISTENT DEFAULT   POSSIBLE
tcp   ecn                 rw   active  active     passive   never,passive,
                                                                   active
tcp   extra_priv_ports    rw   --      1,65535    2049,4045 1-65535
tcp   largest_anon_port   rw   32768   32768      65535     1024-65535
tcp   sack                rw   active  --         active    never,passive,
                                                                   active
tcp   recv_buf            rw   29567   --         49152     2048-1073741824
tcp   send_buf            rw   21354   --         49152     4096-1073741824
tcp   max_buf             ro   65536   --         32768     4096-1073741824
tcp   smallest_anon_port  rw   32768   --         32768     1024-65535
tcp   smallest_nonpriv_port rw 1024    --         1024      1024-32768
```

EXAMPLE 9 Configuring Global IPv4 Forwarding

The following command sequence configures global IPv4 forwarding and overrides that setting for interface net0.

```
# ipadm set-prop -p forwarding=on ipv4
# ipadm set-ifprop -p forwarding=off -m ipv4 net0
# ipadm show-prop -p forwarding ipv4
PROTO PROPERTY              PERM CURRENT PERSISTENT DEFAULT POSSIBLE
ipv4  forwarding           rw   on      on         off     on,off

# show-ifprop -p forwarding -m ipv4 net0
IFNAME PROPERTY        PROTO PERM CURRENT PERSISTENT DEFAULT  POSSIBLE
net0   forwarding      ipv4  rw   off     off        off      on,off
```

EXAMPLE 10 Using Qualifiers in set-prop Subcommand

The following command sequence uses the plus and minus (+, –) qualifiers to add 1047, 1048, and 1049 as extra privileged ports for TCP.

```
# ipadm set-prop -p extra_priv_ports=1047 tcp
# ipadm set-prop -p extra_priv_ports+=1048 tcp
# ipadm set-prop -p extra_priv_ports+=1049 tcp
# ipadm set-prop -p extra_priv_ports+=1050 tcp
```

The following command deletes 1048 as extra privileged port.

```
# ipadm set-prop -p extra_priv_ports-=1048
```

The following command displays all the extra privileged ports for TCP.

```
# ipadm show-prop -p extra_priv_ports tcp
PROTO PROPERTY             PERM CURRENT    PERSISTENT DEFAULT   POSSIBLE
ipv4  extra_priv_ports     rw   1047,1049, 1047,1049, 2049,4045 1-65535
                                1050       1050
```

EXAMPLE 11 Enabling and Disabling Objects

The following command sequences enables and disables interface and address objects and display the results of those actions.

```
# ipadm create-ip net1
# ipadm create-addr -T static -a local=10.2.3.4/24 net1/v4static
# ipadm set-addrprop -p private=yes net1/v4static
# ipadm show-addr net1/v4static
ADDROBJ        TYPE   STATE    ADDR
net1/v4static  static ok       10.2.3.4/24
```

The following command disables the address object net1/v4static.

```
# ipadm disable-addr -t net1/v4static
# ipadm show-addr net1/v4static
```

EXAMPLE 11   Enabling and Disabling Objects   *(Continued)*

```
ADDROBJ          TYPE   STATE      ADDR
net1/v4static  static ok        10.2.3.4/24
```

The following command disables the interface object net1.

```
# ipadm disable-if -t net1
# ipadm show-if net1 -o all
IFNAME     CLASS    STATE      ACTIVE CURRENT        PERSISTENT OVER
net1       ip       disabled no     bm---------- --46        --
```

The following command enables the interface object from the persistent configuration.

```
# ipadm enable-if -t net1
# ipadm show-if net1 -o all
IFNAME     CLASS    STATE      ACTIVE CURRENT        PERSISTENT OVER
net1       ip       ok         yes    bm--------46 --46        --

# ipadm show-addr net1/v4static
ADDROBJ          TYPE   STATE      ADDR
net1/v4static  static ok        10.2.3.4/24
```

Note that when the interface object is enabled all the address objects configured on that interface are enabled also.

The following command creates persistent configuration for the net0 interface in a non-global exclusive-IP zone so that the net0 interface will be configured with the set of addresses made available through the allowed-address resource from the global zone on the next reboot.

```
# ipadm create-ip net0
```

The net0 interface can also be configured with the available set of allowed-address values in the non-global exclusive-IP zone without a reboot by executing the following commands:

```
# ipadm disable-if -t net0
# ipadm enable-if -t net0
```

EXAMPLE 12   Creating IPMP Interfaces

The following command sequence creates an IPMP interface and adds underlying interfaces to it.

```
# ipadm create-ip e1000g0
# ipadm create-ip e1000g1
# ipadm create-ip e1000g2
# ipadm set-ifprop -p standby=on -m ip e1000g2
# ipadm create-ipmp testgroup0
# ipadm add-ipmp -i e1000g0 -i e1000g1 -i e1000g2 testgroup0
# ipadm create-addr -T static -a local=192.168.80.5/24 testgroup0/data1
```

EXAMPLE 12   Creating IPMP Interfaces   *(Continued)*

```
# ipadm create-addr -T static -a local=192.168.80.6/24 testgroup0/data2
# ipadm show-if
IFNAME     CLASS      STATE     ACTIVE OVER
lo0        loopback ok        yes    --
net0       ip         ok        yes    --
e1000g0    ip         ok        yes    --
e1000g1    ip         ok        yes    --
ipmp0      ipmp       ok        yes    e1000g0 e1000g1
```

The following command sequence disables and subsequently enables the IPMP interface.

```
# ipadm disable-if -t testgroup0
ipadm show-if
IFNAME     CLASS      STATE     ACTIVE OVER
lo0        loopback ok        yes    --
net0       ip         ok        yes    --
e1000g0    ip         disabled no     --
e1000g1    ip         disabled no     --
ipmp0      ipmp       disabled no     e1000g0 e1000g1
# ipadm enable-if -t testgroup0
```

The following command sequence removes underlying interface from the IPMP interface and then deletes the IPMP interface.

```
ipadm remove-ipmp -i e1000g0 -i e1000g1 testgroup0
ipadm delete-ipmp testgroup0
```

Name ipf – alter packet filtering lists for IP packet input and output

Synopsis ipf [-6AdDEInoPRrsvVyzZ] [-l block | pass | nomatch]
      [-T *optionlist*] [-F i | o | a | s | S] -f *filename*
      [-f *filename*...]

Description The ipf utility is part of a suite of commands associated with the Solaris IP Filter feature. See
ipfilter(5).

The ipf utility opens the filenames listed (treating a hyphen (-) as stdin) and parses the file for
a set of rules which are to be added or removed from the packet filter rule set.

If there are no parsing problems, each rule processed by ipf is added to the kernel's internal
lists. Rules are added to the end of the internal lists, matching the order in which they appear
when given to ipf.

ipf's use is restricted through access to /dev/ipauth, /dev/ipl, and /dev/ipstate. The
default permissions of these files require ipf to be run as root for all operations.

Enabling Solaris IP
Filter Feature
Solaris IP Filter is installed with the Solaris operating system. However, packet filtering is not
enabled by default. Use the following procedure to activate the Solaris IP Filter feature.

1. Assume a role that includes the IP Filter Management rights profile (see rbac(5)) or
become superuser.

2. Configure system and services' firewall policies. See svc.ipfd(1M) and ipf(4).

3. (Optional) Create a network address translation (NAT) configuration file. See
ipnat.conf(4).

4. (Optional) Create an address pool configuration file. See ippool(4).

Create an ipool.conf file if you want to refer to a group of addresses as a single address
pool. If you want the address pool configuration file to be loaded at boot time, create a file
called /etc/ipf/ippool.conf in which to put the address pool. If you do not want the
address pool configuration file to be loaded at boot time, put the ippool.conf file in a
location other than /etc/ipf and manually activate the rules.

5. Enable Solaris IP Filter, as follows:

    # **svcadm enable network/ipfilter**

To re-enable packet filtering after it has been temporarily disabled either reboot the machine
or enter the following command:

svcadm enable network/ipfilter

...which essentially executes the following ipf commands:

1. Enable Solaris IP Filter:

    # **ipf -E**

2. Load ippools:

 # ippool -f *<ippool configuration file>*

See ippool(1M).

3. (Optional) Activate packet filtering:

ipf -f *<ipf configuration file>*

4. (Optional) Activate NAT:

ipnat -f *<IPNAT configuration file>*

See ipnat(1M).

Note – If you reboot your system, the IPfilter configuration is automatically activated.

Options The following options are supported:

-6

This option is required to parse IPv6 rules and to have them loaded. Loading of IPv6 rules is subject to change in the future.

-A

Set the list to make changes to the active list (default).

-d

Turn debug mode on. Causes a hex dump of filter rules to be generated as it processes each one.

-D

Disable the filter (if enabled). Not effective for loadable kernel versions.

-E

Enable the filter (if disabled). Not effective for loadable kernel versions.

-F i|o|a

Specifies which filter list to flush. The parameter should either be i (input), o (output) or a (remove all filter rules). Either a single letter or an entire word starting with the appropriate letter can be used. This option can be before or after any other, with the order on the command line determining that used to execute options.

-F s|S

To flush entries from the state table, use the -F option in conjuction with either s (removes state information about any non-fully established connections) or S (deletes the entire state table). You can specify only one of these two options. A fully established connection will show up in ipfstat -s output as 4/4, with deviations either way indicating the connection is not fully established.

-f *filename*

Specifies which files ipf should use to get input from for modifying the packet filter rule lists.

-I

Set the list to make changes to the inactive list.

-l pass | block | nomatch

Toggles default logging of packets. Valid arguments to this option are pass, block and nomatch. When an option is set, any packet which exits filtering and matches the set category is logged. This is most useful for causing all packets that do not match any of the loaded rules to be logged.

-n

Prevents ipf from making any ioctl calls or doing anything which would alter the currently running kernel.

-o

Force rules by default to be added/deleted to/from the output list, rather than the (default) input list.

-P

Add rules as temporary entries in the authentication rule table.

-R

Disable both IP address-to-hostname resolution and port number-to-service name resolution.

-r

Remove matching filter rules rather than add them to the internal lists.

-s

Swap the currently active filter list to be an alternative list.

-T *optionlist*

Allows run-time changing of IPFilter kernel variables. To allow for changing, some variables require IPFilter to be in a disabled state (-D), others do not. The *optionlist* parameter is a comma-separated list of tuning commands. A tuning command is one of the following:

list

Retrieve a list of all variables in the kernel, their maximum, minimum, and current value.

single variable name

Retrieve its current value.

variable name with a following assignment

To set a new value.

Examples follow:

```
# Print out all IPFilter kernel tunable parameters
ipf -T list
```

```
# Display the current TCP idle timeout and then set it to 3600
ipf -D -T fr_tcpidletimeout,fr_tcpidletimeout=3600 -E

# Display current values for fr_pass and fr_chksrc, then set
# fr_chksrc to 1.
ipf -T fr_pass,fr_chksrc,fr_chksrc=1
```

-v

Turn verbose mode on. Displays information relating to rule processing.

-V

Show version information. This will display the version information compiled into the ipf binary and retrieve it from the kernel code (if running or present). If it is present in the kernel, information about its current state will be displayed; for example, whether logging is active, default filtering, and so forth).

-y

Manually resync the in-kernel interface list maintained by IP Filter with the current interface status list.

-z

For each rule in the input file, reset the statistics for it to zero and display the statistics prior to them being zeroed.

-Z

Zero global statistics held in the kernel for filtering only. This does not affect fragment or state statistics.

Files /dev/ipauth
/dev/ipl
/dev/ipstate
Links to IP Filter pseudo devices.

/etc/ipf/ipf.conf
Location of ipf startup configuration file. See ipf(4).

/usr/share/ipfilter/examples/
Contains numerous IP Filter examples.

Oracle Solaris Administration: IP Services

Diagnostics   Needs to be run as root for the packet filtering lists to actually be affected inside the kernel.

Name ipfs – saves and restores information for NAT and state tables

Synopsis ipfs [-nv] -l

ipfs [-nv] -u

ipfs [-nv] [-d *dirname*] -R

ipfs [-nv] [-d *dirname*] -W

ipfs [-nNSv] [-f *filename*] -r

ipfs [-nNSv] [-f *filename*] -w

ipfs [-nNSv] -f *filename* -i *<if1>,<if2>*

Description The ipfs utility enables the saving of state information across reboots. Specifically, the utility allows state information created for NAT entries and rules using "keep state" to be locked (modification prevented) and then saved to disk. Then, after a reboot, that information is restored. The result of this state-saving is that connections are not interrupted.

Options The following options are supported:

-d Change the default directory used with -R and -W options for saving state information.

-n Do not take any action that would affect information stored in the kernel or on disk.

-v Provides a verbose description of ipfs activities.

-N Operate on NAT information.

-S Operate on filtering state information.

-u Unlock state tables in the kernel.

-l Lock state tables in the kernel.

-r Read information in from the specified file and load it into the kernel. This requires the state tables to have already been locked and does not change the lock once complete.

-w Write information out to the specified file and from the kernel. This requires the state tables to have already been locked and does not change the lock once complete.

-R Restores all saved state information, if any, from two files, ipstate.ipf and ipnat.ipf, stored in the /var/db/ipf directory. This directory can be changed with the -d option. The state tables are locked at the beginning of this operation and unlocked once complete.

-W Saves in-kernel state information, if any, out to two files, ipstate.ipf and ipnat.ipf, stored in the /var/db/ipf directory. This directory can be changed with the -d option. The state tables are locked at the beginning of this operation and unlocked once complete.

Files ■ /var/db/ipf/ipstate.ipf
■ /var/db/ipf/ipnat.ipf
■ /dev/ipl
■ /dev/ipstate
■ /dev/ipnat

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/ipfilter
Interface Stability	Committed

See Also ipf(1M), ipmon(1M), ipnat(1M), attributes(5)

Diagnostics Arguably, the -W and -R operations should set the locking and, rather than undo it, restore it to what it was previously.

Fragment table information is currently not saved.

Name ipfstat – reports on packet filter statistics and filter list

Synopsis ipfstat [-6aACdfghIilnoRstv]

ipfstat [-C] [-D *addrport*] [-P *protocol*] [-S *addrport*]
    [-T *refreshtime*]

Description The ipfstat command is part of a suite of commands associated with the Solaris IP Filter
feature. See ipfilter(5).

The ipfstat command examines /dev/kmem using the symbols _fr_flags, _frstats,
_filterin, and _filterout. To run and work, it needs to be able to read both /dev/kmem and
the kernel itself.

The default behavior of ipfstat is to retrieve and display the statistics which have been
accumulated over time as the kernel has put packets through the filter.

The role of ipfstat is to display current kernel statistics gathered as a result of applying the
filters in place (if any) to packets going in and out of the kernel. This is the default operation
when no command line parameters are present. When supplied with either -i or -o, ipfstat
will retrieve and display the appropriate list of filter rules currently installed and in use by the
kernel.

ipfstat uses kernel device files to obtain information. The default permissions of these files
require ipfstat to be run as root for all operations.

The ipfstat command supports the kstat(3KSTAT) kernel facility. Because of this support,
as an alternative to ipfstat, you can use kstat(1M). For example:

kstat -m ipf

Using the ipfstat -t option causes ipfstat to enter the state top mode. In this mode the
state table is displayed similarly to the way the Unix top utility displays the process table. The
-C, -D, -P, -S and -T command line options can be used to restrict the state entries that will be
shown and to specify the frequency of display updates.

In state top mode, use the following keys to influence the displayed information:

d   Select information to display.

l   Redraw the screen.

q   Quit the program.

s   Switch between different sorting criteria.

r   Reverse the sorting criteria.

States can be sorted by protocol number, by number of IP packets, by number of bytes, and by
time-to-live of the state entry. The default is to sort by the number of bytes. States are sorted in
descending order, but you can use the r key to sort them in ascending order.

It is not possible to interactively change the source, destination, and protocol filters or the refresh frequency. This must be done from the command line.

The screen must have at least 80 columns for correct display. However, ipfstat does not check the screen width.

Only the first *X*-5 entries that match the sort and filter criteria are displayed (where *X* is the number of rows on the display). There is no way to see additional entries.

Options The following options are supported:

-6	Display filter lists and states for IPv6, if available. This option might change in the future.
-a	Display the accounting filter list and show bytes counted against each rule.
-A	Display packet authentication statistics.
-C	Valid only in combination with -t. Display "closed" states as well in the top. Normally, a TCP connection is not displayed when it reaches the CLOSE_WAIT protocol state. With this option enabled, all state entries are displayed.
-d	Produce debugging output when displaying data.
-D *addrport*	Valid only in combination with -t. Limit the state top display to show only state entries whose destination IP address and port match the *addrport* argument. The *addrport* specification is of the form *ipaddress*[,*port*]. The *ipaddress* and *port* should be either numerical or the string any (specifying any IP address and any port, in that order). If the -D option is not specified, it defaults to -D any,any.
-f	Show fragment state information (statistics) and held state information (in the kernel) if any is present.
-g	Show groups currently configured (both active and inactive).
-h	Show per-rule the number of times each one scores a "hit". For use in combination with -i.
-i	Display the filter list used for the input side of the kernel IP processing.
-I	Swap between retrieving inactive/active filter list details. For use in combination with -i.
-l	When used with -s, show a list of active state entries (no statistics).
-n	Show the rule number for each rule as it is printed.
-o	Display the filter list used for the output side of the kernel IP processing.

-P *protocol*		Valid only in combination with -t. Limit the state top display to show only state entries that match a specific protocol. The argument can be a protocol name (as defined in /etc/protocols) or a protocol number. If this option is not specified, state entries for any protocol are specified.
-R		Disable both IP address-to-hostname resolution and port number-to-service name resolution.
-S *addrport*		Valid only in combination with -t. Limit the state top display to show only state entries whose source IP address and port match the *addrport* argument. The *addrport* specification is of the form *ipaddress*[,*port*]. The *ipaddress* and *port* should be either numerical or the string any (specifying any IP address and any port, in that order). If the -S option is not specified, it defaults to -S any,any.
-s		Show packet/flow state information (statistics only).
-T *refreshtime*		Valid only in combination with -t. Specifies how often the state top display should be updated. The refresh time is the number of seconds between an update. Any positive integer can be used. The default (and minimal update time) is 1.
-t		Show the state table in a way similar to the way the Unix utility, top, shows the process table. States can be sorted in a number of different ways.
-v		Turn verbose mode on. Displays additional debugging information.

Oracle Solaris Administration: IP Services

Name   ipmgmtd – IP network interfaces and TCP/IP tunables management daemon

Synopsis   /lib/inet/ipmgmtd

svc:/network/ip-interface-management:default

Description   ipmgmtd is a system daemon that handles administrative events for network IP interfaces and IP/TCP/UDP/SCTP/ICMP tunables. It is controlled through the service management facility (SMF) service instance:

svc:/network/ip-interface-management:default

The ipmgmtd daemon is started automatically by the SMF service and should not be invoked directly. It does not constitute an administrative or a programming interface. The administrative interface for managing IP interfaces and the aforementioned protocol tunables is through ipadm(1M).

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Private

See Also   ipadm(1M), attributes(5)

Name ipmon – monitors /dev/ipl for logged packets

Synopsis ipmon [-abDFhnpstvxX] [-N *device*] [[o] [NSI]] [-O [NSI]]
[-P *pidfile*] [-S *device*] [-f *device*] [*filename*]

Description The ipmon command is part of a suite of commands associated with the Solaris IP Filter feature. See ipfilter(5).

The ipmon command opens /dev/ipl for reading and awaits data to be saved from the packet filter. The binary data read from the device is reprinted in human readable form. However, IP addresses are not mapped back to hostnames, nor are ports mapped back to service names. The output goes to standard output, by default, or a filename, if specified on the command line. Should the -s option be used, output is sent instead to syslogd(1M). Messages sent by means of syslog have the day, month, and year removed from the message, but the time (including microseconds), as recorded in the log, is still included.

Messages generated by ipmon consist of whitespace-separated fields. Fields common to all messages are:

- The date of packet receipt. This is suppressed when the message is sent to syslog.

- The time of packet receipt. This is in the form *HH*:*MM*:*SS.F*, for hours, minutes, seconds, and fractions of a second (which can be several digits long).

- The name of the interface on which the packet was processed, for example, ib1.

- The group and rule number of the rule, for example, @0:17. These can be viewed with ipfstat -in for input rules or ipfstat -in for output rules. See ipfstat(1M).

- The action: p for passed, b for blocked, s for a short packet, n did not match any rules, or L for a log rule.

- The addresses. This is actually three fields: the source address and port (separated by a comma), the symbol →, and the destination address and port. For example: 209.53.17.22,80 → 198.73.220.17,1722.

- PR followed by the protocol name or number, for example, PR tcp.

- len followed by the header length and total length of the packet, for example, len 20 40.

If the packet is a TCP packet, there will be an additional field starting with a hyphen followed by letters corresponding to any flags that were set. See ipf.conf(4) for a list of letters and their flags.

If the packet is an ICMP packet, there will be two fields at the end, the first always being icmp, the next being the ICMP message and submessage type, separated by a slash. For example, icmp 3/3 for a port unreachable message.

Options The following options are supported:

-a

Open all of the device logfiles for reading log entries. All entries are displayed to the same output device (stderr or syslog).

-b

For rules which log the body of a packet, generate hex output representing the packet contents after the headers.

-D

Cause ipmon to turn itself into a daemon. Using subshells or backgrounding of ipmon is not required to turn it into an orphan so it can run indefinitely.

-f *device*

Specify an alternative device/file from which to read the log information for normal IP Filter log records.

-F

Flush the current packet log buffer. The number of bytes flushed is displayed, even if the result is zero.

-h

Displays usage information.

-n

IP addresses and port numbers will be mapped, where possible, back into hostnames and service names.

-N *device*

Set the logfile to be opened for reading NAT log records from or to *device*.

-o *letter*

Specify which log files from which to actually read data. N, NAT logfile; S, state logfile; I, normal IP Filter logfile. The -a option is equivalent to using -o NSI.

-O *letter*

Specify which log files you do not wish to read from. This is most commonly used in conjunction with the -a. Letters available as parameters are the same as for -o.

-p

Cause the port number in log messages always to be printed as a number and never attempt to look it up.

-P *pidfile*

Write the PD of the ipmon process to a file. By default this is /var/run/ipmon.pid.

-s

Packet information read in will be sent through syslogd rather than saved to a file. The default facility when compiled and installed is local0. The following levels are used:

LOG_INFO

Packets logged using the log keyword as the action rather than pass or block.

LOG_NOTICE

Packets logged that are also passed.

LOG_WARNING
   Packets logged that are also blocked.

LOG_ERR
   Packets that have been logged and that can be considered "short".

-S *device*
   Set the logfile to be opened for reading state log records from or to *device*.

-t
   Read the input file/device in the way performed by tail(1).

-v
   Show TCP window, ack, and sequence fields

-x
   Show the packet data in hex.

-X
   Show the log header record data in hex.

Files
- /dev/ipl
- /dev/ipnat
- /dev/ipstate

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/ipfilter
Interface Stability	Committed

Oracle Solaris Administration: IP Services

Diagnostics   ipmon expects data that it reads to be consistent with how it should be saved and aborts if it fails an assertion which detects an anomaly in the recorded data.

Name   ipmpstat – display IPMP subsystem status

Synopsis   `ipmpstat [-n] [-o` *field*`[,...] [-P]] -a|-g|-i|-p|-t`

Description   The `ipmpstat` command concisely displays information about the IPMP subsystem. It
supports five different output modes, each of which provides a different view of the IPMP
subsystem (address, group, interface, probe, and target), described below. At most one output
mode may be specified per invocation, and the displayed information is guaranteed to be
self-consistent. It also provides a parseable output format which may be used by scripts to
examine the state of the IPMP subsystem. Only basic privileges are needed to invoke
`ipmpstat`, with the exception of probe mode which requires all privileges.

Options   The following options are supported:

-a
   Display IPMP data address information ("address" output mode).

-g
   Display IPMP group information ("group" output mode).

-i
   Display IP interface information ("interface" output mode).

-n
   Display IP addresses numerically, rather than attempting to resolve them to hostnames.
   This option may be used in any output mode.

-o *field*[,...]
   Display only the specified output fields, in order. The list of field names is case-insensitive
   and comma-separated. The field names that are supported depend on the selected output
   mode, described below. The special field name `all` may be used to display all fields for a
   given output mode.

-p
   Display IPMP probe information ("probe" output mode).

-t
   Display IPMP target information ("target" output mode).

-P
   Display using a machine-parseable format, described below. If this option is specified, an
   explicit list of fields must be specified using the -o option.

Output Modes   The `ipmpstat` utility supports the output modes listed below. Note that these modes map to
some of the options described above.

Address Mode
   Address mode displays the state of all IPMP data addresses on the system. The following
   output fields are supported:

ADDRESS

The hostname (or IP address) associated with the information. Note that because duplicate down addresses may exist, the address must be taken together with the GROUP to form a unique identity. For a given IPMP group, if duplicate addresses exist, at most one will be displayed, and an up address will always take precedence.

STATE

The state of the address. Either up if the address is IFF_UP (see ifconfig(1M)), or down if the address is not IFF_UP.

GROUP

The IPMP IP interface hosting the address.

INBOUND

The underlying IP interface that will receive packets for this address. This may change in response to external events such as IP interface failure. If this field is empty, then the system will not accept IP packets sent to this address (for example, because the address is down or because there are no active IP interfaces left in the IPMP group).

OUTBOUND

The underlying IP interfaces that will send packets using this source address. This may change in response to external events such as IP interface failure. If this field is empty, then the system will not send packets with this address as a source (for example, because the address is down or because there are no active IP interfaces left in the IPMP group).

If -o is not specified, all output fields are displayed.

Group Mode

Group mode displays the state of all IPMP groups on the system. The following output fields are supported:

GROUP

The IPMP IP interface name associated with the information. For the anonymous group (see in.mpathd(1M)), this field will be empty.

GROUPNAME

The IPMP group name. For the anonymous group, this field will be empty.

STATE

The state of the group:

ok	All interfaces in the group are usable.
degraded	Some (but not all) interfaces in the group are usable.
failed	No interfaces in the group are usable.

FDT

The probe-based failure detection time. If probe-based failure detection is disabled, this field will be empty.

INTERFACES
The list of underlying IP interfaces in the group. The list is divided into three parts:

1. Active interfaces are listed first and not enclosed in any brackets or parenthesis. Active interfaces are those being used by the system to send or receive data traffic.

2. INACTIVE interfaces are listed next and enclosed in parenthesis. INACTIVE interfaces are those that are functioning, but not being used according to administrative policy.

3. Unusable interfaces are listed last and enclosed in brackets. Unusable interfaces are those that cannot be used at all in their present configuration (for example, FAILED or OFFLINE).

If -o is not specified, all output fields are displayed.

Interface Mode
Interface mode displays the state of all IP interfaces that are tracked by in.mpathd on the system. The following output fields are supported:

INTERFACE
The IP interface name associated with the information.

ACTIVE
Either yes or no, depending on whether the IP interface is being used by the system for IP data traffic.

GROUP
The IPMP IP interface associated with the IP interface. For IP interfaces in the anonymous group (see in.mpathd(1M)), this field will be empty.

FLAGS
Assorted information about the IP interface:

i   Unusable due to being INACTIVE.

s   Marked STANDBY.

m   Nominated to send/receive IPv4 multicast for its IPMP group.

b   Nominated to send/receive IPv4 broadcast for its IPMP group.

M   Nominated to send/receive IPv6 multicast for its IPMP group.

d   Unusable due to being down.

h   Unusable due to being brought OFFLINE by in.mpathd because of a duplicate hardware address.

LINK
The state of link-based failure detection:

up
   The link is up.

down
> The link is down.

unknown
> The network driver does not report link state changes.

PROBE
> The state of probe-based failure detection:

ok
> Probes detect no problems.

failed
> Probes detect failure.

unknown
> Probes cannot be sent since no suitable probe targets are known.

disabled
> Probes have been disabled because a unique IP test address has not been configured.

STATE
> The overall state of the interface:

ok
> The interface is online and functioning properly based on the configured failure detection methods.

failed
> The interface is online but has a link state of down or a probe state of failed.

offline
> The interface is offline.

unknown
> The interface is online but may or may not be functioning because the configured failure detection methods are in unknown states.

If -o is not specified, all output fields are displayed.

Probe Mode
> Probe mode displays information about the probes being sent by in.mpathd. Unlike other output modes, this mode runs until explicitly terminated using Ctrl-C. The following output fields are supported:

TIME
> The time the probe was sent, relative to when ipmpstat was started. If the probe was sent prior to starting ipmpstat, the time will be negative.

PROBE

An identifier representing the probe. The identifier embeds a prefix denoting the probe type, followed by a numerical identifier for the probe. The permissible values for the probe type are:

i   ICMP probes

t   transitive probes

ICMP probes are sent from active interfaces; the numeric identifier of the probe is incremented for each IP probe sent by in.mpathd over a given active interface. The numeric identifier matches the icmp_seq field of the ICMP probe packet and can be used for a more detailed analysis by packet monitoring tools.

When the IPMP group does not have any NOFAILOVER test addresses configured on any of the interfaces in the group, transitive probes are sent from all interfaces that are not actively being used for receiving data packets. The numeric identifier of transitive probes is incremented for each transitive probe sent from a given interface. The format of a probe packet is internal to the implementation.

INTERFACE

The IP interface the probe was sent on.

TARGET

The hostname (or IP address) of the target to which an ICMP probe is sent from an active interface or the name of the IP interface to which the transitive probe is sent.

NETRTT

The network round-trip-time for the probe. This is the time between when the IP module sends the probe and when the IP module receives the acknowledgment. If in.mpathd has concluded that the probe has been lost, this field will be empty.

RTT

The total round-trip-time for the probe. This is the time between when in.mpathd starts executing the code to send the probe, and when it completes processing the ack. If in.mpathd has concluded that the probe has been lost, this field will be empty. Spikes in the total round-trip time that are not present in the network round-trip time indicate that the local system itself is overloaded.

RTTAVG

The average round-trip-time to TARGET over INTERFACE. This aids identification of slow targets. If there is insufficient data to calculate the average, this field will be empty.

RTTDEV

The standard deviation for the round-trip-time to TARGET over INTERFACE. This aids identification of jittery targets. If there is insufficient data to calculate the standard deviation, this field will be empty.

If -o is not specified, all fields except for RTTAVG and RTTDEV are displayed.

Target Mode

Target mode displays IPMP probe target information. The following output fields are supported:

INTERFACE

The IP interface name associated with the information.

MODE

The probe target discovery mode:

routes   Probe targets found by means of the routing table.

multicast   Probe targets found by means of multicast ICMP probes.

disabled   All probe-based failure detection is disabled.

transitive   Failure detection is by means of transitive probing, where the health of the IP interface is determined by probing other active interfaces in the group.

TESTADDR

The source address used in outgoing probes. Active interfaces that are being used for data traffic, as well as interfaces that have been explicitly configured with NOFAILOVER test addresses, will have the hostname (or IP address) that is used for sending and receiving the ICMP probes. All other interfaces in the group will display the name of the interface from which the probes are sent. Note that if an active IP interface is configured with both IPv4 and IPv6 test addresses, probe target information will be displayed separately for each test address.

TARGETS

A space-separated list of probe target hostnames (or IP addresses) for ICMP probes, or target interfaces for transitive probes. The IP targets will be listed in firing order, and, if no probe targets could be found, this field will be empty.

If -o is not specified, all output fields are displayed.

Output Format   By default, ipmpstat uses a human-friendly tabular format for its output modes, where each row contains one or more fields of information about a given object, which is in turn uniquely identified by one or more of those fields. In this format, a header identifying the fields is displayed above the table (and after each screenful of information), fields are separated by whitespace, empty fields are represented by - - (double hyphens), and other visual aids are used. If the value for a field cannot be determined, its value will be displayed as "?" and a diagnostic message will be output to standard error.

Machine-parseable format also uses a tabular format, but is designed to be efficient to programmatically parse. Specifically, machine-parseable format differs from human-friendly format in the following ways:

■   No headers are displayed.

- Fields with empty values yield no output, rather than showing - -.

- Fields are separated by a single colon (:), rather than variable amounts of whitespace.

- If multiple fields are requested, and a literal : or a backslash (\) occur in a field's value, they are escaped by prefixing them with \.

Examples   EXAMPLE 1   Obtaining Failure Detection Time of a Specific Interface

The following code uses the machine-parseable output format to create a ksh function that outputs the failure detection time of a given IPMP IP interface:

```
getfdt() {
    ipmpstat -gP -o group,fdt | while IFS=: read group fdt; do
        [[ "$group" = "$1" ]] && { echo "$fdt"; return; }
    done
}
```

Attributes   See attributes(5) for descriptions of the following attributes:

/usr/sbin/ipmpstat:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed
Machine-Parseable Format	Committed
Human-Friendly Format	Not-an-Interface

/usr/sbin/ipmpstat is not a Committed interface.

See Also   if_mpadm(1M), ifconfig(1M), in.mpathd(1M), attributes(5)

Name ipnat – user interface to the NAT subsystem

Synopsis ipnat [-CdFhlnRrsv] -f *filename*

Description The ipnat utility opens a specified file (treating - as stdin) and parses it for a set of rules that are to be added or removed from the IP NAT.

If there are no parsing problems, each rule processed by ipnat is added to the kernel's internal lists. Rules are appended to the internal lists, matching the order in which they appear when given to ipnat.

ipnat's use is restricted through access to /dev/ipauth, /dev/ipl, and /dev/ipstate. The default permissions of these files require ipnat to be run as root for all operations.

ipnat's use is restricted through access to /dev/ipnat. The default permissions of /dev/ipnat require ipnat to be run as root for all operations.

Options The following options are supported:

-C   Delete all entries in the current NAT rule listing (NAT rules).

-d   Turn debug mode on. Causes a hex dump of filter rules to be generated as it processes each one.

-F   Delete all active entries in the current NAT translation table (currently active NAT mappings).

-f *filename* Parse specified file for rules to be added or removed from the IP NAT. *filename* can be stdin.

-h   Print number of hits for each MAP/Redirect filter.

-l   Show the list of current NAT table entry mappings.

-n   Prevents ipf from doing anything, such as making ioctl calls, which might alter the currently running kernel.

-R   Disable both IP address-to-hostname resolution and port number-to-service name resolution.

-r   Remove matching NAT rules rather than add them to the internal lists.

-s   Retrieve and display NAT statistics.

-v   Turn verbose mode on. Displays information relating to rule processing and active rules/table entries.

Files /dev/ipnat   Link to IP Filter pseudo device.

/dev/kmem   Special file that provides access to virtual address space.

/etc/ipf/ipnat.conf   Location of ipnat startup configuration file.

/usr/share/ipfilter/examples/   Contains numerous IP Filter examples.

Attributes   See attributes(5) for descriptions of the following attributes:

Name   ippool – user interface to the IP Filter pools

Synopsis   ippool -a [-dnv] [-m *poolname*] [-o *role*] -i *ipaddr*
              [/*netmask*]

ippool -A [-dnv] [-m *poolname*] [-o *role*] [-S *seed*]
       [-t *type*]

ippool -f *file* [-dnuv]

ippool -F [-dv] [-o *role*] [-t *type*]

ippool -h [-dv] [-m *poolname*] [-t *type*]

ippool -l [-dv] [-m *poolname*] [-t *type*]

ippool -r [-dnv] [-m *poolname*] [-o *role*] -i *ipaddr*
       [/*netmask*]

ippool -R [-dnv] [-m *poolname*] [-o *role*] [-t *type*]

ippool -s [-dtv] [-M *core*] [-N *namelist*]

Description   The ippool utility is used to manage information stored in the IP pools subsystem of IP Filter
software. Configuration file information can be parsed and loaded into the kernel and
currently configured pools can be removed, changed, or inspected.

ippool's use is restricted through access to /dev/ippool. The default permissions of
/dev/ippool require ippool to be run as root for all operations.

The command line options used are divided into two sections: the global options and the
instance-specific options.

ippool's use is restricted through access to /dev/ipauth, /dev/ipl, and /dev/ipstate. The
default permissions of these files require ippool to be run as root for all operations.

Options   ippool supports the option categories described below.

Global Options   The following global options are supported:

-d   Toggle debugging of processing the configuration file.

-n   Prevents ippool from doing anything, such as making ioctl calls, that would alter the
        currently running kernel.

-v   Turn verbose mode on.

Instance-Specific   The following instance-specific options are supported:
Options
-a   Add a new data node to an existing pool in the kernel.

-A   Add a new (empty) pool to the kernel.

-f *file*   Read in IP pool configuration information from *file* and load it into the kernel.

-F   Flush loaded pools from the kernel.

-h	Display a list of pools of the type: hash loaded in the kernel.
-l	Display a list of pools of the type: tree loaded in the kernel.
-r	Remove an existing data node from a pool in the kernel.
-R	Remove an existing pool from within the kernel.
-s	Display IP pool statistical information.

Other Options   The following, additional options are supported:

-i *ipaddr*[/*netmask*]	Sets the IP address for the operation being undertaken with an all-one's mask or, optionally, a specific netmask, given in either dotted-quad notation or as a single integer.
-m *poolname*	Sets the pool name for the current operation.
-M *core*	Specify an alternative path to /dev/kmem from which to retrieve statistical information.
-N *namelist*	Specify an alternative path to lookup symbol name information when retrieving statistical information.
-o *role*	Sets the role with which this pool is to be used. Currently only ipf, auth, and count are accepted as arguments to this option.
-S *seed*	Sets the hashing seed to the number specified. For use with hash-type pools only.
-t *type*	Sets the type of pool being defined. Must be one of pool, hash, or group-map.
-u	When parsing a configuration file, rather than load new pool data into the kernel, unload it.

Files

/dev/ippool	Link to IP Filter pseudo device.
/dev/kmem	Special file that provides access to virtual address space.
/etc/ipf/ippool.conf	Location of ippool startup configuration file.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/ipfilter
Interface Stability	Committed

Name   ipqosconf – configure the IPQoS facility

Synopsis   /usr/sbin/ipqosconf

/usr/sbin/ipqosconf -a *conf_file* [-vs]

/usr/sbin/ipqosconf -c

/usr/sbin/ipqosconf -f

/usr/sbin/ipqosconf -l

/usr/sbin/ipqosconf -L

Description   The ipqosconf utility configures the Quality of Service facility of the Internet Protocol (IP). Only superusers can use this command.

Without arguments, ipqosconf displays the actual IPQoS configuration.

Configuration is not preserved across reboot. You must apply the configuration every time that the machine reboots. To apply the configuration early in the boot phase, you can populate the /etc/inet/ipqosinit.conf file, which is then read from the svc:/network/initial:default service.

Options   The following options are supported:

-a *conf_file*   Apply the configuration in *conf_file*. If the *conf_file* is –, ipqosconf reads from standard input.

-c   Populate the boot file with the current configuration.

-f   Flush the configuration.

-l   List the current applied configuration.

-L   List the current configuration in verbose mode.

In addition to the information that the -l option provides, the -L option provides filters and classes configured through other means than the iqposconf command. This option also provides the full set of filters that were created by ipqosconf by representing a multi-homed host in a configuration file

-s   Log messages to syslog during an -a operation.

-v   Toggle verbose mode during an -a operation.

The -v option causes all messages to go to the console in addition to their normal destination. Messages intended to go to syslog, because the -s flag is set or because it is a log message, still go to syslog as well as the console.

Configuration File The configuration file is composed of a format version and a succession of configuration (action) blocks. There are different configuration blocks for each type of action that is being configured.

Format Version The first line of the configuration file specifies the format version contained in the configuration file.

The following entry specifies the format version:

```
fmt_version x.x
```

where *x.x* is the format version. `1.0` is the only supported version.

Configuration Blocks Following the format version, are a succession of configuration (action) blocks that are different for each type of action being configured. A configuration block always has the following structure:

```
action {
      name action_name
      module module_name
      params_clause | ""
      cf_clauses
}

action_name       ::= string
module_name       ::= ipgpc | dlcosmk | dscpmk | flowacct | tswtclmt |
                       tokenmt

params_clause     ::= params {
                            parameters
                            params_stats | ""
                        }

parameters        ::= prm_name_value parameters | ""

prm_name_value    ::= param_name param_value
```

Modules The *param_name* and the types of *param_value* are specific to a given module.

```
params_stats      ::= global_stats boolean

cf_clauses        ::= class_clause cf_clauses |
                       filter_clause cf_clauses | ""

class_clause      ::= class {
                            name class_name
                            next_action next_action_name
                            class_stats | ""
                        }
```

```
class_name      ::= string
next_action_name ::= string
class_stats     ::= enable_stats boolean
boolean         ::= TRUE | FALSE

filter_clause   ::= filter {
                         name filter_name
                         class class_name
                         parameters
                    }

filter_name     ::= string
```

There must be exactly one configuration block belonging to module ipgpc. The action must be named ipgpc.classify. All other actions should be reachable from ipgpc by way of parameters of type action or the next_action of a class.

The set of types that are used for parameters of the different modules are:

```
action       ::=    string
protocol     ::=    1..255
port         ::=    1..65535
uint8        ::=    0..255
uint32       ::=    0..4294967296
int32        ::=    -2147483648..2147483648
address      ::=    <see the description section>
ifname       ::=    <interface name recognized by SIOGLIFINDEX ioctl>
enum         ::=    string | { string_list }
boolean      ::=    TRUE | FALSE
integer_array ::=   { range_value_list }
map_index    ::=    uint32
address      ::=    ip_address | ip_node_name
user         ::=    uid | username
uid          ::=    0..65535
username     ::=    string
string_list          ::=    string sl_entrys
sl_entrys            ::=    ',' string sl_entrys | ""
range_value_list     ::=    range_value_entry range_value_entrys
range_value_entry    ::=    range ':' integer_array_value
range               ::=    uint32 '-' uint32
integer_array_value  ::=    string | integer_array_number
integer_array_number ::=    uint8 | uint32
range_value_entrys   ::=    ';' range_value_entry range_value_entrys | ""
ip_node_name         ::=    string
ip_address           ::=    v4_address | v6_address
v4_address           ::=    v4_ip_address / v4_cidr_mask |
v4_ip_address
```

```
v4_cidr_mask          ::=   1-32
v6_address            ::=   v6_ip_address / v6_cidr_mask |
v6_ip_address
v6_cidr_mask          ::=   1-128
```

METER module tokenmt configuration syntax:

```
red_action_name       action
yellow_action_name    action
green_action_name     action
committed_rate        uint32
committed_burst       uint32
peak_rate             uint32
<if present this signifies that this will be a two rate meter, not
   a single rate meter>
peak_burst            uint32
<this is the 'peak' burst size for a two rate meter, but
   the 'excess' burst size for a single rate meter>
color_aware           boolean
color_map             integer_array
global_stats          boolean
```

METER module tswtclmt configuration syntax:

```
red_action_name       action
yellow_action_name    action
green_action_name     action
committed_rate        uint32
peak_rate             uint32
window                uint32
global_stats          boolean
```

MARKER module dscpmk configuration syntax:

```
next_action         action
dscp_map            int_array
dscp_detailed_stats boolean
global_stats        boolean
```

MARKER module dlcosmk configuration syntax:

```
next_action         action
cos                 map_index
global_stats        boolean
```

CLASSIFIER module ipgpc configuration syntax:

```
user            user
projid          int32
if_name         ifname
```

```
direction           enum {
                    LOCAL_IN,
                    LOCAL_OUT,
                    FWD_IN,
                    FWD_OUT}
protocol            protocol
dsfield             uint8
dsfield_mask        uint8
saddr               address
daddr               address
sport               port
dport               port
priority            uint32
precedence          uint32
ip_version          enum {
                    V4,
                    V6 }
global_stats        boolean
```

ACCOUNTING module flowacct configuration syntax:

```
next_action     action
timer           uint32
timeout         uint32
max_limit       uint32
```

Types   *action*   A string of characters with a matching action definition. The character string can be up to twenty three characters in length. To allow for spaces the string needs to be enclosed in quotes and cannot span lines. Two special actions are pre-defined and can not have an explicit action definition. The two pre-defined actions are continue and drop. continue causes the packet that is passed to it to continue normal processing. drop causes the packet that is passed to it to be dropped.

address   A machine name or address recognized by getipnodebyname(3SOCKET). If a machine name is specified, and ip_version has been defined, the query is done using that address family. If a machine name is not specified and ip_version has not been defined, the query is done using the AI_DEFAULT flag to getipnodebyname()(..AF_INET6..). CIDR address masks following an IP address are allowed. Specify the CIDR address masks as 1-32 (for v4) or 1-128 (for v6). CIDR addresses are disallowed for node names.

enum   Either one of the supported values or comma delimited list of support values, enclosed in curly braces.

ifname   A non-NULL, existing interface name recognized by the SIOGLIFINDEX socket ioctl.

integer_array   A comma delimited set of *range*/*value* pairs, enclosed in curly braces.

Specify *range* in the format *x-y*, where *x* and *y* are integers that denote the range of array indexes to which the value applies. The minimum value for both *x* and *y* is 0. The maximum value for *x* is particular to the parameter. Any array indexes not referred to in the set of ranges are left at their previous value.

map_index A non-negative integer used as an index into any maps associated with a parameter of this type.

The maximum value of this type is dictated by the number of entries in the associated maps. The index starts at 0.

port Either a service name recognized by getservbyname(3SOCKET) or an integer 1-65535.

protocol Either a protocol name recognized by getprotobyname(3SOCKET) or an integer 1-255.

string A character string. Enclose *string* in quotes. *string* cannot span multiple lines.

user Either a valid user ID or username for the system that is being configured.

Parameters The configuration file can contain the following parameters

color_aware A value of TRUE or FALSE, indicating whether or not the configured action takes account of the previous packet coloring when classifying.

color_map An integer array that defines which values of the dscp field correspond with which colors for when the color_aware parameter is set to TRUE.

committed_burst The committed burst size in bits.

committed_rate The committed rate in bits per second.

cos The value used to determine the underlying driver level priority applied to the packet which is defined in 802.1D.

daddr The destination address of the datagram.

direction The value used to build a filter matching only part of the traffic.

This parameter is of type enum with valid values of LOCAL_IN (local bound traffic), LOCAL_OUT (local sourced traffic), FWD_IN (forwarded traffic entering the system), and FWD_OUT (forwarded traffic exiting the system).

dport The destination port of the datagram.

dscp_detailed_stats   A value of TRUE or FALSE that determines whether detailed statistics are switched on for this dscp action.

Specify TRUE to switch on or FALSE to switch off.

dscp_map   The *integer_array* that supplies the values that IP packets with a given dscp value have their dscp re-marked with.

The existing value is used to index into the array where the new value is taken from. The array is of size 64, meaning valid indexes are 0-63 and valid values are also 0-63.

dsfield   The DS field of the IP datagram header. This is an 8–bit value, with each bit position corresponding with the same one in the header; this enables matches to be done on the CU bits. If you specify this parameter, you must also specify the dsfield_mask parameter.

dsfield_mask   The mask applied to the dsfield parameter to determine the bits against which to match. This is an 8-bit value, with each bit position corresponding with the same one in the dsfield parameter.

global_stats   A value of TRUE or FALSE to enable or disable the statistic collection for this action.

green_action_name   The action to be executed for packets that are deemed to be green.

if_name   The name of an interface recognized by the SIOGLIFINDEX ioctl. This parameter is of type ifname.

ip_version   This parameter is of type enum and has valid values of V4 and V6.

If it is set to V4 only then only ipv4addresses are requested for a specified hostname. If it is set to V6, only ipv6 addresses are returned if there are any, otherwise v4 mapped v6 addresses are returned. If both V4 and V6 are specified, or if ip_version is not specified, then both ipv4 and ipv6 addresses are requested for a specified hostname.

max_limit   The maximum number of flow entries present at one time in the flowacct actions in the memory resident table.

next_action   The action to be executed when the current action is complete.

This value can be either the name of an action defined in the configuration file, or one of the two special action types: drop and continue.

peak_burst   The peak burst size, for a two rate meter, or excess burst size, for a single rate meter, in bits.

peak_rate   The peak rate in bits per second.

precedence	An integer that is used to order filters. If there are two matching filters that have the same priority value, the one with the lower precedence value is the one matched. This parameter should be used because the order of the filters in a configuration file has no influence on their relative precedence.
priority	An integer that represents the relative priority of a filter. If there are two matching filters, the one with the higher priority value is the one matched. Multiple filters can have the same priority.
projid	The project ID of the process sending the data. This value is always -1 for received traffic.
protocol	The Upper Layer Protocol against which this entry is matched.
red_action_name	The action to be executed for packets that are determined to be red.
saddr	The source address of the datagram.
sport	The source port of the datagram.
timeout	The timeout in milliseconds after which flows are written to the accounting file.
timer	The period in milliseconds at which timed-out flows are checked for.
user	The user ID or username of the process sending the data. This value is always -1 for received traffic.
window	The window size in ms.
yellow_action_name	The action to be executed for packets that are determined to be yellow.

Security   None.

Examples   EXAMPLE 1   Sending All Traffic From eng to the AF 1 Class of Service

This example sends all traffic from eng to the AF 1 class of service. It is documented in four separate steps:

The following step creates a tokenmt action with three outcomes:

```
#meter for class 1.
action {
        name AF_CL1
        module tokenmt
        params{
                committed_rate 64
                committed_burst 75
                peak_burst 150
```

EXAMPLE 1   Sending All Traffic From eng to the AF 1 Class of Service   *(Continued)*

```
                    global_stats TRUE
                    red_action_name drop
                    yellow_action_name markAF12
                    green_action_name markAF11
        }
}
```

The following step creates two dscpmk actions:

```
#class 1, low drop precedence.
action {
        name markAF11
        module dscpmk
        params{
            dscp_map {0-63:28}
            dscp_detailed_stats TRUE
              global_stats TRUE
              next_action acct1
        }
}
#class 1, medium drop precedence.
action {
        name markAF12
        module dscpmk
        params {
                dscp_map {0-63:30}
              dscp_detailed_stats TRUE
              global_stats TRUE
              next_action acct1
        }
}
```

The following step creates an accounting action:

```
#billing for transmitted class 1 traffic.
action {
        name acct1
        module flowacct
        params {
                timer 10
                timeout 30
                global_stats TRUE
max_limit 1024
next_action continue
        }
}
```

ipqosconf(1M)

EXAMPLE 1 Sending All Traffic From eng to the AF 1 Class of Service   *(Continued)*

The following step creates an ipgpc action:

```
#traffic from eng sent, traffic from ebay dropped.
action {
        name ipgpc.classify
        module ipgpc
        class {
                name from_eng
                enable_stats TRUE
                next_action AF_CL1
        }
        class {
                name from_ebay
                enable_stats TRUE
                next_action drop
        }

        filter {
                name from_eng
                saddr eng-subnet
                class from_eng
        }
        filter {
                name from_ebay
                saddr ebay-subnet
                class from_ebay
        }
}
```

Files
/etc/inet/ipqosinit.conf	Contains the IPQoS configuration loaded at boot time. If this file exists, it is read from the network/initial:default service.
/etc/inet/ipqosconf.1.sample	Sample configuration file for an application server
/etc/inet/ipqosconf.2.sample	Sample configuration file that meters the traffic for a specified application
/etc/inet/ipqosconf.3.sample	Sample configuration file that marks the ethernet headers of web traffic with a given user priority

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/ipqos

1M

ATTRIBUTE TYPE	**ATTRIBUTE VALUE**
Interface Stability	Committed

See Also syslog(3C), getipnodebyname(3SOCKET), getprotobyname(3SOCKET), getservbyname(3SOCKET), attributes(5), dlcosmk(7ipp), dscpmk(7ipp), flowacct(7ipp), ipgpc(7ipp), ipqos(7ipp), tokenmt(7ipp), tswtclmt(7ipp)

Diagnostics ipqosconf sends messages to syslog of facility user, severity notice when any changes are made to the IPQoS configuration.

Errors that occur during an ipqosconf operation send an error message to the console by default. For the application of a new configuration if the -s option is set then these messages are sent to syslog as facility user, severity error instead. If the -v option is present during an application then all error and change notificationmessages are sent to the console as well as their default destination.

Name ipsecalgs – configure the IPsec protocols and algorithms table

Synopsis `ipsecalgs`

`ipsecalgs -l`

`ipsecalgs -s`

`ipsecalgs -a [-P` *protocol-number* `| -p` *protocol-name*`] -k` *keylen-list*
    `[-i` *inc*`] [-K` *default-keylen*`] -b` *blocklen-list* `-n` *alg-names*
    `-N` *alg-number* `-m` *mech-name* `[-I` *initialization-vector_length*`]`
    `[-M` *MAC-length*`] [-S` *length-of-salt*`] [-F` *flags*`] [-f] [-s]`

`ipsecalgs -P` *protocol-number* `-p` *protocol-name*
    `[-e` *exec-mode*`] [-f] [-s]`

`ipsecalgs -r -p` *protocol-name* `[] -N` *alg-number* `[-s]`

`ipsecalgs -R -P` *protocol-number* `[-s]`

`ipsecalgs -R -p` *protocol-name* `[-s]`

`ipsecalgs -e` *exec-mode* `-P` *protocol-number* `[-s]`

`ipsecalgs -e` *exec-mode* `-p` *protocol-name* `[-s]`

Description Use the `ipsecalgs` command to query and modify the IPsec protocol and algorithms stored in `/etc/inet/ipsecalgs`. You can use the `ipsecalgs` command to do the following:

- list the currently defined IPsec protocols and algorithms
- modify IPsec protocols definitions
- modify IPsec algorithms definitions

Never edit the `/etc/inet/ipsecalgs` file manually. The valid IPsec protocols and algorithms are described by the ISAKMP DOI. See *RFC 2407*. In the general sense, a Domain of Interpretation (DOI) defines data formats, network traffic exchange types, and conventions for naming security-relevant information such as security policies or cryptographic algorithms and modes. For `ipsecalgs`, the DOI defines naming and numbering conventions for algorithms and the protocols they belong to. These numbers are defined by the Internet Assigned Numbers Authority (IANA). Each algorithm belongs to a protocol. Algorithm information includes supported key lengths, block or MAC length, and the name of the cryptographic mechanism corresponding to that algorithm. This information is used by the IPsec modules, `ipsecesp`(7P) and `ipsecah`(7P), to determine the authentication and encryption algorithms that can be applied to IPsec traffic.

The following protocols are predefined:

IPSEC_PROTO_ESP   Defines the encryption algorithms (transforms) that can be used by
                   IPsec to provide data confidentiality.

IPSEC_PROTO_AH   Defines the authentication algorithms (transforms) that can be used by
                   IPsec to provide authentication.

The mechanism name specified by an algorithm entry must correspond to a valid Solaris Cryptographic Framework mechanism. You can obtain the list of available mechanisms by using the cryptoadm(1M) command.

Applications can retrieve the supported algorithms and their associated protocols by using the functions getipsecalgbyname(3NSL), getipsecalgbynum(3NSL), getipsecprotobyname(3NSL) and getipsecprotobynum(3NSL).

Modifications to the protocols and algorithm by default update only the contents of the /etc/inet/ipsecalgs configuration file. In order for the new definitions to be used for IPsec processing, the changes must be communicated to the kernel using the -s option. See NOTES for a description of how the ipsecalgs configuration is synchronized with the kernel at system restart.

When invoked without arguments, ipsecalgs displays the list of mappings that are currently defined in /etc/inet/ipsecalgs. You can obtain the corresponding kernel table of protocols and algorithms by using the -l option.

Options ipsecalgs supports the following options:

-a

Adds an algorithm of the protocol specified by the -P option. The algorithm name(s) are specified with the -n option. The supported key lengths and block sizes are specified with the -k, -i, and -b options.

-b

Specifies the block or MAC lengths of an algorithm, in bytes. Set more than one block length by separating the values with commas.

-e

Designates the execution mode of cryptographic requests for the specified protocol in the absence of cryptographic hardware provider. See cryptoadm(1M). *exec-mode* can be one of the following values:

sync   Cryptographic requests are processed synchronously in the absence of a cryptographic hardware provider. This execution mode leads to better latency when no cryptographic hardware providers are available

async   Cryptographic requests are always processed asynchronously in the absence of cryptographic hardware provider. This execution can improve the resource utilization on a multi-CPU system, but can lead to higher latency when no cryptographic hardware providers are available.

This option can be specified when defining a new protocol or to modify the execution mode of an existing protocol. By default, the sync execution mode is used in the absence of a cryptographic hardware provider.

-f

Used with the -a option to force the addition of an algorithm or protocol if an entry with the same name or number already exists.

-i

Specifies the valid key length increments in bits. This option must be used when the valid key lengths for an algorithm are specified by a range with the -k option.

-K

Specifies the default key lengths for an algorithm, in bits. If the -K option is not specified, the minimum key length will be determined as follows:

- If the supported key lengths are specified by range, the default key length will be the minimum key length.

- If the supported key lengths are specified by enumeration, the default key length will be the first listed key length.

-k

Specifies the supported key lengths for an algorithm, in bits. You can designate the supported key lengths by enumeration or by range.

Without the -i option, -k specifies the supported key lengths by enumeration. In this case, *keylen-list* consists of a list of one or more key lengths separated by commas, for example:

128,192,256

The listed key lengths need not be increasing, and the first listed key length will be used as the default key length for that algorithm unless the -K option is used.

With the -i option, -k specifies the range of supported key lengths for the algorithm. The minimum and maximum key lengths must be separated by a dash ('-') character, for example:

32-448

-l

Displays the kernel algorithm tables.

-m

Specifies the name of the cryptographic framework mechanism name corresponding to the algorithm. Cryptographic framework mechanisms are described in the cryptoadm(1M) man page.

-N

Specifies an algorithm number. The algorithm number for a protocol must be unique. IANA manages the algorithm numbers. See *RFC 2407*.

-n

Specifies one or more names for an algorithm. When adding an algorithm with the -a option, *alg-names* contains a string or a comma-separated list of strings, for example:

des-cbs,des

When used with the -r option to remove an algorithm, *alg-names* contains one of the valid algorithm names.

-P

Adds a protocol of the number specified by *protocol-number* with the name specified by the -p option. This option is also used to specify an IPsec protocol when used with the -a and the -R options. Protocol numbers are managed by the IANA. See *RFC 2407*.

-p

Specifies the name of the IPsec protocol.

-R

Removes and IPsec protocol from the algorithm table. The protocol can be specified by number by using the -P option or by name by using the -p option. The algorithms associated with the protocol are removed as well.

-r

Removes the mapping for an algorithm The algorithm can be specified by algorithm number using the -N option or by algorithm name using the -A option.

-s

Synchronizes the kernel with the contents of /etc/inet/ipsecalgs. The contents of /etc/inet/ipsecalgs are always updated, but new information is not passed on to the kernel unless the -s is used. See NOTES for a description of how the ipsecalgs configuration is synchronized with the kernel at system restart.

The following options allow optional parameters to be configured. These are currently only used for combined mode algorithms, that is, algorithms that provide encryption and authentication in a single operation.

-I

The length of the Initialization Vector (IV) in bytes. The default IV length is the same as the block length.

-M

The length of the MAC or ICV in bytes for combined mode algorithms.

-S

The number of bytes of salt needed by the algorithm. The salt needs to be provided by the key management mechanism.

-F

Algorithm flags. These influence the way in which the kernel handles security tasks, especially authentication, in the kernel. They are also used by ipseckey(1M) and ipsecconf(1M). Flags can be specified as a comma-separated list of tokens; see the example below. The following tokens are supported:

COUNTERMODE
> The algorithm uses counter mode.

COMBINED
> The algorithm provides encryption and authentication in the same operation.

CCM
> The cryptographic framework mechanism needs a CK_AES_CCM_PARAMS structure.

GMAC
> The cryptographic framework mechanism needs a CK_AES_GMAC_PARAMS structure.

GCM
> The cryptographic framework mechanism needs a CK_AES_GCM_PARAMS structure.

CBC
> This flag indicates the algorithm uses Cipher-block chaining. The cryptographic framework mechanism does not need a params structure. This is also the default, this flag can be omitted.

The algorithm flags can be displayed with the -l option.

Examples   EXAMPLE 1   Adding a Protocol for IPsec Encryption

The following example shows how to add a protocol for IPsec encryption:

```
example# ipsecalgs -P 3 -p "IPSEC_PROTO_ESP"
```

EXAMPLE 2   Adding the Blowfish Algorithm

The following example shows how to add the Blowfish algorithm:

```
example# ipsecalgs -a -P 3 -k 32-488 -K 128 -i 8 -n "blowfish" \
  -b 8 -N 7 -m CKM_BF_CBC
```

EXAMPLE 3   Updating the Kernel Algorithm Table

The following example updates the kernel algorithm table with the currently defined protocol and algorithm definitions:

```
example# svcadm refresh ipsecalgs
```

EXAMPLE 4   Adding the AES Galois/Counter Mode (GCM) Algorithm

The following command adds this algorithm.

```
example# ipsecalgs -a -P3 -k 128-256 -K 128 -i 64 -N 20 -b 16 \
-n "aes-gcm16,aes-gcm" -m CKM_AES_GCM -M 16 -I 8 -S 4 \
-F GCM,COMBINED,COUNTER
```

Files   /etc/inet/ipsecalgs
   File that contains the configured IPsec protocols and algorithm definitions. Never edit this
   file manually.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

   Network Working Group. November 1998.

Notes   When protocols or algorithm definitions that are removed or altered, services that rely upon
   these definitions can become unavailable. For example, if the IPSEC_PROTO_ESP protocol is
   removed, then IPsec cannot encrypt and decrypt packets.

   Synchronization of the ipsecalgs configuration with the kernel at system startup is provided
   by the following smf(5) service:

   svc:/network/ipsec/ipsecalgs:default

   The IPsec services are delivered as follows:

   svc:/network/ipsec/policy:default (enabled)
   svc:/network/ipsec/ipsecalgs:default (enabled)
   svc:/network/ipsec/manual-key:default (disabled)
   svc:/network/ipsec/ike:default (disabled)

   Services that are delivered disabled are delivered that way because the system administrator
   must create configuration files for those services before enabling them. See ipseckey(1M) and
   ike.config(4). The default policy for the policy service is to allow all traffic to pass without
   IPsec protection. See ipsecconf(1M).

   The correct administrative procedure is to create the configuration file for each service, then
   enable each service using svcadm(1M), as shown in the following example:

   example# **svcadm enable ipsecalgs**

   The service's status can be queried using the svcs(1) command.

   If the ipsecalgs configuration is modified, the new configuration should be resynchronized
   as follows:

```
example# svcadm refresh ipsecalgs
```

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using svcadm(1M). A user who has been assigned the authorization shown below can perform these actions:

```
solaris.smf.manage.ipsec
```

See auths(1), user_attr(4), rbac(5).

The ipsecalgs smf(5) service does not have any user-configurable properties.

The smf(5) framework records any errors in the service-specific log file. Use any of the following commands to examine the logfile property:

```
example# svcs -l ipsecalgs
example# svcprop ipsecalgs
example# svccfg -s ipsecalgs listprop
```

This command requires sys_ip_config privilege to operate and thus can run in the global zone and in exclusive-IP zones. All shared-IP zones share the same available set of algorithms; however, you can use ipsecconf(1M) to set up system policy that uses differing algorithms for various shared-IP zones. All exclusive-IP zones have their own set of algorithms.

Name ipsecconf – configure system wide IPsec policy

Synopsis /usr/sbin/ipsecconf

/usr/sbin/ipsecconf -a *file* [-q]

/usr/sbin/ipsecconf -c *file*

/usr/sbin/ipsecconf -d [-i *tunnel-name*] {*index*, *tunnel-name*, *index*}

/usr/sbin/ipsecconf -f [-i *tunnel-name*]

/usr/sbin/ipsecconf -F

/usr/sbin/ipsecconf -Fa *file* [-q]

/usr/sbin/ipsecconf -l [-i *tunnel-name*] [-n]

/usr/sbin/ipsecconf -L [-n]

/usr/sbin/ipsecconf -r *file* [-q]

Description The ipsecconf utility configures the IPsec policy for a host or for one of its tunnels. Once the policy is configured, all outbound and inbound datagrams are subject to policy checks as they exit and enter the host or tunnel. For the host policy, if no entry is found, no policy checks will be completed, and all the traffic will pass through. For a tunnel, if no entry is found and there is at least one entry for the tunnel, the traffic will automatically drop. The difference in behavior is because of the assumptions about IPsec tunnels made in many implementations. Datagrams that are being forwarded will not be subjected to policy checks that are added using this command. See ifconfig(1M) and dladm(1M) for information on how to protect forwarded packets. Depending upon the match of the policy entry, a specific action will be taken.

This command can be run only by superuser.

Each entry can protect traffic in either one direction (requiring a pair of entries) or by a single policy entry which installs the needed symmetric sadb rules.

When the command is issued without any arguments, the list of file policy entries loaded are shown. To display the (spd p.e.s) use the -l option. Both will display the index number for the entry. To specify a single tunnel's SPD, use the -i option in combination with -l. To specify all SPDs, both host and for all tunnels, use -L.

Note, since one file policy entry (FPE) can generate multiple SPD pol entries (SPEs), the list of FPEs may not show all the actual entries. However, it is still useful in determining what what rules have been added to get the spd into its current state.

You can use the -d option with the index to delete a given policy in the system. If the -d option removes an FPE entry that produces multiple SPEs, only then SPD with the same policy index as the FPE will be removed. This can produce a situation where there may be SPEs when there are no FPEs.

As with -l, -d can use the -i flag to indicate a tunnel. An alternate syntax is to specify a tunnel name, followed by a comma (,), followed by an index. For example, ip.tun0,1.

With no options, the entries are displayed in the order that they were added, which is not necessarily the order in which the traffic match takes place.

To view the order in which the traffic match will take place, use the -l option. The rules are ordered such that all bypass rules are checked first, then ESP rules, then AH rules. After that, they are checked in the order entered.

Policy entries are not preserved across system restarts. Permanent policy entries should be added to /etc/inet/ipsecinit.conf. This file is read by the following smf(5) service:

```
svc:/network/ipsec/policy
```

See NOTES for more information on managing IPsec security policy and SECURITY for issues in securing /etc/inet/ipsecinit.conf.

Options ipsecconf supports the following options:

-a *file*

Add the IPsec policy to the system as specified by each entry in the file. An IPsec configuration file contains one or more entries that specify the configuration. Once the policy is added, all outbound and inbound datagrams are subject to policy checks.

Entries in the files are described in the Operands section below. Examples can be found in the Examples section below.

Policy is latched for TCP/UDP sockets on which a connect(3SOCKET) or accept(3SOCKET) is issued. So, the addition of new policy entries may not affect such endpoints or sockets. However, the policy will be latched for a socket with an existing non-null policy. Thus, make sure that there are no preexisting connections that will be subject to checks by the new policy entries.

The feature of policy latching explained above may change in the future. It is not advisable to depend upon this feature.

The default behavior is to append new rules to the existing policy. If a new rule conflicts with an existing rule, an error is reported, the new rule will not be added.

To add a new rule that conflicts with an existing rule, the existing rule must be removed (see below) or the existing policy flushed. If the policy is flushed, IPsec will not protect any network traffic until a new policy is added.

The -F (flush) flag can be combined with -a to perform an atomic policy replacement; the existing policy will be replaced by the new policy described in the config file. By combining these two flags, there is not even a small window when the system is without a policy, which is the case when the flush and add commands are run sequentially.

-c *file*

Check the syntax of the configuration file and report any errors without making any changes to the policy. This option is useful when debugging configurations and when smf(5) reports a configuration error. See SECURITY.

-d *index*

Delete the host policy denoted by the index. The index is obtained by invoking ipsecconf without any arguments, or with the -l option. See DESCRIPTION for more information. Once the entry is deleted, all outbound and inbound datagrams affected by this policy entry will not be subjected to policy checks. Be advised that with connections for which the policy has been latched, packets will continue to go out with the same policy, even if it has been deleted. It is advisable to use the -l option to find the correct policy index.

-d *name,index*

Delete the policy entry denoted by *index* on a tunnel denoted by *name*. Since tunnels affect traffic that might originate off-node, latching does not apply as it does in the host policy case. Equivalent to: -d *index* -i *name*.

-f

Flush all the policies in the system. Constraints are similar to the -d option with respect to latching and host versus per-tunnel behavior.

-F

Flush all policies on all tunnels and also flush all host policies. See discussion of combining the -F and -a options, under -a, above.

-i *name*

Specify a tunnel interface name for use with the -d, -f, or -l flags.

-l

Listing of a single policy table, defaulting to the host policy. When ipsecconf is invoked without any arguments, a complete list of policy entries with indexes added by the user since boot is displayed. The current table can differ from the previous one if, for example, a multi-homed entry was added or policy reordering occurred, or if a single rule entry generates two spd rules In the case of a multi-homed entry, all the addresses are listed explicitly. If a mask was not specified earlier but was instead inferred from the address, it will be explicitly listed here. This option is used to view policy entries in the correct order. The outbound and inbound policy entries are listed separately.

-L

Lists all policy tables, including host policy and all tunnel instances (including configured but unplumbed).

If -i is specified, -L lists the policy table for a specific tunnel interface.

-n

Show network addresses, ports, protocols in numbers. The -n option may only be used with the -l option.

-q

Quiet mode. Suppresses the warning message generated when adding policies.

-r *file*
> Remove IPsec policy rules from the system as specified by each entry in *file*. The format of
> the file contents is the same as is specified with the -a option. The file could be created with
> ipsecconf -l and then modified with an editor.

Operands Each policy entry contains three parts specified as follows:

```
{pattern} action {properties}
```

or

```
{pattern} action {properties} ["or" action {properties}]*
```

Every policy entry begins on a new line and can span multiple lines. If an entry exceeds the
length of a line, you should split it only within a "braced" section or immediately before the
first (left-hand) brace of a braced section. Avoid using the backslash character (\). See
EXAMPLES.

The *pattern* section, as shown in the syntax above, specifies the traffic pattern that should be
matched against the outbound and inbound datagrams. If there is a match, a specific *action*
determined by the second argument will be taken, depending upon the *properties* of the policy
entry.

If there is an or in the rule (multiple action-properties for a given pattern), a transmitter will
use the first action-property pair that works, while a receiver will use any that are acceptable.

pattern and *properties* are name-value pairs where name and value are separated by a <space>,
<tab> or <newline>. Multiple name-value pairs should be separated by <space>, <tab> or
<newline>. The beginning and end of the pattern and properties are marked by { and }
respectively.

Files can contain multiple policy entries. An unspecified name-value pair in the *pattern* will be
considered as a wildcard. Wildcard entries match any corresponding entry in the datagram.

One thing to remember is that UDP port 500 is always bypassed regardless of any policy
entries. This is a requirement for in.iked(1M) to work.

File can be commented by using a # as the first character. Comments may be inserted either at
the beginning or the end of a line.

The complete syntax of a policy entry is:

```
policy ::= { <pattern1> } <action1> { <properties1> } |
    { <pattern2> } <action2> { <properties2> }
    [ 'or' <action2> { <properties2>} ]*

    pattern1 ::= <pattern_name_value_pair1>*

    pattern2 ::= <pattern_name_value_pair2>*
```

```
action1 ::= apply | permit | bypass | pass
action2 ::=  bypass | pass | drop | ipsec

properties1 ::=   {<prop_name_value_pair1>}
properties2 ::=   {<prop_name_value_pair2>}

pattern_name_value_pair1 ::=
   saddr <address>/<prefix> |
   src   <address>/<prefix> |
   srcaddr <address>/<prefix> |
   smask <mask> |
   sport <port> |
   daddr <address>/<prefix> |
   dst <address>/<prefix> |
   dstaddr <address>/<prefix> |
   dmask <mask> |
   dport <port> |
   ulp <protocol> |
   proto <protocol> |
   type <icmp-type> |
   type <number>-<number> |
   code <icmp-code>
   code <number>-<number>
   tunnel <interface-name> |
   negotiate <tunnel,transport>

pattern_name_value_pair2 ::=
   raddr <address>/<prefix> |
   remote <address>/<prefix> |
   rport <port> |
   laddr <address>/<prefix> |
   local <address>/<prefix> |
   lport <port> |
   ulp <protocol> |
   type <icmp-type> |
   type <number>-<number> |
   code <icmp-code> |
   code <number>-<number>
   proto <protocol>  |
   tunnel <interface-name> |
   negotiate <tunnel,transport> |
   dir <dir_val2>

address ::= <IPv4 dot notation> | <IPv6 colon notation> |
            <String recognized by gethostbyname>|
            <String recognized by getnetbyname>
```

```
prefix ::=  <number>

mask ::= <0xhexdigit[hexdigit]> | <0Xhexdigit[hexdigit]> |
            <IPv4 dot notation>

port ::= <number>| <String recognized by getservbyname>

protocol ::=  <number>| <String recognized by getprotobyname>

prop_name_value_pair1 ::=
    auth_algs <auth_alg> |
    encr_algs <encr_alg> |
    encr_auth_algs <auth_alg> |
    sa <sa_val> |
    dir <dir_val1>

prop_name_value_pair2 ::=
    auth_algs <auth_alg> |
    encr_algs <encr_alg> |
    encr_auth_algs <auth_alg> |
    sa <sa_val>

auth_alg ::=  <auth_algname> ['(' <keylen> ')']
auth_algname ::= any | md5 | hmac-md5 | sha | sha1 | hmac-sha |
                 hmac-sha1 | hmac-sha256 | hmac-sha384 |
                 hmac-sha512 | aes-gmac128 | aes-gmac192 |
                 aes-gmac256 | <number>

encr_alg ::= <encr_algname> ['(' <keylen> ')']
encr_algname ::= any | aes | aes-cbc | des | des-cbc | 3des |
                 3des-cbc | blowfish | blowfish-cbc | aes-ccm |
                 aes-gcm | aes-none-gmac | <number>

keylen ::= <number> | <number>'..' | '..'<number> | <number>'..' \
<number>

sa_val ::= shared | unique

dir_val1 ::= out | in
dir_val2 ::= out | in | both

number ::= < 0 | 1 | 2 ... 9> <number>
icmp-type ::= <number> | unreach | echo | echorep | squench |
              redir | timex | paramprob | timest | timestrep |
              inforeq | inforep | maskreq | maskrep | unreach6 |
              pkttoobig6 | timex6 | paramprob6 | echo6 | echorep6 |
              router-sol6 | router-ad6 | neigh-sol6 | neigh-ad6 |
```

```
                    redir6

icmp-code ::= <number> | net-unr | host-unr | proto-unr | port-unr |
               needfrag | srcfail | net-unk | host-unk | isolate |
               net-prohib | host-prohib | net-tos | host-tos |
               filter-prohib | host-preced | cutoff-preced |
               no-route6 | adm-prohib6 | addr-unr6 | port-unr6 |
               hop-limex6 | frag-re-timex6 | err-head6 | unrec-head6 |
               unreq-opt6
```

Policy entries may contain the following (name value) pairs in the *pattern* field. Each (name value) pair may appear only once in given policy entry.

laddr/plen
local/plen
> The value that follows is the local address of the datagram with the prefix length. Only plen leading bits of the source address of the packet will be matched. plen is optional. Local means destination on incoming and source on outgoing packets. The source address value can be a hostname as described in getaddrinfo(3SOCKET) or a network name as described in getnetbyname(3XNET) or a host address or network address in the Internet standard dot notation. See inet_addr(3XNET). If a hostname is given and getaddrinfo(3SOCKET) returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

raddr/plen
remote/plen
> The value that follows is the remote address of the datagram with the prefix length. Only plen leading bits of the remote address of the packet will be matched. plen is optional. Remote means source on incoming packets and destination on outgoing packets. The remote address value can be a hostname as described in getaddrinfo(3SOCKET) or a network name as described in getnetbyname(3XNET) or a host address or network address in the Internet standard dot notation. See inet_addr(3XNET). If a hostname is given and getaddrinfo(3SOCKET) returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

src/plen
srcaddr/plen
saddr/plen
> The value that follows is the source address of the datagram with the prefix length. Only *plen* leading bits of the source address of the packet will be matched. *plen* is optional.

> The source address value can be a hostname as described in getaddrinfo(3SOCKET) or a network name as described in getnetbyname(3XNET) or a host address or network address in the Internet standard dot notation. See inet_addr(3XNET).

> If a hostname is given and getaddrinfo(3SOCKET) returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

daddr/plen
dest/plen
dstaddr/plen

> The value that follows is the destination address of the datagram with the prefix length. Only *plen* leading bits of the destination address of the packet will be matched. *plen* is optional.
>
> See *saddr* for valid values that can be given. If multiple source and destination addresses are found, then a policy entry that covers each source address-destination address pair will be added to the system.

smask

> For IPv4 only. The value that follows is the source mask. If prefix length is given with *saddr*, this should not be given. This can be represented either in hexadecimal number with a leading 0x or 0X, for example, 0xffff0000, 0Xffff0000 or in the Internet decimal dot notation, for example, 255.255.0.0 and 255.255.255.0. The mask should be contiguous and the behavior is not defined for non-contiguous masks.
>
> *smask* is considered only when *saddr* is given.
>
> For both IPv4 and IPv6 addresses, the same information can be specified as a *slen* value attached to the *saddr* parameter.

dmask

> Analogous to *smask.*

lport

> The value that follows is the local port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in getservbyname(3XNET)

rport

> The value that follows is the remote port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in getservbyname(3XNET)

sport

> The value that follows is the source port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in getservbyname(3XNET)

dport

> The value that follows is the destination port of the datagram. This can be either a port number or a string as described in getservbyname(3XNET) searched with NULL proto argument.

proto *ulp*

> The value that follows is the Upper Layer Protocol that this entry should be matched against. It could be a number or a string as described in getprotobyname(3XNET). If no smask or plen is specified, a plen of 32 for IPv4 or 128 for IPv6 will be used, meaning a host. If the *ulp* is icmp or ipv6-icmp, any action applying IPsec must be the same for all icmp rules.

type *num* or *num-num*

The value that follows is the ICMP type that this entry should be matched against. type must be a number from 0 to 255, or one of the appropriate icmp-type keywords. Also, *ulp* must be present and must specify either icmp or ipv6-icmp. A range of types can be specified with a hyphen separating numbers.

code *num* or *num-num*

The value that follows is the ICMP code that this entry should be matched against. The value following the keyword code must be a number from 0 to 254 or one of the appropriate icmp-code keywords. Also, type must be present. A range of codes can be specified with a hyphen separating numbers.

tunnel *name*

Specifies a tunnel network interface, as configured with ifconfig(1M). If a tunnel of *name* does not yet exist, the policy entries are added anyway, and joined with the tunnel state when it is created. If a tunnel is unplumbed, its policy entries disappear.

negotiate *tunnel*

negotiate *transport*

For per-tunnel security, specify whether the IPsec SAs protecting the traffic should be tunnel-mode SAs or transport-mode SAs. If transport-mode SAs are specified, no addresses can appear in the policy entry. Transport-mode is backward compatible with Solaris 9, and tunnel IPsec policies configured with ifconfig(1M) will show up as transport mode entries here.

Policy entries may contain the following (name-value) pairs in the properties field. Each (name-value) pair may appear only once in a given policy entry.

auth_algs

An acceptable value following this implies that IPsec AH header will be present in the outbound datagram. Values following this describe the authentication algorithms that will be used while applying the IPsec AH on outbound datagrams and verified to be present on inbound datagrams. See *RFC 2402*.

This entry can contain either a string or a decimal number.

string

This should be either MD5 or HMAC-MD5 denoting the HMAC-MD5 algorithm as described in *RFC 2403*, and SHA1, or HMAC-SHA1 or SHA or HMAC-SHA denoting the HMAC-SHA algorithm described in *RFC 2404*. You can use the ipsecalgs(1M) command to obtain the complete list of authentication algorithms.

The string can also be ANY, which denotes no-preference for the algorithm. Default algorithms will be chosen based upon the SAs available at this time for manual SAs and the key negotiating daemon for automatic SAs. Strings are not case-sensitive.

number
   A number in the range 1-255. This is useful when new algorithms can be dynamically
   loaded.

If *auth_algs* is not present, the AH header will not be present in the outbound datagram,
and the same will be verified for the inbound datagram.

encr_algs
   An acceptable value following this implies that IPsec ESP header will be present in the
   outbound datagram. The value following this describes the encryption algorithms that will
   be used to apply the IPsec ESP protocol to outbound datagrams and verify it to be present
   on inbound datagrams. See *RFC 2406*.

   This entry can contain either a string or a decimal number. Strings are not case-sensitive.

   string
      Can be one of the following:

string value:	Algorithm Used:	See RFC:
DES or DES-CBC	DES-CBC	2405
3DES or 3DES-CBC	3DES-CBC	2451
BLOWFISH or BLOWFISH-CBC	BLOWFISH-CBC	2451
AES or AES-CBC	AES-CBC	2451
AES-CCM	AES-CCM	4309
AES-GCM	AES_GCM	4106

      You can use the ipsecalgs(1M) command to obtain the complete list of authentication
      algorithms.

      The value can be NULL, which implies a NULL encryption, pursuant to *RFC 2410*. This
      means that the payload will not be encrypted. The string can also be ANY, which indicates
      no-preference for the algorithm. Default algorithms will be chosen depending upon the
      SAs available at the time for manual SAs and upon the key negotiating daemon for
      automatic SAs. Strings are not case-sensitive.

   number
      A decimal number in the range 1-255. This is useful when new algorithms can be
      dynamically loaded.

encr_auth_algs
   An acceptable value following encr_auth_algs implies that the IPsec ESP header will be
   present in the outbound datagram. The values following encr_auth_algs describe the

authentication algorithms that will be used while applying the IPsec ESP protocol on outbound datagrams and verified to be present on inbound datagrams. See *RFC 2406*. This entry can contain either a string or a number. Strings are case-insensitive.

string
    Valid values are the same as the ones described for auth_algs above.

number
    This should be a decimal number in the range 1-255. This is useful when new algorithms can be dynamically loaded.

If encr_algs is present and encr_auth_algs is not present in a policy entry, the system will use an ESP SA regardless of whether the SA has an authentication algorithm or not.

If encr_algs is not present and encr_auth_algs is present in a policy entry, null encryption will be provided, which is equivalent to encr_algs with NULL, for outbound and inbound datagrams.

If both encr_algs and encr_auth_algs are not present in a policy entry, ESP header will not be present for outbound datagrams and the same will be verified for inbound datagrams.

If both encr_algs and encr_auth_algs are present in a policy entry, ESP header with integrity checksum will be present on outbound datagrams and the same will be verified for inbound datagrams.

For encr_algs, encr_auth_algs, and auth_algs a key length specification may be present. This is either a single value specifying the only valid key length for the algorithm or a range specifying the valid minimum and/or maximum key lengths. Minimum or maximum lengths may be omitted.

dir
    Values following this decides whether this entry is for outbound or inbound datagram. Valid values are strings that should be one of the following:

    out
        This means that this policy entry should be considered only for outbound datagrams.

    in
        This means that this policy entry should be considered only for inbound datagrams.

    both
        This means that this policy entry should be considered for both inbound and outbound datagrams

    This entry is not needed when the action is "apply", "permit" or "ipsec". But if it is given while the action is "apply" or "permit", it should be "out" or "in" respectively. This is mandatory when the action is "bypass".

sa

> Values following this decide the attribute of the security association. Value indicates whether a unique security association should be used or any existing SA can be used. If there is a policy requirement, SAs are created dynamically on the first outbound datagram using the key management daemon. Static SAs can be created using `ipseckey(1M)`. The values used here determine whether a new SA will be used/obtained. Valid values are strings that could be one of the following:

> unique

>> Unique Association. A new/unused association will be obtained/used for packets matching this policy entry. If an SA that was previously used by the same 5 tuples, that is, {Source address, Destination address, Source port, Destination Port, Protocol (for example, TCP/UDP)} exists, it will be reused. Thus uniqueness is expressed by the 5 tuples given above. The security association used by the above 5 tuples will not be used by any other socket. For inbound datagrams, uniqueness will not be verified.

>> For tunnel-mode tunnels, `unique` is ignored. SAs are assigned per-rule in tunnel-mode tunnels. For transport-mode tunnels, `unique` is implicit, because the enforcement happens only on the outer-packet addresses and protocol value of either IPv4-in-IP or IPv6-in-IP.

> shared

>> Shared association. If an SA exists already for this source-destination pair, it will be used. Otherwise a new SA will be obtained. This is the default.

> This is mandatory only for outbound policy entries and should not be given for entries whose action is "bypass". If this entry is not given for inbound entries, for example, when "dir" is in or "action" is permit, it will be assumed to be shared.

Action follows the pattern and should be given before properties. It should be one of the following and this field is mandatory.

ipsec

> Use IPsec for the datagram as described by the properties, if the pattern matches the datagram. If ipsec is given without a dir spec , the pattern is matched to incoming and outgoing datagrams.

apply

> Apply IPsec to the datagram as described by the properties, if the pattern matches the datagram. If apply is given, the pattern is matched only on the outbound datagram.

permit

> Permit the datagram if the pattern matches the incoming datagram and satisfies the constraints described by the properties. If it does not satisfy the properties, discard the datagram. If permit is given, the pattern is matched only for inbound datagrams.

bypass
pass

Bypass any policy checks if the pattern matches the datagram. `dir` in the properties decides whether the check is done on outbound or inbound datagrams. All the `bypass` entries are checked before checking with any other policy entry in the system. This has the highest precedence over any other entries. `dir` is the only field that should be present when action is `bypass`.

drop
Drop any packets that match the pattern.

If the file contains multiple policy entries, for example, they are assumed to be listed in the order in which they are to be applied. In cases of multiple entries matching the outbound and inbound datagram, the first match will be taken. The system will reorder the policy entry, that is, add the new entry before the old entry, only when:

The level of protection is "stronger" than the old level of protection.

Currently, strength is defined as:

AH and ESP > ESP > AH

The standard uses of AH and ESP were what drove this ranking of "stronger". There are flaws with this. ESP can be used either without authentication, which will allow cut-and-paste or replay attacks, or without encryption, which makes it equivalent or slightly weaker than AH. An administrator should take care to use ESP properly. See ipsecesp(7P) for more details.

If the new entry has `bypass` as action, `bypass` has the highest precedence. It can be added in any order, and the system will still match all the `bypass` entries before matching any other entries. This is useful for key management daemons which can use this feature to bypass IPsec as it protects its own traffic.

Entries with both AH (`auth_algs` present in the policy entry) and ESP (`encr_auth_algs` or `encr_auth_algs` present in the policy entry) protection are ordered after all the entries with AH and ESP and before any AH–only and ESP–only entries. In all other cases the order specified by the user is not modified, that is, newer entries are added at the end of all the old entries. See Examples.

A new entry is considered duplicate of the old entry if an old entry matches the same traffic pattern as the new entry. See Examples for information on duplicates.

Security If, for example, the policy file comes over the wire from an NFS mounted file system, an adversary can modify the data contained in the file, thus changing the policy configured on the machine to suit his needs. Administrators should be cautious about transmitting a copy of the policy file over a network.

To prevent non-privileged users from modifying the security policy, ensure that the configuration file is writable only by trusted users.

The configuration file is defined by a property of the policy smf(5) service. The default configuration file, is /etc/inet/ipsecinit.conf. This can be changed using the svcprop(1) command. See NOTES for more details.

The policy description language supports the use of tokens that can be resolved by means of a name service, using functions such as gethostbyname(3NSL). While convenient, these functions are only secure as the name service the system is configured to use. Great care should be taken to secure the name service if it is used to resolve elements of the security policy.

If your source address is a host that can be looked up over the network and your naming system itself is compromised, then any names used will no longer be trustworthy.

If the name switch is configured to use a name service that is not local to the system, bypass policy entries might be required to prevent the policy from preventing communication to the name service. See nsswitch.conf(4).

Policy is latched for TCP/UDP sockets on which a connect(3SOCKET) or accept(3SOCKET) has been issued. Adding new policy entries will not have any effect on them. This feature of latching may change in the future. It is not advisable to depend upon this feature.

The ipsecconf command can only be run by a user who has sufficient privilege to open the pf_key(7P) socket. The appropriate privilege can be assigned to a user with the Network IPsec Management profile. See profiles(1), rbac(5), prof_attr(4).

Make sure to set up the policies before starting any communications, as existing connections may be affected by the addition of new policy entries. Similarly, do not change policies in the middle of a communication.

Note that certain ndd tunables affect how policies configured with this tool are enforced; see ipsecesp(7P) for more details.

Examples   EXAMPLE 1   Protecting Outbound TCP Traffic With ESP and the AES Algorithm

The following example specified that any TCP packet from spiderweb to arachnid should be encrypted with AES, and the SA could be a shared one. It does not verify whether or not the inbound traffic is encrypted.

```
#
# Protect the outbound TCP traffic between hosts spiderweb
# and arachnid with ESP and use AES algorithm.
#
{
     laddr spiderweb
     raddr arachnid
     ulp tcp
     dir out
} ipsec {
```

EXAMPLE 1   Protecting Outbound TCP Traffic With ESP and the AES Algorithm   *(Continued)*

```
        encr_algs AES
}
```

EXAMPLE 2   Verifying Whether or Not Inbound Traffic is Encrypted

Example 1 does not verify whether or not the inbound traffic is encrypted. The entry in this example protects inbound traffic:

```
#
# Protect the TCP traffic on inbound with ESP/DES from arachnid
# to spiderweb
#
{
        laddr spiderweb
        raddr arachnid
        ulp tcp
        dir in
} ipsec {
        encr_algs AES
}
```

sa can be absent for inbound policy entries as it implies that it can be a shared one. Uniqueness is not verified on inbound. Note that in both the above entries, authentication was never specified. This can lead to cut and paste attacks. As mentioned previously, though the authentication is not specified, the system will still use an ESP SA with encr_auth_alg specified, if it was found in the SA tables.

EXAMPLE 3   Protecting All Traffic Between Two Hosts

The following example protects both directions at once:

```
{
        laddr spiderweb
        raddr arachnid
        ulp tcp
} ipsec {
        encr_algs AES
}
```

EXAMPLE 4   Authenticating All Inbound Traffic to the Telnet Port

This entry specifies that any inbound datagram to telnet port should come in authenticated with the SHA1 algorithm. Otherwise the datagram should not be permitted. Without this entry, traffic destined to port number 23 can come in clear. sa is not specified, which implies that it is shared. This can be done only for inbound entries. You need to have an equivalent entry to protect outbound traffic so that the outbound traffic is authenticated as well, remove the dir.

EXAMPLE 4 Authenticating All Inbound Traffic to the Telnet Port   *(Continued)*

```
#
# All the inbound traffic to the telnet port should be
# authenticated.
#
{
      lport telnet
      dir in
} ipsec {
      auth_algs sha1
}
```

EXAMPLE 5 Verifying Inbound Traffic is Null-Encrypted

The first entry specifies that any packet with address host-B should not be checked against any policies. The second entry specifies that all inbound traffic from network-B should be encrypted with a NULL encryption algorithm and the MD5 authentication algorithm. NULL encryption implies that ESP header will be used without encrypting the datagram. As the first entry is bypass it need not be given first in order, as bypass entries have the highest precedence. Thus any inbound traffic will be matched against all bypass entries before any other policy entries.

```
#
# Make sure that all inbound traffic from network-B is NULL
# encrypted, but bypass for host-B alone from that network.
# Add the bypass first.
{
raddr host-B
    dir in
} bypass {}

# Now add for network-B.
{
    raddr network-B/16
    dir in
} ipsec {
encr_algs NULL
encr_auth_algs md5
}
```

EXAMPLE 6 Entries to Bypass Traffic from IPsec

The first two entries provide that any datagram leaving the machine with source port 53 or coming into port number 53 should not be subjected to IPsec policy checks, irrespective of any other policy entry in the system. Thus the latter two entries will be considered only for ports other than port number 53.

EXAMPLE 6 Entries to Bypass Traffic from IPsec   *(Continued)*

```
#
# Bypass traffic for port no 53
     #
{lport 53} bypass {}
{rport 53} bypass {}
{raddr spiderweb } ipsec {encr_algs any sa unique}
```

EXAMPLE 7 Protecting Outbound Traffic

```
 #
     # Protect the outbound traffic from all interfaces.
     #
{raddr spiderweb dir out} ipsec {auth_algs any sa unique}
```

If the gethostbyname(3XNET) call for spiderweb yields multiple addresses, multiple policy entries will be added for all the source address with the same properties.

```
{
    laddr arachnid
    raddr spiderweb
    dir in
} ipsec {auth_algs any sa unique}
```

If the gethostbyname(3XNET) call for spiderweb and the gethostbyname(3XNET) call for arachnid yield multiple addresses, multiple policy entries will be added for each (saddr daddr) pair with the same properties. Use ipsecconf -l to view all the policy entries added.

EXAMPLE 8 Bypassing Unauthenticated Traffic

```
#
# Protect all the outbound traffic with ESP except any traffic
# to network-b which should be authenticated and bypass anything
# to network-c
#
{raddr network-b/16 dir out} ipsec {auth_algs any}
{dir out} ipsec {encr_algs any}
{raddr network-c/16 dir out} bypass {} # NULL properties
```

Note that bypass can be given anywhere and it will take precedence over all other entries. NULL pattern matches all the traffic.

EXAMPLE 9 Encrypting IPv6 Traffic with 3DES and MD5

The following entry on the host with the link local address fe80::a00:20ff:fe21:4483 specifies that any outbound traffic between the hosts wtih IPv6 link-local addresses fe80::a00:20ff:fe21:4483 and fe80::a00:20ff:felf:e346 must be encrypted with 3DES and MD5.

EXAMPLE 9   Encrypting IPv6 Traffic with 3DES and MD5   *(Continued)*

```
{
    laddr fe80::a00:20ff:fe21:4483
    raddr fe80::a00:20ff:felf:e346
    dir out
} ipsec {
    encr_algs 3DES
    encr_auth_algs MD5
}
```

EXAMPLE 10   Verifying IPv6 Traffic is Authenticated with SHA1

The following two entries require that all IPv6 traffic to and from the IPv6 site-local network fec0:abcd::0/32 be authenticated with SHA1.

```
{raddr fec0:abcd::0/32} ipsec { auth_algs SHA1 }
```

EXAMPLE 11   Key Lengths

```
# use aes at any key length
{raddr spiderweb} ipsec {encr_algs aes}

# use aes with a 192 bit key
{raddr spiderweb} ipsec {encr_algs aes(192)}

# use aes with any key length up to 192 bits
# i.e. 192 bits or less
{raddr spiderweb} ipsec {encr_algs aes(..192)}

# use aes with any key length of 192 or more
# i.e. 192 bits or more
{raddr spiderweb} ipsec {encr_algs aes(192..)}

#use aes with any key from 192 to 256 bits
{raddr spiderweb} ipsec {encr_algs aes(192..256)}

#use any algorithm with a key of 192 bits or longer
{raddr spiderweb} ipsec {encr_algs any(192..)}
```

EXAMPLE 12   Correct and Incorrect Policy Entries

The following are examples of correctly formed policy entries:

```
{ raddr that_system rport telnet } ipsec { encr_algs 3des encr_auth_algs
sha1 sa shared}

{
        raddr that_system
        rport telnet
```

EXAMPLE 12 Correct and Incorrect Policy Entries   *(Continued)*

```
} ipsec {
        encr_algs 3des
        encr_auth_algs sha1
        sa shared
}

{ raddr that_system rport telnet } ipsec
        { encr_algs 3des encr_auth_algs sha1 sa shared}

{ raddr that_system rport telnet } ipsec
        { encr_algs 3des encr_auth_algs sha1 sa shared} or ipsec
        { encr_algs aes encr_auth_algs sha1 sa shared}
```

...and the following is an incorrectly formed entry:

```
{ raddr that_system rport telnet } ipsec
        { encr_algs 3des encr_auth_algs sha1 sa shared}
        or ipsec { encr_algs aes encr_auth_algs sha1 sa shared}
```

In the preceding, incorrect entry, note that the third line begins with "or ipsec". Such an entry causes ipsecconf to return an error.

EXAMPLE 13   Allowing Neighbor Discovery to Occur in the Clear

The following two entries require that all IPv6 traffic to and from the IPv6 site-local network fec0:abcd::0/32 be authenticated with SHA1. The second entry allows neighbor discovery to operate correctly.

```
{raddr fec0:abcd::0/32} ipsec { auth_algs SHA1 }
{raddr fec0:abcd::0/32 ulp ipv6-icmp type 133-137  dir both }
    pass { }
```

EXAMPLE 14   Using "or"

The following entry allows traffic using the AES or Blowfish algorithms from the remote machine spiderweb:

```
{raddr spiderweb} ipsec {encr_algs aes} or ipsec {encr_algs blowfish}
```

EXAMPLE 15   Configuring a Tunnel to be Backward-Compatible with Solaris 9

The following example is equivalent to "encr_algs aes encr_auth_algs md5" in ifconfig(1M):

```
{tunnel ip.tun0 negotiate transport} ipsec {encr_algs aes
                                            encr_auth_algs md5}
```

EXAMPLE 16 Configuring a Tunnel to a VPN client with an Assigned Address

The following example assumes a distinct "inside" network with its own topology, such that a client's default route goes "inside".

```
# Unlike route(1m), the default route has to be spelled-out.
{tunnel ip.tun0 negotiate tunnel raddr client-inside/32
laddr 0.0.0.0/0} ipsec {encr_algs aes encr_auth_algs sha1}
```

EXAMPLE 17 Transit VPN router between Two Tunnelled Subnets and a Third

The following example specifies a configuration for a VPN router that routes between two tunnelled subnets and a third subnet that is on-link. Consider remote-site A, remote-site B, and local site C, each with a /24 address allocation.

```
# ip.tun0 between me (C) and remote-site A.
# Cover remote-site A to remote-side B.
{tunnel ip.tun0 negotiate tunnel raddr A-prefix/24 laddr
B-prefix/24} ipsec {encr_algs 3des encr_auth_algs md5}

# Cover remote-site A traffic to my subnet.
{tunnel ip.tun0 negotiate tunnel raddr A-prefix/24 laddr
C-prefix/24} ipsec {encr_algs 3des encr_auth_algs md5}

# ip.tun1 between me (C) and remote-site B.
# Cover remote-site B to remote-site A.
{tunnel ip.tun1 negotiate tunnel raddr B-prefix/24 laddr
A-prefix/24} ipsec {encr_algs aes encr_auth_algs sha1}

# Cover remote-site B traffic to my subnet.
{tunnel ip.tun1 negotiate tunnel raddr B-prefix/24 laddr
C-prefix/24} ipsec {encr_algs aes encr_auth_algs md5}
```

EXAMPLE 18 Using Combined Mode Ciphers

Combined mode ciphers provide data privacy and message authentication in a single operation. They are treated as special versions of encr_algs. They provide message authentication without the need to specify encr_auth_algs. The two combined mode ciphers supported are:

aes-ccm
   AES CCM Mode(Counter with CBC-MAC)

aes-gcm
   AES GCM Mode (Galois/Counter)

The parameters used are the same as any other encr_algs value. In both examples, the number in the algorithm token indicates the length of the Integrity Check Vector (ICV). See ipsecalgs(1M).

EXAMPLE 18 Using Combined Mode Ciphers   *(Continued)*

```
# simple example using transport mode
{laddr 192.168.99.2 raddr 192.168.99.3} ipsec
    {encr_algs aes-gcm sa shared}
# simple example using CCM mode and 128 bit keys
{laddr 192.168.99.100 raddr 192.168.99.200} ipsec
    {encr_algs aes-ccm(128) sa shared}
```

EXAMPLE 19 Using AES GMAC

The AES GMAC algorithm is a hash algorithm that provides message authentication. An Integrity Check Vector (ICV) is calculated and transmitted as part of the authenticated packet.

The AES GMAC algorithm can be used in ESP mode, in which case the packet data and the ESP header are authenticated. When used with IPsec ESP, AES GMAC can only be specified as an encryption algorithm, even though it does not provide any encryption.

```
# simple example using AES GMAC and 128 bit keys for ESP
{laddr 192.168.99.100 raddr 192.168.99.200} ipsec
    {encr_algs aes-none-gmac(128) sa shared}
```

The above example is analogous to the following invalid example:

```
{laddr 192.168.99.100 raddr 192.168.99.200} ipsec
    {encr_algs null encr_auth_algs aes-gmac(128) sa shared}
```

When used with ESP, the aes-none-gmac algorithm takes the key length as an optional argument, the supported key lengths can be displayed using the ipsecalgs(1M) command.

The AES GMAC algorithm can be used in AH mode, in which case the whole packet, including the IP header, is authenticated. When used with IPsec AH, AES GMAC can only be specified as an authentication algorithm.

```
# simple example using AES GMAC and 128 bit keys for AH
{laddr 192.168.99.100 raddr 192.168.99.200} ipsec
    {auth_algs aes-gmac128 sa shared}
```

When used with AH, each key length has its own DOI number, the key length does not need to be specified as an argument.

Files /var/run/ipsecpolicy.conf

Cache of IPsec policies currently configured for the system, maintained by ipsecconf command. Do not edit this file.

/etc/inet/ipsecinit.conf

File containing IPsec policies to be installed at system restart by the policy smf(5) service. See NOTES for more information.

/etc/inet/ipsecinit.sample

Sample input file for ipsecconf.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

Diagnostics   Bad "string" on line *N*.
Duplicate "string" on line *N*.
　　　string refers to one of the names in pattern or properties. A Bad string indicates that an argument is malformed; a Duplicate string indicates that there are multiple arguments of a similar type, for example, multiple Source Address arguments.

Interface name already selected
　　　Dual use of -i *name* and *name,index* for an index.

Error before or at line *N*.
　　　Indicates parsing error before or at line *N*.

Non-existent index
    Reported when the *index* for delete is not a valid one.

spd_msg return: File exists
    Reported when there is already a policy entry that matches the traffic of this new entry.

Notes IPsec manual keys are managed by the service management facility, smf(5). The services listed below manage the components of IPsec. These services are delivered as follows:

```
svc:/network/ipsec/policy:default (enabled)
svc:/network/ipsec/ipsecalgs:default (enabled)
svc:/network/ipsec/manual-key:default (disabled)
svc:/network/ipsec/ike:default (disabled)
```

The manual-key service is delivered disabled. The system administrator must create manual IPsec Security Associations (SAs), as described in ipseckey(1M), before enabling that service.

The policy service is delivered enabled, but without a configuration file, so that, as a starting condition, packets are not protected by IPsec. After you create the configuration file /etc/inet/ipsecinit.conf, as described in this man page, and refresh the service (svcadm refresh, see below), the policy contained in the configuration file is applied. If there is an error in this file, the service enters maintenance mode.

Services that are delivered disabled are delivered that way because the system administrator must create configuration files for those services before enabling them. See ike.config(4) for the ike service.

See ipsecalgs(1M) for the ipsecalgs service.

The correct administrative procedure is to create the configuration file for each service, then enable each service using svcadm(1M).

If the configuration needs to be changed, edit the configuration file then refresh the service, as follows:

example# **svcadm refresh policy**

The smf(5) framework will record any errors in the service-specific log file. Use any of the following commands to examine the logfile property:

example# **svcs -l policy**
example# **svcprop policy**
example# **svccfg -s policy listprop**

The following property is defined for the policy service:

```
config/config_file
```

This property can be modified using svccfg(1M) by users who have been assigned the following authorization:

solaris.smf.value.ipsec

See auths(1), user_attr(4), rbac(5).

The service needs to be refreshed using svcadm(1M) before the new property is effective. General non-modifiable properties can be viewed with the svcprop(1) command.

```
# svccfg -s ipsec/policy setprop config/config_file = /new/config_file
# svcadm refresh policy
```

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using svcadm(1M). A user who has been assigned the authorization shown below can perform these actions:

solaris.smf.manage.ipsec

The service's status can be queried using the svcs(1) command.

The ipsecconf command is designed to be managed by the policy smf(5) service. While the ipsecconf command can be run from the command line, this is discouraged. If the ipsecconf command is to be run from the command line, the policy smf(5) service should be disabled first. See svcadm(1M).

Name ipseckey – manually manipulate an IPsec Security Association Database (SADB)

Synopsis ipseckey [-nvp]

ipseckey [-nvp] -f *filename*

ipseckey -c *filename*

ipseckey [-nvp] [delete | delete-pair | get] SA_TYPE {EXTENSION *value*...}

ipseckey [-np] [monitor | passive_monitor | pmonitor]

ipseckey [-nvp] flush {SA_TYPE}

ipseckey [-nvp] dump {SA_TYPE}

ipseckey [-nvp] save SA_TYPE {*filename*}

ipseckey [-nvp] -s *filename*

Description The ipseckey command is used to manually manipulate the security association databases of the network security services, ipsecah(7P) and ipsecesp(7P). You can use the ipseckey command to set up security associations between communicating parties when automated key management is not available.

While the ipseckey utility has only a limited number of general options, it supports a rich command language. The user may specify requests to be delivered by means of a programmatic interface specific for manual keying. See pf_key(7P). When ipseckey is invoked with no arguments, it will enter an interactive mode which prints a prompt to the standard output and accepts commands from the standard input until the end-of-file is reached. Some commands require an explicit security association ("SA") type, while others permit the SA type to be unspecified and act on all SA types.

ipseckey uses a PF_KEY socket and the message types SADB_ADD, SADB_DELETE, SADB_GET, SADB_UPDATE, SADB_FLUSH, and SADB_X_PROMISC. Thus, you must be a superuser to use this command.

ipseckey handles sensitive cryptographic keying information. Please read the Security section for details on how to use this command securely.

Options -c [*filename*]
　　Analogous to the -f option (see following), except that the input is not executed but only checked for syntactical correctness. Errors are reported to stderr. This option is provided to debug configurations without making changes. See SECURITY and "Service Management Facility" for more information.

-f [*filename*]
　　Read commands from an input file, *filename*. The lines of the input file are identical to the command line language. The load command provides similar functionality. The -s option or the save command can generate files readable by the -f argument.

-n

Prevent attempts to print host and network names symbolically when reporting actions. This is useful, for example, when all name servers are down or are otherwise unreachable.

-p

Paranoid. Do not print any keying material, even if saving SAs. Instead of an actual hexadecimal digit, print an X when this flag is turned on.

-s [*filename*]

The opposite of the -f option. If '-' is given for a *filename*, then the output goes to the standard output. A snapshot of all current SA tables will be output in a form readable by the -f option. The output will be a series of add commands, but with some names not used. This occurs because a single name may often indicate multiple addresses.

-v

Verbose. Print the messages being sent into the PF_KEY socket, and print raw seconds values for lifetimes.

Commands   add

Add an SA. Because it involves the transfer of keying material, it cannot be invoked from the shell, lest the keys be visible in ps(1) output. It can be used either from the interactive ipseckey> prompt or in a command file specified by the -f command. The add command accepts all extension-value pairs described below.

update

Update SA lifetime, and in the cases of larval SAs (leftover from aborted automated key management), keying material and other extensions. Like add, this command cannot be invoked from the shell because keying material would be seen by the ps(1) command. It can be used either from the interactive ipseckey> prompt or in a command file specified by the -f command. The update command accepts all extension-value pairs, but normally is only used for SA lifetime updates.

update-pair

As update, but apply the update to the SA and its paired SA, if there is one.

delete

Delete a specific SA from a specific SADB. This command requires the spi extension, and the dest extension for IPsec SAs. Other extension-value pairs are superfluous for a delete message. If the SA to be deleted is paired with another SA, the SA is deleted and the paired SA is updated to indicate that it is now unpaired.

delete-pair

Delete a specific SA from a specific SADB. If the SA is paired with another SA, delete that SA too. This command requires the spi extension and the dest extension for the IPsec SA, or its pair.

get

Lookup and display a security association from a specific SADB. Like delete, this command only requires spi and dest for IPsec.

flush
Remove all SA for a given SA_TYPE, or all SA for all types.

monitor
Continuously report on any PF_KEY messages. This uses the SADB_X_PROMISC message to enable messages that a normal PF_KEY socket would not receive to be received. See pf_key(7P).

passive_monitor
Like monitor, except that it does not use the SADB_X_PROMISC message.

pmonitor
Synonym for passive_monitor.

dump
Will display all SAs for a given SA type, or will display all SAs. Because of the large amount of data generated by this command, there is no guarantee that all SA information will be successfully delivered, or that this command will even complete.

save
Is the command analog of the -s option. It is included as a command to provide a way to snapshot a particular SA type, for example, esp or ah.

help
Prints a brief summary of commands.

SA_TYPE all
Specifies all known SA types. This type is only used for the flush and dump commands. This is equivalent to having no SA type for these commands.

ah
Specifies the IPsec Authentication Header ("AH") SA.

esp
Specifies the IPsec Encapsulating Security Payload ("ESP") SA.

Extension Value Types Commands like add, delete, get, and update require that certain extensions and associated values be specified. The extensions will be listed here, followed by the commands that use them, and the commands that require them. Requirements are currently documented based upon the IPsec definitions of an SA. Required extensions may change in the future. <number> can be in either hex (0xnnn), decimal (nnn) or octal (0nnn).<string> is a text string. <hexstr> is a long hexadecimal number with a bit-length. Extensions are usually paired with values; however, some extensions require two values after them.

spi <*number*>
Specifies the security parameters index of the SA. This extension is required for the add, delete, get and update commands.

pair-spi <*number*>

> When pair-spi is used with the add or update commands, the SA being added or updated
> will be paired with the SA defined by pair-spi. A pair of SAs can be updated or deleted
> with a single command.
>
> The two SAs that make up the pair need to be in opposite directions from the same pair of
> IP addresses. The command will fail if either of the SAs specified are already paired with
> another SA.
>
> If the pair-spi token is used in a command and the SA defined by pair-spi does not exist, the
> command will fail. If the command was add and the pairing failed, the SA to be added will
> instead be removed.

inbound | outbound

> These optional flags specify the direction of the SA. When the inbound or outbound flag is
> specified with the add command, the kernel will insert the new SA into the specified hash
> table for faster lookups. If the flag is omitted, the kernel will decide into which hash table to
> insert the new SA based on its knowledge the IP addresses specified with the src and dst
> extensions.
>
> When these flags are used with the update, delete, update-pair or get commands, the
> flags provide a hint as to the hash table in which the kernel should find the SA.

replay <*number*>

> Specifies the replay window size. If not specified, the replay window size is assumed to be
> zero. It is not recommended that manually added SAs have a replay window. This
> extension is used by the add and update commands.

replay_value <*number*>

> Specifies the replay value of the SA. This extension is used by the add and update
> commands.

state <*string*>|<*number*>

> Specifies the SA state, either by numeric value or by the strings "larval", "mature",
> "dying" or "dead". If not specified, the value defaults to mature. This extension is used by
> the add and update commands.

auth_alg <*string*>|<*number*>
authalg <string>|<number>

> Specifies the authentication algorithm for an SA, either by numeric value, or by strings
> indicating an algorithm name. Current authentication algorithms include:
>
> HMAC-MD5
> > md5, hmac-md5
>
> HMAC-SH-1
> > sha, sha-1, hmac-sha1, hmac-sha

HMAC-SHA-256
   sha256, sha-256, hmac-sha256, hmac-sha-256

HMAC-SHA-384
   sha384, sha-384, hmac-sha384, hmac-sha-384

HMAC-SHA-512
   sha512, sha-512, hmac-sha512, hmac-sha-512

Often, algorithm names will have several synonyms. This extension is required by the add command for certain SA types. It is also used by the update command.

Use the ipsecalgs(1M) command to obtain the complete list of authentication algorithms.

encr_alg <*string*>|<*number*>
encralg <*string*>|<*number*>
   Specifies the encryption algorithm for an SA, either by numeric value, or by strings indicating an algorithm name. Current encryption algorithms include DES ("des"), Triple-DES ("3des"), Blowfish ("blowfish"), and AES ("aes"). This extension is required by the add command for certain SA types. It is also used by the update command.

   Use the ipsecalgs(1M) command to obtain the complete list of encryption algorithms.

The next six extensions are lifetime extensions. There are two varieties, "hard" and "soft". If a hard lifetime expires, the SA will be deleted automatically by the system. If a soft lifetime expires, an SADB_EXPIRE message will be transmitted by the system, and its state will be downgraded to dying from mature. See pf_key(7P). The monitor command to key allows you to view SADB_EXPIRE messages.

idle_addtime <*number*>
idle_usetime <*number*>
   Specifies the number of seconds that this SA can exist if the SA is not used before the SA is revalidated. If this extension is not present, the default value is half of the hard_addtime (see below). This extension is used by the add and update commands.

soft_bytes <*number*>
hard_bytes <*number*>
   Specifies the number of bytes that this SA can protect. If this extension is not present, the default value is zero, which means that the SA will not expire based on the number of bytes protected. This extension is used by the add and update commands.

soft_addtime <*number*>
hard_addtime <*number*>
   Specifies the number of seconds that this SA can exist after being added or updated from a larval SA. An update of a mature SA does not reset the initial time that it was added. If this extension is not present, the default value is zero, which means the SA will not expire based on how long it has been since it was added. This extension is used by the add and update commands.

soft_usetime <*number*>
hard_usetime <*number*>

> Specifies the number of seconds this SA can exist after first being used. If this extension is not present, the default value is zero, which means the SA will not expire based on how long it has been since it was added. This extension is used by the add and update commands.

saddr *address* | *name*
srcaddr *address* | *name*
saddr6 *IPv6 address*
srcaddr6 *IPv6 address*
src *address* | *name*
src6 *IPv6 address*

> srcaddr *address* and src *address* are synonyms that indicate the source address of the SA. If unspecified, the source address will either remain unset, or it will be set to a wildcard address if a destination address was supplied. To not specify the source address is valid for IPsec SAs. Future SA types may alter this assumption. This extension is used by the add, update, get and delete commands.

daddr <*address*>|<*name*>
dstaddr <*address*>|<*name*>
daddr6 <*IPv6 address*>|<*name*>
dstaddr6 <*IPv6 address*>|<*name*>
dst <*addr*>|<*name*>
dst6 <*IPv6 address*>|<*name*>

> dstaddr <*addr*> and dst <*addr*> are synonyms that indicate the destination address of the SA. If unspecified, the destination address will remain unset. Because IPsec SAs require a specified destination address and spi for identification, this extension, with a specific value, is required for the add, update, get and delete commands.

> If a name is given, ipseckey will attempt to invoke the command on multiple SAs with all of the destination addresses that the name can identify. This is similar to how ipsecconf handles addresses.

> If dst6 or dstaddr6 is specified, only the IPv6 addresses identified by a name are used.

sport <*portnum*>

> sport specifies the source port number for an SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

dport <*portnum*>

> sport specifies the destination port number for an SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

encap <*protocol*>

> Identifies the protocol used to encapsulate NAT-traversal IPsec packets. Other NAT-traversal parameters (nat_*) are below. The only acceptable value for <*protocol*> currently is udp.

proto <*protocol number*>
ulp <*protocol number*>
    proto, and its synonym ulp, specify the IP protocol number of the SA.

nat_loc <*address*>|<*name*>
    If the local address in the SA (source or destination) is behind a NAT, this extension indicates the NAT node's globally-routable address. This address can match the SA's local address if there is a nat_lport (see below) specified.

nat_rem <*address*>|<*name*>
    If the remote address in the SA (source or destination) is behind a NAT, this extension indicates that node's internal (that is, behind-the-NAT) address. This address can match the SA's local address if there is a nat_rport (see below) specified.

nat_lport <*portnum*>
    Identifies the local UDP port on which encapsulation of ESP occurs.

nat_rport <*portnum*>
    Identifies the remote UDP port on which encapsulation of ESP occurs.

isrc <*address*> | <*name*>[/<*prefix*>]
innersrc <*address*> | <*name*>[/<*prefix*>]
isrc6 <*address*> | <*name*>[/<*prefix*>]
innersrc6 <*address*> | <*name*>[/<*prefix*>]
proxyaddr <*address*> | <*name*>[/<*prefix*>]
proxy <*address*> | <*name*>[/<*prefix*>]
    isrc <*address*>[/<*prefix*>] and innersrc <*address*>[/<*prefix*>] are synonyms. They indicate the inner source address for a tunnel-mode SA.

    An inner-source can be a prefix instead of an address. As with other address extensions, there are IPv6-specific forms. In such cases, use only IPv6-specific addresses or prefixes.

    Previous versions referred to this value as the proxy address. The usage, while deprecated, remains.

idst <*address*> | <*name*>[/<*prefix*>]
innerdst <*address*> | <*name*>[/<*prefix*>]
idst6 <*address*> | <*name*>[/<*prefix*>]
innerdst6 <*address*> | <*name*>[/<*prefix*>]
    idst <*address*>[/<*prefix*>] and innerdst <*address*>[/<*prefix*>] are synonyms. They indicate the inner destination address for a tunnel-mode SA.

    An inner-destination can be a prefix instead of an address. As with other address extensions, there are IPv6-specific forms. In such cases, use only IPv6-specific addresses or prefixes.

innersport <*portnum*>
isport <*portnum*>

innersport specifies the source port number of the inner header for a tunnel-mode SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

innerdport <*portnum*>
idport <*portnum*>
 innerdport specifies the destination port number of the inner header for a tunnel-mode SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

iproto <*protocol number*>iulp <*protocol number*>
 iproto, and its synonym iulp, specify the IP protocol number of the inner header of a tunnel-mode SA.

authkey <*hexstring*>
 Specifies the authentication key for this SA. The key is expressed as a string of hexadecimal digits, with an optional / at the end, for example, 123/12. Bits are counted from the most-significant bits down. For example, to express three '1' bits, the proper syntax is the string "e/3". For multi-key algorithms, the string is the concatenation of the multiple keys. This extension is used by the add and update commands.

encrkey <*hexstring*>
 Specifies the encryption key for this SA. The syntax of the key is the same as authkey. A concrete example of a multi-key encryption algorithm is 3des, which would express itself as a 192-bit key, which is three 64-bit parity-included DES keys. This extension is used by the add and update commands.

reserved_bits <*number*>
 The last <*number*> bits of the encrkey string are marked as reserved in the PF_KEY message. This option is only for testing certain encryption algorithms.

Certificate identities are very useful in the context of automated key management, as they tie the SA to the public key certificates used in most automated key management protocols. They are less useful for manually added SAs. Unlike other extensions, srcidtype takes two values, a *type*, and an actual *value*. The type can be one of the following:

prefix
 An address prefix.

fqdn
 A fully-qualified domain name.

domain
 Domain name, synonym for fqdn.

user_fqdn
 User identity of the form *user@fqdn*.

mailbox
 Synonym for user_fqdn.

The *value* is an arbitrary text string that should identify the certificate.

srcidtype <*type, value*>
Specifies a source certificate identity for this SA. This extension is used by the add and update commands.

dstidtype <*type, value*>
Specifies a destination certificate identity for this SA. This extension is used by the add and update commands

Label extensions are used on Trusted Extensions to associate sensitivity labels with the traffic carried inside a security association. These extensions are not allowed unless Trusted Extensions is enabled.

label *label*
Defines the sensitivity label of traffic carried by this SA. Disallowed on systems not using Trusted Extensions.

outer-label *label*
Defines the sensitivity of the ciphertext traffic belonging to this SA; this label will appear in the outer packet header. Disallowed on systems not using Trusted Extensions. Incorrect use of this extension might allow label policy to be circumvented.

implicit-label *label*
Defines the sensitivity of the ciphertext traffic belonging to this SA and request that this SA not contain an explicit on-the-wire label. Disallowed on systems not using Trusted Extensions. Incorrect use of this extension might allow label policy to be circumvented.

Tunnel Mode versus Transport Mode SAs An IPsec SA is a Tunnel Mode SA if the "proto" value is either 4 (ipip) or 41 (ipv6) *and* there is an inner-address or inner-port value specified. Otherwise, the SA is a Transport Mode SA.

Security Keying material is very sensitive and should be generated as randomly as possible. Some algorithms have known weak keys. IPsec algorithms have built-in weak key checks, so that if a weak key is in a newly added SA, the add command will fail with an invalid value.

The ipseckey command allows a privileged user to enter cryptographic keying information. If an adversary gains access to such information, the security of IPsec traffic is compromised. The following issues should be taken into account when using the ipseckey command.

1. Is the TTY going over a network (interactive mode)?

   - If it is, then the security of the keying material is the security of the network path for this TTY's traffic. Using ipseckey over a clear-text telnet or rlogin session is risky.
   - Even local windows might be vulnerable to attacks where a concealed program that reads window events is present.

2. Is the file accessed over the network or readable to the world (-f option)?

   - A network-mounted file can be sniffed by an adversary as it is being read.
   - A world-readable file with keying material in it is also risky.

3. The ipseckey command is designed to be managed by the manual-key smf(5) service. Because the smf(5) log files are world-readable, the ipseckey does not record any syntax errors in the log files, as these errors might include secret information.

If a syntax error is found when the manual-key smf(5) service is enabled, the service enters maintenance mode. The log file will indicate that there was a syntax error, but will not specify what the error was.

The administrator should use ipeckey -c *filename* from the command line to discover the cause of the errors. See OPTIONS.

If your source address is a host that can be looked up over the network and your naming system itself is compromised, then any names used will not be trustworthy.

Security weaknesses often lie in misapplication of tools, not in the tools themselves. Administrators are urged to be cautious when using ipseckey. The safest mode of operation is probably on a console or other hard-connected TTY.

For further thoughts on this subject, see the afterward by Matt Blaze in Bruce Schneier's *Applied Cryptography: Protocols, Algorithms, and Source Code in C.*

Service Management Facility

IPsec manual keys are managed by the service management facility, smf(5). The services listed below manage the components of IPsec. These services are delivered as follows:

```
svc:/network/ipsec/policy:default (enabled)
svc:/network/ipsec/ipsecalgs:default (enabled)
svc:/network/ipsec/manual-key:default (disabled)
svc:/network/ipsec/ike:default (disabled)
```

The manual-key service is delivered disabled. The system administrator must create manual IPsec Security Associations (SAs), as described in this man page, before enabling that service.

The policy service is delivered enabled, but without a configuration file, so that, as a starting condition, packets are not protected by IPsec. After you create the configuration file /etc/inet/ipsecinit.conf and refresh the service (svcadm refresh, see below), the policy contained in the configuration file is applied. If there is an error in this file, the service enters maintenance mode. See ipsecconf(1M).

Services that are delivered disabled are delivered that way because the system administrator must create configuration files for those services before enabling them. See ike.config(4) for the ike service.

See ipsecalgs(1M) for the ipsecalgs service.

The correct administrative procedure is to create the configuration file for each service, then enable each service using svcadm(1M).

If the configuration needs to be changed, edit the configuration file then refresh the service, as follows:

example# **svcadm refresh manual-key**

Warning: To prevent ipseckey complaining about duplicate Associations, the ipseckey command flushes the Security Association Data Base (SADB) when the ipseckey command is run from smf(5), before adding any new Security Associations defined in the configuration file. This differs from the command line behavior where the SADB is not flushed before adding new Security Associations.

The smf(5) framework will record any errors in the service-specific log file. Use any of the following commands to examine the logfile property:

example# **svcs -l manual-key**
example# **svcprop manual-key**
example# **svccfg -s manual-key listprop**

The following property is defined for the manual-key service:

config/config_file

This property can be modified using svccfg(1M) by users who have been assigned the following authorization:

solaris.smf.value.ipsec

See auths(1), user_attr(4), rbac(5).

The service needs to be refreshed using svcadm(1M) before the new property is effective. General non-modifiable properties can be viewed with the svcprop(1) command.

**svccfg -s ipsec/manual-key setprop config/config_file = **
/new/config_file
svcadm refresh manual-key

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using svcadm(1M). A user who has been assigned the authorization shown below can perform these actions:

solaris.smf.manage.ipsec

The service's status can be queried using the svcs(1) command.

The ipseckey command is designed to be run under smf(5) management. While the ipsecconf command can be run from the command line, this is discouraged. If the ipseckey command is to be run from the command line, the manual-key smf(5) service should be disabled first. See svcadm(1M).

Examples   **EXAMPLE 1**   Emptying Out All SAs

To empty out all SA:

example# **ipseckey flush**

EXAMPLE 2 Flushing Out IPsec AH SAs Only

To flush out only IPsec AH SAs:

example# **ipseckey flush ah**

EXAMPLE 3 Saving All SAs To Standard Output

To save all SAs to the standard output:

example# **ipseckey save all**

EXAMPLE 4 Saving ESP SAs To The File /tmp/snapshot

To save ESP SAs to the file /tmp/snapshot:

example# **ipseckey save esp /tmp/snapshot**

EXAMPLE 5 Deleting an IPsec SA

To delete an IPsec SA, only the SPI and the destination address are needed:

example# **ipseckey delete esp spi 0x2112 dst 224.0.0.1**

An alternative would be to delete the SA and the SAs pair if it has one:

example# **ipseckey delete-pair esp spi 0x2112 dst 224.0.0.1**

EXAMPLE 6 Getting Information on an IPsec SA

Likewise, getting information on a SA only requires the destination address and SPI:

example# **ipseckey get ah spi 0x5150 dst mypeer**

EXAMPLE 7 Adding or Updating IPsec SAs

Adding or updating SAs requires entering interactive mode:

```
example# ipseckey
ipseckey> add ah spi 0x90125 src me.domain.com dst you.domain.com \
          authalg md5 authkey 1234567890abcdef1234567890abcdef
ipseckey> update ah spi 0x90125 dst you.domain.com hard_bytes \
          16000000
ipseckey> exit
```

Adding two SAs that are linked together as a pair:

```
example# ipseckey
ipseckey> add esp spi 0x2345 src me.domain.com dst you.domain.com \
   authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
   encralg des encrkey be02938e7def2839
ipseckey> add esp spi 0x5432 src me.domain.com dst you.domain.com \
   authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
   encralg des encrkey be02938e7def2839 pair-spi 0x2345
```

EXAMPLE 7   Adding or Updating IPsec SAs   *(Continued)*

```
ipseckey> exit
```

EXAMPLE 8   Adding an SA in the Opposite Direction

In the case of IPsec, SAs are unidirectional. To communicate securely, a second SA needs to be added in the opposite direction. The peer machine also needs to add both SAs.

```
example# ipseckey
ipseckey> add ah spi 0x2112 src you.domain.com dst me.domain.com \
        authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
        hard_bytes 16000000
ipseckey> exit
```

EXAMPLE 9   Monitoring PF_KEY Messages

Monitoring for PF_KEY messages is straightforward:

```
example# ipseckey monitor
```

EXAMPLE 10   Using Commands in a File

Commands can be placed in a file that can be parsed with the -f option. This file may contain comment lines that begin with the "#" symbol. For example:

```
# This is a sample file for flushing out the ESP table and
# adding a pair of SAs.

flush esp

### Watch out!  I have keying material in this file.  See the
### SECURITY section in this manual page for why this can be
### dangerous .

add esp spi 0x2112 src me.domain.com dst you.domain.com \
    authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
    encralg des encrkey be02938e7def2839 hard_usetime 28800
add esp spi 0x5150 src you.domain.com dst me.domain.com \
    authalg md5 authkey 930987dbe09743ade09d92b4097d9e93 \
    encralg des encrkey 8bd4a52e10127deb hard_usetime 28800

## End of file  -  This is a gratuitous comment
```

EXAMPLE 11   Adding SAs for IPv6 Addresses

The following commands from the interactive-mode create an SA to protect IPv6 traffic between the site-local addresses

```
example # ipseckey
ipseckey> add esp spi 0x6789 src6 fec0:bbbb::4483 dst6 fec0:bbbb::7843\
        authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
```

EXAMPLE 11 Adding SAs for IPv6 Addresses   *(Continued)*

```
            encralg des encrkey be02938e7def2839 hard_usetime 28800
ipseckey>exit
```

EXAMPLE 12 Linking Two SAs as a Pair

The following command links two SAs together, as a pair:

```
example# ipseckey update esp spi 0x123456 dst 192.168.99.2 \
pair-spi 0x654321
```

Files /etc/inet/secret/ipseckeys
Default configuration file used at boot time. See "Service Management Facility" and
SECURITY for more information.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

pf_key(7P)

Schneier, B., *Applied Cryptography: Protocols, Algorithms, and Source Code in C.* Second ed.
New York, New York: John Wiley & Sons, 1996.

Diagnostics The ipseckey command parses the configuration file and reports any errors. In the case of
multiple errors, ipseckey reports as many of these as possible.

The ipseckey command does not attempt to use a COMMAND that has a syntax error. A COMMAND
might be syntactically correct but can nevertheless generate an error because the kernel
rejected the request made to pf_key(7P). This might occur because a key had an invalid length
or because an unsupported algorithm was specified.

If there are any errors in the configuration file, ipseckey reports the number of valid
COMMANDS and the total number of COMMANDS parsed.

Parse error on line *N*.
    If an interactive use of ipseckey would print usage information, this would print instead.
    Usually proceeded by another diagnostic. Because COMMANDS can cover more than a single
    line in the configuration file by using the backslash character to delimit lines, its not always
    possible to pinpoint in the configuration file the exact line that caused the error.

Unexpected end of command line.
    An additional argument was expected on the command line.

Unknown
 A value for a specific extension was unknown.

Address type *N* not supported.
 A name-to-address lookup returned an unsupported address family.

N is not a bit specifier
bit length *N* is too big for
string is not a hex string
 Keying material was not entered appropriately.

Can only specify single
 A duplicate extension was entered.

Don't use extension for *<string>* for *<command>*.
 An extension not used by a command was used.

One of the entered values is incorrect: Diagnostic code *NN*: *<msg>*
 This is a general invalid parameter error. The diagnostic code and message provides more
 detail about what precise value was incorrect and why.

Notes In spite of its IPsec-specific name, ipseckey is analogous to route(1M), in that it is a
command-line interface to a socket-based administration engine, in this case, PF_KEY. PF_KEY
was originally developed at the United States Naval Research Laboratory.

To have machines communicate securely with manual keying, SAs need to be added by all
communicating parties. If two nodes wish to communicate securely, both nodes need the
appropriate SAs added.

In the future ipseckey may be invoked under additional names as other security protocols
become available to PF_KEY.

This command requires sys_ip_config privilege to operate and thus can run in the global
zone and in exclusive-IP zones. The global zone can set up security associations with
ipseckey to protect traffic for shared-IP zones on the system.

Name iscsiadm – enable management of iSCSI initiators

Synopsis iscsiadm *subcommand direct-object* [*options*] [*operand*]

Description The iscsiadm command enables management of the iSCSI (Internet SCSI) initiator on a host. iscsiadm is implemented as a set of subcommands, many with their own options, which are described in the section for that subcommand. Options not associated with a particular subcommand are described under OPTIONS.

iscsiadm works only when the following service is online:

svc:/network/iscsi/initiator:default

The iscsiadm command supports the following subcommands, which are described in detail in subsections that follow:

add   Adds element(s) to an object.

list   Lists element(s) of an object.

modify   Modifies attributes of an object.

remove   Removes an element from an object.

The iscsiadm subcommands operate on a *direct-object*. These are described in the section for each subcommand.

The iscsiadm command supports the Internet Storage Name Service (iSNS) for the discovery of iSCSI targets. The command supports the Challenge Handshake Authentication Protocol (CHAP) for authentication.

add Subcommand The syntax for the add subcommand is:

iscsiadm add *direct_object* [*operands*...]

The add subcommand adds the following *direct_object*s:
