## Using This Documentation

---

*Centrally Managing Encryption and Certificates in Oracle® Solaris 11.2* explains how to administer and use encryption, and how to create and manage private/public key certificates.

- **Overview** – Describes concepts revolving around the Cryptographic Framework and Key Management Framework and tasks for using these technologies to secure files.
- **Audience** – System administrators who must implement security on the enterprise.
- **Required knowledge** – Familiarity with security concepts and terminology.

## Product Documentation Library

Late-breaking information and known issues for this product are included in the documentation library at <http://www.oracle.com/pls/topic/lookup?ctx=E36784>.

## Access to Oracle Support

Oracle customers have access to electronic support through My Oracle Support. For information, visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info> or visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs> if you are hearing impaired.

## Feedback

Provide feedback about this documentation at <http://www.oracle.com/goto/docfeedback>.

# Cryptographic Framework

---

This chapter describes the Cryptographic Framework feature of Oracle Solaris, and covers the following topics:

- [“Introduction to the Cryptographic Framework” on page 7](#)
- [“Concepts in the Cryptographic Framework” on page 9](#)
- [“Cryptographic Framework Commands and Plugins” on page 11](#)
- [“Cryptographic Services and Zones” on page 13](#)
- [“Cryptographic Framework and FIPS 140” on page 13](#)
- [“OpenSSL Support in Oracle Solaris” on page 14](#)

To administer and use the Cryptographic Framework, see [Chapter 3, “Cryptographic Framework”](#).

## What's New in Cryptography for Oracle Solaris 11.2

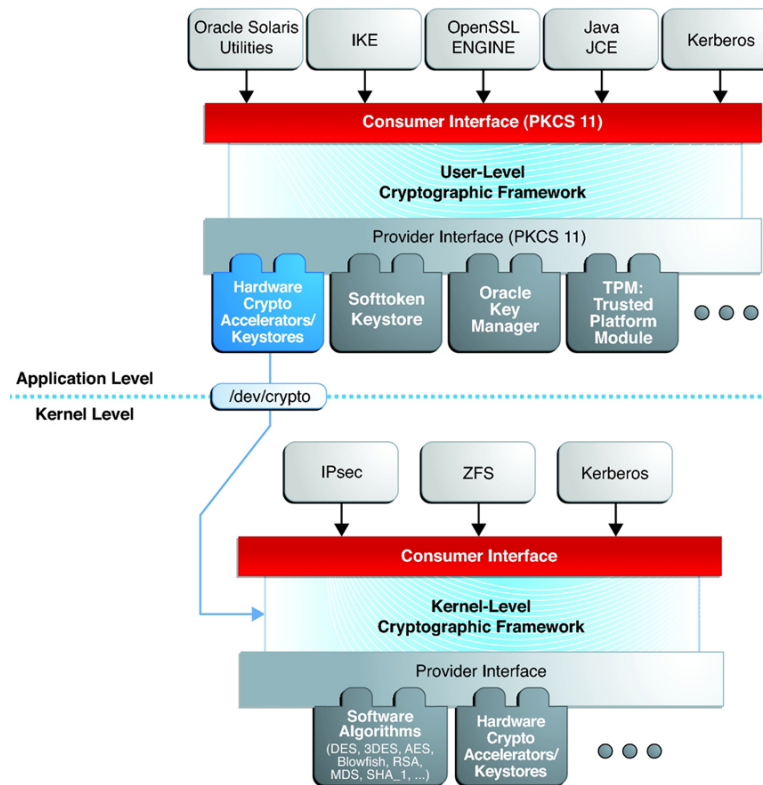

This section highlights information for existing customers about new features in encryption support in this release.

- Oracle Solaris supports both FIPS-capable and non FIPS-capable versions of OpenSSL.
- On SPARC T4 systems with cryptographic optimizations, cryptographic instructions are available directly in hardware, which enables cryptographic operations to run faster.
- The Cryptographic Framework supports Camellia, a 128-bit block cipher that is similar to AES and is mostly used in the Japanese market.

## Introduction to the Cryptographic Framework

The Cryptographic Framework provides a common store of algorithms and PKCS #11 libraries to handle cryptographic requirements. The PKCS #11 libraries are implemented according to the RSA Security Inc. PKCS #11 Cryptographic Token Interface (Cryptoki) standard.

FIGURE 1-1 Cryptographic Framework Levels

At the kernel level, the framework currently handles cryptographic requirements for ZFS, Kerberos and IPsec, as well as hardware. User-level consumers include the OpenSSL engine, Java Cryptographic Extensions (JCE), Libsasl, and IKE (Internet Key Protocol). The kernel SSL (`kssl`) proxy uses the Cryptographic Framework. For more information, see “[SSL Kernel Proxy Encrypts Web Server Communications](#)” in “[Securing the Network in Oracle Solaris 11.2](#)” and the `ksslcfg(1M)` man page.

Export law in the United States requires that the use of open cryptographic interfaces be licensed. The Cryptographic Framework satisfies the current law by requiring that kernel cryptographic providers and PKCS #11 cryptographic providers be signed. For further discussion, see the information about the `elfsign` command in “[User-Level Commands in the Cryptographic Framework](#)” on page 12.

The framework enables *providers* of cryptographic services to have their services used by many *consumers* in Oracle Solaris. Another name for providers is *plugins*. The framework supports three types of plugins:

- User-level plugins – Shared objects that provide services by using PKCS #11 libraries, such as `/var/user/$USER/pkcs11_softtoken.so.1`.
- Kernel-level plugins – Kernel modules that provide implementations of cryptographic algorithms in software, such as [AES](#).

Many of the algorithms in the framework are optimized for x86 with the SSE2 instruction set and for SPARC hardware. For T-Series optimizations, see [“Cryptographic Framework and SPARC T-Series Servers” on page 17](#).

- Hardware plugins – Device drivers and their associated hardware accelerators. The Niagara chips and Oracle's ncp and n2cp device drivers are one example. A hardware accelerator offloads expensive cryptographic functions from the operating system. Sun Crypto Accelerator 6000 board is one example.

The framework implements a standard interface, the PKCS #11, v2.20 amendment 3 library, for user-level providers. The library can be used by third-party applications to reach providers. Third parties can also add signed libraries, signed kernel algorithm modules, and signed device drivers to the framework. These plugins are added when the Image Packaging System (IPS) installs the third-party software. For a diagram of the major components of the framework, see [Figure 1-1](#).

## Concepts in the Cryptographic Framework

Note the following descriptions of concepts and corresponding examples that are useful when working with the Cryptographic Framework.

- **Algorithms** – Cryptographic algorithms are established, recursive computational procedures that encrypt or hash input. Encryption algorithms can be symmetric or asymmetric. Symmetric algorithms use the same key for encryption and decryption. Asymmetric algorithms, which are used in public-key cryptography, require two keys. Hashing functions are also algorithms.

Examples of algorithms include:

- Symmetric algorithms, such as AES and ECC
- Asymmetric algorithms, such as Diffie-Hellman and RSA
- Hashing functions, such as SHA256

- **Consumers** – Users of the cryptographic services that come from providers. Consumers can be applications, end users, or kernel operations.

Examples of consumers include:

- Applications, such as IKE
- End users, such as a regular user who runs the `encrypt` command
- Kernel operations, such as IPsec

- **Keystore** – In the Cryptographic Framework, persistent storage for token objects, often used interchangeably with **token**. For information about a reserved keystore, see **Metaslot** in this list of definitions.

- **Mechanism** – The Application of a mode of an algorithm for a particular purpose. For example, a DES mechanism that is applied to authentication, such as CKM\_DES\_MAC, is a separate mechanism from a DES mechanism that is applied to encryption, CKM\_DES\_CBC\_PAD.
- **Metaslot** – A single slot that presents a union of the capabilities of other slots which are loaded in the framework. The metaslot eases the work of dealing with all of the capabilities of the providers that are available through the framework. When an application that uses the metaslot requests an operation, the metaslot determines which actual slot will perform the operation. Metaslot capabilities are configurable, but configuration is not required. The metaslot is on by default. For more information, see the [cryptoadm\(1M\)](#) man page.

The metaslot does not have its own keystore. Rather, the metaslot reserves the use of a keystore from one of the actual slots in the Cryptographic Framework. By default, the metaslot reserves the Sun Crypto Softtoken keystore. The keystore that is used by the metaslot is not shown as one of the available slots.

Users can specify an alternate keystore for metaslot by setting the environment variables `#{METASLOT_OBJECTSTORE_SLOT}` and `#{METASLOT_OBJECTSTORE_TOKEN}`, or by running the `cryptoadm` command. For more information, see the [libpkcs11\(3LIB\)](#), [pkcs11\\_softtoken\(5\)](#), and [cryptoadm\(1M\)](#) man pages.
- **Mode** – A version of a cryptographic algorithm. For example, CBC (Cipher Block Chaining) is a different mode from ECB (Electronic Code Book). The AES algorithm has two modes: CKM\_AES\_ECB and CKM\_AES\_CBC.
- **Policy** – The choice, by an administrator, of which mechanisms to make available for use. By default, all providers and all mechanisms are available for use. The enabling or disabling of any mechanism would be an application of policy. For examples of setting and applying policy, see “[Administering the Cryptographic Framework](#)” on page 33.
- **Providers** – Cryptographic services that consumers use. Providers plug in to the framework, so are also called *plugins*.

Examples of providers include:

  - PKCS #11 libraries, such as `/var/user/$USER/pkcs11_softtoken.so`
  - Modules of cryptographic algorithms, such as `aes` and `arcfour`
  - Device drivers and their associated hardware accelerators, such as the `mca` driver for the Sun Crypto Accelerator 6000
- **Slot** – An interface to one or more cryptographic devices. Each slot, which corresponds to a physical reader or other device interface, might contain a token. A token provides a logical view of a cryptographic device in the framework.
- **Token** – In a slot, a token provides a logical view of a cryptographic device in the framework.

## Cryptographic Framework Commands and Plugins

The framework provides commands for administrators, for users, and for developers who supply providers.

- Administrative commands – The `cryptoadm` command provides a `list` subcommand to list the available providers and their capabilities. Regular users can run the `cryptoadm list` and the `cryptoadm --help` commands.

All other `cryptoadm` subcommands require you to assume a role that includes the Crypto Management rights profile, or to become superuser. Subcommands such as `disable`, `install`, and `uninstall` are available for administering the framework. For more information, see the [cryptoadm\(1M\)](#) man page.

The `svcadm` command is used to manage the `kcfd` daemon and to refresh cryptographic policy in the kernel. For more information, see the [svcadm\(1M\)](#) man page.

- User-level commands – The `digest` and `mac` commands provide file integrity services. The `encrypt` and `decrypt` commands protect files from eavesdropping. To use these commands, see [Table 3-1](#).

## Administrative Commands in the Cryptographic Framework

The `cryptoadm` command administers a running Cryptographic Framework. The command is part of the Crypto Management rights profile. This profile can be assigned to a role for secure administration of the Cryptographic Framework. You use the `cryptoadm` command to do the following:

- Disable or enable provider mechanisms
- Disable or enable the metaslot

The `svcadm` command is used to enable, refresh, and disable the cryptographic services daemon, `kcfd`. This command is part of the Service Management Facility (SMF) feature of Oracle Solaris. `svc:/system/cryptosvcs` is the service instance for the Cryptographic Framework. For more information, see the [smf\(5\)](#) and [svcadm\(1M\)](#) man pages.

## User-Level Commands in the Cryptographic Framework

The Cryptographic Framework provides user-level commands to check the integrity of files, to encrypt files, and to decrypt files.

- `digest` command – Computes a [message digest](#) for one or more files or for stdin. A digest is useful for verifying the integrity of a file. [SHA1](#) and [MD5](#) are examples of digest functions.
- `mac` command – Computes a [message authentication code \(MAC\)](#) for one or more files or for stdin. A MAC associates data with an authenticated message. A MAC enables a receiver to verify that the message came from the sender and that the message has not been tampered with. The `sha1_mac` and `md5_hmac` mechanisms can compute a MAC.
- `encrypt` command – Encrypts files or stdin with a symmetric cipher. The `encrypt -l` command lists the algorithms that are available. Mechanisms that are listed under a user-level library are available to the `encrypt` command. The framework provides AES, DES, 3DES (Triple-DES), and ARCFOUR mechanisms for user encryption.
- `decrypt` command – Decrypts files or stdin that were encrypted with the `encrypt` command. The `decrypt` command uses the identical key and mechanism that were used to encrypt the original file.
- `elfsign` command – Provides a means to sign providers to be used with the Cryptographic Framework. Typically, this command is run by the developer of a provider. The `elfsign` command has subcommands to request a certificate, sign binaries, and verify the signature on a binary. Unsigned binaries cannot be used by the Cryptographic Framework. Providers that have verifiable signed binaries can use the framework.

## Plugins to the Cryptographic Framework

Third parties can plug their providers into the Cryptographic Framework. A third-party provider can be one of the following objects:

- PKCS #11 shared library
- Loadable kernel software module, such as an encryption algorithm, MAC function, or digest function
- Kernel device driver for a hardware accelerator

The objects from a provider must be signed with a certificate from Oracle. The certificate request is based on a private key that the third party selects, and a certificate that Oracle provides. The certificate request is sent to Oracle, which registers the third party and then issues the certificate. The third party then signs its provider object with the certificate from Oracle.

The loadable kernel software modules and the kernel device drivers for hardware accelerators must also register with the kernel. Registration is through the Cryptographic Framework SPI (service provider interface).

## Cryptographic Services and Zones

The global zone and each non-global zone has its own `/system/cryptosvc` service. When the cryptographic service is enabled or refreshed in the global zone, the `kcfd` daemon starts in the global zone, user-level policy for the global zone is set, and kernel policy for the system is set. When the service is enabled or refreshed in a non-global zone, the `kcfd` daemon starts in the zone, and user-level policy for the zone is set. Kernel policy was set by the global zone.

For more information about zones, see [“Introduction to Oracle Solaris Zones”](#). For more information about using SMF to manage persistent applications, see [Chapter 1, “Introduction to the Service Management Facility,”](#) in [“Managing System Services in Oracle Solaris 11.2”](#) and the `smf(5)` man page.

## Cryptographic Framework and FIPS 140

FIPS 140 is a U.S. Government computer security standard for cryptography modules. Oracle Solaris systems offer two providers of cryptographic algorithms that are approved for FIPS 140-2 Level 1.

Those providers are:

- The Cryptographic Framework of Oracle Solaris provides two FIPS 140-approved modules. The *userland* module supplies cryptography for applications that run in user space. The *kernel* module provides cryptography for kernel-level processes.
- The OpenSSL object module provides FIPS 140-approved cryptography for SSH and web applications.

Note the following key considerations:

- Because FIPS 140-2 provider modules are CPU intensive, they are not enabled by default. As the system administrator, you are responsible for enabling the providers in FIPS 140 mode and configuring applications that use the FIPS-approved algorithms.
- If you have a strict requirement to use only FIPS 140-2 validated cryptography, you must be running the Oracle Solaris11.1 SRU5.5 release or the Oracle Solaris11.1 SRU3 release. Oracle completed a FIPS 140-2 validation against the Solaris Cryptographic Framework in these two specific releases. Oracle Solaris11.2 builds on this validated foundation and includes software improvements that address performance, functionality, and reliability.

Whenever possible, you should configure Oracle Solaris11.2 in FIPS 140-2 mode to take advantage of these improvements.

For information, see [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2 ”](#). This article covers the following topics:

- Overview of FIPS 140-2 Level 1 cryptography in Oracle Solaris
- Enabling FIPS 140 providers
- Enabling FIPS 140 consumers
- Example of enabling two applications in FIPS 140 mode
- FIPS 140-approved algorithms and certificate references

The following additional information is available:

- [“How to Switch to the FIPS 140-Capable OpenSSL Implementation” on page 14](#)
- [“Create a Boot Environment with FIPS 140 Enabled ” on page 42](#)

## OpenSSL Support in Oracle Solaris

Oracle Solaris supports two implementations of OpenSSL:

- FIPS 140 capable OpenSSL
- Non FIPS 140 capable OpenSSL

Both implementations have been upgraded to be compatible with the latest OpenSSL version from the OpenSSL project, which is OpenSSL 1.0.1. With regards to the versions libraries, both are API/ABI compatible.

While both implementations are present in the OS, only one implementation can be active at a time. To determine which OpenSSL implementation is active on the system, use the `pkg mediator openssl` command.

### ▼ How to Switch to the FIPS 140-Capable OpenSSL Implementation

By default, the non FIPS 140-capable OpenSSL implementation is active in Oracle Solaris. However, you can choose the security for your system and select implementation that you want.

1. **Become an administrator.**
2. **Ensure that both implementations are on the system.**

---

```
$ pkg mediator -a openssl
```

---

**Caution** - The OpenSSL implementation to which you are switching must exist in the system. Otherwise, if you switch to an implementation that is not in the system, the system might become unusable.

---

### 3. Switch to a different OpenSSL implementation.

```
# pkg set-mediator [--be-name name] -I implementation openssl
```

where *implementation* is either `default` or `fips-140` and *name* is a name for a new clone of the current boot environment. The clone will have the specified implementation active.

---

**Note** - When `--be-name` is specified, the command creates a backup of the current boot environment. When you reboot, the system will run the new, cloned boot environment with the new implementation.

---

For more information about the `pkg set-mediator` command, see [“Changing the Preferred Application”](#) in [“Adding and Updating Software in Oracle Solaris 11.2”](#).

### 4. Reboot the system.

### 5. (Optional) Verify that the switch was successful and that your preferred OpenSSL implementation is active.

```
# pkg mediator openssl
```

#### Example 1-1 Switching to the FIPS 140-Capable OpenSSL Implementation

This example changes a system's OpenSSL implementation to be FIPS 140 capable.

```
# pkg mediator -a openssl
MEDIATOR VER. SRC. VERSION IMPL. SRC. IMPLEMENTATION
openssl vendor vendor default
openssl system system fips-140

# pkg set-mediator --be-name BE2 -I fips-140 openssl
# reboot

# pkg mediator openssl
MEDIATOR VER. SRC. VERSION IMPL. SRC. IMPLEMENTATION
openssl vendor vendor default
```

## About SPARC T-Series Systems and the Cryptographic Framework

---

This chapter describes the Cryptographic Framework on SPARC T-series servers and the optimizations in Oracle Solaris 11 that enhance the performance of cryptographic functions.

### Cryptographic Framework and SPARC T-Series Servers

The Cryptographic Framework supplies the SPARC T-Series systems with cryptographic mechanisms, and optimizes some mechanisms for these servers. Three cryptographic mechanisms are optimized for data at rest and in motion: AES-CBC, AES-CFB128, and ARCFOUR. The DES cryptographic mechanism is optimized for OpenSSL, and, by optimizing arbitrary-precision arithmetic (bignum), so are RSA and DSA. Other optimizations include small packet performance for handshakes and data in motion.

The following cryptographic mechanisms are available in this release:

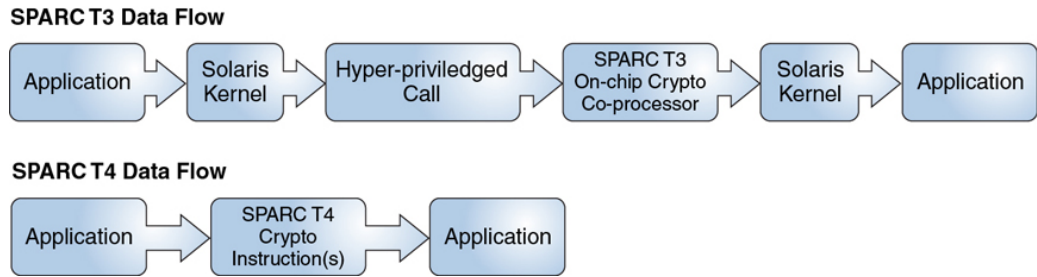

- AES-XTS – Used for data at rest
- SHA-224 – SHA2 mechanism
- AES-XCBC-MAC – Used for IPsec

### Cryptographic Optimizations in SPARC T-4 Systems

Beginning with the SPARC T4 microprocessor, new instructions to perform cryptography functions have become available directly in hardware. The instructions are non-privileged. Thus, any program can use the instructions without requiring any kernel environment, root permissions, or other special setup. Cryptography is performed directly on the hardware instead of using numerous low-level instructions. Cryptographic operations are therefore faster compared to operations on systems whose previous SPARC processors had separate processing units for cryptography.

The following comparison shows the differences in the data flow between SPARC T-3 systems and SPARC T-4 systems with cryptographic optimizations.

**FIGURE 2-1** Data Flow Comparison Between SPARC T-Systems

The following table provides a detailed comparison of cryptographic functions in SPARC T microprocessor units combined with specific Oracle Solaris releases.

**TABLE 2-1** Cryptographic Performance on SPARC T-Series Servers

Feature/ Software Consumer	T-3 and Previous Systems	T-4 Systems Running Oracle Solaris 10	T-4 Systems Running Oracle Solaris 11
SSH	Automatically enabled with Solaris 10 5/09 and later.  Disable/Enable with the Use OpenSSLEngine clause in /etc/ssh/sshd_config.	Requires patch 147707-01.  Disable/Enable with the Use OpenSSLEngine clause in /etc/ssh/sshd_config.	Automatically enabled.  Disable/Enable with the UseOpenSSLEngine clause in /etc/ssh/sshd_config.
Java/JCE	Automatically enabled.  Configure in \$JAVA_HOME/jre/lib/security/java.security.	Automatically enabled.  Configure in \$JAVA_HOME/jre/lib/security/java.security.	Automatically enabled.  Configure in \$JAVA_HOME/jre/lib/security/java.security.
ZFS Crypto	Not available.	Not available.	HW crypto automatically enabled if dataset is encrypted.
IPsec	Automatically enabled.	Automatically enabled.	Automatically enabled.
OpenSSL	Use -engine pkcs11	Requires patch 147707-01  Use -engine pkcs11	The T4 optimization is automatically used.  (Optionally use -engine pkcs11.) pkcs11 recommended for RSA/DSA at this time.

Feature/ Software Consumer	T-3 and Previous Systems	T-4 Systems Running Oracle Solaris 10	T-4 Systems Running Oracle Solaris 11
KSSL (Kernel SSL proxy)	Automatically enabled.	Automatically enabled.	Automatically enabled.
Oracle TDE	Not supported.	Pending patch.	Automatically enabled with Oracle DB 11.2.0.3 and ASO.
Apache SSL	Configure with SSLCrypto Device pkcs11	Configure with SSLCrypto Device pkcs11	Configure with SSLCryptoDevice pkcs11
Logical Domains	Assign crypto units to domains.	Functionality always available, no configuration required.	Functionality always available, no configuration required.

The T4 crypto instructions include the following:

- aes\_kexpand0, aes\_kexpand1, aes\_kexpand2  
These instructions perform *key expansion*. They expand the 128-bit, 192-bit, or 256-bit user-provided key into a key schedule that is used internally during encryption and decryption. The aes\_kexpand2 instruction is used only for AES-256. The other two aes\_kexpand instructions are used for all three key lengths: AES-128, AES-192, and AES-256.
- aes\_eround01, aes\_eround23, aes\_eround01\_l, aes\_eround\_23\_l  
These instructions are used for AES encryption *rounds* or transformations. According to the AES standard in FIPS 197, the number of rounds used (for example 10, 12, or 14) varies according to AES key length because using larger keys presumably indicates a desire for more robust encryption at the cost of more computation.
- aes\_dround01, aes\_dround23, aes\_dround01\_l, aes\_dround\_23\_l  
These instructions are used for AES decryption rounds in a similar way as with encryption.
- Instructions for DES/DES-3, Kasumi, Camellia, Montgomery multiply/square root (for RSA Bignum), and CRC32c checksums
- MD5, SHA1, and SHA2 digest instructions

The SPARC T4 hardware cryptographic instructions are available and used automatically on SPARC T4 systems running Oracle Solaris 11 by means of the built-in t4 engine on the system's T4 microprocessor. Beginning with Oracle Solaris 11.2, those instructions are now embedded in the OpenSSL upstream code. Thus, in this release, OpenSSL 1.0.1e is delivered with a patch to enable it to use those instructions.

For more information about the T4 instructions, refer to the following articles.

- ["SPARC T4 OpenSSL Engine"](https://blogs.oracle.com/DanX/entry/sparc_t4_openssl_engine) ([https://blogs.oracle.com/DanX/entry/sparc\\_t4\\_openssl\\_engine](https://blogs.oracle.com/DanX/entry/sparc_t4_openssl_engine))
- ["How to tell if SPARC T4 crypto is being used?"](https://blogs.oracle.com/DanX/entry/how_to_tell_if_sparc) ([https://blogs.oracle.com/DanX/entry/how\\_to\\_tell\\_if\\_sparc](https://blogs.oracle.com/DanX/entry/how_to_tell_if_sparc))

- "Exciting Crypto Advances with the T4 processor and Oracle Solaris 11" (<http://bubbva.blogspot.com/2011/11/exciting-crypto-advances-with-t4.html>)
- "SPARC T4 Digest and Crypto Optimizations in Solaris 11.1" ([https://blogs.oracle.com/DanX/entry/sparc\\_t4\\_digest\\_and\\_crypto](https://blogs.oracle.com/DanX/entry/sparc_t4_digest_and_crypto))

## Determining Whether the System Supports SPARC T4 Optimizations

To determine whether the T4 optimizations are being used, use the `isainfo` command. The inclusion of `sparcv9` and `aes` in the output indicates that the system is using the optimizations.

```
$ isainfo -v
64-bit sparcv9 applications
  crc32c cbcond pause mont mpmul sha512 sha256 sha1 md5 camellia kasumi
  des aes ima hpc vis3 fmaf asi_blk_init vis2 vis popc
```

## Determining Your System's OpenSSL Version

To check the version of OpenSSL that is running on your system, type `openssl version`. The output is similar to the following:

```
OpenSSL 1.0.0j 10 May 2012
```

## Verifying That Your System Has OpenSSL with SPARC T4 Optimizations

To determine whether your system supports OpenSSL with SPARC T4 optimizations, check the `libcrypto.so` library as follows:

```
# nm /lib/libcrypto.so.1.0.0 | grep des_t4
[5239] | 504192| 300|FUNC |GLOB |3 |12 |des_t4_cbc_decrypt
[5653] | 503872| 300|FUNC |GLOB |3 |12 |des_t4_cbc_encrypt
[4384] | 505024| 508|FUNC |GLOB |3 |12 |des_t4_edec3_cbc_decrypt
[2963] | 504512| 508|FUNC |GLOB |3 |12 |des_t4_edec3_cbc_encrypt
[4111] | 503712| 156|FUNC |GLOB |3 |12 |des_t4_key_expand
```

If the command does not generate any output, then your system does not support the SPARC T4 optimizations for OpenSSL.

# Cryptographic Framework

---

This chapter describes how to use the Cryptographic Framework, and covers the following topics:

- [“Protecting Files With the Cryptographic Framework” on page 21](#)
- [“Administering the Cryptographic Framework” on page 33](#)

## Protecting Files With the Cryptographic Framework

This section describes how to generate symmetric keys, how to create checksums for file integrity, and how to protect files from eavesdropping. The commands in this section can be run by regular users. Developers can write scripts that use these commands.

To setup your system in FIPS 140 mode, you must use FIPS-validated algorithms, modes, and key lengths. Refer to [“FIPS 140 Algorithm Lists and Certificate References for Oracle Solaris Systems”](#) in [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2 ”](#).

The Cryptographic Framework can help you protect your files. The following task map points to procedures for listing the available algorithms, and for protecting your files cryptographically.

**TABLE 3-1** Protecting Files With the Cryptographic Framework Task Map

Task	Description	For Instructions
Generate a symmetric key.	Generates a key of user-specified length. Optionally, stores the key in a file, a PKCS #11 keystore, or an NSS keystore.  For FIPS 140-approved mode, select a key type, mode, and key length that has been validated for FIPS. See <a href="#">“FIPS 140 Algorithms in the Cryptographic Framework”</a> in <a href="#">“Using a FIPS 140 Enabled System in Oracle Solaris 11.2 ”</a> .	<a href="#">“How to Generate a Symmetric Key by Using the pktool Command” on page 22</a>

Task	Description	For Instructions
Provide a checksum that ensures the integrity of a file.	Verifies that the receiver's copy of a file is identical to the file that was sent.	<a href="#">“How to Compute a Digest of a File” on page 27</a>
Protect a file with a message authentication code (MAC).	Verifies to the receiver of your message that you were the sender.	<a href="#">“How to Compute a MAC of a File” on page 29</a>
Encrypt a file, and then decrypt the encrypted file.	Protects the content of files by encrypting the file. Provides the encryption parameters to decrypt the file.	<a href="#">“How to Encrypt and Decrypt a File” on page 31</a>

## ▼ How to Generate a Symmetric Key by Using the `pktool` Command

Some applications require a symmetric key for encryption and decryption of communications. In this procedure, you create a symmetric key and store it.

If your site has a random number generator, you can use the generator to create a random number for the key. This procedure does not use your site's random number generator.

### 1. (Optional) If you plan to use a keystore, create it.

- To create and initialize a PKCS #11 keystore, see [“How to Generate a Passphrase by Using the `pktool setpin` Command” on page 61](#).
- To create and initialize an NSS database, see the sample command in [Example 4-5](#).

### 2. Generate a random number for use as a symmetric key.

Use one of the following methods.

#### ■ Generate a key and store it in a file.

The advantage of a file-stored key is that you can extract the key from this file to use in an application's key file, such as the `/etc/inet/secret/ipseckeys` file or IPsec. The usage statement shows the arguments.

```
% pktool genkey keystore=file
...genkey keystore=file
outkey=key-fn
[ keytype=aes|arcfour|des|3des|generic ]
[ keylen=key-size (AES, ARCFOUR or GENERIC only)]
[ print=y|n ]
```

`outkey=key-fn`

The filename where the key is stored.

`keytype=specific-symmetric-algorithm`

For a symmetric key of any length, the value is generic. For a particular algorithm, specify `aes`, `arcfour`, `des`, or `3des`.

For FIPS 140-approved algorithms, select a key type that has been validated for FIPS. See [“FIPS 140 Algorithms in the Cryptographic Framework”](#) in [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#).

`keylen=size-in-bits`

The length of the key in bits. The number must be divisible by 8. Do *not* specify for `des` or `3des`.

For FIPS 140-approved algorithms, select a key length that has been validated for FIPS. See [“FIPS 140 Algorithms in the Cryptographic Framework”](#) in [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#).

`print=n`

Prints the key to the terminal window. By default, the value of `print` is `n`.

#### ■ **Generate a key and store it in a PKCS #11 keystore.**

The advantage of the PKCS #11 keystore is that you can retrieve the key by its label. This method is useful for keys that encrypt and decrypt files. You must complete [Step 1](#) before using this method. The usage statement shows the arguments. The brackets around the keystore argument indicate that when the keystore argument is not specified, the key is stored in the PKCS #11 keystore.

```
$ pktool genkey keystore=pkcs11
...genkey [ keystore=pkcs11 ]
label=key-label
[ keytype=aes|arcfour|des|3des|generic ]
[ keylen=key-size (AES, ARCFOUR or GENERIC only)]
[ token=token[:manuf[:serial]]]
[ sensitive=y|n ]
[ extractable=y|n ]
[ print=y|n ]
```

`label=key-label`

A user-specified label for the key. The key can be retrieved from the keystore by its label.

`keytype=specific-symmetric-algorithm`

For a symmetric key of any length, the value is generic. For a particular algorithm, specify `aes`, `arcfour`, `des`, or `3des`.

For FIPS 140-approved algorithms, select a key type that has been validated for FIPS. See [“FIPS 140 Algorithms in the Cryptographic Framework”](#) in [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#).

`keylen=size-in-bits`

The length of the key in bits. The number must be divisible by 8. Do *not* specify for `des` or `3des`.

For FIPS 140-approved algorithms, select a key length that has been validated for FIPS. See [“FIPS 140 Algorithms in the Cryptographic Framework”](#) in [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#).

`token=token`

The token name. By default, the token is `Sun Software PKCS#11 softtoken`.

`sensitive=n`

Specifies the sensitivity of the key. When the value is `y`, the key cannot be printed by using the `print=y` argument. By default, the value of `sensitive` is `n`.

`extractable=y`

Specifies that the key can be extracted from the keystore. Specify `n` to prevent the key from being extracted.

`print=n`

Prints the key to the terminal window. By default, the value of `print` is `n`.

#### ■ **Generate a key and store it in an NSS keystore.**

You must complete [Step 1](#) before using this method. The usage statement shows the arguments.

```
$ pktool genkey keystore=nss
...genkey keystore=nss
label=key-label
[ keytype=aes|arcfour|des|3des|generic ]
[ keylen=key-size (AES, ARCFOUR or GENERIC only)]
[ token=token[:manuf[:serial]]]
[ dir=directory-path ]
[ prefix=DBprefix ]
```

`label=key-label`

A user-specified label for the key. The key can be retrieved from the keystore by its label.

`keytype=specific-symmetric-algorithm`

For a symmetric key of any length, the value is `generic`. For a particular algorithm, specify `aes`, `arcfour`, `des`, or `3des`.

For FIPS 140-approved algorithms, select a key type that has been validated for FIPS. See [“FIPS 140 Algorithms in the Cryptographic Framework”](#) in [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#).

`keylen=size-in-bits`

The length of the key in bits. The number must be divisible by 8. Do *not* specify for `des` or `3des`.

For FIPS 140-approved algorithms, select a key length that has been validated for FIPS. See [“FIPS 140 Algorithms in the Cryptographic Framework”](#) in [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#).

`token=token`

The token name. By default, the token is the NSS internal token.

`dir=directory`

The directory path to the NSS database. By default, `directory` is the current directory.

`prefix=directory`

The prefix to the NSS database. The default is no prefix.

### 3. (Optional) Verify that the key exists.

Use one of the following commands, depending on where you stored the key.

- **Verify the key in the `key-fn` file.**

```
% pktool list keystore=file objtype=key [infile=key-fn]
Found n keys.
Key #1 - keytype:location (keylen)
```

- **Verify the key in the PKCS #11 or the NSS keystore.**

For PKCS #11, use the following command:

```
$ pktool list keystore=pkcs11 objtype=key
Enter PIN for keystore:
Found n keys.
Key #1 - keytype:location (keylen)
```

Alternately, replace `keystore=pkcs11` with `keystore=nss` in the command.

**Example 3-1** Creating a Symmetric Key by Using the `pktool` Command

In the following example, a user creates a PKCS #11 keystore for the first time and then generates a large symmetric key for an application. Finally, the user verifies that the key is in the keystore.

Note that the initial password for a PKCS #11 keystore is `changeme`. The initial password for an NSS keystore is an empty password.

```
# pktool setpin
Create new passphrase:      Type password
Re-enter new passphrase:   Retype password
Passphrase changed.
% pktool genkey label=specialappkey keytype=generic keylen=1024
Enter PIN for Sun Software PKCS#11 softtoken :      Type password

% pktool list objtype=key
Enter PIN for Sun Software PKCS#11 softtoken :      Type password
No.      Key Type      Key Len.      Key Label
-----
Symmetric keys:
1        Symmetric      1024         specialappkey
```

**Example 3-2** Creating a FIPS-approved AES Key by Using the `pktool` Command

In the following example, a secret key for the AES algorithm is created using a FIPS-approved algorithm and key length. The key is stored in a local file for later decryption. The command protects the file with `400` permissions. When the key is created, the `print=y` option displays the generated key in the terminal window.

The user who owns the keyfile retrieves the key by using the `od` command.

```
% pktool genkey keystore=file outkey=256bit.file1 keytype=aes keylen=256 print=y
Key Value ="aaa2df1d10f02eae2595d48964847757a6a49cf86c4339cd5205c24ac8c8873"
% od -x 256bit.file1

00000000 aaa2 df1d 10f0 2eae e259 5d48 9648 4775
00000020 7a6a 49cf 86c4 339c d520 5c24 ac8c 8873
00000040
```

**Example 3-3** Creating a Symmetric Key for IPsec Security Associations

In the following example, the administrator manually creates the keying material for IPsec SAs and stores them in files. Then, the administrator copies the keys to the `/etc/inet/secret/ipseckeys` file and destroys the original files.

First, the administrator creates and displays the keys that the IPsec policy requires:

```
# pktool genkey keystore=file outkey=ipencrin1 keytype=generic keylen=192 print=y
Key Value ="294979e512cb8e79370dabecadc3fcbb849e78d2d6bd2049"
# pktool genkey keystore=file outkey=ipencrout1 keytype=generic keylen=192 print=y
```

```

Key Value ="9678f80e33406c86e3d1686e50406bd0434819c20d09d204"
# pktool genkey keystore=file outkey=ipspi1 keytype=generic keylen=32 print=y
Key Value ="acbeaa20"
# pktool genkey keystore=file outkey=ipspi2 keytype=generic keylen=32 print=y
Key Value ="19174215"
# pktool genkey keystore=file outkey=ipsha21 keytype=generic keylen=256 print=y
Key Value ="659c20f2d6c3f9570bcee93e96d95e2263aca4eeb3369f72c5c786af4177fe9e"
# pktool genkey keystore=file outkey=ipsha22 keytype=generic keylen=256 print=y
Key Value ="b041975a0e1fce0503665c3966684d731fa3dbb12fcf87b0a837b2da5d82c810"

```

Then, the administrator creates the following `/etc/inet/secret/ipseckeys` file:

```

## SPI values require a leading 0x.
## Backslashes indicate command continuation.
##
## for outbound packets on this system
add esp spi 0xacbeaa20 \
src 192.168.1.1 dst 192.168.2.1 \
encr_alg aes auth_alg sha256 \
encrkey 294979e512cb8e79370dabecadc3fcbb849e78d2d6bd2049 \
authkey 659c20f2d6c3f9570bcee93e96d95e2263aca4eeb3369f72c5c786af4177fe9e
##
## for inbound packets
add esp spi 0x19174215 \
src 192.168.2.1 dst 192.168.1.1 \
encr_alg aes auth_alg sha256 \
encrkey 9678f80e33406c86e3d1686e50406bd0434819c20d09d204 \
authkey b041975a0e1fce0503665c3966684d731fa3dbb12fcf87b0a837b2da5d82c810

```

After verifying that the syntax of the `ipseckeys` file is valid, the administrator destroys the original key files.

```

# ipseckey -c /etc/inet/secret/ipseckeys
# rm ipencrin1 ipencrout1 ipspi1 ipspi2 ipsha21 ipsha22

```

The administrator copies the `ipseckeys` file to the communicating system by using the `ssh` command or another secure mechanism. On the communicating system, the protections are reversed. The first entry in the `ipseckeys` file protects inbound packets, and the second entry protects outbound packets. No keys are generated on the communicating system.

**Next Steps** To proceed with using the key to create a message authentication code (MAC) for a file, see [“How to Compute a MAC of a File” on page 29](#).

## ▼ How to Compute a Digest of a File

When you compute a digest of a file, you can check to see that the file has not been tampered with by comparing digest outputs. A digest does not alter the original file.

### 1. List the available digest algorithms.

```
% digest -l
md5
sha1
sha224
sha256
sha384
sha512
```

---

**Note** - Whenever possible, select a FIPS-approved algorithm, per list at [“FIPS 140 Algorithms in the Cryptographic Framework”](#) in [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#).

---

## 2. Compute the digest of the file and save the digest listing.

Provide an algorithm with the `digest` command.

```
% digest -v -a algorithm input-file > digest-listing
```

`-v` Displays the output in the following format:

```
algorithm (input-file) = digest
```

`-a algorithm` The algorithm to use to compute a digest of the file. Type the algorithm as the algorithm appears in the output of [Step 1](#).

---

**Note** - Whenever possible, select a FIPS-approved algorithm, listed at [“FIPS 140 Algorithms in the Cryptographic Framework”](#) in [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#).

---

*input-file* The input file for the `digest` command.

*digest-listing* The output file for the `digest` command.

### Example 3-4 Computing a Digest With the SHA1 Mechanism

In the following example, the `digest` command uses the SHA1 mechanism to provide a directory listing. The results are placed in a file.

```
% digest -v -a sha1 docs/* > $HOME/digest.docs.legal.05.07
% more ~/digest.docs.legal.05.07
sha1 (docs/legal1) = 1df50e8ad219e34f0b911e097b7b588e31f9b435
sha1 (docs/legal2) = 68efa5a636291bde8f33e046eb33508c94842c38
sha1 (docs/legal3) = 085d991238d61bd0cfa2946c183be8e32ccc6c9
sha1 (docs/legal4) = f3085eae7e2c8d008816564fdf28027d10e1d983
```

## ▼ How to Compute a MAC of a File

A message authentication code, or MAC, computes a digest for the file and uses a secret key to further protect the digest. A MAC does not alter the original file.

### 1. List the available mechanisms.

```
% mac -l
Algorithm      Keysize:  Min  Max
-----
des_mac        64      64
sha1_hmac      8       512
md5_hmac       8       512
sha224_hmac    8       512
sha256_hmac    8       512
sha384_hmac    8      1024
sha512_hmac    8      1024
```

---

**Note** - Each supported algorithm is an alias to the most commonly used and least restricted version of a particular algorithm type. The output above shows available algorithm names and the keysize for each algorithm. Whenever possible, use a supported algorithm that matches a FIPS-approved algorithm with a FIPS-approved key length, listed at [“FIPS 140 Algorithms in the Cryptographic Framework”](#) in [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#).

---

### 2. Generate a symmetric key of the appropriate length.

You can provide either a [passphrase](#) from which a key will be generated or you can provide a key.

- If you provide a passphrase, you must store or remember the passphrase. If you store the passphrase online, the passphrase file should be readable only by you.
- If you provide a key, it must be the correct size for the mechanism. You can use the `pktool` command. For the procedure and some examples, see [“How to Generate a Symmetric Key by Using the `pktool` Command”](#) on page 22.

### 3. Create a MAC for a file.

Provide a key and use a symmetric key algorithm with the `mac` command.

```
% mac [-v] -a algorithm [-k keyfile | -K key-label [-T token]] input-file
```

`-v` Displays the output in the following format:

```
algorithm (input-file) = mac
```

`-a algorithm` The algorithm to use to compute the MAC. Type the algorithm as the algorithm appears in the output of the `mac -l` command.

<code>-k <i>keyfile</i></code>	The file that contains a key of algorithm-specified length.
<code>-K <i>key-label</i></code>	The label of a key in the PKCS #11 keystore.
<code>-T <i>token</i></code>	The token name. By default, the token is Sun Software PKCS#11 softtoken. It is used only when the <code>-K <i>key-label</i></code> option is used.
<code><i>input-file</i></code>	The input file for the MAC.

**Example 3-5** Computing a MAC With SHA1\_HMAC and a Passphrase

In the following example, the email attachment is authenticated with the SHA1\_HMAC mechanism and a key that is derived from a passphrase. The MAC listing is saved to a file. If the passphrase is stored in a file, the file should not be readable by anyone but the user.

```
% mac -v -a sha1_hmac email.attach
Enter passphrase:      Type passphrase
sha1_hmac (email.attach) = 2b31536d3b3c0c6b25d653418db8e765e17fe07b
% echo "sha1_hmac (email.attach) = 2b31536d3b3c0c6b25d653418db8e765e17fe07b" \
>> ~/sha1hmac.daily.05.12
```

**Example 3-6** Computing a MAC With SHA1\_HMAC and a Key File

In the following example, the directory manifest is authenticated with the SHA1\_HMAC mechanism and a secret key. The results are placed in a file.

```
% mac -v -a sha1_hmac \
-k $HOME/keyf/05.07.mack64 docs/* > $HOME/mac.docs.legal.05.07
% more ~/mac.docs.legal.05.07
sha1_hmac (docs/legal1) = 9b31536d3b3c0c6b25d653418db8e765e17fe07a
sha1_hmac (docs/legal2) = 865af61a3002f8a457462a428cdb1a88c1b51ff5
sha1_hmac (docs/legal3) = 076c944cb2528536c9aebd3b9f9be367e07b61dc7
sha1_hmac (docs/legal4) = 7aede27602ef6e4454748cbd3821e0152e45beb4
```

**Example 3-7** Computing a MAC With SHA1\_HMAC and a Key Label

In the following example, the directory manifest is authenticated with the SHA1\_HMAC mechanism and a secret key. The results are placed in the user's PKCS #11 keystore. The user initially created the keystore and the password to the keystore by using the `pktool setpin` command.

```
% mac -a sha1_hmac -K legaldocs0507 docs/*
Enter pin for Sun Software PKCS#11 softtoken:      Type password
```

To retrieve the MAC from the keystore, the user uses the verbose option, and provides the key label and the name of the directory that was authenticated.

```
% mac -v -a sha1_hmac -K legaldocs0507 docs/*
```

```

Enter pin for Sun Software PKCS#11 softtoken:    Type password
sha1_hmac (docs/legal1) = 9b31536d3b3c0c6b25d653418db8e765e17fe07a
sha1_hmac (docs/legal2) = 865af61a3002f8a457462a428cdb1a88c1b51ff5
sha1_hmac (docs/legal3) = 076c944cb2528536c9aebd3b9fbe367e07b61dc7
sha1_hmac (docs/legal4) = 7aede27602ef6e4454748cbd3821e0152e45beb4

```

## ▼ How to Encrypt and Decrypt a File

When you encrypt a file, the original file is not removed or changed. The output file is encrypted.

For solutions to common errors related to the encrypt command, see the section that follows the examples.

---

**Note** - When encrypting and decrypting files, try to use FIPS-approved algorithms with approved key lengths whenever possible. See the list at [“FIPS 140 Algorithms in the Cryptographic Framework”](#) in [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#). Run the `encrypt -l` command to view available algorithms and their key lengths.

---

### 1. Create a symmetric key of the appropriate length.

You can provide either a [passphrase](#) from which a key will be generated or you can provide a key.

- If you provide a passphrase, you must store or remember the passphrase. If you store the passphrase online, the passphrase file should be readable only by you.
- If you provide a key, it must be the correct size for the mechanism. You can use the `pktool` command. For the procedure and some examples, see [“How to Generate a Symmetric Key by Using the `pktool` Command”](#) on page 22.

### 2. Encrypt a file.

Provide a key and use a symmetric key algorithm with the `encrypt` command.

```
% encrypt -a algorithm [-v] \
[-k keyfile | -K key-label [-T token]] [-i input-file] [-o output-file]
```

`-a algorithm`      The algorithm to use to encrypt the file. Type the algorithm as the algorithm appears in the output of the `encrypt -l` command. Whenever possible, select a FIPS-approved algorithm, per list at [“FIPS 140 Algorithms in the Cryptographic Framework”](#) in [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#).

<code>-k keyfile</code>	The file that contains a key of algorithm-specified length. The key length for each algorithm is listed, in bits, in the output of the <code>encrypt -l</code> command.
<code>-K key-label</code>	The label of a key in the PKCS #11 keystore.
<code>-T token</code>	The token name. By default, the token is <code>Sun Software PKCS#11 softtoken</code> . It is used only when the <code>-K key-label</code> option is used.
<code>-i input-file</code>	The input file that you want to encrypt. This file is left unchanged by the command.
<code>-o output-file</code>	The output file that is the encrypted form of the input file.

**Example 3-8** Creating an AES Key for Encrypting Your Files

In the following example, a user creates and stores an AES key in an existing PKCS #11 keystore for use in encryption and decryption. The user can verify that the key exists and can use the key, but cannot view the key itself.

```
% pktool genkey label=MyAESkeynumber1 keytype=aes keylen=256
Enter PIN for Sun Software PKCS#11 softtoken : Type password

% pktool list objtype=key
Enter PIN for Sun Software PKCS#11 softtoken : Type password
No.      Key Type      Key Len.      Key Label
-----
Symmetric keys:
1        AES           256           MyAESkeynumber1
```

To use the key to encrypt a file, the user retrieves the key by its label.

```
% encrypt -a aes -K MyAESkeynumber1 -i encryptthisfile -o encryptedthisfile
```

To decrypt the `encryptedthisfile` file, the user retrieves the key by its label.

```
% decrypt -a aes -K MyAESkeynumber1 -i encryptedthisfile -o sameasencryptthisfile
```

**Example 3-9** Encrypting and Decrypting With AES and a Passphrase

In the following example, a file is encrypted with the AES algorithm. The key is generated from the passphrase. If the passphrase is stored in a file, the file should not be readable by anyone but the user.

```
% encrypt -a aes -i ticket.to.ride -o ~/enc/e.ticket.to.ride
Enter passphrase: Type passphrase
Re-enter passphrase: Type passphrase again
```

The input file, `ticket.to.ride`, still exists in its original form.

To decrypt the output file, the user uses the same passphrase and encryption mechanism that encrypted the file.

```
% decrypt -a aes -i ~/enc/e.ticket.to.ride -o ~/d.ticket.to.ride
Enter passphrase: Type passphrase
```

#### Example 3-10 Encrypting and Decrypting With AES and a Key File

In the following example, a file is encrypted with the AES algorithm. AES mechanisms use a key of 128 bits, or 16 bytes.

```
% encrypt -a aes -k ~/keyf/05.07.aes16 \
-i ticket.to.ride -o ~/enc/e.ticket.to.ride
```

The input file, `ticket.to.ride`, still exists in its original form.

To decrypt the output file, the user uses the same key and encryption mechanism that encrypted the file.

```
% decrypt -a aes -k ~/keyf/05.07.aes16 \
-i ~/enc/e.ticket.to.ride -o ~/d.ticket.to.ride
```

**Troubleshooting** The following messages indicate that the key that you provided to the `encrypt` command is not permitted by the algorithm that you are using.

- `encrypt: unable to create key for crypto operation: CKR_ATTRIBUTE_VALUE_INVALID`
- `encrypt: failed to initialize crypto operation: CKR_KEY_SIZE_RANGE`

If you pass a key that does not meet the requirements of the algorithm, you must supply a better key using one of the following methods:

- Use a passphrase. The framework then provides a key that meets the requirements.
- Pass a key size that the algorithm accepts. For example, the DES algorithm requires a key of 64 bits. The 3DES algorithm requires a key of 192 bits.

## Administering the Cryptographic Framework

This section describes how to administer the software providers and the hardware providers in the Cryptographic Framework. Software providers and hardware providers can be removed from use when desirable. For example, you can disable the implementation of an algorithm from one software provider. You can then force the system to use the algorithm from a different software provider.

**Note** - An important component of administering the Cryptographic Framework is to plan and implement your policy regarding FIPS 140, the U.S. Government computer security standard for cryptography modules.

If you have a strict requirement to use only FIPS 140-2 validated cryptography, you must be running the Oracle Solaris11.1 SRU5.5 release or the Oracle Solaris11.1 SRU3 release. Oracle completed a FIPS 140-2 validation against the Solaris Cryptographic Framework in these two specific releases. Oracle Solaris11.2 builds on this validated foundation and includes software improvements that address performance, function, and reliability. Whenever possible, you should configure Oracle Solaris11.2 in FIPS 140-2 mode to take advantage of these improvements.

Review [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2 ”](#) and plan an overall FIPS policy for your systems.

The following task map points to procedures for administering software and hardware providers in the Cryptographic Framework.

**TABLE 3-2** Administering the Cryptographic Framework Task Map

Task	Description	For Instructions
Plan your FIPS policy for your systems.	Decide on your plan for enabling FIPS-approved providers and consumers and implement your plan.	<a href="#">“Using a FIPS 140 Enabled System in Oracle Solaris 11.2 ”</a>
List the providers in the Cryptographic Framework.	Lists the algorithms, libraries, and hardware devices that are available for use in the Cryptographic Framework.	<a href="#">“Listing Available Providers” on page 35</a>
Enable FIPS 140 mode.	Runs the Cryptographic Framework to a U. S. government standard for cryptography modules.	<a href="#">“How to Create a Boot Environment with FIPS 140 Enabled” on page 42</a>
Add a software provider.	Adds a PKCS #11 library or a kernel module to the Cryptographic Framework. The provider must be signed.	<a href="#">“How to Add a Software Provider” on page 40</a>
Prevent the use of a user-level mechanism.	Removes a software mechanism from use. The mechanism can be enabled again.	<a href="#">“How to Prevent the Use of a User-Level Mechanism” on page 44</a>
Temporarily disable mechanisms from a kernel module.	Temporarily removes a mechanism from use. Usually used for testing.	<a href="#">“How to Prevent the Use of a Kernel Software Mechanism” on page 46</a>
Uninstall a library.	Removes a user-level software provider from use.	<a href="#">Example 3-17</a>
Uninstall a kernel provider.	Removes a kernel software provider from use.	<a href="#">Example 3-19</a>

Task	Description	For Instructions
Disable mechanisms from a hardware provider.	Ensures that selected mechanisms on a hardware accelerator are not used.	<a href="#">“How to Disable Hardware Provider Mechanisms and Features” on page 48</a>
Restart or refresh cryptographic services.	Ensures that cryptographic services are available.	<a href="#">“How to Refresh or Restart All Cryptographic Services” on page 50</a>

## Listing Available Providers

Hardware providers are automatically located and loaded. For more information, see [driver.conf\(4\)](#) man page.

When you have hardware that expects to plug in to the Cryptographic Framework, the hardware registers with the SPI in the kernel. The framework checks that the hardware driver is signed. Specifically, the framework checks that the object file of the driver is signed with a certificate that Oracle issues.

For example, the Sun Crypto Accelerator 6000 board (*mca*), the *ncp* driver for the cryptographic accelerator on the UltraSPARC T1 and T2 processors (*ncp*), the *n2cp* driver for the UltraSPARC T2 processors (*n2cp*), and the */dev/crypto* driver for the T-Series systems plug hardware mechanisms into the framework.

For information about getting your provider signed, see the information about the `elfsign` command in [“User-Level Commands in the Cryptographic Framework” on page 12](#).

To list available providers, you use the `cryptoadm list` commands with different options depending on the specific information you want to obtain.

- Listing all the providers on the system.

The contents and format of the providers list varies for different Oracle Solaris releases and different platforms. Run the `cryptoadm list` command on your system to see the providers that your system supports. Only those mechanisms at the user level are available for direct use by regular users.

```
% cryptoadm list
User-level providers:      /* for applications */
Provider: /usr/lib/security/$ISA/pkcs11_kernel.so
Provider: /usr/lib/security/$ISA/pkcs11_softtoken.so
Provider: /usr/lib/security/$ISA/pkcs11_tpm.so

Kernel software providers: /* for IPsec, kssl, Kerberos */
des
```

```

aes
arcfour
blowfish
camellia
ecc
sha1
sha2
md4
md5
rsa
swrand
n2rng/0      /* for hardware */
ncp/0
n2cp/0

```

- Listing the providers and their mechanisms in the Cryptographic Framework.

You can view the strength and modes, such as ECB and CBC, of the available mechanisms. However, some of the listed mechanisms might be unavailable for use. See the next item for instructions about how to list which mechanisms can be used.

The following output is truncated for display purposes.

```

% cryptoadm list -m [provider=provider]
User-level providers:
=====

Provider: /usr/lib/security/$ISA/pkcs11_kernel.so

Mechanisms:
CKM_DSA
CKM_RSA_X_509
CKM_RSA_PKCS
...
CKM_SHA256_HMAC_GENERAL
CKM_SSL3_MD5_MAC

Provider: /usr/lib/security/$ISA/pkcs11_softtoken.so
Mechanisms:
CKM_DES_CBC
CKM_DES_CBC_PAD
CKM_DES_ECB
CKM_DES_KEY_GEN
CKM_DES_MAC_GENERAL
...
CKM_ECDSA_SHA1
CKM_ECDH1_DERIVE

```

```
Provider: /usr/lib/security/$ISA/pkcs11_tpm.so
/usr/lib/security/$ISA/pkcs11_tpm.so: no slots presented.
```

Kernel providers:

```
=====
des: CKM_DES_ECB,CKM_DES_CBC,CKM_DES3_ECB,CKM_DES3_CBC
aes: CKM_AES_ECB,CKM_AES_CBC,CKM_AES_CTR,CKM_AES_CCM, \
     CKM_AES_GCM,CKM_AES_GMAC,
CKM_AES_CFB128,CKM_AES_XTS,CKM_AES_XCBC_MAC
arcfour: CKM_RC4
blowfish: CKM_BLOWFISH_ECB,CKM_BLOWFISH_CBC
ecc: CKM_EC_KEY_PAIR_GEN,CKM_ECDH1_DERIVE,CKM_ECDSA, \
     CKM_ECDSA_SHA1
sha1: CKM_SHA_1,CKM_SHA_1_HMAC,CKM_SHA_1_HMAC_GENERAL
sha2: CKM_SHA224,CKM_SHA224_HMAC,...CKM_SHA512_256_HMAC_GENERAL

md4: CKM_MD4
md5: CKM_MD5,CKM_MD5_HMAC,CKM_MD5_HMAC_GENERAL
rsa: CKM_RSA_PKCS,CKM_RSA_X_509,CKM_MD5_RSA_PKCS, \
     CKM_SHA1_RSA_PKCS,CKM_SHA224_RSA_PKCS,
CKM_SHA256_RSA_PKCS,CKM_SHA384_RSA_PKCS,CKM_SHA512_RSA_PKCS
swrand: No mechanisms presented.
n2rng/0: No mechanisms presented.
ncp/0: CKM_DSA,CKM_RSA_X_509,CKM_RSA_PKCS,CKM_RSA_PKCS_KEY_PAIR_GEN,
CKM_DH_PKCS_KEY_PAIR_GEN,CKM_DH_PKCS_DERIVE,CKM_EC_KEY_PAIR_GEN,
CKM_ECDH1_DERIVE,CKM_ECDSA
n2cp/0: CKM_DES_CBC,CKM_DES_CBC_PAD,CKM_DES_ECB,CKM_DES3_CBC, \
     ...CKM_SSL3_SHA1_MAC
```

- Listing the available cryptographic mechanisms.

Policy determines which mechanisms are available for use. The administrator sets the policy. An administrator can choose to disable mechanisms from a particular provider. The `-p` option displays the list of mechanisms that are permitted by the policy that the administrator has set.

```
% cryptoadm list -p [provider=provider]
```

```
User-level providers:
=====
/usr/lib/security/$ISA/pkcs11_kernel.so: \
    all mechanisms are enabled.random is enabled.
/usr/lib/security/$ISA/pkcs11_softtoken.so: \
    all mechanisms are enabled, random is enabled.
/usr/lib/security/$ISA/pkcs11_tpm.so: all mechanisms are enabled.
```

Kernel providers:

```
=====
des: all mechanisms are enabled.
```

```

aes: all mechanisms are enabled.
arcfour: all mechanisms are enabled.
blowfish: all mechanisms are enabled.
ecc: all mechanisms are enabled.
sha1: all mechanisms are enabled.
sha2: all mechanisms are enabled.
md4: all mechanisms are enabled.
md5: all mechanisms are enabled.
rsa: all mechanisms are enabled.
swrand: random is enabled.
n2rng/0: all mechanisms are enabled. random is enabled.
ncp/0: all mechanisms are enabled.
n2cp/0: all mechanisms are enabled.

```

The following examples show additional specific uses of the `cryptoadm list` command.

**EXAMPLE 3-11** Listing Cryptographic Information of a Specific Provider

Specifying the provider in the `cryptoadm options` command limits the output only to information that is applicable to the provider.

```

# cryptoadm enable provider=dca/0 random
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled, except CKM_MD5, CKM_MD5_HMAC,...
random is enabled.

```

The following output shows only the mechanisms are enabled. The random generator continues to be disabled.

```

# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled, except CKM_MD5,CKM_MD5_HMAC,...

# cryptoadm enable provider=dca/0 mechanism=all
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled. random is disabled.

```

The following output shows every feature and mechanism on the board is enabled.

```

# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled, except CKM_DES_ECB,CKM_DES3_ECB.
random is disabled.

# cryptoadm enable provider=dca/0 all
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled. random is enabled.

```

**EXAMPLE 3-12** Finding User-Level Cryptographic Mechanisms Only

In the following example, all mechanisms that the user-level library, `pkcs11_softtoken`, offers are listed.

```
% cryptoadm list -m provider=/usr/lib/security/\
  $ISA/pkcs11_softtoken.so
Mechanisms:
CKM_DES_CBC
CKM_DES_CBC_PAD
CKM_DES_ECB
CKM_DES_KEY_GEN
CKM_DES_MAC_GENERAL
CKM_DES_MAC
...
CKM_ECDSA
CKM_ECDSA_SHA1
CKM_ECDH1_DERIVE
```

**EXAMPLE 3-13** Determining Which Cryptographic Mechanisms Perform Which Functions

Mechanisms perform specific cryptographic functions, such as signing or key generation. The `-v -m` options display every mechanism and its functions.

In this instance, the administrator wants to determine for which functions the `CKM_ECDSA*` mechanisms can be used.

```
% cryptoadm list -vm
User-level providers:
=====
Provider: /usr/lib/security/$ISA/pkcs11_kernel.so
Number of slots: 3
Slot #2
Description: ncp/0 Crypto Accel Asym 1.0
...
CKM_ECDSA          163 571 X . . . X . X . . . . .
...

Provider: /usr/lib/security/$ISA/pkcs11_softtoken.so
...
CKM_ECDSA          112 571 . . . . X . X . . . . .
CKM_ECDSA_SHA1    112 571 . . . . X . X . . . . .
...
Kernel providers:
=====
...
ecc: CKM_EC_KEY_PAIR_GEN,CKM_ECDH1_DERIVE,CKM_ECDSA,CKM_ECDSA_SHA1
...

```

The listing indicates that these mechanisms are available from the following user-level providers:

- `CKM_ECDSA` and `CKM_ECDSA_SHA1` – As software implementation in `/usr/lib/security/$ISA/pkcs11_softtoken.so` library
- `CKM_ECDSA` – Accelerated by `ncp/0 Crypto Accel Asym 1.0` in `/usr/lib/security/$ISA/pkcs11_kernel.so` library

Each item in an entry represents a piece of information about the mechanism. For these ECC mechanisms, the listing indicates the following:

- Minimum length – 112 bytes
- Maximum length – 571 bytes
- Hardware – Is or is not available on hardware.
- Encrypt – Is not used to encrypt data.
- Decrypt – Is not used to decrypt data.
- Digest – Is not used to create message digests.
- Sign – Is used to sign data.
- Sign + Recover – Is not used to sign data, where the data can be recovered from the signature.
- Verify – Is used to verify signed data.
- Verify + Recover – Is not used to verify data that can be recovered from the signature.
- Key generation – Is not used to generate a private key.
- Pair generation – Is not used to generate a key pair.
- Wrap – Is not used to wrap. that is, encrypt, an existing key.
- Unwrap – Is not used to unwrap a wrapped key.
- Derive – Is not used to derive a new key from a base key.
- EC Caps – Absent EC capabilities that are not covered by previous items

## Adding a Software Provider

The following procedure explains how to add providers to the system. You must become an administrator who is assigned the Crypto Management rights profile. For more information, see [“Using Your Assigned Administrative Rights”](#) in [“Securing Users and Processes in Oracle Solaris 11.2”](#).

### ▼ How to Add a Software Provider

#### 1. List the software providers that are available to the system.

```
% cryptoadm list
User-level providers:
Provider: /usr/lib/security/$ISA/pkcs11_kernel.so
Provider: /usr/lib/security/$ISA/pkcs11_softtoken.so
/usr/lib/security/$ISA/pkcs11_tpm.so: all mechanisms are enabled.

Kernel software providers:
des
aes
arcfour
```

```

blowfish
camellia
sha1
sha2
md4
md5
rsa
swrand
n2rng/0
ncp/0
n2cp/0

```

## 2. Add the provider from a repository.

Existing provider software has been issued a certificate by Oracle.

## 3. Refresh the providers.

You need to refresh providers if you added a software provider, or if you added hardware and specified policy for the hardware.

```
# svcadm refresh svc:/system/cryptosvc
```

## 4. Locate the new provider on the list.

In this case, a new kernel software provider was installed.

```

# cryptoadm list
...
Kernel software providers:
des
aes
arcfour
blowfish
camellia
ecc
sha1
sha2
md4
md5
rsa
swrand
sha3      <-- added provider
...

```

### Example 3-14 Adding a User-Level Software Provider

In the following example, a signed PKCS #11 library is installed.

```

# pkgadd -d /cdrom/cdrom0/PKCSNew
  Answer the prompts
# svcadm refresh system/cryptosvc
# cryptoadm list
user-level providers:
=====

```

```
/usr/lib/security/$ISA/pkcs11_kernel.so
/usr/lib/security/$ISA/pkcs11_softtoken.so
/usr/lib/security/$ISA/pkcs11_tpm.so
/opt/lib/$ISA/libpkcs11.so.1    <-- added provider
```

Developers who are testing a library with the Cryptographic Framework can install the library manually.

```
# cryptoadm install provider=/opt/lib/\$ISA/libpkcs11.so.1
```

## Create a Boot Environment with FIPS 140 Enabled

By default, FIPS 140 mode is disabled in Oracle Solaris. In this procedure, you create a new boot environment (BE) for FIPS 140 mode, then enable FIPS 140 and boot into the new BE. By giving you a backup BE, this method enables you to quickly recover from system panics that can result from FIPS 140 compliance tests.

For an overview about FIPS, see [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#). See, also, the [cryptoadm\(1M\)](#) man page and [“Cryptographic Framework and FIPS 140” on page 13](#).

### ▼ How to Create a Boot Environment with FIPS 140 Enabled

**Before You Begin** You must assume the root role. For more information, see [“Using Your Assigned Administrative Rights”](#) in [“Securing Users and Processes in Oracle Solaris 11.2”](#).

#### 1. Determine if the system is in FIPS 140 mode.

```
% cryptoadm list fips-140
User-level providers:
=====
/usr/lib/security/$ISA/pkcs11_softtoken: FIPS-140 mode is disabled.

Kernel software providers:
=====
des: FIPS-140 mode is disabled.
aes: FIPS-140 mode is disabled.
ecc: FIPS-140 mode is disabled.
sha1: FIPS-140 mode is disabled.
sha2: FIPS-140 mode is disabled.
rsa: FIPS-140 mode is disabled.
swrand: FIPS-140 mode is disabled.

Kernel hardware providers:
=====:
```

#### 2. Create a new BE for your FIPS 140 version of the Cryptographic Framework.

Before you enable FIPS 140 mode, you must first create, activate, and boot a new BE by using the `beadm` command. A FIPS 140-enabled system runs compliance tests that can cause a panic if they fail. Therefore, it is important to have an available BE that you can boot to get your system up and running while you debug issues with the FIPS 140 boundary.

**a. Create a BE based on your current BE.**

In this example, you create a BE named `S11.1-FIPS`.

```
# beadm create S11.1-FIPS-140
```

**b. Activate that BE.**

```
# beadm activate S11.1-FIPS-140
```

**c. Reboot the system.**

**d. Enable FIPS 140 mode in the new BE.**

```
# cryptoadm enable fips-140
```

---

**Note** - This subcommand does not disable the non-FIPS 140 approved algorithms from the user-level `pkcs11_softtoken` library and the kernel software providers. The consumers of the framework are responsible for using only FIPS 140-approved algorithms.

For more information about the effects of FIPS 140 mode, see [“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”](#). See, also, the [`cryptoadm\(1M\)`](#) man page.

---

**3. When you want to run without FIPS 140 enabled, disable FIPS 140 mode.**

You can reboot to the original BE or disable FIPS 140 in the current BE.

■ **Boot to the original BE.**

```
# beadm list
BE           Active Mountpoint Space  Policy Created
--           - - - - -
S11.1        -      -           48.22G  static 2012-10-10 10:10
S11.1-FIPS-140 NR     /           287.01M  static 2012-11-18 18:18
# beadm activate S11.1
# beadm list
BE           Active Mountpoint Space  Policy Created
--           - - - - -
S11.1        R      -           48.22G  static 2012-10-10 10:10
S11.1-FIPS-140 N      /           287.01M  static 2012-11-18 18:18
# reboot
```

- **Disable FIPS 140 mode in the current BE and reboot.**

```
# cryptoadm disable fips-140
```

FIPS 140 mode remains in operation until the system is rebooted.

```
# reboot
```

## Preventing the Use of Mechanisms

If some of the cryptographic mechanisms from a library provider should not be used, you can remove selected mechanisms. You might consider preventing the use of mechanisms if, for example, the same mechanism in another library performs better, or if a security vulnerability is being investigated.

If the Cryptographic Framework provides multiple modes of a provider such as AES, you might remove a slow mechanism from use, or a corrupted mechanism. You might also use this procedure to remove an algorithm with proven security vulnerabilities.

You can selectively disable mechanisms and the random number feature from a hardware provider. To enable them again, see [Example 3-22](#). The hardware in this example, the Sun Crypto Accelerator 1000 board, provides a random number generator.

### ▼ How to Prevent the Use of a User-Level Mechanism

**Before You Begin** You must become an administrator who is assigned the Crypto Management rights profile. For more information, see [“Using Your Assigned Administrative Rights”](#) in [“Securing Users and Processes in Oracle Solaris 11.2”](#).

1. **List the mechanisms that are offered by a particular user-level software provider.**

```
% cryptoadm list -m provider=/usr/lib/security/\$ISA/pkcs11_softtoken.so
/usr/lib/security/$ISA/pkcs11_softtoken.so:
CKM_DES_CBC,CKM_DES_CBC_PAD,CKM_DES_ECB,CKM_DES_KEY_GEN,
CKM_DES3_CBC,CKM_DES3_CBC_PAD,CKM_DES3_ECB,CKM_DES3_KEY_GEN,
CKM_AES_CBC,CKM_AES_CBC_PAD,CKM_AES_ECB,CKM_AES_KEY_GEN,
...
```

2. **List the mechanisms that are available for use.**

```
$ cryptoadm list -p
user-level providers:
=====
...
/usr/lib/security/$ISA/pkcs11_softtoken.so: all mechanisms are enabled.
random is enabled.
```

...

### 3. Disable the mechanisms that should not be used.

```
$ cryptoadm disable provider=/usr/lib/security/\$ISA/pkcs11_softtoken.so \
> mechanism=CKM_DES_CBC,CKM_DES_CBC_PAD,CKM_DES_ECB
```

### 4. List the mechanisms that are available for use.

```
$ cryptoadm list -p provider=/usr/lib/security/\$ISA/pkcs11_softtoken.so
/usr/lib/security/$ISA/pkcs11_softtoken.so: all mechanisms are enabled,
except CKM_DES_ECB,CKM_DES_CBC_PAD,CKM_DES_CBC. random is enabled.
```

#### Example 3-15 Enabling a User-Level Software Provider Mechanism

In the following example, a disabled DES mechanism is again made available for use.

```
$ cryptoadm list -m provider=/usr/lib/security/\$ISA/pkcs11_softtoken.so
/usr/lib/security/$ISA/pkcs11_softtoken.so:
CKM_DES_CBC,CKM_DES_CBC_PAD,CKM_DES_ECB,CKM_DES_KEY_GEN,
CKM_DES3_CBC,CKM_DES3_CBC_PAD,CKM_DES3_ECB,CKM_DES3_KEY_GEN,
...
$ cryptoadm list -p provider=/usr/lib/security/\$ISA/pkcs11_softtoken.so
/usr/lib/security/$ISA/pkcs11_softtoken.so: all mechanisms are enabled,
except CKM_DES_ECB,CKM_DES_CBC_PAD,CKM_DES_CBC. random is enabled.
$ cryptoadm enable provider=/usr/lib/security/\$ISA/pkcs11_softtoken.so \
> mechanism=CKM_DES_ECB
$ cryptoadm list -p provider=/usr/lib/security/\$ISA/pkcs11_softtoken.so
/usr/lib/security/$ISA/pkcs11_softtoken.so: all mechanisms are enabled,
except CKM_DES_CBC_PAD,CKM_DES_CBC. random is enabled.
```

#### Example 3-16 Enabling All User-Level Software Provider Mechanisms

In the following example, all mechanisms from the user-level library are enabled.

```
$ cryptoadm enable provider=/usr/lib/security/\$ISA/pkcs11_softtoken.so all
$ cryptoadm list -p provider=/usr/lib/security/\$ISA/pkcs11_softtoken.so
/usr/lib/security/$ISA/pkcs11_softtoken.so: all mechanisms are enabled.
random is enabled.
```

#### Example 3-17 Permanently Removing a User-Level Library

In the following example, a libpkcs11.so.1 library from the /opt directory is removed.

```
$ cryptoadm uninstall provider=/opt/lib/\$ISA/libpkcs11.so.1
$ cryptoadm list
user-level providers:
/usr/lib/security/$ISA/pkcs11_kernel.so
/usr/lib/security/$ISA/pkcs11_softtoken.so
/usr/lib/security/$ISA/pkcs11_tpm.so

kernel providers:
...
```

## ▼ How to Prevent the Use of a Kernel Software Mechanism

**Before You Begin** You must become an administrator who is assigned the Crypto Management rights profile. For more information, see [“Using Your Assigned Administrative Rights”](#) in [“Securing Users and Processes in Oracle Solaris 11.2”](#).

### 1. List the mechanisms that are offered by a particular kernel software provider.

```
$ cryptoadm list -m provider=aes
aes: CKM_AES_ECB,CKM_AES_CBC,CKM_AES_CTR,CKM_AES_CCM,CKM_AES_GCM,
CKM_AES_GMAC,CKM_AES_CFB128,CKM_AES_XTS,CKM_AES_XCBC_MAC
```

### 2. List the mechanisms that are available for use.

```
$ cryptoadm list -p provider=aes
aes: all mechanisms are enabled.
```

### 3. Disable the mechanism that should not be used.

```
$ cryptoadm disable provider=aes mechanism=CKM_AES_ECB
```

### 4. List the mechanisms that are available for use.

```
$ cryptoadm list -p provider=aes
aes: all mechanisms are enabled, except CKM_AES_ECB.
```

#### **Example 3-18** Enabling a Kernel Software Provider Mechanism

In the following example, a disabled AES mechanism is again made available for use.

```
cryptoadm list -m provider=aes
aes: CKM_AES_ECB,CKM_AES_CBC,CKM_AES_CTR,CKM_AES_CCM,
CKM_AES_GCM,CKM_AES_GMAC,CKM_AES_CFB128,CKM_AES_XTS,CKM_AES_XCBC_MAC
$ cryptoadm list -p provider=aes
aes: all mechanisms are enabled, except CKM_AES_ECB.
$ cryptoadm enable provider=aes mechanism=CKM_AES_ECB
$ cryptoadm list -p provider=aes
aes: all mechanisms are enabled.
```

#### **Example 3-19** Temporarily Removing Kernel Software Provider Availability

In the following example, the AES provider is temporarily removed from use. The `unload` subcommand is useful to prevent a provider from being loaded automatically while the provider is being uninstalled. For example, the `unload` subcommand might be used when modifying a mechanism of this provider.

```
$ cryptoadm unload provider=aes

$ cryptoadm list
...
Kernel software providers:
```

```

des
aes (inactive)
arcfour
blowfish
ecc
sha1
sha2
md4
md5
rsa
swrand
n2rng/0
ncp/0
n2cp/0

```

The AES provider is unavailable until the Cryptographic Framework is refreshed.

```
$ svcadm refresh system/cryptosvc
```

```
$ cryptoadm list
```

```

...
Kernel software providers:
des
aes
arcfour
blowfish
camellia
ecc
sha1
sha2
md4
md5
rsa
swrand
n2rng/0
ncp/0
n2cp/0

```

If a kernel consumer is using the kernel software provider, the software is not unloaded. An error message is displayed and the provider continues to be available for use.

**Example 3-20** Permanently Removing Software Provider Availability

In the following example, the AES provider is removed from use. Once removed, the AES provider does not appear in the policy listing of kernel software providers.

```
$ cryptoadm uninstall provider=aes
```

```
$ cryptoadm list
```

```

...
Kernel software providers:
des
arcfour
blowfish
camellia
ecc

```

```
sha1
sha2
md4
md5
rsa
swrand
n2rng/0
ncp/0
n2cp/0
```

If a kernel consumer is using the kernel software provider, an error message is displayed and the provider continues to be available for use.

**Example 3-21** Reinstalling a Removed Kernel Software Provider

In the following example, the AES kernel software provider is reinstalled. To reinstall a removed kernel provider, you must enumerate the mechanisms to be installed.

```
$ cryptoadm install provider=aes \
mechanism=CKM_AES_ECB,CKM_AES_CBC,CKM_AES_CTR,CKM_AES_CCM,
CKM_AES_GCM,CKM_AES_GMAC,CKM_AES_CFB128,CKM_AES_XTS,CKM_AES_XCBC_MAC

$ cryptoadm list
...
Kernel software providers:
des
aes
arcfour
blowfish
camellia
ecc
sha1
sha2
md4
md5
rsa
swrand
n2rng/0
ncp/0
n2cp/0
```

## ▼ How to Disable Hardware Provider Mechanisms and Features

**Before You Begin** You must become an administrator who is assigned the Crypto Management rights profile. For more information, see [“Using Your Assigned Administrative Rights”](#) in [“Securing Users and Processes in Oracle Solaris 11.2”](#).

- **Choose the mechanisms or feature to disable.**

List the hardware provider.

```
# cryptoadm list
```

```
...
Kernel hardware providers:
dca/0
```

- **Disable selected mechanisms.**

```
# cryptoadm list -m provider=dca/0
dca/0: CKM_RSA_PKCS, CKM_RSA_X_509, CKM_DSA, CKM_DES_CBC, CKM_DES3_CBC
random is enabled.
# cryptoadm disable provider=dca/0 mechanism=CKM_DES_CBC,CKM_DES3_CBC
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled except CKM_DES_CBC,CKM_DES3_CBC.
random is enabled.
```

- **Disable the random number generator.**

```
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled. random is enabled.
# cryptoadm disable provider=dca/0 random
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled. random is disabled.
```

- **Disable all mechanisms. Do not disable the random number generator.**

```
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled. random is enabled.
# cryptoadm disable provider=dca/0 mechanism=all
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are disabled. random is enabled.
```

- **Disable every feature and mechanism on the hardware.**

```
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled. random is enabled.
# cryptoadm disable provider=dca/0 all
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are disabled. random is disabled.
```

### Example 3-22 Enabling Mechanisms and Features on a Hardware Provider

In the following examples, disabled mechanisms on a piece of hardware are selectively enabled.

```
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled except CKM_DES_ECB,CKM_DES3_ECB
.
random is enabled.
# cryptoadm enable provider=dca/0 mechanism=CKM_DES3_ECB
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled except CKM_DES_ECB.
random is enabled.
```

In the following example, only the random generator is enabled.

```
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled, except CKM_MD5,CKM_MD5_HMAC,...
random is disabled.
# cryptoadm enable provider=dca/0 random
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled, except CKM_MD5,CKM_MD5_HMAC,...
random is enabled.
```

In the following example, only the mechanisms are enabled. The random generator continues to be disabled.

```
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled, except CKM_MD5,CKM_MD5_HMAC,...
random is disabled.
# cryptoadm enable provider=dca/0 mechanism=all
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled. random is disabled.
```

In the following example, every feature and mechanism on the board is enabled.

```
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled, except CKM_DES_ECB,CKM_DES3_ECB.
random is disabled.
# cryptoadm enable provider=dca/0 all
# cryptoadm list -p provider=dca/0
dca/0: all mechanisms are enabled. random is enabled.
```

## Refreshing or Restarting All Cryptographic Services

By default, the Cryptographic Framework is enabled. When the `kcfd` daemon fails for any reason, the Service Management Facility (SMF) can be used to restart cryptographic services. For more information, see the [smf\(5\)](#) and [svcadm\(1M\)](#) man pages. For the effect on zones of restarting cryptographic services, see [“Cryptographic Services and Zones” on page 13](#).

### ▼ How to Refresh or Restart All Cryptographic Services

**Before You Begin** You must become an administrator who is assigned the Crypto Management rights profile. For more information, see [“Using Your Assigned Administrative Rights” in “Securing Users and Processes in Oracle Solaris 11.2”](#).

#### 1. Check the status of cryptographic services.

```
% svcs cryptosvc
STATE      STIME    FMRI
offline    Dec_09   svc:/system/cryptosvc:default
```

**2. Enable cryptographic services.**

```
# svcadm enable svc:/system/cryptosvc
```

**Example 3-23** Refreshing Cryptographic Services

In the following example, cryptographic services are refreshed in the global zone. Therefore, kernel-level cryptographic policy in every non-global zone is also refreshed.

```
# svcadm refresh system/cryptosvc
```

## Key Management Framework

---

The Key Management Framework (KMF) feature of Oracle Solaris provides tools and programming interfaces for managing public key objects. Public key objects include X.509 certificates and public/private key pairs. The formats for storing these objects can vary. KMF also provides a tool for managing policies that define the use of X.509 certificates by applications. KMF supports third-party plugins.

This chapter covers the following topics:

- [“Managing Public Key Technologies” on page 53](#)
- [“Key Management Framework Utilities” on page 54](#)
- [“Using the Key Management Framework” on page 55](#)

### Managing Public Key Technologies

KMF centralizes the management of public key technologies (PKI). Oracle Solaris has several different applications that make use of PKI technologies. Each application provides its own programming interfaces, key storage mechanisms, and administrative utilities. If an application provides a policy enforcement mechanism, the mechanism applies to that application only. With KMF, applications use a unified set of administrative tools, a single set of programming interfaces, and a single policy enforcement mechanism. These features manage the PKI needs of all applications that adopt these interfaces.

KMF unifies the management of public key technologies with the following interfaces:

- `pktool` command – Manages PKI objects, such as certificates, in a variety of keystores.
- `kmfcfg` command – Manages the PKI policy database and third-party plugins.  
PKI policy decisions include operations such as the validation method for an operation. Also, PKI policy can limit the scope of a certificate. For example, PKI policy might assert that a certificate can be used only for specific purposes. Such a policy would prevent that certificate from being used for other requests.
- KMF library – Contains programming interfaces that abstract the underlying keystore mechanism.

Applications do not have to choose one particular keystore mechanism, but can migrate from one mechanism to another mechanism. The supported keystores are PKCS #11, NSS, and OpenSSL. The library includes a pluggable framework so that new keystore mechanisms can be added. Therefore, applications that use the new mechanisms would require only minor modifications to use a new keystore.

## Key Management Framework Utilities

KMF provides methods for managing the storage of keys and provides the overall policy for the use of those keys. KMF can manage the policy, keys, and certificates for three public key technologies:

- Tokens from PKCS #11 providers, that is, from the Cryptographic Framework
- NSS, that is, Network Security Services
- OpenSSL, a file-based keystore

The `kmfcfg` tool can create, modify, or delete KMF policy entries. The tool also manages plugins to the framework. KMF manages keystores through the `pktool` command. For more information, see the [kmfcfg\(1\)](#) and [pktool\(1\)](#) man pages, and the following sections.

### KMF Policy Management

KMF policy is stored in a database. This policy database is accessed internally by all applications that use the KMF programming interfaces. The database can constrain the use of the keys and certificates that are managed by the KMF library. When an application attempts to verify a certificate, the application checks the policy database. The `kmfcfg` command modifies the policy database.

### KMF Plugin Management

The `kmfcfg` command provides the following subcommands for plugins:

- `list plugin` – Lists plugins that are managed by KMF.
- `install plugin` – Installs the plugin by the module's path name and creates a keystore for the plugin. To remove the plugin from KMF, you remove the keystore.
- `uninstall plugin` – Removes the plugin from KMF by removing its keystore.
- `modify plugin` – Enables the plugin to be run with an option that is defined in the code for the plugin, such as `debug`.

For more information, see the [kmfcfg\(1\)](#) man page. For the procedure, see “[How to Manage Third-Party Plugins in KMF](#)” on page 68.

## KMF Keystore Management

KMF manages the keystores for three public key technologies, PKCS #11 tokens, NSS, and OpenSSL. For all of these technologies, the `pktool` command enables you to do the following:

- Generate a self-signed certificate
- Generate a certificate request
- Generate a symmetric key
- Generate a public/private key pair
- Generate a PKCS #10 certificate signing request (CSR) to be sent to an external certificate authority (CA) to be signed
- Sign a PKCS #10 CSR
- Import objects into the keystore
- List the objects in the keystore
- Delete objects from the keystore
- Download a CRL

For the PKCS #11 and NSS technologies, the `pktool` command also enables you to set a PIN by generating a passphrase for the keystore or for an object in the keystore.

For examples of using the `pktool` utility, see the [pktool\(1\)](#) man page and [Table 4-1](#).

## Using the Key Management Framework

This section describes how to use the `pktool` command to manage your public key objects, such as passwords, passphrases, files, keystores, certificates, and CRLs.

The Key Management Framework (KMF) enables you to centrally manage public key technologies.

**TABLE 4-1** Using the Key Management Framework Task Map

Task	Description	For Instructions
Create a certificate.	Creates a certificate for use by PKCS #11, NSS, or OpenSSL.	<a href="#">“How to Create a Certificate by Using the <code>pktool gencert</code> Command”</a> on page 56

Task	Description	For Instructions
Export a certificate.	Creates a file with the certificate and its supporting keys. The file can be protected with a password.	<a href="#">“How to Export a Certificate and Private Key in PKCS #12 Format” on page 59</a>
Import a certificate.	Imports a certificate from another system.	<a href="#">“How to Import a Certificate Into Your Keystore” on page 58</a>
	Imports a certificate in PKCS #12 format from another system.	<a href="#">Example 4-2</a>
Generate a passphrase.	Generates a passphrase for access to a PKCS #11 keystore or an NSS keystore.	<a href="#">“How to Generate a Passphrase by Using the <code>pktool setpin</code> Command” on page 61</a>
Generate a symmetric key.	Generates symmetric keys for use in encrypting files, in creating a MAC of a file, and for applications.	<a href="#">“How to Generate a Symmetric Key by Using the <code>pktool</code> Command” on page 22</a>
Generate a key pair.	Generates a public/private key pair for use with applications.	<a href="#">“How to Generate a Key Pair by Using the <code>pktool genkeypair</code> Command” on page 62</a>
Generate a PKCS #10 CSR.	Generates a PKCS #10 certificate signing request (CSR) for an external certificate authority (CA) to sign.	<a href="#">pktool(1) man page</a>
Sign a PKCS #10 CSR.	Signs a PKCS #10 CSR.	<a href="#">“How to Sign a Certificate Request by Using the <code>pktool signcsr</code> Command” on page 66</a>
Add a plugin to KMF.	Installs, modifies, and lists a plugin. Also, removes the plugin from the KMF.	<a href="#">“How to Manage Third-Party Plugins in KMF” on page 68</a>

## ▼ How to Create a Certificate by Using the `pktool gencert` Command

This procedure creates a self-signed certificate and stores the certificate in the PKCS #11 keystore. As a part of this operation, an RSA public/private key pair is also created. The private key is stored in the keystore with the certificate.

### 1. Generate a self-signed certificate.

```
% pktool gencert [keystore=keystore] label=label-name \  
subject=subject-DN serial=hex-serial-number keytype=rsa/dsa keylen=key-size
```

`keystore=keystore` Specifies the keystore by type of public key object. The value can be `nss`, `pkcs11`, or `file`. This keyword is optional.

<code>label=label-name</code>	Specifies a unique name that the issuer gives to the certificate.
<code>subject=subject-DN</code>	Specifies the distinguished name for the certificate.
<code>serial=hex-serial-number</code>	Specifies the serial number in hexadecimal format. The issuer of the certificate chooses the number, such as <code>0x0102030405</code> .
<code>keytype=key type</code>	Optional variable that specifies the type of private key associated with the certificate. Check the <code>pktool(1)</code> man page to find available key types for the selected keystore.  To use a FIPS 140-approved key, check the approved key types at <a href="#">“FIPS 140 Algorithms in the Cryptographic Framework”</a> in <a href="#">“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”</a> .
<code>keylen=key size</code>	Optional variable that specifies the length of the private key associated with the certificate.  To use a FIPS 140-approved key, check the approved key lengths for the key type that you selected at <a href="#">“FIPS 140 Algorithms in the Cryptographic Framework”</a> in <a href="#">“Using a FIPS 140 Enabled System in Oracle Solaris 11.2”</a> .

## 2. Verify the contents of the keystore.

```
% pktool list
Found number certificates.
1. (X.509 certificate)
Label: label-name
ID: fingerprint that binds certificate to private key
Subject: subject-DN
Issuer: distinguished-name
Serial: hex-serial-number
n. ...
```

This command lists all certificates in the keystore. In the following example, the keystore contains one certificate only.

### Example 4-1 Creating a Self-Signed Certificate by Using `pktool`

In the following example, a user at My Company creates a self-signed certificate and stores the certificate in a keystore for PKCS #11 objects. The keystore is initially empty. If the keystore has not been initialized, the PIN for the softtoken is `changeme`, and you can use the `pktool setpin` command to reset the PIN. Note that a FIPS-approved key type and key length, RSA 2048, is specified in the command options.

```
% pktool gencert keystore=pkcs11 label="My Cert" \
subject="C=US, O=My Company, OU=Security Engineering Group, CN=MyCA" \
```

```
serial=0x00000001 keytype=rsa keylen=2048
Enter pin for Sun Software PKCS#11 softtoken:    Type PIN for token

% pktool list
No.  Key Type  Key Len.  Key Label
-----
Asymmetric public keys:
1    RSA                My Cert
Certificates:
1    X.509 certificate
Label: My Cert
ID: d2:7e:20:04:a5:66:e6:31:90:d8:53:28:bc:ef:55:55:dc:a3:69:93
Subject: C=US, O=My Company, OU=Security Engineering Group, CN=MyCA
Issuer: C=US, O=My Company, OU=Security Engineering Group, CN=MyCA
...
...
Serial: 0x00000010
...
```

## ▼ How to Import a Certificate Into Your Keystore

This procedure describes how to import a file with PKI information that is encoded with PEM or with raw DER into your keystore. For an export procedure, see [Example 4-4](#).

### 1. Import the certificate.

```
% pktool import keystore=keystore infile=infile-name label=label-name
```

### 2. If you are importing private PKI objects, provide passwords when prompted.

#### a. At the prompt, type the password for the file.

If you are importing PKI information that is private, such as an export file in PKCS #12 format, the file requires a password. The creator of the file that you are importing provides you with the PKCS #12 password.

```
Enter password to use for accessing the PKCS12 file:    Type PKCS #12 password
```

#### b. At the prompt, type the password for your keystore.

```
Enter pin for Sun Software PKCS#11 softtoken:    Type PIN for token
```

### 3. Verify the contents of the keystore.

```
% pktool list
Found number certificates.
1. (X.509 certificate)
Label: label-name
ID: fingerprint that binds certificate to private key
Subject: subject-DN
Issuer: distinguished-name
```

```
Serial: hex-serial-number
```

```
2. ...
```

#### Example 4-2 Importing a PKCS #12 File Into Your Keystore

In the following example, the user imports a PKCS #12 file from a third party. The `pktool import` command extracts the private key and the certificate from the `gracedata.p12` file and stores them in the user's preferred keystore.

```
% pktool import keystore=pkcs11 infile=gracedata.p12 label=GraceCert
Enter password to use for accessing the PKCS12 file: Type PKCS #12 password
Enter pin for Sun Software PKCS#11 softtoken: Type PIN for token
Found 1 certificate(s) and 1 key(s) in gracedata.p12
% pktool list
No. Key Type Key Len. Key Label
-----
Asymmetric public keys:
1 RSA GraceCert
Certificates:
1 X.509 certificate
Label: GraceCert
ID: 71:8f:11:f5:62:10:35:c2:5d:b4:31:38:96:04:80:25:2e:ad:71:b3
Subject: C=US, O=My Company, OU=Security Engineering Group, CN=MyCA
Issuer: C=US, O=My Company, OU=Security Engineering Group, CN=MyCA
Serial: 0x00000010
```

#### Example 4-3 Importing an X.509 Certificate Into Your Keystore

In the following example, the user imports an X.509 certificate in PEM format into the user's preferred keystore. This public certificate is not protected with a password. The user's public keystore is also not protected by a password.

```
% pktool import keystore=pkcs11 infile=somecert.pem label="TheirCompany Root Cert"
% pktool list
No. Key Type Key Len. Key Label
-----
Certificates:
1 X.509 certificate
Label: TheirCompany Root Cert
ID: ec:a2:58:af:83:b9:30:9d:de:b2:06:62:46:a7:34:49:f1:39:00:0e
Subject: C=US, O=TheirCompany, OU=Security, CN=TheirCompany Root CA
Issuer: C=US, O=TheirCompany, OU=Security, CN=TheirCompany Root CA
Serial: 0x00000001
```

## ▼ How to Export a Certificate and Private Key in PKCS #12 Format

You can create a file in PKCS #12 format to export private keys and their associated X.509 certificate to other systems. Access to the file is protected by a password.

**1. Find the certificate to export.**

```
% pktool list
Found number certificates.
1. (X.509 certificate)
Label: label-name
ID: fingerprint that binds certificate to private key
Subject: subject-DN
Issuer: distinguished-name
Serial: hex-serial-number

2. ...
```

**2. Export the keys and certificate.**

Use the keystore and label from the `pktool list` command. Provide a file name for the export file. If the name contains a space, surround the name with double quotes.

```
% pktool export keystore=keystore outfile=outfile-name label=label-name
```

**3. Protect the export file with a password.**

At the prompt, type the current password for the keystore. At this point, you create a password for the export file. The receiver must provide this password when importing the file.

```
Enter pin for Sun Software PKCS#11 softtoken:      Type PIN for token
Enter password to use for accessing the PKCS12 file:  Create PKCS #12 password
```

---

**Tip** - Send the password separately from the export file. Best practice suggests that you provide the password out of band, such as during a telephone call.

---

**Example 4-4** Exporting a Certificate and Private Key in PKCS #12 Format

In the following example, a user exports the private keys with their associated X.509 certificate into a standard PKCS #12 file. This file can be imported into other keystores. The PKCS #11 password protects the source keystore. The PKCS #12 password is used to protect private data in the PKCS #12 file. This password is required to import the file.

```
% pktool list
No.  Key Type  Key Len.  Key Label
-----
Asymmetric public keys:
1    RSA                My Cert
Certificates:
1    X.509 certificate
Label: My Cert
ID: d2:7e:20:04:a5:66:e6:31:90:d8:53:28:bc:ef:55:55:dc:a3:69:93
Subject: C=US, O=My Company, OU=Security Engineering Group, CN=MyCA
Issuer: C=US, O=My Company, OU=Security Engineering Group, CN=MyCA
Serial: 0x000001

% pktool export keystore=pkcs11 outfile=mydata.p12 label="My Cert"
```

Enter pin for Sun Software PKCS#11 softtoken:     *Type PIN for token*  
 Enter password to use for accessing the PKCS12 file:     *Create PKCS #12 password*

The user then telephones the recipient and provides the PKCS #12 password.

## ▼ How to Generate a Passphrase by Using the `pktool setpin` Command

You can generate a passphrase for an object in a keystore, and for the keystore itself. The passphrase is required to access the object or keystore. For an example of generating a passphrase for an object in a keystore, see [Example 4-4](#).

### 1. Generate a passphrase for access to a keystore.

```
% pktool setpin keystore=nss|pkcs11 [dir=directory]
```

The default directory for key storage is `/var/username`.

The initial password for a PKCS #11 keystore is `changeme`. The initial password for an NSS keystore is an empty password.

### 2. Answer the prompts.

When prompted for the current token passphrase, type the token PIN for a PKCS #11 keystore, or press the Return key for an NSS keystore.

```
Enter current token passphrase:     Type PIN or press the Return key  

Create new passphrase:             Type the passphrase that you want to use  

Re-enter new passphrase:           Retype the passphrase  

Passphrase changed.
```

The keystore is now protected by *passphrase*. If you lose the passphrase, you lose access to the objects in the keystore.

### 3. (Optional) Display a list of tokens.

```
# pktool tokens
```

The output depends on whether the metaslot is enabled. For more information about the metaslot, see [“Concepts in the Cryptographic Framework” on page 9](#).

- If the metaslot is enabled, the `pktools token` command generates output similar to the following:

ID Slot	Name	Token Name	Flags
--	-----	-----	-----
0	Sun Metaslot	Sun Metaslot	
1	Sun Crypto Softtoken	Sun Software PKCS#11 softtoken	LIX

```
2          PKCS#11 Interface for TPM  TPM                               LXS
```

- If the metaslot is disabled, the `pktool token` command generates output similar to the following:

ID Slot	Name	Token Name	Flags
--	-----	-----	-----
1	Sun Crypto Softtoken	Sun Software PKCS#11 softtoken	LIX
2	PKCS#11 Interface for TPM	TPM	LXS

In the two output versions, flags can be any combination of the following:

- L – login required
- I – initialized
- X – User PIN expired
- S – SO PIN expired

**Example 4-5** Protecting a Keystore With a Passphrase

The following example shows how to set the passphrase for an NSS database. Because no passphrase has been created, the user presses the Return key at the first prompt.

```
% pktool setpin keystore=nss dir=/var/nss
Enter current token passphrase: Press the Return key
Create new passphrase: has8n0NdaH
Re-enter new passphrase: has8n0NdaH
Passphrase changed.
```

## ▼ How to Generate a Key Pair by Using the `pktool genkeypair` Command

Some applications require a public/private key pair. In this procedure, you create these key pairs and store them.

1. **(Optional) If you plan to use a keystore, create the keystore.**
  - To create and initialize a PKCS #11 keystore, see [“How to Generate a Passphrase by Using the `pktool setpin` Command” on page 61.](#)
  - To create and initialize an NSS keystore, see [Example 4-5.](#)
2. **Create the key pair.**

Use one of the following methods.

- **Create the key pair and store the key pair in a file.**

File-based keys are created for applications that read keys directly from files on the disk. Typically, applications that directly use OpenSSL cryptographic libraries require that you store the keys and certificates for the application in files.

---

**Note** - The file keystore does not support elliptic curve (ec) keys and certificates.

---

```
% pktool genkeypair keystore=file outkey=key-filename \
[format=der|pem] [keytype=rsa|dsa] [keylen=key-size]
```

`keystore=file`

The value `file` specifies the file type of storage location for the key.

`outkey=key-filename`

Specifies the name of the file where the key pair is stored.

`format=der|pem`

Specifies the encoding format of the key pair. `der` output is binary, and `pem` output is ASCII.

`keytype=rsa|dsa`

Specifies the type of key pair that can be stored in a file keystore. For definitions, see [DSA](#) and [RSA](#).

`keylen=key-size`

Specifies the length of the key in bits. The number must be divisible by 8. To determine possible key sizes, use the `cryptoadm list -vm` command.

- **Create the key pair and store it in a PKCS #11 keystore.**

You must complete [Step 1](#) before using this method.

The PKCS #11 keystore is used to store objects on a hardware device. The device could be a Sun Crypto Accelerator 6000 card, a trusted platform module (TPM) device, or a smart card that is plugged into the Cryptographic Framework. PKCS #11 can also be used to store objects in the `softtoken`, or software-based token, which stores the objects in a private subdirectory on the disk. For more information, see the [pkcs11\\_softtoken\(5\)](#) man page.

You can retrieve the key pair from the keystore by a label that you specify.

```
% pktool genkeypair label=key-label \
[token=token[:manuf[:serial]]] \
```

```
[keytype=rsa|dsa|ec] [curve=ECC-Curve-Name] \  
[keylen=key-size] [listcurves]
```

`label=key-label`

Specifies a label for the key pair. The key pair can be retrieved from the keystore by its label.

`token=token[:manuf[:serial]]`

Specifies the token name. By default, the token name is Sun Software PKCS#11 softtoken.

`keytype=rsa|dsa|ec [curve=ECC-Curve-Name]`

Specifies the keypair type. For the elliptic curve (ec) type, optionally specifies a curve name. Curve names are listed as output to the `listcurves` option.

`keylen=key-size`

Specifies the length of the key in bits. The number must be divisible by 8.

`listcurves`

Lists the elliptic curve names that can be used as values to the `curve=` option for an ec key type.

#### ■ **Generate the key pair and store it in an NSS keystore.**

The NSS keystore is used by servers that rely on NSS as their primary cryptographic interface.

You must complete [Step 1](#) before using this method.

```
% pktool keystore=nss genkeypair label=key-nickname \  
[token=token[:manuf[:serial]]] \  
[dir=directory-path] [prefix=database-prefix] \  
[keytype=rsa|dsa|ec] [curve=ECC-Curve-Name] \  
[keylen=key-size] [listcurves]
```

`keystore=nss`

The value `nss` specifies the NSS type of storage location for the key.

`label=nickname`

Specifies a label for the key pair. The key pair can be retrieved from the keystore by its label.

`token=token[:manuf[:serial]]`

Specifies the token name. By default, the token is Sun Software PKCS#11 softtoken.

`dir=directory`

Specifies the directory path to the NSS database. By default, *directory* is the current directory.

`prefix=database-prefix`

Specifies the prefix to the NSS database. The default is no prefix.

`keytype=rsa|dsa|ec [curve=ECC-Curve-Name]`

Specifies the keypair type. For the elliptic curve type, optionally specifies a curve name. Curve names are listed as output to the `listcurves` option.

`keylen=key-size`

Specifies the length of the key in bits. The number must be divisible by 8.

`listcurves`

Lists the elliptic curve names that can be used as values to the `curve=` option for an ec key type.

### 3. (Optional) Verify that the key exists.

Use one of the following commands, depending on where you stored the key:

- **Verify the key in the *key-filename* file.**

```
% pktool list keystore=file objtype=key infile=key-filename
Found n keys.
Key #1 - keytype:location (keylen)
```

- **Verify the key in the PKCS #11 keystore.**

```
$ pktool list objtype=key
Enter PIN for keystore:
Found n keys.
Key #1 - keytype:location (keylen)
```

- **Verify the key in the NSS keystore.**

```
% pktool list keystore=nss dir=directory objtype=key
```

#### Example 4-6 Creating a Key Pair by Using the `pktool` Command

In the following example, a user creates a PKCS #11 keystore for the first time. After determining the key sizes for RSA key pairs, the user then generates a key pair for an application. Finally, the user verifies that the key pair is in the keystore. The user notes that the second instance of the RSA key pair can be stored on hardware. Because the user does not specify a token argument, the key pair is stored as a Sun Software PKCS#11 softtoken.

```
# pktool setpin
Create new passphrase:
Re-enter new passphrase:      Retype password
Passphrase changed.
% cryptoadm list -vm | grep PAIR
...
CKM_DSA_KEY_PAIR_GEN          512 3072 . . . . . X . . . . .
CKM_RSA_PKCS_KEY_PAIR_GEN     256 8192 . . . . . X . . . . .
...
CKM_RSA_PKCS_KEY_PAIR_GEN     256 2048 X . . . . . X . . . . .
ecc: CKM_EC_KEY_PAIR_GEN,CKM_ECDH1_DERIVE,CKM_ECDSA,CKM_ECDSA_SHA1
% pktool genkeypair label=specialappkeypair keytype=rsa keylen=2048
Enter PIN for Sun Software PKCS#11 softtoken :      Type password

% pktool list
Enter PIN for Sun Software PKCS#11 softtoken :      Type password
No.      Key Type      Key Len.      Key Label
-----
Asymmetric public keys:
1         RSA                specialappkeypair
```

**Example 4-7** Creating a Key Pair That Uses the Elliptic Curve Algorithm

In the following example, a user adds an elliptic curve (ec) key pair to the keystore, specifies a curve name, and verifies that the key pair is in the keystore.

```
% pktool genkeypair listcurves
secp112r1, secp112r2, secp128r1, secp128r2, secp160k1
.
.
.
c2pnb304w1, c2tnb359v1, c2pnb368w1, c2tnb431r1, prime192v2
prime192v3
% pktool genkeypair label=eckeypair keytype=ec curves=c2tnb431r1
% pktool list
Enter PIN for Sun Software PKCS#11 softtoken :      Type password
No.      Key Type      Key Len.      Key Label
-----
Asymmetric public keys:
1         ECDSA                eckeypair
```

## ▼ How to Sign a Certificate Request by Using the `pktool signcsr` Command

This procedure is used to sign a PKCS #10 certificate signing request (CSR). The CSR can be in PEM or DER format. The signing process issues an X.509 v3 certificate. To generate a PKCS #10 CSR, see the [pktool\(1\)](#) man page.

**Before You Begin** This procedure assumes that you are a certificate authority (CA), you have received a CSR, and it is stored in a file.

**1. Collect the following information for the required arguments to the `pktool signcsr` command:**

<code>signkey</code>	If you have stored the signer's key in a PKCS #11 keystore, <code>signkey</code> is the label that retrieves this private key. If you have stored the signer's key in an NSS keystore or a file keystore, <code>signkey</code> is the file name that holds this private key.
<code>csr</code>	Specifies the file name of the CSR.
<code>serial</code>	Specifies the serial number of the signed certificate.
<code>outcert</code>	Specifies the file name for the signed certificate.
<code>issuer</code>	Specifies your CA issuer name in distinguished name (DN) format.

For information about optional arguments to the `signcsr` subcommand, see the [pktool\(1\)](#) man page.

**2. Sign the request and issue the certificate.**

For example, the following command signs the certificate with the signer's key from the PKCS #11 repository:

```
# pktool signcsr signkey=CASigningKey \  
csr=fromExampleCoCSR \  
serial=0x12345678 \  
outcert=ExampleCoCert2010 \  
issuer="O=Oracle Corporation, \  
OU=Oracle Solaris Security Technology, L=Redwood City, ST=CA, C=US, \  
CN=rootsign Oracle"
```

The following command signs the certificate with the signer's key from a file:

```
# pktool signcsr signkey=CASigningKey \  
csr=fromExampleCoCSR \  
serial=0x12345678 \  
outcert=ExampleCoCert2010 \  
issuer="O=Oracle Corporation, \  
OU=Oracle Solaris Security Technology, L=Redwood City, ST=CA, C=US, \  
CN=rootsign Oracle"
```

**3. Send the certificate to the requester.**

You can use email, a web site, or another mechanism to deliver the certificate to the requester.

For example, you could use email to send the `ExampleCoCert2010` file to the requester.

## ▼ How to Manage Third-Party Plugins in KMF

You identify your plugin by giving it a keystore name. When you add the plugin to KMF, the software identifies it by its keystore name. The plugin can be defined to accept an option. This procedure includes how to remove the plugin from KMF.

### 1. Install the plugin.

```
% /usr/bin/kmfcfg install keystore=keystore-name \  
modulepath=path-to-plugin [option="option-string"]
```

where

*keystore-name* Specifies a unique name for the keystore that you provide.

*path-to-plugin* Specifies the full path to the shared library object for the KMF plugin.

*option-string* Specifies an optional argument to the shared library object.

### 2. List the plugins.

```
% kmfcfg list plugin  
keystore-name:path-to-plugin [(built-in)] | [;option=option-string]
```

### 3. To remove the plugin, uninstall it and verify its removal.

```
% kmfcfg uninstall keystore=keystore-name  
% kmfcfg plugin list
```

#### Example 4-8 Calling a KMF Plugin With an Option

In the following example, the administrator stores a KMF plugin in a site-specific directory. The plugin is defined to accept a debug option. The administrator adds the plugin and verifies that the plugin is installed.

```
# /usr/bin/kmfcfg install keystore=mykmfplug \  
modulepath=/lib/security/site-modules/mykmfplug.so  
# kmfcfg list plugin  
KMF plugin information:  
-----  
pkcs11:kmf_pkcs11.so.1 (built-in)  
file:kmf_openssl.so.1 (built-in)  
nss:kmf_nss.so.1 (built-in)  
mykmfplug:/lib/security/site-modules/mykmfplug.so  
# kmfcfg modify plugin keystore=mykmfplug option="debug"
```

```
# kmfcfg list plugin
KMF plugin information:
-----
...
mykmfplug:/lib/security/site-modules/mykmfplug.so;option=debug
```

The plugin now runs in debugging mode.

# Security Glossary

---

<b>Access Control List (ACL)</b>	An access control list (ACL) provides finer-grained file security than traditional UNIX file protection provides. For example, an ACL enables you to allow group read access to a file, while allowing only one member of that group to write to the file.
<b>admin principal</b>	A user principal with a name of the form <i>username/admin</i> (as in <i>jdoe/admin</i> ). An admin principal can have more privileges (for example, to change policies) than a regular user principal. See also <a href="#">principal name</a> , <a href="#">user principal</a> .
<b>AES</b>	Advanced Encryption Standard. A symmetric 128-bit block data encryption technique. The U.S. government adopted the Rijndael variant of the algorithm as its encryption standard in October 2000. AES replaces <a href="#">user principal</a> encryption as the government standard.
<b>algorithm</b>	A cryptographic algorithm. This is an established, recursive computational procedure that encrypts or hashes input.
<b>application server</b>	See <a href="#">network application server</a> .
<b>asynchronous audit event</b>	Asynchronous events are the minority of system events. These events are not associated with any process, so no process is available to be blocked and later woken up. Initial system boot and PROM enter and exit events are examples of asynchronous events.
<b>audit files</b>	Binary audit logs. Audit files are stored separately in an audit file system.
<b>audit policy</b>	The global and per-user settings that determine which audit events are recorded. The global settings that apply to the audit service typically affect which pieces of optional information are included in the audit trail. Two settings, <code>cnt</code> and <code>ahlt</code> , affect the operation of the system when the audit queue fills. For example, audit policy might require that a sequence number be part of every audit record.
<b>audit trail</b>	The collection of all audit files from all hosts.
<b>authenticated rights profile</b>	A <a href="#">rights profile</a> that requires the assigned user or role to type a password before executing an operation from the profile. This behavior is similar to <code>sudo</code> behavior. The length of time that the password is valid is configurable.
<b>authentication</b>	The process of verifying the claimed identity of a principal.

- authenticator** Authenticators are passed by clients when requesting tickets (from a KDC) and services (from a server). They contain information that is generated by using a session key known only by the client and server, that can be verified as of recent origin, thus indicating that the transaction is secure. When used with a ticket, an authenticator can be used to authenticate a user principal. An authenticator includes the principal name of the user, the IP address of the user's host, and a time stamp. Unlike a ticket, an authenticator can be used only once, usually when access to a service is requested. An authenticator is encrypted by using the session key for that client and that server.
- authorization** 1. In Kerberos, the process of determining if a principal can use a service, which objects the principal is allowed to access, and the type of access that is allowed for each object.
2. In user rights management, a right that can be assigned to a role or user (or embedded in a rights profile) for performing a class of operations that are otherwise prohibited by security policy. Authorizations are enforced at the user application level, not in the kernel.
- basic set** The set of privileges that are assigned to a user's process at login. On an unmodified system, each user's initial inheritable set equals the basic set at login.
- Blowfish** A symmetric block cipher algorithm that takes a variable-length key from 32 bits to 448 bits. Its author, Bruce Schneier, claims that Blowfish is optimized for applications where the key does not change often.
- certificate** A public key certificate is a set of data that encodes a public key value, including some information about the generation of the certificate, such as a name and who signed it, a hash or checksum of the certificate, and a digital signature of the hash. Together, these values form the certificate. The digital signature ensures that the certificate has not been modified.
- For more information, see [key](#).
- client** Narrowly, a process that makes use of a network service on behalf of a user; for example, an application that uses `rlogin`. In some cases, a server can itself be a client of some other server or service.
- More broadly, a host that a) receives a Kerberos credential, and b) makes use of a service that is provided by a server.
- Informally, a principal that makes use of a service.
- client principal** (RPCSEC\_GSS API) A client (a user or an application) that uses RPCSEC\_GSS-secured network services. Client principal names are stored in the form of `rpc_gss_principal_t` structures.
- clock skew** The maximum amount of time that the internal system clocks on all hosts that are participating in the Kerberos authentication system can differ. If the clock skew is exceeded between any of the participating hosts, requests are rejected. Clock skew can be specified in the `krb5.conf` file.
- confidentiality** See [privacy](#).

---

<b>consumer</b>	In the Cryptographic Framework feature of Oracle Solaris, a consumer is a user of the cryptographic services that come from providers. Consumers can be applications, end users, or kernel operations. Kerberos, IKE, and IPsec are examples of consumers. For examples of providers, see <a href="#">provider</a> .
<b>credential</b>	An information package that includes a ticket and a matching session key. Used to authenticate the identity of a principal. See also <a href="#">ticket</a> , <a href="#">session key</a> .
<b>credential cache</b>	A storage space (usually a file) that contains credentials that are received from the KDC.
<b>cryptographic algorithm</b>	See <a href="#">algorithm</a> .
<b>DES</b>	Data Encryption Standard. A symmetric-key encryption method developed in 1975 and standardized by ANSI in 1981 as ANSI X.3.92. DES uses a 56-bit key.
<b>device allocation</b>	Device protection at the user level. Device allocation enforces the exclusive use of a device by one user at a time. Device data is purged before device reuse. Authorizations can be used to limit who is permitted to allocate a device.
<b>device policy</b>	Device protection at the kernel level. Device policy is implemented as two sets of privileges on a device. One set of privileges controls read access to the device. The second set of privileges controls write access to the device. See also <a href="#">policy</a> .
<b>Diffie-Hellman protocol</b>	Also known as public key cryptography. An asymmetric cryptographic key agreement protocol that was developed by Diffie and Hellman in 1976. The protocol enables two users to exchange a secret key over an insecure medium without any prior secrets. Diffie-Hellman is used by <a href="#">Kerberos</a> .
<b>digest</b>	See <a href="#">message digest</a> .
<b>DSA</b>	Digital Signature Algorithm. A public key algorithm with a variable key size from 512 to 4096 bits. The U.S. Government standard, DSS, goes up to 1024 bits. DSA relies on <a href="#">SHA1</a> for input.
<b>ECDSA</b>	Elliptic Curve Digital Signature Algorithm. A public key algorithm that is based on elliptic curve mathematics. An ECDSA key size is significantly smaller than the size of a DSA public key needed to generate a signature of the same length.
<b>effective set</b>	The set of privileges that are currently in effect on a process.
<b>flavor</b>	Historically, <i>security flavor</i> and <i>authentication flavor</i> had the same meaning, as a flavor that indicated a type of authentication (AUTH_UNIX, AUTH_DES, AUTH_KERB). RPCSEC_GSS is also a security flavor, even though it provides integrity and privacy services in addition to authentication.
<b>forwardable ticket</b>	A ticket that a client can use to request a ticket on a remote host without requiring the client to go through the full authentication process on that host. For example, if the user david obtains a forwardable ticket while on user jennifer's machine, david can log in to his own machine

without being required to get a new ticket (and thus authenticate himself again). See also [proxiable ticket](#).

<b>FQDN</b>	Fully qualified domain name. For example, <code>central.example.com</code> (as opposed to simply <code>denver</code> ).
<b>GSS-API</b>	The Generic Security Service Application Programming Interface. A network layer that provides support for various modular security services, including the Kerberos service. GSS-API provides for security authentication, integrity, and privacy services. See also <a href="#">authentication</a> , <a href="#">integrity</a> , <a href="#">privacy</a> .
<b>hardening</b>	The modification of the default configuration of the operating system to remove security vulnerabilities that are inherent in the host.
<b>hardware provider</b>	In the Cryptographic Framework feature of Oracle Solaris, a device driver and its hardware accelerator. Hardware providers offload expensive cryptographic operations from the computer system, thus freeing CPU resources for other uses. See also <a href="#">provider</a> .
<b>host</b>	A system that is accessible over a network.
<b>host principal</b>	A particular instance of a service principal in which the principal (signified by the primary name <code>host</code> ) is set up to provide a range of network services, such as <code>ftp</code> , <code>rcp</code> , or <code>rlogin</code> . An example of a host principal is <code>host/central.example.com@EXAMPLE.COM</code> . See also <a href="#">server principal</a> .
<b>inheritable set</b>	The set of privileges that a process can inherit across a call to <code>exec</code> .
<b>initial ticket</b>	A ticket that is issued directly (that is, not based on an existing ticket-granting ticket). Some services, such as applications that change passwords, might require tickets to be marked <code>initial</code> so as to assure themselves that the client can demonstrate a knowledge of its secret key. This assurance is important because an initial ticket indicates that the client has recently authenticated itself (instead of relying on a ticket-granting ticket, which might exist for a long time).
<b>instance</b>	The second part of a principal name, an instance qualifies the principal's primary. In the case of a service principal, the instance is required. The instance is the host's fully qualified domain name, as in <code>host/central.example.com</code> . For user principals, an instance is optional. Note, however, that <code>jdoe</code> and <code>jdoe/admin</code> are unique principals. See also <a href="#">primary</a> , <a href="#">principal name</a> , <a href="#">service principal</a> , <a href="#">user principal</a> .
<b>integrity</b>	A security service that, in addition to user authentication, provides for the validity of transmitted data through cryptographic checksumming. See also <a href="#">authentication</a> , <a href="#">privacy</a> .
<b>invalid ticket</b>	A postdated ticket that has not yet become usable. An invalid ticket is rejected by an application server until it becomes validated. To be validated, an invalid ticket must be presented to the KDC by the client in a TGS request, with the <code>VALIDATE</code> flag set, after its start time has passed. See also <a href="#">postdated ticket</a> .
<b>KDC</b>	Key Distribution Center. A machine that has three Kerberos V5 components:

- Principal and key database
- Authentication service
- Ticket-granting service

Each realm has a master KDC and should have one or more slave KDCs.

**Kerberos** An authentication service, the protocol that is used by that service, or the code that is used to implement that service.

The Kerberos implementation in Oracle Solaris that is closely based on Kerberos V5 implementation.

While technically different, “Kerberos” and “Kerberos V5” are often used interchangeably in the Kerberos documentation.

Kerberos (also spelled Cerberus) was a fierce, three-headed mastiff who guarded the gates of Hades in Greek mythology.

**Kerberos policy** A set of rules that governs password usage in the Kerberos service. Policies can regulate principals' accesses, or ticket parameters, such as lifetime.

**key** 1. Generally, one of two main types of keys:

- A *symmetric key* – An encryption key that is identical to the decryption key. Symmetric keys are used to encrypt files.
- An *asymmetric key* or *public key* – A key that is used in public key algorithms, such as Diffie-Hellman or RSA. Public keys include a private key that is known only by one user, a public key that is used by the server or general resource, and a private-public key pair that combines the two. A private key is also called a *secret key*. The public key is also called a *shared key* or *common key*.

2. An entry (principal name) in a keytab file. See also [keytab file](#).

3. In Kerberos, an encryption key, of which there are three types:

- A *private key* – An encryption key that is shared by a principal and the KDC, and distributed outside the bounds of the system. See also [private key](#).
- A *service key* – This key serves the same purpose as the private key, but is used by servers and services. See also [service key](#).
- A *session key* – A temporary encryption key that is used between two principals, with a lifetime limited to the duration of a single login session. See also [session key](#).

**keystore** A keystore holds passwords, passphrases, certificates, and other authentication objects for retrieval by applications. A keystore can be specific to a technology, or a location that several applications use.

**keytab file** A key table file that contains one or more keys (principals). A host or service uses a keytab file in the much the same way that a user uses a password.

<b>kvno</b>	Key version number. A sequence number that tracks a particular key in order of generation. The highest kvno is the latest and most current key.
<b>least privilege</b>	A security model which gives a specified process only a subset of superuser powers. The least privilege model assigns enough privilege to regular users that they can perform personal administrative tasks, such as mount file systems and change the ownership of files. On the other hand, processes run with just those privileges that they need to complete the task, rather than with the full power of superuser, that is, all privileges. Damage due to programming errors like buffer overflows can be contained to a non-root user, which has no access to critical abilities like reading or writing protected system files or halting the machine.
<b>limit set</b>	The outside limit of what privileges are available to a process and its children.
<b>MAC</b>	<ol style="list-style-type: none"><li>1. See <a href="#">message authentication code (MAC)</a>.</li><li>2. Also called labeling. In government security terminology, MAC is Mandatory Access Control. Labels such as Top Secret and Confidential are examples of MAC. MAC contrasts with DAC, which is Discretionary Access Control. UNIX permissions are an example of DAC.</li><li>3. In hardware, the unique system address on a LAN. If the system is on an Ethernet, the MAC is the Ethernet address.</li></ol>
<b>master KDC</b>	The main KDC in each realm, which includes a Kerberos administration server, <code>kadmind</code> , and an authentication and ticket-granting daemon, <code>krb5kdc</code> . Each realm must have at least one master KDC, and can have many duplicate, or slave, KDCs that provide authentication services to clients.
<b>MD5</b>	An iterative cryptographic hash function that is used for message authentication, including digital signatures. The function was developed in 1991 by Rivest. Its use is deprecated.
<b>mechanism</b>	<ol style="list-style-type: none"><li>1. A software package that specifies cryptographic techniques to achieve data authentication or confidentiality. Examples: Kerberos V5, Diffie-Hellman public key.</li><li>2. In the Cryptographic Framework feature of Oracle Solaris, an implementation of an algorithm for a particular purpose. For example, a DES mechanism that is applied to authentication, such as <code>CKM_DES_MAC</code>, is a separate mechanism from a DES mechanism that is applied to encryption, <code>CKM_DES_CBC_PAD</code>.</li></ol>
<b>message authentication code (MAC)</b>	MAC provides assurance of data integrity and authenticates data origin. MAC does not protect against eavesdropping.
<b>message digest</b>	A message digest is a hash value that is computed from a message. The hash value almost uniquely identifies the message. A digest is useful for verifying the integrity of a file.
<b>minimization</b>	The installation of the minimal operating system that is necessary to run the server. Any software that does not directly relate to the operation of the server is either not installed, or deleted after the installation.

<b>name service scope</b>	The scope in which a role is permitted to operate, that is, an individual host or all hosts that are served by a specified naming service such as NIS LDAP.
<b>network application server</b>	A server that provides a network application, such as ftp. A realm can contain several network application servers.
<b>network policies</b>	The settings that network utilities configure to protect network traffic. For information about network security, see <a href="#">“Securing the Network in Oracle Solaris 11.2”</a> .
<b>nonattributable audit event</b>	An audit event whose initiator cannot be determined, such as the AUE_BOOT event.
<b>NTP</b>	Network Time Protocol. Software from the University of Delaware that enables you to manage precise time or network clock synchronization, or both, in a network environment. You can use NTP to maintain clock skew in a Kerberos environment. See also clock skew.
<b>PAM</b>	Pluggable Authentication Module. A framework that allows for multiple authentication mechanisms to be used without having to recompile the services that use them. PAM enables Kerberos session initialization at login.
<b>passphrase</b>	A phrase that is used to verify that a private key was created by the passphrase user. A good passphrase is 10-30 characters long, mixes alphabetic and numeric characters, and avoids simple prose and simple names. You are prompted for the passphrase to authenticate use of the private key to encrypt and decrypt communications.
<b>password policy</b>	The encryption algorithms that can be used to generate passwords. Can also refer to more general issues around passwords, such as how often the passwords must be changed, how many password attempts are permitted, and other security considerations. Security policy requires passwords. Password policy might require passwords to be encrypted with the AES algorithm, and might make further requirements related to password strength.
<b>permitted set</b>	The set of privileges that are available for use by a process.
<b>policy</b>	<p>Generally, a plan or course of action that influences or determines decisions and actions. For computer systems, policy typically means security policy. Your site's security policy is the set of rules that define the sensitivity of the information that is being processed and the measures that are used to protect the information from unauthorized access. For example, security policy might require that systems be audited, that devices must be allocated for use, and that passwords be changed every six weeks.</p> <p>For the implementation of policy in specific areas of the Oracle Solaris OS, see <a href="#">audit policy</a>, <a href="#">policy in the Cryptographic Framework</a>, <a href="#">device policy</a>, <a href="#">Kerberos policy</a>, <a href="#">password policy</a>, and <a href="#">rights policy</a>.</p>
<b>policy for public key technologies</b>	In the Key Management Framework (KMF), policy is the management of certificate usage. The KMF policy database can put constraints on the use of the keys and certificates that are managed by the KMF library.

<b>policy in the Cryptographic Framework</b>	In the Cryptographic Framework feature of Oracle Solaris, policy is the disabling of existing cryptographic mechanisms. The mechanisms then cannot be used. Policy in the Cryptographic Framework might prevent the use of a particular mechanism, such as CKM_DES_CBC, from a provider, such as DES.
<b>postdated ticket</b>	A postdated ticket does not become valid until some specified time after its creation. Such a ticket is useful, for example, for batch jobs that are intended to run late at night, since the ticket, if stolen, cannot be used until the batch job is run. When a postdated ticket is issued, it is issued as <code>invalid</code> and remains that way until a) its start time has passed, and b) the client requests validation by the KDC. A postdated ticket is normally valid until the expiration time of the ticket-granting ticket. However, if the postdated ticket is marked <code>renewable</code> , its lifetime is normally set to be equal to the duration of the full life time of the ticket-granting ticket. See also <a href="#">invalid ticket</a> , <a href="#">renewable ticket</a> .
<b>primary</b>	The first part of a principal name. See also <a href="#">instance</a> , <a href="#">principal name</a> , <a href="#">realm</a> .
<b>principal</b>	<ol style="list-style-type: none"><li>1. A uniquely named client/user or server/service instance that participates in a network communication. Kerberos transactions involve interactions between principals (service principals and user principals) or between principals and KDCs. In other words, a principal is a unique entity to which Kerberos can assign tickets. See also <a href="#">principal name</a>, <a href="#">service principal</a>, <a href="#">user principal</a>.</li><li>2. (RPCSEC_GSS API) See <a href="#">client principal</a>, <a href="#">server principal</a>.</li></ol>
<b>principal name</b>	<ol style="list-style-type: none"><li>1. The name of a principal, in the format <code>primary/instance@REALM</code>. See also <a href="#">instance</a>, <a href="#">primary</a>, <a href="#">realm</a>.</li><li>2. (RPCSEC_GSS API) See <a href="#">client principal</a>, <a href="#">server principal</a>.</li></ol>
<b>principle of least privilege</b>	See <a href="#">least privilege</a> .
<b>privacy</b>	A security service, in which transmitted data is encrypted before being sent. Privacy also includes data integrity and user authentication. See also <a href="#">authentication</a> , <a href="#">integrity</a> , <a href="#">service</a> .
<b>private key</b>	A key that is given to each user principal, and known only to the user of the principal and to the KDC. For user principals, the key is based on the user's password. See also <a href="#">key</a> .
<b>private-key encryption</b>	In private-key encryption, the sender and receiver use the same key for encryption. See also <a href="#">public-key encryption</a> .
<b>privilege</b>	<ol style="list-style-type: none"><li>1. In general, a power or capability to perform an operation on a computer system that is beyond the powers of a regular user. Superuser privileges are all the <a href="#">rights</a> that superuser is granted. A privileged user or privileged application is a user or application that has been granted additional rights.</li><li>2. A discrete right on a process in an Oracle Solaris system. Privileges offer a finer-grained control of processes than does <code>root</code>. Privileges are defined and enforced in the kernel.</li></ol>

---

	Privileges are also called <i>process privileges</i> or <i>kernel privileges</i> . For a full description of privileges, see the <a href="#">privileges(5)</a> man page.
<b>privilege escalation</b>	Gaining access to resources that are outside the range of resources that your assigned rights, including rights that override the defaults, permit. The result is that a process can perform unauthorized operations.
<b>privilege model</b>	A stricter model of security on a computer system than the superuser model. In the privilege model, processes require privilege to run. Administration of the system can be divided into discrete parts that are based on the privileges that administrators have in their processes. Privileges can be assigned to an administrator's login process. Or, privileges can be assigned to be in effect for certain commands only.
<b>privilege set</b>	<p>A collection of privileges. Every process has four sets of privileges that determine whether a process can use a particular privilege. See <a href="#">limit set</a>, <a href="#">effective set</a> set, <a href="#">permitted set</a> set, and <a href="#">inheritable set</a> set.</p> <p>Also, the <a href="#">basic set</a> set of privileges is the collection of privileges that are assigned to a user's process at login.</p>
<b>privilege-aware</b>	Programs, scripts, and commands that turn on and off the use of privilege in their code. In a production environment, the privileges that are turned on must be supplied to the process, for example, by requiring users of the program to use a rights profile that adds the privileges to the program. For a full description of privileges, see the <a href="#">privileges(5)</a> man page.
<b>privileged application</b>	An application that can override system controls. The application checks for security attributes, such as specific UIDs, GIDs, authorizations, or privileges.
<b>privileged user</b>	A user who is assigned rights beyond the rights of regular user on a computer system. See also <a href="#">trusted users</a> .
<b>profile shell</b>	In rights management, a shell that enables a role (or user) to run from the command line any privileged applications that are assigned to the role's rights profiles. The profile shell versions correspond to the available shells on the system, such as the <code>pfbash</code> version of <code>bash</code> .
<b>provider</b>	In the Cryptographic Framework feature of Oracle Solaris, a cryptographic service that is provided to consumers. PKCS #11 libraries, kernel cryptographic modules, and hardware accelerators are examples of providers. Providers plug in to the Cryptographic Framework, so are also called <i>plugins</i> . For examples of consumers, see <a href="#">consumer</a> .
<b>proxiable ticket</b>	A ticket that can be used by a service on behalf of a client to perform an operation for the client. Thus, the service is said to act as the client's proxy. With the ticket, the service can take on the identity of the client. The service can use a proxiable ticket to obtain a service ticket to another service, but it cannot obtain a ticket-granting ticket. The difference between a proxiable ticket and a forwardable ticket is that a proxiable ticket is only valid for a single operation. See also <a href="#">forwardable ticket</a> .
<b>public object</b>	A file that is owned by the root user and readable by the world, such as any file in the <code>/etc</code> directory.

<b>public-key encryption</b>	An encryption scheme in which each user has two keys, one public key and one private key. In public-key encryption, the sender uses the receiver's public key to encrypt the message, and the receiver uses a private key to decrypt it. The Kerberos service is a private-key system. See also <a href="#">private-key encryption</a> .
<b>QOP</b>	Quality of Protection. A parameter that is used to select the cryptographic algorithms that are used in conjunction with the integrity service or privacy service.
<b>RBAC</b>	Role-based access control, the user rights management feature of Oracle Solaris. See <a href="#">rights</a> .
<b>RBAC policy</b>	See <a href="#">rights policy</a> .
<b>realm</b>	<ol style="list-style-type: none"><li>1. The logical network that is served by a single Kerberos database and a set of Key Distribution Centers (KDCs).</li><li>2. The third part of a principal name. For the principal name <code>jdoe/admin@CORP.EXAMPLE.COM</code>, the realm is <code>CORP.EXAMPLE.COM</code>. See also <a href="#">principal name</a>.</li></ol>
<b>reauthentication</b>	The requirement to provide a password to perform a computer operation. Typically, <code>sudo</code> operations require reauthentication. Authenticated rights profiles can contain commands that require reauthentication. See <a href="#">authenticated rights profile</a> .
<b>relation</b>	A configuration variable or relationship that is defined in the <code>kdc.conf</code> or <code>krb5.conf</code> files.
<b>renewable ticket</b>	Because having tickets with very long lives is a security risk, tickets can be designated as renewable. A renewable ticket has two expiration times: a) the time at which the current instance of the ticket expires, and b) maximum lifetime for any ticket. If a client wants to continue to use a ticket, the client renews the ticket before the first expiration occurs. For example, a ticket can be valid for one hour, with all tickets having a maximum lifetime of ten hours. If the client that holds the ticket wants to keep it for more than an hour, the client must renew the ticket. When a ticket reaches the maximum ticket lifetime, it automatically expires and cannot be renewed.
<b>rights</b>	An alternative to the all-or-nothing superuser model. User rights management and process rights management enable an organization to divide up superuser's privileges and assign them to users or roles. Rights in Oracle Solaris are implemented as kernel privileges, authorizations, and the ability to run a process as a specific UID or GID. Rights can be collected in a <a href="#">rights profile</a> and a <a href="#">role</a> .
<b>rights policy</b>	The security policy that is associated with a command. Currently, <code>solaris</code> is the valid policy for Oracle Solaris. The <code>solaris</code> policy recognizes privileges and extended privilege policy, authorizations, and <code>setuid</code> security attributes.
<b>rights profile</b>	Also referred to as a profile. A collection of security overrides that can be assigned to a role or user. A rights profile can include authorizations, privileges, commands with security attributes, and other rights profiles that are called supplementary profiles.
<b>role</b>	A special identity for running privileged applications that only assigned users can assume.

---

<b>RSA</b>	A method for obtaining digital signatures and public key cryptosystems. The method was first described in 1978 by its developers, Rivest, Shamir, and Adleman.
<b>scan engine</b>	A third-party application, residing on an external host, that examines a file for known viruses.
<b>SEAM</b>	The product name for the initial version of Kerberos on Solaris systems. This product is based on the Kerberos V5 technology that was developed at the Massachusetts Institute of Technology. SEAM is now called the Kerberos service. It continues to differ slightly from the MIT version.
<b>secret key</b>	See <a href="#">private key</a> .
<b>Secure Shell</b>	A special protocol for secure remote login and other secure network services over an insecure network.
<b>security attributes</b>	Overrides to security policy that enable an administrative command to succeed when the command is run by a user other than superuser. In the superuser model, the <code>setuid</code> root and <code>setgid</code> programs are security attributes. When these attributes are applied to a command, the command succeeds no matter who runs the command. In the <a href="#">privilege model</a> , kernel privileges and other <a href="#">rights</a> replace <code>setuid</code> root programs as security attributes. The privilege model is compatible with the superuser model, in that the privilege model also recognizes the <code>setuid</code> and <code>setgid</code> programs as security attributes.
<b>security flavor</b>	See <a href="#">flavor</a> .
<b>security mechanism</b>	See <a href="#">mechanism</a> .
<b>security policy</b>	See <a href="#">policy</a> .
<b>security service</b>	See <a href="#">service</a> .
<b>seed</b>	A numeric starter for generating random numbers. When the starter originates from a random source, the seed is called a <i>random seed</i> .
<b>separation of duty</b>	Part of the notion of <a href="#">least privilege</a> . Separation of duty prevents one user from performing or approving all operations that complete a transaction. For example, in <a href="#">RBAC</a> , you can separate the creation of a login user from the assignment of security overrides. One role creates the user. A separate role can assign security attributes, such as rights profiles, roles, and privileges to existing users.
<b>server</b>	A principal that provides a resource to network clients. For example, if you <code>ssh</code> to the system <code>central.example.com</code> , then that system is the server that provides the <code>ssh</code> service. See also <a href="#">service principal</a> .
<b>server principal</b>	(RPCSEC_GSS API) A principal that provides a service. The server principal is stored as an ASCII string in the form <code>service@host</code> . See also <a href="#">client principal</a> .

<b>service</b>	<ol style="list-style-type: none"><li>1. A resource that is provided to network clients, often by more than one server. For example, if you <code>rlogin</code> to the machine <code>central.example.com</code>, then that machine is the server that provides the <code>rlogin</code> service.</li><li>2. A security service (either integrity or privacy) that provides a level of protection beyond authentication. See also <a href="#">integrity</a> and <a href="#">privacy</a>.</li></ol>
<b>service key</b>	An encryption key that is shared by a service principal and the KDC, and is distributed outside the bounds of the system. See also <a href="#">key</a> .
<b>service principal</b>	A principal that provides Kerberos authentication for a service or services. For service principals, the primary name is a name of a service, such as <code>ftp</code> , and its instance is the fully qualified host name of the system that provides the service. See also <a href="#">host principal</a> , <a href="#">user principal</a> .
<b>session key</b>	A key that is generated by the authentication service or the ticket-granting service. A session key is generated to provide secure transactions between a client and a service. The lifetime of a session key is limited to a single login session. See also <a href="#">key</a> .
<b>SHA1</b>	Secure Hashing Algorithm. The algorithm operates on any input length less than $2^{64}$ to produce a message digest. The SHA1 algorithm is input to <a href="#">DSA</a> .
<b>single-system image</b>	A single-system image is used in Oracle Solaris auditing to describe a group of audited systems that use the same naming service. These systems send their audit records to a central audit server, where the records can be compared as if the records came from one system.
<b>slave KDC</b>	A copy of a master KDC, which is capable of performing most functions of the master. Each realm usually has several slave KDCs (and only one master KDC). See also <a href="#">KDC</a> , <a href="#">master KDC</a> .
<b>software provider</b>	In the Cryptographic Framework feature of Oracle Solaris, a kernel software module or a PKCS #11 library that provides cryptographic services. See also <a href="#">provider</a> .
<b>stash file</b>	A stash file contains an encrypted copy of the master key for the KDC. This master key is used when a server is rebooted to automatically authenticate the KDC before it starts the <code>kadmind</code> and <code>krb5kdc</code> processes. Because the stash file includes the master key, the stash file and any backups of it should be kept secure. If the encryption is compromised, then the key could be used to access or modify the KDC database.
<b>superuser model</b>	The typical UNIX model of security on a computer system. In the superuser model, an administrator has all-or-nothing control of the system. Typically, to administer the machine, a user becomes superuser ( <code>root</code> ) and can do all administrative activities.
<b>synchronous audit event</b>	The majority of audit events. These events are associated with a process in the system. A non-attributable event that is associated with a process is a synchronous event, such as a failed login.
<b>TGS</b>	Ticket-Granting Service. That portion of the KDC that is responsible for issuing tickets.

<b>TGT</b>	Ticket-Granting Ticket. A ticket that is issued by the KDC that enables a client to request tickets for other services.
<b>ticket</b>	An information packet that is used to securely pass the identity of a user to a server or service. A ticket is valid for only a single client and a particular service on a specific server. A ticket contains the principal name of the service, the principal name of the user, the IP address of the user's host, a time stamp, and a value that defines the lifetime of the ticket. A ticket is created with a random session key to be used by the client and the service. Once a ticket has been created, it can be reused until the ticket expires. A ticket only serves to authenticate a client when it is presented along with a fresh authenticator. See also <a href="#">authenticator</a> , <a href="#">credential</a> , <a href="#">service</a> , <a href="#">session key</a> .
<b>ticket file</b>	See <a href="#">credential cache</a> .
<b>trusted users</b>	Users whom you have decided can perform administrative tasks at some level of trust. Typically, administrators create logins for trusted users first and assign administrative rights that match the users' level of trust and ability. These users then help configure and maintain the system. Also called <i>privileged users</i> .
<b>user principal</b>	A principal that is attributed to a particular user. A user principal's primary name is a user name, and its optional instance is a name that is used to describe the intended use of the corresponding credentials (for example, jdoe or jdoe/admin). Also known as a user instance. See also <a href="#">service principal</a> .
<b>virtual private network (VPN)</b>	A network that provides secure communication by using encryption and tunneling to connect users over a public network.
