Oracle® Retail
Service-Oriented Architecture Enabler Tool Guide
Release 13.2

January 2011
Value-Added Reseller (VAR) Language

Oracle Retail VAR Applications

The following restrictions and provisions only apply to the programs referred to in this section and licensed to you. You acknowledge that the programs may contain third party software (VAR applications) licensed to Oracle. Depending upon your product and its version number, the VAR applications may include:

(i) the MicroStrategy Components developed and licensed by MicroStrategy Services Corporation (MicroStrategy) of McLean, Virginia to Oracle and imbedded in the MicroStrategy for Oracle Retail Data Warehouse and MicroStrategy for Oracle Retail Planning & Optimization applications.

(ii) the Wavelink component developed and licensed by Wavelink Corporation (Wavelink) of Kirkland, Washington, to Oracle and imbedded in Oracle Retail Mobile Store Inventory Management.

(iii) the software component known as Access Via™ licensed by Access Via of Seattle, Washington, and imbedded in Oracle Retail Signs and Oracle Retail Labels and Tags.

(iv) the software component known as Adobe Flex™ licensed by Adobe Systems Incorporated of San Jose, California, and imbedded in Oracle Retail Promotion Planning & Optimization application.

You acknowledge and confirm that Oracle grants you use of only the object code of the VAR Applications. Oracle will not deliver source code to the VAR Applications to you. Notwithstanding any other term or condition of the agreement and this ordering document, you shall not cause or permit alteration of any VAR Applications. For purposes of this section, "alteration" refers to all alterations, translations, upgrades, enhancements, customizations or modifications of all or any portion of the VAR Applications including all reconfigurations, reassembly or reverse assembly, re-engineering or reverse engineering and recompilations or reverse compilations of the VAR Applications or any derivatives of the VAR Applications. You acknowledge that it shall be a breach of the agreement to utilize the relationship, and/or confidential information of the VAR Applications for purposes of competitive discovery.

The VAR Applications contain trade secrets of Oracle and Oracle's licensors and Customer shall not attempt, cause, or permit the alteration, decompilation, reverse engineering, disassembly or other reduction of the VAR Applications to a human perceivable form. Oracle reserves the right to replace, with functional equivalent software, any of the VAR Applications in future releases of the applicable program.

Preface

The Oracle Retail Service-Oriented Architecture Enabler (RSE) Tool Guide provides information about the tool as well as installation instructions.

Audience

The Oracle Retail Service-Oriented Architecture Enabler (RSE) Tool Guide is written for the following audience:

- Database administrators (DBA)
- System analysts and designers
- Integrators and implementation staff

Related Documents

For more information, see the following documents in the Oracle Retail Integration Bus 13.2 documentation set:

- Oracle Retail Integration Bus Data Model
- Oracle Retail Integration Bus Implementation Guide
- Oracle Retail Integration Bus Installation Guide
- Oracle Retail Integration Bus Operations Guide
- Oracle Retail Integration Bus Release Notes
- Oracle Retail Integration Bus Hospital Administration Guide

- Oracle Retail Functional Artifact Generator Guide

Customer Support

To contact Oracle Customer Support, access My Oracle Support at the following URL:

https://support.oracle.com

When contacting Customer Support, please provide the following:

- Product version and program/module name
- Functional and technical description of the problem (include business impact)
- Detailed step-by-step instructions to re-create
- Exact error message received
- Screen shots of each step you take

**Review Patch Documentation**

When you install the application for the first time, you install either a base release (for example, 13.2) or a later patch release (for example, 13.2.1). If you are installing the base release, additional patch, and bundled hot fix releases, read the documentation for all releases that have occurred since the base release before you begin installation. Documentation for patch and bundled hot fix releases can contain critical information related to the base release, as well as information about code changes since the base release.

**Oracle Retail Documentation on the Oracle Technology Network**

Documentation is packaged with each Oracle Retail product release. Oracle Retail product documentation is also available on the following Web site:

http://www.oracle.com/technology/documentation/oracle_retail.html

(Data Model documents are not available through Oracle Technology Network. These documents are packaged with released code, or you can obtain them through My Oracle Support.)

Documentation should be available on this Web site within a month after a product release.

**Conventions**

The following text conventions are used in this document:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.</td>
</tr>
<tr>
<td><em>italic</em></td>
<td>Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.</td>
</tr>
<tr>
<td><code>monospace</code></td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>
The purpose of the Retail Service-Oriented Architecture Enabler (RSE) tool is to provide a standard, consistent way to develop Web services for PL/SQL and Java EE applications. Because it allows them to expose their business logic, the focus of development can be on the business logic code, not on the Web service infrastructure.

The RSE tool creates Web service provider end-points, consumer clients for Web service providers, and templates for interfacing with PL/SQL APIs and Java EE APIs.

The tool also produces design time and run time artifacts. It works in conjunction with another RTG tool, the Retail Functional Artifact Generator.

**Note:** For more information on the tool, see the *Oracle Retail Functional Artifact Generator Guide*.

**Major Features of the RSE Tool**

The following is a list of the essential features of the RSE tool:

- The RSE tool is standards based.
  - All services are generated in a consistent and standard manner.
  - All services are SOAP/HTTP based Web services.
  - All services comply to the JAX-WS specification.
  - All services are WS-Addressing enabled.
  - WS-Security can be plugged into these Web services without any code change.
  - All Web services are Document Literal Wrapped.
  - Generated services are capable of using SOAP headers.
- The RSE tool generates technology-specific API templates for PL/SQL APIs and Java EE.
  - It supports PL/SQL as a Web service provider.
  - PL/SQL code can directly call any third party SOAP/HTTP based Web services.
  - It supports java code as a Web service provider.
  - It supports java code as a Web service consumer.
Generation by the RSE tool is controlled by a single Service Definition Library XML file.
- By creating Web services from the high level abstraction in the Service Definition Library, top down Web services development is supported.
- All service operation inputs and outputs are validated against the XML schema.
- There is a single source truth for all service and domain object documentation.
- The same documentation is propagated to static WSDL, Java/PLSQL API code, UDDI published content, and live WSDL.
- The Service Definition Library XML file is a service-oriented architecture governance asset.

The generated services deploy in any Java EE 5 compliant application server, with certification on Oracle WebLogic Server. (Services are deployable to a clustered Java EE application server.)

The generated services are callable as SOAP based Web services over SOAP/HTTP, local EKJB calls, remote EJB calls, or POJO services.

All services support Web service versioning strategy.
All generated Web services are forward and backward compatible.

For every Web service, a static WSDL is generated. (The generated static WSDL pulls in all of the Business Object (BO) and Web service level documentation.

All deployed services can be published to any standard UDDI registry.
- UDDI publishing has been tested with both WebLogicServer and Oracle Service Repository (OSR).
- Every generated <appname>-service.ear contains an Infrastructure Management Service that can "talk to" the UDDI registry and publish all the services available within the.ear to the registry.

Services can take advantage of Oracle Database Real Application Cluster (RAC).

The RSE tool has built-in functionality.
- Every service generated has a ping operation to test for network connectivity.
- A Service Operation Context is passed to both Java EE and PL/SQL service provider API implementation code.
- The Web service consumer generated has client side asynchronous service invocation capability.
- User-defined WebService Faults are automatically generated and handled by the infrastructure at runtime. The definitions are made in the Service Definition Library XML file.

All Web service operations are transactional. A SOAP Fault response automatically rolls back the service operations transaction. A success response automatically commits the service operations transaction.

Web service consumers do not participate in the Web service provider side transaction. There is no transaction context propagation from client to server.
Concepts

Service-oriented architecture (SOA) is a strategy for constructing business-focused, software systems from loosely coupled, interoperable building blocks (called Services) that can be combined and reused quickly, within and between enterprises, to meet business needs (as described in Oracle Fusion Reference Architecture, SOA Foundation Release 1.0).

Service Infrastructure products focus on enabling SOA projects, rather than developing new business function, or providing for other business driven needs. The goal of Service Infrastructure is to enable the delivery teams to deliver SOA projects faster, and to make the overall SOA undertaking much more manageable.

The Retail Service-Oriented Architecture Enabler Tool (RSE) is designed and developed to support the creation of Web Services by allowing a high level abstraction, higher than the WSDL, and tailored to the business analyst/functional analyst. The Business Analyst can easily understand, define, and design without knowing the intricacies of WSDLs and the technical details of the implementation. This approach also is called top-down Web services development.

What is a Service?

A Service can be described as a way of packaging reusable software building blocks to provide functionality to users and to other services. A service is an independent, self-sufficient, functional unit of work that is discoverable, manageable, and measurable, has the ability to be versioned, and offers functionality that is required by a set of users or consumers.

A logical definition of a Service has three components:

- Contract: A description of what the service provides (and its constraints).
- Interface: The means by which the service is invoked.
- Implementation: The deployed code and configuration of infrastructure.

Oracle Fusion Reference Architecture (OFRA)

It is important to understand the position and role of the RSE tool within the broader context of service-oriented architecture and development. It is beyond the scope of this document to cover the range of SOA approaches and methodologies, but it is necessary to cover some aspects to place the tool in the appropriate context.

Oracle has developed and published the Oracle Fusion Reference Architecture (OFRA) for building and integrating enterprise-class solutions, part of the IT Strategies from Oracle collection.

The Oracle Fusion Architecture Framework is a collection of assets designed to provide guidance on building solutions for the Oracle Fusion solution environment, which includes the Oracle Fusion Reference Architecture (OFRA). The following diagrams and definitions are from OFRA documentation.

Note: See Oracle Practitioner Guide Software Engineering in an SOA Environment Release 1.0 E14486-01.

As with traditional software engineering, service engineering also begins with requirements and analysis, as illustrated below:

![Service Analysis Diagram]

After Service Analysis, the next phase is Service Delivery, which includes the core delivery engineering activities. In this phase, a service candidate is molded into one or more services. Service candidates entering this phase have been justified for realization and scheduled for release.

![Service Delivery Diagram]

Service Delivery begins with Service Definition, which primarily determines service boundaries as well as the construction of the service contract.

Service Design then acts upon the Service contracts to develop the Services’ interfaces. The process of defining a Service interface is much more involved than simply coming up with the input and output for the Service. Service design analyzes the contract from the consumer’s perspective, and is influenced by factors such as scope (enterprise, LOB, application, and so on), message exchange patterns (MEPs) as well as non-functional requirements such as expected volume, and response time requirements (specified in the contract).

Service Implementation ensures that all aspects of the Service contracts are implemented and upheld through the delivery of business logic as well as the deployment to Service Infrastructure. The implementation must faithfully realize the Service Contract and interface which are defined through Service definition and design.

**Note:** See: Oracle Fusion Reference Architecture, Overview. Release 1.0 E14482-01
Where Does RSE Fit?

The Retail Service-Oriented Architecture Enabler (RSE) is a Service Infrastructure tool developed by Oracle Retail to enable the adoption of service-oriented architecture (SOA) and avoid some of the typical pitfalls of many SOA projects. It addresses many common issues, such as versioning, contract design, security, consistency, reuse, documentation, governance, compliance, and customization. It does this by enforcing SOA Best Practices and patterns that are proven and time tested by various SOA pioneers.

The tool provides the capability for business analysts and developers to define the correct service contract. It provides ease-of-use and a level of abstraction such that the domain experts or subject matter experts are not required to understand code to design services. The SOA developers can be 100% focused on implementing the business logic code behind the service and do not have to worry about SOA infrastructure issues such as versioning and customization.

The Retail Service-Oriented Architecture Enabler Tool fits within the Service Delivery phases. The appropriate use of the tool is after the service analysis phases and the development team is ready for service definition and design. The RSE tool outputs can then be used in the Service Implementation.

RSE is designed to support this type of approach, which also is called top-down Web services development.

Technical Specifications

The Oracle Retail SOA Enabler tool has dependencies on Oracle Retail application installations. This section covers these requirements.

Supported Operating Systems

<table>
<thead>
<tr>
<th>Supported On</th>
<th>Version Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle WebLogic Server OS</td>
<td>OS certified with OracleWebLogic Server 11 g Release 3 (10.3.3). Options are AIX 6.1 and OEL 5 update 2.</td>
</tr>
<tr>
<td>Oracle WebLogic Server</td>
<td>Oracle WebLogic Server 11g Release 3 (10.3.3).</td>
</tr>
</tbody>
</table>
This chapter explains how to deploy the Retail Service-Oriented Architecture Enabler tool to an Oracle WebLogic application server as a Web application.

**Installation as a Web Application in Oracle WebLogic**

The steps below describe how to deploy the Retail Service-Oriented Architecture Enabler tool to an Oracle WebLogic Application Server as a Web application.

**Prerequisites**

- The retail-soa-enabler-gui.war file is located within the directory structure of the RetailSOAEnabler13.2.0ForAll13.2.0Apps_eng_ga.tar. Locate and extract the contents to a location that is accessible by the browser for deployment.

- The installation and base configuration of the Oracle WebLogic Server is beyond the scope of this document. Work with the Application Server Administration team to determine the physical and logical placement of the retail-soa-enabler-gui component within the WebLogic Server deployment.

**Note:** See "Technical Specifications" in Chapter 1.

**Note:** See the Oracle WebLogic Server 11g Release 3 (10.3.3) Installation Guide.
Deploy the Retail Service-Oriented Architecture Enabler

Using the WebLogic Server Administration Console, complete the following steps:

1. Navigate to the Deployments page.
2. Click Install.

   **Note:** If the application has already been installed, see "Redeploy the Application".

The "Locate deployment to install and prepare for deployment" page is displayed. Follow the instructions to locate the retail-soa-enabler-gui.war file.

3. Select Upload Files.
4. On the "Upload a Deployment to the admin server" page, use the Browse button to locate the retail-soa-enabler-gui.war file in the "Deployment Archive."
5. Select the retail-soa-enabler-gui.war.
6. Click Next and move to "Choose targeting style."
7. Select "Install this deployment as an application."
8. Click Next and move to Optional Settings.
9. Click Next and move to "Review your choices and click Finish."
10. Select No, I will review the configuration later.
11. Click Finish to deploy the application.

Verify the Retail Service-Oriented Architecture Enabler

1. Navigate to the Deployments page.
2. Locate the "retail-soa-enabler-gui" on the Summary of Deployments page.
3. Click the name, retail-soa-enabler-gui, to move to the "Settings for the retail-soa-enabler-gui."
4. Select the Testing tab.
5. Click the index.jsp URL in the Test Point.
6. The URL should open to the Retail Service-Oriented Architecture Enabler Home page.
7. The installation is complete. See Chapter 4, "User Interface Usage."
Redeploy the Application

If the retail-soa-enabler-gui application has already been deployed, follow these steps:

1. If the retail-soa-enabler-gui application is running, select Stop and When Work Completes or Force Stop Now, depending on the environment. The recommended option always is When Work Completes.

2. Select Delete.

3. The retail-soa-enabler-gui should now not show on the Summary of Deployment page.

4. Return to the appropriate step in "Deploy the Retail Service-Oriented Architecture Enabler."
Installation as a Web Application in Oracle WebLogic
This chapter describes the tool inputs and tool outputs associated with RSE.

Tool Inputs

Tool inputs include the following:

- ServiceProviderDefLibrary.xml
- XSDs and retail-public-payload-java-beans.jar
- PL/SQL Oracle Objects
- WSDL

ServiceProviderDefLibrary.xml

This is the definition file for Provider services for both PL/SQL and Java EE services, and conforms to the ServiceProviderDefLibrary.xsd schema. This definition file contains a high level definition of a set of services which use Retail Business Objects (BOs) as inputs and outputs.

XSDs and retail-public-payload-java-beans.jar

- The RSE tool references JAXB created java beans based on the BO source schema XSDs. These beans are contained in the retail-public-payload-java-beans.jar.
- The RSE tool will use Oracle Retail BOs from retail-public-payload-java-beans.jar and custom BOs from custom-retail-public-payload-java-beans.jar.
- The jar file is located in the WebLogic deployment directory where the RSE tool is deployed.
- The jar file is created using the Retail Artifact Generator from the source BO XSDs.
- The jar file also contains the source XSDs themselves, which will be used by the deployed service to validate all requests and responses against.

PL/SQL Oracle Objects

These are artifacts that are created from the XSDs using the Retail Artifact Generator. The Objects have to installed into the database and accessible to the target Web service APIs generated by RSE.
**WSDL**

For the Web service consumers, the input is the WSDL of the Web service provider that the service will be consuming.

**Tool Outputs**

Tool outputs include the following:

- PL/SQL Provider Web Service
- PL/SQL Consumer Web Service
- Java EE Provider Web Service
- Java EE Consumer Web Service

**PL/SQL Provider Web Service**

PL/SQL Applications (such as the Oracle Retail Merchandising System) use Oracle Objects, which are similar to the Oracle Retail RIB style APIs. The tool generates a Web service provider layer between the external clients and the PL/SQL APIs to provide the Web service functionality.

The RSE PL/SQL provider output is a zip file. The filename convention is `<app>_PLSQLServiceProvider.zip`. For example, `rms_PLSQLServiceProvider.zip`. The zip file contains the following:

- `<ServiceName>ProviderImplSpec.sql`

  This is the specification for the `<ServiceName>`. It creates the package for the `<ServiceName>` in the `<app>` database. It describes all the operations and their IN and OUT parameters for the service.
- `<ServiceName>ProviderImplBody.sql`
  This is the package body for the `<ServiceName>`. This is where the application teams have to write the business logic.

- `<app>-service.ear`
  The `.ear` file has to be deployed on an Oracle WebLogic. The steps for deployment are given RSE PLSQL WS Install Guide.

- `ServiceProviderDefLibrary.xml`
  This is a copy of the `ServiceProviderDefLibrary.xml` file that was used to create the output.

- `<ServiceName>Service.wsdl`
  This is a WSDL file describing the generated Web service. This WSDL file will be fully documented, pulling in documentation elements from both the service def file as well as the BO XSD files. This is a single file with all types inlined. It can be used as input to create a consumer for the generated provider.

**PL/SQL Consumer Web Service**

Database
Human Actor
The Retail Service-Oriented Architecture Enabler (RSE) tool produces design time and run time artifacts, and it works in conjunction with another tool, the Retail Functional Artifact Generator.

**Note:** See the *Retail Functional Artifact Generator Guide*.

The graphical user interface (GUI) for RSE is hosted on an Oracle WebLogic server as a Web application. Once installed and configured, the GUI is accessed through a URL (http://host:port/contextroot). For example, http://linux1:7001/retail-soa-enabler-gui.

The RSE user interface has three tabs, or sections:

- Home
- Server Provider
- Service Consumer

The user interface is designed to be easy to use. Online help is available, including examples for each function.
The following is the Home Page.
Service Provider

The service provider screen gives the option of selecting the Provider type (a Java EE or a PL/SQL service provider).

A PL/SQL service provider can be used by PL/SQL applications such as RMS to expose PL/SQL packages as Web services. The Java EE service provider option allows Java EE applications to create Web services using Oracle Retail payload classes as input and outputs.

The generated Web services do not have any business logic in them. They provide only the framework for the development of Web services.

The inputs for creating Java EE or a PL/SQL Web services are:

- Service Definition Library XML file
- Custom Business Objects jar file
- Service Implementation jar file

Service Definition Library XML File

The mandatory input for creating a Java EE or a PL/SQL service provider is a Service Definition Library XML file. This file should contain all the details about the Web services that need to be created.

Note: See Chapter 5, “Service Definition Library XML File.”
Custom Business Objects Jar File

While creating Web services, users may want to use their own payloads extend the existing payloads. These payloads are known as custom payloads and can be provided to the tool as an input for creating Web services. The service provider screen has a field for custom Business Objects jar file. It allows the user to upload a jar file which contains the custom payloads. This jar file is optional; if this is not provided the base payloads are used to create the Web services.

Note: See the Oracle Retail Functional Artifact Generator Guide for how to create a custom Business Objects jar file.

Localization Business Object Jar File

While creating Web services, users may want to use localized version of payloads. These payloads are known as localized payloads and can be provided to the tool as an input for creating Web services. The service provider screen has a field for localization Business Object Jar file. It allows the user to upload a jar file which contains the localized payloads. This jar file is optional; if this is not provided, the base payloads are used to create the Web services.

Note: See the Oracle Retail Functional Artifacts Generator Guide for how to create a localization Business Objects jar file.

Service Implementation Jar File

This jar file is used only while creating Java EE Web services. While creating Java EE Web services the tool generates empty implementation for the services. Users will have to create their own implementation classes for the Web services and use those classes in the generation of the .ear file in the zip file.

After putting entering the file names in all the text boxes, click Generate Stub. This generates a .zip file with an .ear file, which is deployed to a WebLogic server.

Note: See Chapter 7, "Creating the Java EE Implementation Jar".
Service Consumer

The Service Consumer tab allows for the creation of a Java EE or PL/SWL service consumer. After an input WSDL file is selected, the tool runs. When the tool is finished, the consumer distribution zip file can be downloaded to a specific location.

Help

Click the Help link on the right upper corner of the Home page for a brief description of the Service Provider and Service Consumer functionality.
The Service Definition Library SML file (ServiceDef) is the mandatory input for creating a Java EE or a PL/SQL service provider. This file should contain all the details about the Web services that need to be created.

This chapter provides a detailed description of each section of the schema as well as instructions for managing the Service Definition Library XML file.

**Schema Definition**

This section discusses the elements of the schema, beginning with the root element and including child elements.

**serviceProviderDefLibrary**

This is the root element of the schema. The following is an example of the `serviceProviderDefLibrary` element:

```xml
<xs:element name="serviceProviderDefLibrary">
  <xs:complexType>
    <xs:sequence>
      <xs:element ref="service" maxOccurs="unbounded" />
    </xs:sequence>
    <xs:attribute name="appName" type="xs:string" use="required"/>
    <xs:attribute name="version" type="xs:string" use="optional" default="v1"/>
    <xs:attribute name="serviceNamespacePattern" type="xs:string" use="optional" default="http://www.oracle.com/retail/APPNAME/integration/services/SERVICENAMEService/VERSION"/>
  </xs:complexType>
</xs:element>
```

**Attributes**

The `serviceProviderDefLibrary` has the following attributes:

- **appName**

  This is the name of the application for which the .ear file is being built. When the .ear file is generated, the name of the .ear file starts with the application name. The format of the generated .ear file is `<appName>-service.ear`. For example, if the `appName` is "rms," the .ear file name is rms-service.ear.
- **serviceNamespacePattern**
  This attribute specifies the pattern for the namespaces that are generated for the Web services. The default value for this attribute is `http://www.oracle.com/retail/APPNAME/integration/services/SERVICENAME/VERSION`.

- **Version**
  This is the version of the service definition.

**Elements**
The `serviceProviderDefLibrary` contains the following elements:

**service**
Each service element in `serviceProviderDefLibrary` represents one Web service. The service provider definition should have at least one service defined in it.

The following is an example of the service element:

```xml
<xs:element name="service">
  <xs:complexType>
    <xs:sequence>
      <xs:element ref="documentation" minOccurs="0" />
      <xs:element ref="operation" maxOccurs="unbounded" />
    </xs:sequence>
    <xs:attribute name="name" type="xs:string" use="required" />
    <xs:attribute name="serviceNamespace" type="xs:string" use="optional" default="v1" />
    <xs:attribute name="serviceVersion" type="xs:string" use="optional" default="v1" />
    <xs:attribute name="custom" type="xs:boolean" use="optional" default="false" />
  </xs:complexType>
</xs:element>
```

The service element has the following attributes:

- **name**
  This is the name of the Web service to be created.

- **serviceNamespace**
  This is the namespace in which the Web service will be created.

- **serviceVersion**
  This is the version of the Web service. The default value is v1.

- **custom**
  This attribute specifies whether the service is a custom service. A custom service uses custom payload as input or output for any of its methods.
The service element contains the following elements:

- **Documentation**
  
  This field describes the purpose of the service.

- **Operation**
  
  The operation represents the method in the generated Web service. Each service should contain at least one operation.

  The following is an example of the operation element:

  ```xml
  <xs:element name="operation">
    <xs:complexType>
      <xs:sequence>
        <xs:element ref="documentation" minOccurs="0" />
        <xs:element ref="input" />
        <xs:element ref="output" minOccurs="0" />
        <xs:element ref="fault" minOccurs="0" maxOccurs="unbounded" />
      </xs:sequence>
      <xs:attribute name="name" type="xs:string" use="required"/>
      <xs:attribute name="suffix" default="inputType">
        <xs:simpleType>
          <xs:restriction base="xs:string">
            <xs:enumeration value="inputType" />
            <xs:enumeration value="outputType" />
            <xs:enumeration value="NONE" />
          </xs:restriction>
        </xs:simpleType>
      </xs:attribute>
      <xs:attribute name="custom" type="xs:boolean" use="optional" default="false"/>
    </xs:complexType>
  </xs:element>
  ```

  The operation element has the following attributes:

  - **name**
    
    This is the name of the operation.

  - **suffix**
    
    This is the string to be added to the end of the operation name. One of the following values are supported for this attribute:
    
    - **inputType**
      
      If the suffix value is inputType, the input type name of the operation is added to the generated method name. For example, if the operation name is "create" and input type for that operation name is SupplierDesc, the generated operation name will be createSupplierDesc.
    
    - **outputType**
      
      If the suffix value is outputType, the output type name of the operation is added to the generated method name. For example, if the operation name is "create" and output type for that operation name is SupplierRef, the generated operation name will be createSupplierRef.
Managing the Service Definition Library XML File

The Service Definition Library XML file is the single source of truth for the RSE tool. This section discusses the creation and management of the file.

Creating the File

The Service Definition Library XML example in "Appendix: Sample ServiceProviderDefLibrary.xml" can be used as the initial template. Use the instructions in the Service Definition Library XML File section to construct the ServiceDef according to the goals of the Service requirements.

As discussed in the Concepts section, the creation of this file is the result of the analysis phase and part of the Service Design phase. The template provides the placeholders for the standard Service components: Service name, operation name, and the contracts for each of the operations, as well as the standard faults.

The ServiceDef should be created and managed (or governed) as a service-oriented architecture asset in a source code control system. It is as important as the Service Contracts (XSDS) and implementation source code.

---

- NONE

  If the suffix value is NONE, a suffix is not added to the operation name.

  **Note:** If no value is provided for the suffix attribute, inputType is used as the default value.

- custom

  If the operation is custom, this attribute should be set to true. The operation is considered custom if it uses a custom payload for input or output.

The operation element contains the following child elements.

- Documentation
- Input
- Output
- Fault
  
  Fault contains the following elements:
  
  - Documentation
    
    The description of the fault.
  
  - Faulttype
    
    The name of the fault.
Changing the Version of the File

To change the version of the service definition library file, a "version" attribute must be added to the root element, serviceProviderDefLibrary.

For example:

```xml
<serviceProviderDefLibrary appName="rms"
xmlns=http://www.oracle.com/retail/integration/services/serviceProviderDefLibrary/
v1
version="v2"
xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance">
...
</serviceProviderDefLibrary>
```

Changing the appName Attribute in the File

To change the application name in the services, edit the appName attribute in the root element, serviceProviderDefLibrary.

For example:

```xml
<serviceProviderDefLibrary appName="editThisAppName"
xmlns=http://www.oracle.com/retail/integration/services/serviceProviderDefLibrary/
v1
version="v2"
xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance">
...
</serviceProviderDefLibrary>
```

Renaming a Service or Operation Name in the File

To rename a service, edit the "name" attribute in the "service" element.

For example:

```xml
<serviceProviderDefLibrary appName="rms"
xmlns=http://www.oracle.com/retail/integration/services/serviceProviderDefLibrary/
v1
version="v2"
xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance">
  ...
  <service name="EditThisName">
  ...
  </service>
</serviceProviderDefLibrary>
```

To rename an operation in the service, edit the "name" attribute of "other operation" element.

Adding a New Service or New Operation to the File

To add a new service to library, add a new "service" element with its child elements.

For example:

```xml
<serviceProviderDefLibrary appName="rmscostchange"
xmlns=http://www.oracle.com/retail/integration/services/serviceProviderDefLibrary/
v1
version="v2"
xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance">
...
</serviceProviderDefLibrary>
```
Managing the Service Definition Library XML File

```
<service name="ExistingService">
    <operation name="existingOperation">
        <documentation></documentation>
        <input type="XXX">
            <documentation></documentation>
        </input>
        <output type="YYY">
            <documentation></documentation>
        </output>
        <fault faultType="IllegalArgumentWSFaultException">
            <documentation>Throw this exception when a "soap:Client" side message problem occurs.</documentation>
        </fault>
        <fault faultType="EntityAlreadyExistsWSFaultException">
            <documentation>Throw this exception when the attempt made to create a object that already exists.</documentation>
        </fault>
        <fault faultType="IllegalStateWSFaultException">
            <documentation>Throw this exception when an unknown "soap:Server" side problem occurs.</documentation>
        </fault>
    </operation>
</service>

<service name="AddedNewServiceName">
    <operation name="Operation">
        <documentation></documentation>
        <input type="XXX">
            <documentation></documentation>
        </input>
        <output type="YYY">
            <documentation></documentation>
        </output>
        <fault faultType="IllegalArgumentWSFaultException">
            <documentation>Throw this exception when a "soap:Client" side message problem occurs.</documentation>
        </fault>
        <fault faultType="EntityAlreadyExistsWSFaultException">
            <documentation>Throw this exception when the attempt made to create a object that already exists.</documentation>
        </fault>
        <fault faultType="IllegalStateWSFaultException">
            <documentation>Throw this exception when an unknown "soap:Server" side problem occurs.</documentation>
        </fault>
    </operation>
</service>

... 
```

To add a new operation to a service, add the "operation" element with its child elements.

For example:
```
<service name="service">
    <service name="ServiceName">
        <operation name="NewAddedOperation">
```

Oracle Retail Service-Oriented Architecture Enabler Tool Guide
Managing the Service Definition Library XML File

<documentation></documentation>
<input type="XXX">
  <documentation></documentation>
</input>
<output type="YYY">
  <documentation></documentation>
</output>
<fault faultType="IllegalArgumentWSFaultException">
  <documentation>Throw this exception when a "soap:Client" side message problem occurs.</documentation>
</fault>
<fault faultType="EntityAlreadyExistsWSFaultException">
  <documentation>Throw this exception when the attempt made to create a object that already exists.</documentation>
</fault>
<fault faultType="IllegalStateWSFaultException">
  <documentation>Throw this exception when an unknown "soap:Server" side problem occurs.</documentation>
</fault>
</operation>
<operation name="ExistingOperation">
  <documentation></documentation>
  <input type="XXX">
    <documentation></documentation>
  </input>
  <output type="YYY">
    <documentation></documentation>
  </output>
  <fault faultType="IllegalArgumentWSFaultException">
    <documentation>Throw this exception when a "soap:Client" side message problem occurs.</documentation>
  </fault>
  <fault faultType="EntityAlreadyExistsWSFaultException">
    <documentation>Throw this exception when the attempt made to create a object that already exists.</documentation>
  </fault>
  <fault faultType="IllegalStateWSFaultException">
    <documentation>Throw this exception when an unknown "soap:Server" side problem occurs.</documentation>
  </fault>
</operation>
</service>

Deleting a Service or Deleting Operations from the File

To delete a service from the library, remove the "service" element and all its child elements from the library.

To delete an operation from the service, delete the "operation" element and all its child elements.
Defining New Exceptions to the Operations

Users can define a new exception in the service definition library. The RSE tool creates the artifacts with this new exception.

For example:

```xml
<operation name="ExistingOperation">
  <documentation></documentation>
  <input type="XXX">
    <documentation></documentation>
  </input>
  <output type="YYY">
    <documentation></documentation>
  </output>
  <fault faultType="IllegalArgumentWSFaultException">
    <documentation>Throw this exception when a "soap:Client" side message problem occurs.</documentation>
  </fault>
  <fault faultType="EntityAlreadyExistsWSFaultException">
    <documentation>Throw this exception when the attempt made to create a object that already exists.</documentation>
  </fault>
  <fault faultType="IllegalStateWSFaultException">
    <documentation>Throw this exception when an unknown "soap:Server" side problem occurs.</documentation>
  </fault>
  <fault faultType="UserDefinedException">
    <documentation>This is user defined exception for a particular scenerio.</documentation>
  </fault>
</operation>
```

Using Different Versions of Objects as Input/Output to an Operation

The version difference between objects does not impact the RSE tool, as long as the objects adhere to standards.
This chapter includes standards and conventions for Web service naming and versioning.

Web Service Naming

The following standards and conventions apply to the naming of Web Services.

**The Web service name should be a business noun, concept or process.**

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommendation</td>
<td>The Web service name should be a business noun, a business concept, or a business process.</td>
</tr>
<tr>
<td>Rationale</td>
<td>To be in alignment with other Web service standards.</td>
</tr>
<tr>
<td>Example</td>
<td>Supplier Service</td>
</tr>
</tbody>
</table>

**Avoid verbs when naming Web services.**

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommendation</td>
<td>The Web service name should be a business noun, a business concept, or a business process.</td>
</tr>
<tr>
<td>Rationale</td>
<td>Verbs generally are at the operation level, not at the service level.</td>
</tr>
<tr>
<td>Example</td>
<td>Avoid names such as CreateSupplierService.</td>
</tr>
</tbody>
</table>

**The first 30 characters of the Web service name must be unique.**

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommendation</td>
<td>The first 30 characters of the Web service name must be unique.</td>
</tr>
<tr>
<td>Rationale</td>
<td>Some systems truncate names at 30 characters.</td>
</tr>
<tr>
<td>Example</td>
<td>N/A</td>
</tr>
</tbody>
</table>
The integration/services qualifier should be in the namespace.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommendation</td>
<td>The integration/services qualifier should be in the namespace.</td>
</tr>
<tr>
<td>Rationale</td>
<td></td>
</tr>
<tr>
<td>Example</td>
<td><a href="http://www.oracle.com/retail/rms/integration/services/PayTerm">http://www.oracle.com/retail/rms/integration/services/PayTerm</a> Service.</td>
</tr>
</tbody>
</table>

The Web service namespace should contain the application short name.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommendation</td>
<td>The Web service namespace should contain the application short name.</td>
</tr>
<tr>
<td>Rationale</td>
<td>Multiple applications may publish services with similar names. To categorize and identify which application is hosting what service, the service namespace should contain the application short name.</td>
</tr>
<tr>
<td>Example</td>
<td><a href="http://www.oracle.com/retail/rms/integration/services/PayTerm">http://www.oracle.com/retail/rms/integration/services/PayTerm</a> Service.</td>
</tr>
</tbody>
</table>

The Web service type should be document/literal wrapped.

```
<soap:binding
  transport="http://schemas.xmlsoap.org/soap/http"
  style="document"/>
<operation name="createPayTermBO">
  <ns21:PolicyReference
    xmlns:ns21="http://www.w3.org/ns/ws-policy"
    URI="#PayTermServicePortBinding_createPayTermBO_WSAT_Policy"/>
  <soap:operation soapAction=""/>
  <input>
    <soap:body use="literal"/>
  </input>
```

The Web service must comply with Web Service Basic Profile 1.1.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommendation</td>
<td>The Web service must comply with Web Service Basic Profile 1.1.</td>
</tr>
<tr>
<td>Rationale</td>
<td>The specification is called the WS-I Basic Profile 1.1. It consists of a set of non-proprietary Web services specifications, clarifications, refinements, interpretations, and amplifications of those specifications which promote interoperability.</td>
</tr>
<tr>
<td>Example</td>
<td>N/A</td>
</tr>
</tbody>
</table>
The Web service operation naming pattern should be 
verb<TopLevelComplexType>(TopLevelComplexType variable).

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommendation</td>
<td>The operation name pattern should be either of the following:</td>
</tr>
<tr>
<td></td>
<td>- verb&lt;TopLevelComplexType&gt;(TopLevelComplexType variable)</td>
</tr>
<tr>
<td></td>
<td>- verb&lt;NonTopLevelComplexType&gt;Using&lt;TopLevelComplexType&gt;(TopLevelComplexType variable).</td>
</tr>
<tr>
<td>Rationale</td>
<td>The operation name should reflect the Top Level Complex Type of the service’s primary entity object to ensure the name is unambiguous.</td>
</tr>
<tr>
<td>Example</td>
<td>createItemListBO</td>
</tr>
</tbody>
</table>

**Web Service Versioning**

Service versioning is in the namespace, including the application and the version identifier.

**The service namespace is versioned.**

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommendation</td>
<td>The WSDL for the RBS will have the namespace versioned.</td>
</tr>
<tr>
<td>Rationale</td>
<td>For breaking changes only, the WSDL for the RBS will have the namespace versioned.</td>
</tr>
<tr>
<td></td>
<td><a href="http://www.oracle.com/retail/">http://www.oracle.com/retail/</a>&lt;retail app&gt;/integration/services/&lt;service name&gt;/V&lt;incremental change number&gt;</td>
</tr>
<tr>
<td>Example</td>
<td><a href="http://www.oracle.com/retail/rms/integration/services/PayTerm">http://www.oracle.com/retail/rms/integration/services/PayTerm</a> Service/V2</td>
</tr>
</tbody>
</table>
Creating the Java EE Implementation Jar

Creating Web services with different implementations is a three-step process, as described below.

**Note:** For creating an implementation class, interface classes are required.

### Step 1: Generate Web Services with Default Implementation

Generate the Web services with the default implementation as follows:

1. Provide the Service Definition Library XML file and click **Generate Stub** to create a zip file.

2. The zip file contains a jar file with the interface classes for the Web services. The name pattern of the jar file is `<appName>-service-ejb.jar`.

   For example, if the application name in ServiceDef is rms, the jar file name is `rms-service-ejb.jar`.

   The jar file also contains a properties file named `ServiceProviderImplLookupFactory.properties`. This file contains the name of the Web service interface and the class implementing the Web service.

### Step 2: Implement Interfaces

Implement the interfaces and create the implementation classes. The classes can be packaged in a jar file. Upload the jar file while creating the final ear file.

### Step 3: Upload the jar

When using the Service Implementation Jar File option to upload the jar containing the implementations, the default service implementation jar is not included in the .ear file. Rather, the jar file provided by the user is included. When the Web service is invoked, the service implementation provided by the user is invoked.
Step 3: Upload the jar
This chapter provides a set of implementation notes that may be helpful when implementing the Oracle Retail Service-Oriented Architecture Enabler (RSE) tool. The information included here is intended to provide guidance on the following topics:

- PL/SQL Service Consumer
- PL/SQL Provider Service
- Java EE Web Service Consumer
- Java EE Service Provider
- Web Service Call as a Remote EJB Call
- Web Service Call as a POJO Call
- Deploying the Web Service
- Creating a JDBC Data Source

**Important Note About this Chapter**

The implementation notes in this chapter are intended to provide some guidance in the development and deployment of the Web service layer. This information does not take into account the implementation of the business logic required to complete the application API layer.

The RSE tool and approaches described in this section are complex. A high level of skill and knowledge of the product is required to complete these implementation tasks. Also required is technology specific development of application APIs and the business logic that is needed to complete it.

Any issues that may arise with development tools, development environments, custom APIs, or custom message flows are the responsibility of the customer and not Oracle Retail.
PL/SQL Service Consumer Implementation Notes

To set up the Web service consumer side proxies, complete the following steps:

1. `loadjava -u <username>/<password>@<host>:<port>:<SID> -r -v -f -genmissing dbwsclientws.jar dbwsclientdb102.jar`

   **Note:** "loadjava" is a utility available in Oracle Database.

2. Edit and run `_grant.sql` script as sysdba to give the user proper permission.

3. `loadjava -u <username>/<password>@<host>:<port>:<SID> -r -v -f -genmissing *Consumer.jar`

   **Note:** If the jar already is loaded, drop the jar. If you get ORA-29533 while dropping the jar, drop the individual files.
   
   For example: `dropjava -u <username>/<password>@<host>:<port>:<SID> packageName/SourceName`

4. Run the *Consumer_create.sql* in the schema that will use this API. The schema owner is user granted permission in Step 2.

5. Write a PL/SQL procedure to work as the client to call the Web service. A sample is provided below:

   **Note:** The following sample code is written for the PayTerm Web service. Replace the service endpoint URL and the consumer class name according to the Web service for which the client is generated.

   ```sql
   create or replace PROCEDURE wstestClient IS
   BEGIN
   PayTermServiceConsumer.setEndpoint('http://10.141.26.93:7001/PayTermBean/PayTermService');
   dbms_output.PUT_LINE(PayTermServiceConsumer.getEndPoint());
   dbms_output.PUT_LINE(PayTermServiceConsumer.ping('TestMessage'));
   dbms_output.PUT_LINE('Done.');
   END;
   ```
PL/SQL Provider Service Implementation Notes

The distribution (.zip) file includes an .ear file that contains all the generated code for the service; it is ready to deploy to the application server. The business logic can be implemented in PL/SQL packages in Oracle. The distribution contains the "spec" and body scripts for the packages called by the deployed service.

To complete implementation, follow these steps:

1. Create the PL/SQL service provider distribution file using the RSE tool. The output of this process is the .zip file.

   **Note:** See the section, "Important Note About this Chapter".

2. Extract the <service_name>.ProviderImplSpec.sql and <service_name>ProviderImplBody.sql files from the distribution zip file.

3. These files will be modified to provide a PL/SQL implementation for the service.

4. Extract the <service_name>-service.ear file from the distribution zip file. This file is the generated Web service that will be deployed.

5. Create the JDBC data source.

   **Note:** See "Creating a JDBC Data Source".

6. If not already deployed, deploy the Oracle Objects to the appropriate database user.

   **Note:** See the Oracle Retail Functional Artifact Generator Guide.

7. Modify the PL/SQL body file for the business logic implementation. The <service_name>ProviderImplBody.sql file contains comments about where to implement logic for each method on the service.

8. Install the modified PL/SQL packages to the database. They will be called by the Web service methods.

9. Deploy the <service_name>.ear file to the Oracle WebLogic Server.
Java EE Service Consumer Implementation Notes

The Java Web service consumer artifacts generated by this tool are based on the JAX-WS 2.1 specification. Services can be invoked in synchronous and asynchronous mode by using these artifacts.

To complete implementation, follow these steps:

1. Create a Web service client.
2. Create the application that uses the [WebserviceName]ServiceConsumer.jar and code the your Web service client. The [WebserviceName]ServiceConsumer.jar contains all necessary code to invoke the [WebserviceName]Service WebService.
3. Additional JAX-WS library jars might be required.
4. Deploy the service in the server.
5. Invoke the Web service client to see the results.

Sample Client Code

The code below is an example of how to invoke Oracle Retail's PayTerm Web service. For each Web service, a specific WebServiceConsumer code/jar must be generated that can "talk to" the service.

```java
import java.math.BigDecimal;
import java.net.URL;
import javax.xml.namespace.QName;
import com.oracle.retail.integration.base.bo.paytermdesc.v1.PayTermDesc;
import com.oracle.retail.integration.base.bo.paytermref.v1.PayTermRef;
import com.oracle.retail.rms.integration.services.paytermservice.v1.PayTermPortType;
import com.oracle.retail.rms.integration.services.paytermservice.v1.PayTermService;
import junit.framework.TestCase;

public class PayTermTest extends TestCase{
    public void testCreatePayTerm(){
        try{
            //qname is the namespace of the web service
            QName qName = new QName("http://www.oracle.com/retail/rms/integration/services/PayTermService/v1","PayTermService");

            //wsdlLocation is the URL of the WSDL of the web service
            URL wsdlLocation = new URL("http://10.141.26.93:7001/PayTermBean/PayTermService?WSDL");
        }
    }
}
```

Note: See the section, "Important Note About this Chapter".

Note: The following sample code is for invoking the PayTerm Web service. When you generate Java consumer for a Web service, the generated jar file will contain classes specific to that Web service. Use the appropriate classes in the client code. Service namespace and WSDL location also should be changed accordingly.

```
import java.math.BigDecimal;
import java.net.URL;
import javax.xml.namespace.QName;
import com.oracle.retail.integration.base.bo.paytermdesc.v1.PayTermDesc;
import com.oracle.retail.integration.base.bo.paytermref.v1.PayTermRef;
import com.oracle.retail.rms.integration.services.paytermservice.v1.PayTermPortType;
import com.oracle.retail.rms.integration.services.paytermservice.v1.PayTermService;
import junit.framework.TestCase;

public class PayTermTest extends TestCase{
    public void testCreatePayTerm(){
        try{
            //qname is the namespace of the web service
            QName qName = new QName("http://www.oracle.com/retail/rms/integration/services/PayTermService/v1","PayTermService");

            //wsdlLocation is the URL of the WSDL of the web service
            URL wsdlLocation = new URL("http://10.141.26.93:7001/PayTermBean/PayTermService?WSDL");
        }
    }
}
```
//get the web service instance
PayTermService service = new PayTermService(wsdlLocation, qName);
PayTermPortType port = service.getPayTermPort();

//populate input object for the web service method
PayTermDesc desc = new PayTermDesc();
desc.setTerms("terms");
desc.setDiscdays("1");
desc.setDueDays("1");
desc.setFlagEnabled("t");
desc.setPercent(new BigDecimal("1"));
desc.setRank("1");
desc.setTermsCode("code");
desc.setTermsDesc("desc");
desc.setTermsXrefKey("key");

//call the web service method. here ref is the response object of the web service.
PayTermRef ref = port.createPayTermDesc(desc);

} catch (Exception e) {
    e.printStackTrace();
}
}

Java EE Service Provider Implementation Notes

The RSE tool creates the appropriate provider Web service end-points as well as a skeleton implementation layer where the developer implements business logic. All of this is packaged inside the provider distribution archive file.

The Java EE Provider distribution file provides a sample deployable application and all the libraries that can be used to create Web services using retail payloads. The distribution file follows the naming convention of <appname>_JavaEEServiceProvider.zip. For example, the distribution file for the RMS application is named rms_JavaEEServiceProvider.zip. The <rms> prefix must be replaced with the name of any other application being developed.

The Web services generated by the RSE tool can be implemented and deployed in a number of ways. This section includes three implementation use cases for reference.

---

Note: See the section, "Important Note About this Chapter".

---

Use Case 1: Complete the Generator Provided Stub Code Implementation

1. Generate the distribution file using the RSE tool.
2. Extract the <service_name>-ejb-impl-src.jar file from the zip file.
3. Extract the <service_name>-service.ear file from the zip file.
4. Add business logic code where indicated in the Impl java files.
5. Use the java jar command to re-build the <service_name>-service-ejb-impl.jar file.
6. Use the jar command to update .ear file with the new implementation jar.
7. Deploy the .ear file to the server.
Use Case 2: Provide a Custom impl jar to the RSE Tool

1. Create custom java classes that implement the `<service_name>ServiceProvider` interfaces contained in the `<service_name>-service-ejb.jar` file.
2. Extract the `ServiceProviderImplLookupFactory.properties` file from the `.ear` file.
3. Modify the properties file to point to your implementation classes for the services.
4. Use the jar command to create a jar containing your implementation classes, as well as the modified properties file.
5. Run the RSE tool again and provide the new custom implementation jar file.
6. Extract and deploy the generated `.ear` file to the server.

Use Case 3: Package the Generated Service Classes in an Existing Application

1. Generate the distribution file using the RSE tool.
2. The service interfaces are provided in the `<appname>-service-ejb.jar` file in the distribution file. This jar file should be included in the application classpath.
3. Source code of sample implementations for the service interfaces are provided in the `<appname>-service-ejb-src.jar` file in the distribution file. (If application developers want to use the same classes in their application, they can extract the java files from the jar file and include those in application source code. They also can add their own business logic in the method implementations. If they decide to write their own implementations, they should make sure that the appropriate service interfaces are implemented.)
4. After writing the Web service implementations, the java files should be compiled. The class files can be included in a new jar file or in the same jar file used for the rest of the classes of the application.
5. Modify the `ServiceProviderImplLookupFactory.properties` file to include appropriate class names of service implementations and include it in application classpath. A recommended approach is to include the properties file in the jar file that contains the service implementation classes.
6. Make sure that the following jar files are included in the application ear file:
   - `<appname>-service-ejb.jar`
   - Jar file containing the service implementation classes
   - `jxb-api.jar`
   - `retail-public-payload-java-beans-base.jar`
   - `retail-public-payload-java-beans.jar`
   - `retail-soa-enabler.jar`
7. Include an `ejb-module` in the `application.xml` of the application. The module name should be same as the name of `<appname>-service-ejb.jar` file.
8. The `.ear` file is ready for deployment on the server.
Web Service Call as a Remote EJB Call

This section applies to PL/SQL Web service implementations and Java EE Web service implementations.

A client can call a Web service as a remote EJB call to improve performance by avoiding marshalling and unmarshalling.

---

**Note:** See the section, "Important Note About this Chapter".

---

Prerequisites

1. Get the updated wlfullclient.jar (integration-lib\third-party\oracle\wl\10.3\) & retail-soa-enabler.jar (integration-lib\internal-build\rse\) from the Repository.
2. Run build.xml for retail-soa-enabler.
3. Generate the .ear and deploy it to server.
4. Configure the data source in the server.

Procedure

1. Create a Java file containing the code below inside any package. (See code sample at the end of this section.)
2. Include the following jar files in the classpath:
   - retail-public-payload-java-beans-base.jar
   - retail-public-payload-java-beans.jar
   - oo-jaxb-bo-converter.jar
   - retail-soa-enabler.jar
   - `<appname>-service-ejb.jar`
3. Run code as a Java application.

---

**Note:** The sample code below obtains a context for accessing the WebLogic naming service and calls a lookup method to get the Object inside the container by providing a binding name. It then calls a corresponding Web service method. As an example, the code sample calls the PayTerm service.

```java
import java.util.Properties;
import javax.naming.Context;
import javax.naming.InitialContext;
import javax.naming.NamingException;
import com.oracle.retail.integration.base.bo.paytermdesc.v1.PayTermDesc;
import com.oracle.retail.integration.base.bo.paytermref.v1.PayTermRef;
import com.oracle.retail.integration.services.exception.v1.EntityNotFoundWSFaultException;
import com.oracle.retail.integration.services.exception.v1.IllegalArgumentExceptionWSFaultException;
import com.oracle.retail.integration.services.exception.v1.IllegalStateExceptionWSFaultException;
```
import com.oracle.retail.rms.integration.services.paytermservice.v1.PayTermRemote;

public class WebLogicEjbClient {

        public static void main(String[] args) throws NamingException,
            IllegalArgumentWSFaultException, EntityNotFoundWSFaultException,
            IllegalStateWSFaultException {

            Context ctx = getInitialContext("t3://localhost:7001",
            "weblogic","weblogic");
            Object ref = ctx .lookup("PayTerm#com.oracle.retail.rms.integration.services.
            paytermservice.v1.PayTermRemote");

            PayTermRemote remote = (PayTermRemote)(ref);
            PayTermRef ref = new PayTermRef();
            PayTermDesc desc = remote.findPayTermDesc(ref);

            System.out.println("findPayTermDesc=" + desc);
        }

        static Context getInitialContext(String url, String user, String password)
        throws NamingException {
            Properties h = new Properties();
            h.put(Context.INITIAL_CONTEXT_FACTORY,
            "weblogic.jndi.WLInitialContextFactory");
            h.put(Context.PROVIDER_URL, url);
            h.put(Context.SECURITY_PRINCIPAL, user);
            h.put(Context.SECURITY_CREDENTIALS, password);
            return new InitialContext(h);
        }
    }

**Code Description**

**Code sample 1:**

Context ctx = getInitialContext("t3://localhost:7001", "weblogic","weblogic");

Description: Gets Initial Context object by passing the URL (local WebLogic URL, if
not configured to other), user name, and password of the server.

**Code sample 2:**

Object ref = ctx .lookup("PayTerm#com.oracle.retail.rms.integration.services.
paytermservice.v1.PayTermRemote");

Description: Lookup method retrieves the name of Object. Throws naming exception if
the binding name is missing from the server. Binding name can be found after
deploying the .ear file to the server, at JNDI Tree Page. (Summary of Servers
>examplesServer>view JNDI Tree)
Web Service Call as a POJO Call

This section applies to PL/SQL Web service implementations and Java EE Web service implementations.

If an application is a core Java application, it can still call the Web services classes, but as POJO classes. In this case, the Web service classes act as simple Java classes, and there is no marshalling of XML involved, nor a remote call as an EJB.

The PL/SQL provider services need a database connection to call PL/SQL packages. In the case of a Web service call or an EJB call, the service gets the connection from the data source supplied by the Java EE container through resource injection. But in the case of a Java application, the data source is not available through this mechanism. The connection must be passed to the Web service class before invoking any business methods on it. To achieve this, the caller application must create an instance of the Web service class using the non-default constructor available in the service bean class. An example of the signature of the constructor is below:

```java
public PayTermBean(Connection conn, Map<String, String> serviceContext)
```

**Note:** The bean class is available in the `<appname>-service-ejb.jar` for each Web service generated. For example, if the service name is PayTerm in the service definition XML, the name of the generated bean class will be PayTermBean. This is the class that should be used to call a Web service as a POJO.

In the constructor shown above, the first parameter is for database connection. The second parameter is for the calling application to provide any additional parameters to the bean passed on to the PL/SQL package. When the bean is called as a Web service, an instance of ServiceOpContext class is created by using properties available from an instance of javax.xml.ws.WebServiceContext, available through resource injection. When the bean is called as EJB, then an instance of ServiceOpContext is created from the values in an instance of javax.ejb.EJBContext, available through resource injection. But when the bean is called as a POJO, none of these objects is available. Therefore, a map has been added in the constructor so that the calling application can set the required values. If a null object is passed to the constructor for the map, an empty instance of ServiceOpContext is created. If the map contains a key named "user," a Principal object is created with the value of that key, and it is set in the ServiceOpContext object.
Procedure

**Note:** See the section, "Important Note About this Chapter".

1. Generate the .ear file for Web services and extract the following jar files from it:
   - retail-public-payload-java-beans-base.jar
   - retail-public-payload-java-beans.jar
   - oo-jaxb-bo-converter.jar
   - retail-soa-enabler.jar
   - `<appname>-service-ejb.jar`

2. Include these jar files in the classpath of the Java application that is going to invoke the beans as POJO classes.

3. Write the code to call the bean classes. (Sample code is provided below in this section.)

4. Run the calling class.

**Note:** The connection must be committed or rolled back by the calling application. Because there is no Java EE container available in this case, the bean cannot start and end a transaction. Therefore, it is the responsibility of the calling application to manage the transaction and the connection. In the following sample code, the calling class is committing the connection in case of a successful response from the bean, and it is rolling back the connection in case of any exception thrown by the Web service. The calling application determines how it wants to handle exceptions.

Sample Code for POJO Invocation

```java
public class PayTermService extends TestCase{

    public void testPayTerm(){
        Connection conn = null;
        try{
            //get the database connection
            Class.forName("oracle.jdbc.OracleDriver");
            conn = DriverManager.getConnection("jdbc:oracle:thin:@localhost:1521:orcl","stubby","retek");

            //create map for ServiceOpContext
            Map<String, String> ctxMap = new HashMap<String, String>();
            ctxMap.put("user", "user1");

            //instantiate the web service bean class
            PayTermBean bean = new PayTermBean(conn,ctxMap);

            //populate the input object for web service method
            PayTermRef ref = new PayTermRef();
            ref.setTerms("terms");
            ref.setTermsXrefKey("key");
        }
    }
}
```
Deploying the Web Service

This section applies to PL/SQL Web service implementations and Java EE Web service implementations.

**Note:** See the section, "Important Note About this Chapter".

Complete the following steps using the WebLogic Server Administration Console:

1. Navigate to the Deployments page.
2. Click Install.

**Note:** If the service application has already been installed, see "Redeploy the Service Application".

3. The "Locate deployment to install and prepare for deployment" screen is displayed. Follow the instructions to locate the <service-name>.ear file on the WebLogic Server host.

   If rib-home is located on a host other than the Oracle WebLogic Server, select Upload Files. On the "Upload a Deployment to the admin server" screen, use the browse button to locate the <service-name>.ear file in the "Deployment Archive".

4. Select the igs-service.ear.
5. Click Next to move to "Choose targeting style".
6. Select Install this deployment as an application.
7. Click Next to move to "Optional Settings".
8. Click Next to move to "Review your choices and click Finish".
9. Select No, I will review the configuration later.
10. Click Finish to deploy the application.

Redeploy the Service Application

If the <service-name> application has already been deployed, follow these steps:

1. If the <service-name> application is running, select Stop and When Work Completes or Force Stop Now, depending on the environment. The recommended option always is When Work Completes.
2. Select Delete.
3. The Summary of Deployments should now include the igs-service.
4. Return to "Deploying the Web Service".

Verify the Service Application Installation Using the Administration Console

To verify the Service installations using the Oracle WebLogic Administration Console, follow these steps.

   Note: See Oracle WebLogic Server 11g Release 3 (10.3.3) documentation about the Administration console.

1. Navigate to the Deployments screen.
2. Locate the <service-name> on the Summary of Deployments screen.
3. Click the + next to the ig-service to expand the tree.
4. Locate the Web services section.
5. Click any Web service to move to a Settings for <service name> Service screen.
6. Click the Testing tab.
7. Click the + next to the service name to expand the tree.
8. Click the Test Client link to move to the "WebLogic Test Client" screen.
9. Select Ping Operation.
10. The test page will show the request message and the response message.
Creating a JDBC Data Source

This section applies to PL/SQL Web service implementations and to Java EE Web service implementations.

To create a JDBC Data Source, follow these steps:

1. Log in to the WebLogic administration console. Use the URL, http://<host>:<listen port>/console/login/LoginForm.jsp.
2. Navigate the domain structure tree to Services/JDBC/Data Sources.
3. Click New to start creating the new Data Source. Enter the required information:
   - Name: Enter any name for the data source.
   - JNDI name: This field must be set to "jdbc/RetailWebServiceDs". The generated code for the service will use this JNDI name to look up the data source.
4. Select the transaction options for your data source and click Next.
5. Enter the database name and user information for the data source. Click Next.
6. The screen includes the connection information for your data source. Click Test Configuration to ensure the connection information is correct. If it is correct, the following message is displayed: "Connect test succeeded."
7. Click Next and select a server to deploy the data source to. This is not necessary at this point if you want to deploy the data source to a server at a later time.
8. Click Finish to complete the data source setup. The new data source is displayed on the data sources screen.
9. Click the new data source to view the properties. A default connection pool is created for the data source. Click the Connection Pool tab to view the connection pool properties.
10. The generated JDBC connection URL for the data source is displayed. The Oracle URL is formatted as follows: jdbc:oracle:thin:@<hostname>:<port>:<sid>.
    For example: jdbc:oracle:thin:@localhost:1521:orc
11. If the database is a RAC database, the URL should be in the following format
    jdbc:oracle:thin:@(DESCRIPTION = {ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCP)(HOST = <host>))(PORT = <port>))}(ADDRESS = (PROTOCOL = TCP)(HOST = <host>))(PORT = <port>))(LOAD_BALANCE = yes})(CONNECT_DATA = {SERVICE_NAME = <sid>})
    For example:
    jdbc:oracle:thin:@(DESCRIPTION = {ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCP)(HOST = mspvip72)(PORT = 1521))}(ADDRESS = (PROTOCOL = TCP)(HOST = mspvip73)(PORT = 1521))(LOAD_BALANCE = yes})(CONNECT_DATA = {SERVICE_NAME = dvolr02})
12. Restart the WebLogic instance to apply the data source changes.
Web services can be secured in many ways. The ws-policy tab of Web service in the WebLogic admin console lists the various policy files that can be used to secure Web services. This chapter describes the following methods for securing Web services.

- Simple user name and password authentication
- Password encryption using certificates

Server-Side Setup

This section describes the two-step process required for securing Web services on the server side. These steps are performed using the Oracle WebLogic Servers Administration Console.

Attach Policy File to the Web Service

The usernametoken.xml contains the policy used by the Web Service and is found in the META-INF/policies folder in the .ear file. Complete the following steps to attach the policy file to a Web service:
1. In the Summary of Deployments screen, click the application. In the illustration below, the application is "rms-service."
2. An overview page is displayed, including a list of modules and components installed as part of the application.

3. In the list of Web services, click the one for which you want to enable security. The following screen is displayed, providing an overview of the Web service.
4. On this screen, click the **Configuration** tab. Click the **WS-Policy** tab. The Web service port is shown under Service Endpoints and Operations:
5. Click the + next to the port name. The Web service operations are displayed:

6. You can secure all the Web service operations or select only the operations you want to secure. Click the name of the port. On the Configure a Web Service policy screen, you can attach the policy file to the Web service:
7. From the Available Endpoint Policies list, select policy:usenametoken.xml. Click the right arrow to move it to the drop down list below Chosen Endpoint Policies. Click OK. The Save Deployment Plan Assistant screen is displayed:

8. At the bottom of the Save Deployment Plan Assistant screen, click OK. The following screen is displayed, including status messages near the top:
9. On the Web Service page, under the Testing tab, click the WSDL to view the details of the policy just added to the Web service. The WSDL will contain information similar to the following:

```xml
<?xml version='1.0' encoding='UTF-8'?>
<definitions
xmlns:wssutil="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecuri
ty-utility-1.0.xsd" xmlns:wsp="http://schemas.xmlsoap.org/ws/2004/09/policy"
xmlns:wsaw="http://www.w3.org/2006/05/addressing/soap/"
xmlns:tns="http://www.oracle.com/retail/rms/integration/services/PayTermService/v1" xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns="http://schemas.xmlsoap.org/wsdl/"
targetNamespace="http://www.oracle.com/retail/rms/integration/services/PayTermService/v1" name="PayTermService">
<wsp:UsingPolicy wssutil:Required="true" />
<wsp:Policy>
<ns1:SupportingTokens
xmlns:ns1="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200512">
<ns1:UsernameToken
ns1:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200512/Includ
eToken/AlwaysToRecipient" />
<wsp:Policy>
<ns1:WssUsernameToken10 />
</wsp:Policy>
</ns1:UsernameToken>
</wsp:Policy>
</ns1:SupportingTokens>
</wsp:Policy>
```
Create Roles and Users

This section describes how to add roles and users who can access the Web services.

**Note:** To associate roles and users with Web services, make sure the .ear file containing the Web services has been deployed with the option, “Custom Roles and Policies.” This option is available from the Optional Settings page during the deployment of the .ear file.

1. Within the Oracle WebLogic Services Administration Console, click the **Security Realms** link in the Domain Structure window:

   ![Security Realms](image1)

2. The Summary of Security Realms screen is displayed, including the name of the default realm:

   ![Summary of Security Realms](image2)
3. Click the name of the default realm. The settings for the realm are displayed.

4. On the Settings screen, click the **Users and Groups** tab.

5. In the Users and Groups tab, click the **Users** tab. At the bottom of the Users tab, click **New**. The Create a New User screen is displayed.

6. In the Create a New User screen, enter a user name/password. Leave the default value for Provider. Click **OK** to save the information. The new user is added to the list of users.

Note: Adding roles can be done from the Roles and Policies tab of the security realm or through the Security tab of the Web service. The following instructions are for creating a role through the Security tab of the Web service.

7. Navigate to the Security tab of the Web service. Click the **Roles** tab.

8. In the Roles tab, click **New**. The Create a Web Service Module Role screen is displayed.
9. In the Create a Web Service Module Role screen, enter the role name in the Name field (for example, rmsrole). Leave the default value in the Provider Name field. Click OK. The new role is displayed in the Role tab of the Web service.
To add the user to the role, click the name of the new role in the Roles tab. The Edit Web Service Module Scoped Roles screen is displayed.
11. In the Edit Web Service Module Scoped Roles screen, click **Add Conditions**. The option to Choose a Predicate is displayed.

12. From Predicate List, select User. Click **Next**. An option to Edit Arguments is displayed.
13. In the User Argument Name field, enter the user name created in the security realm. Click **Add**. The name will move down to the box below the **Add** button. Click **Finish**. The following screen is displayed.
14. Click **Save**. The same screen is displayed with this message near the top: "Changes saved successfully."

15. Return to the Security tab of the Web service and click the **Policies** tab.
16. On the Policies tab, click **Add Conditions**. The option to Choose a Predicate is displayed.
17. From Predicate List, select Role. Click **Next**. The option to Edit Arguments is displayed.

18. In the Role Argument Name field, enter the role name created earlier. Click **Add**. The role name will move down to the box below the **Add** button. Click **Finish** to return to the Policy Conditions screen.

19. Click **Save**. The Policy Conditions screen is displayed with a message near the top: "Changes saved successfully."
Client-Side Setup

Web services can be invoked from Java clients as well as PL/SQL clients. This section describes the configuration for invoking a secured Web service from both clients.

Java Client Setup

Client code for calling Web services can be generated using the Java consumer option of the retail-soa-enabler-gui tool. The generated zip file contains all the jar files required for the classpath of the application that calls the Web service. To run the client, follow the steps required to run Java consumer.

The following is sample code for calling a secured Web service.

```java
package com.oracle.retail.rms.client;

import java.net.URL;
import java.util.ArrayList;
import java.util.List;
import java.util.Map;
import javax.xml.namespace.QName;

// Note: The code below is sample code for invoking the PayTerm service. When you generate Java consumer for a Web service, the generated jar file will contain classes specific to that Web service. Use the appropriate classes in the client code. Service namespace and WSDL location also should be changed appropriately.
```
import javax.xml.ws.BindingProvider;
import com.oracle.retail.integration.base.bo.paytermdesc.v1.PayTermDesc;
import com.oracle.retail.integration.base.bo.paytermref.v1.PayTermRef;
import com.oracle.retail.rms.integration.services.paytermservice.v1.PayTermPortType;
import com.oracle.retail.rms.integration.services.paytermservice.v1.PayTermService;
import weblogic.wsee.security.unt.ClientUNTCredentialProvider;
import weblogic.xml.crypto.wss.WSSecurityContext;
import weblogic.xml.crypto.wss.provider.CredentialProvider;
import junit.framework.TestCase;

public class PayTermClient extends TestCase{
    public void testFindPayTerm(){
        try{
            // qName is namespace of the service
            QName qName = new QName("http://www.oracle.com/retail/rms/integration/services/PayTermService/v1","PayTermService");

            // url is the URL of the WSDL of the web service

            // create an instance of the web service
            PayTermService service = new PayTermService(url, qName);
            PayTermPortType port = service.getPayTermPort();

            // set the security credentials in the service context
            List credProviders = new ArrayList();
            CredentialProvider cp = new ClientUNTCredentialProvider("rmsuser","rmsuser1");
            credProviders.add(cp);
            Map<String, Object> rc = ((BindingProvider)port).getRequestContext();
            rc.put(WSSecurityContext.CREDENTIAL_PROVIDER_LIST, credProviders);

            // populate the service method input object
            PayTermRef ref = new PayTermRef();
            ref.setTerms("terms");
            ref.setTermsXrefKey("key");

            // call the web service. here desc is the response object
            PayTermDesc desc = port.findPayTermDesc(ref);

            System.out.println("desc="+desc);
        }catch(Exception e){
            e.printStackTrace();
        }
    }
}
PL/SQL Client Setup

Client code for calling Web services can be generated using the pl/sql consumer option of the retail-soa-enabler-gui tool. The generated zip file contains all the jar files and pl/sql code required to invoke the web service from pl/sql. To run the client, follow the steps required to run pl/sql consumer.

The following is a sample PL/SQL procedure for calling a secured Web service.

```plsql
create or replace
PROCEDURE wstestClient IS
    ref "OBJ_PAYTERMREF" := null;
    objdesc "OBJ_PAYTERMDESC" := null;
    wsm varchar2(100); config varchar2(32000);
BEGIN
    wsm := 'oracle.webservices.dii.interceptor.pipeline.port.config';
    config := '<port-info>
        <runtime enabled="security">
            <security>
                <outbound>
                    <username-token name="" password=""/>
                </outbound>
            </security>
        </runtime>
    </port-info>' ;
    PayTermServiceConsumer.setProperty(wsm, config);
    PayTermServiceConsumer.setEndpoint('http://10.141.22.204:7001/PayTermBean/PayTermService');
    PayTermServiceConsumer.setUsername('rmsuser');
    PayTermServiceConsumer.setPassword('rmsuser2');
    ref := "OBJ_PAYTERMREF"('x','t',null,null,null);
    dbms_output.PUT_LINE(PayTermServiceConsumer.getEndPoint());
    dbms_output.PUT_LINE(PayTermServiceConsumer.ping('TestMessage'));
    objdesc := PayTermServiceConsumer.findPayTermDesc(ref);
    dbms_output.PUT_LINE('Done.');
EXCEPTION
    WHEN OTHERS THEN
        dbms_output.PUT_LINE(SQLCODE);
        dbms_output.PUT_LINE(SQLERRM);
END;
```

Note: The code below is sample code for invoking the PayTerm service. When you generate PL/SQL consumer for a Web service, the generated jar file will contain classes specific to that Web service. Use the appropriate classes in the client code. Service namespace and WSDL location also should be changed appropriately.
Server-Side Setup for Encrypted User Name and Password Token Authentication

There are many predefined policy files provided by WebLogic that can be used for securing Web services. This section describes the process required to secure a Web service where user name and password are encrypted and signed.

The steps to attach the policy file to the Web service are similar to the steps described in the section, Attach Policy File to the Web Service. The only difference is that for the Step 7, policy: Wssp1.2-2007-Wss1.1-UsernameToken-Plain-X509-Basic256.xml, should be selected. The rest of the steps should be followed exactly as they are.

After attaching the policy file, the WSDL of the Web service will include the following content in the header:

```xml
<wsp:UsingPolicy wssutil:Required='true'/>
<wsp:Policy
    wssutil:Id="Wssp1.2-2007-Wss1.0-UsernameToken-Plain-X509-Basic256.xml">
    <ns1:AsymmetricBinding
        xmlns:ns1="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702">
        <wsp:Policy

            <ns1:OnlySignEntireHeadersAndBody/>
        </wsp:Policy>
    </ns1:AsymmetricBinding>
</wsp:Policy>
```
For this policy to work the server has to be able to trust that the key combination used by the client to sign the message is valid. To do this, the client certificate must be signed with a certificate authority that is trusted by the server.

WebLogic instances come with a demo CA. The certificate and key for this are in $WL_HOME/Middleware/wls_server_10.3/server/lib/CertGenCA.der and CertGenCAKey.der. The key does not appear to change between WebLogic installations and is trusted by the default DemoTrust store. For this reason it is very important to never have the DemoTrust store enabled in a production environment. Otherwise, anyone can become trusted fairly easily. Setting up a development environment it is useful.

WebLogic CertGen command can be used to generate keys of the correct length and sign it with the demo CA. A client cert/key pair is required to sign the outgoing message and the server certificate to encrypt the critical portions.

java -classpath $WL_HOME/Middleware/wls_server_10.3/server/lib/weblogic.jar utils.CertGen -certfile ClientCert -keyfile ClientKey -keyfilepass ClientKey -cn rmsuser

This generates the following files. The user name, "rmsuser," should be replaced with the user name, which is same as the user who accesses the Web service:

- ClientCert.der
- ClientCert.pem
- ClientKey.der
- ClientKey.pem

java -classpath $WL_HOME/Middleware/wls_server_10.3/server/lib/weblogic.jar utils.CertGen -certfile ServerCert -keyfile ServerKey -keyfilepass ServerKey -cn rmsuser

This generates the following files. The user name, "rmsuser," should be replaced with the user name, which is same as the user who accesses the Web service:

- ServerCert.der
- ServerCert.pem
- ServerKey.der
- ServerKey.pem
Import these files into key stores using the following commands.

```
java -classpath $WL_HOME/Middleware/wlserver_10.3/server/lib/weblogic.jar
utils.ImportPrivateKey -certfile ClientCert.der -keyfile ClientKey.der
-keyfilepass ClientKey -keystore ClientIdentity.jks -storepass ClientKey -alias
identity -keypass ClientKey

java -classpath $WL_HOME/Middleware/wlserver_10.3/server/lib/weblogic.jar
utils.ImportPrivateKey -certfile ServerCert.der -keyfile ServerKey.der
-keyfilepass ServerKey -keystore ServerIdentity.jks -storepass ServerKey -alias
identity -keypass ServerKey
```

Configure the WebLogic server to use these keys. To configure the server, run the
script from the section, "Reference: configWss.py." Copy the script and save it in the
location from which it will run.

```
Java -classpath $WL_HOME/Middleware/wlserver_10.3/server/lib/weblogic.jar
weblogic.WLST configWss.py <weblogicuser> <weblogicpassword> <weblogichost>
<weblogic admin port> ServerIdentity.jksServerKey identity ServerKey
```

For example:

```
Java -classpath $WL_HOME/Middleware/wlserver_10.3/server/lib/weblogic.jar
weblogic.WLST configWss.py weblogic weblogic1 localhost 7001
/home/wls/ServerIdentity.jks ServerKey identity ServerKey
```

Verify that this command has run properly by looking at the "Web Service Security"
tab on your domain from the WebLogic console. Note that the default_ww
configuration is used for all Web services, unless otherwise indicated.
After the certificate setup for the Web service is finished, create a user in WebLogic with access to the Web service. See Create Roles and Users for information.

After restarting the server, a client can be created to invoke the Web service.

Client Side Setup for Encrypted User Name and Password Token Authentication

The following is sample code for calling a Web service that has been secured using this policy file: policy:Wssp1.2-2007-Wss1.1-UsernameToken-Plain-X509-Basic256.xml

This appendix provides step-by-step instructions for installing the Oracle Retail Service-Oriented Architecture Enabler tool as a Web application in Oracle WebLogic.

**Installation as a Web Application in Oracle WebLogic**

**Deploy the Retail SOA Enabler Application**

Using the WebLogic Server Administration Console, complete the following steps:

1. Navigate to the Deployments page:
2. In the left navigation bar, click Lock & Edit. Click Install.

The Locate deployment to install and prepare for deployment page is displayed. Follow the instructions to locate the retail-soa-enabler-gui.war file.

3. Select Upload Files.

---

**Note:** If the application has already been installed, see the section, "Redeploy the Application."
4. On the Upload a Deployment to the admin server page, use the Browse button to locate the retail-soa-enabler-gui.war file in the Deployment Archive.
5. Select the retail-soa-enabler-gui.war.
6. Click Next and move to “Choose targeting style.”
7. Select "Install this deployment as an application."
8. Select Deployment Target. Click **Next** for Optional Settings.
9. Click **Next** to review your choices. Click **Finish**.

10. Select **No, I will review the configuration later**.
11. Click **Finish** to deploy the application.

12. Click **Activate Changes** to finish the deployment.
13. Select the retail-soa-enabler-gui application. Click Start > Servicing All Requests.
Verify the Retail SOA Enabler Web Application

1. Navigate to the Deployments page.

3. Click retail-soa-enabler-gui to view Settings for the retail-soa-enabler-gui.
4. Select the Testing tab.

5. Click the index.jsp URL in the Test Point.

6. The URL should open to the Retail Service-Oriented Architecture Enabler Home page.
7. The installation is complete. See Chapter 4, "User Interface Usage".
Redeploy the Application

If the retail-soa-enabler-gui application has already been deployed, follow these steps:

1. If the retail-soa-enabler-gui application is running, select Stop and When Work Completes or Force Stop Now, depending on the environment. The recommended option always is When Work Completes.
2. Click Lock & Edit. Click Delete.
3. Click Activate Changes.
4. The retail-soa-enabler-gui should now not show on the "Summary of Deployment" page.
Appendix: Sample ServiceProviderDefLibrary.xml

The sample below can be used as an initial template.

```xml

Appendix: Creating a JDBC Data Source

This section describes the steps required to create a JDBC data source.

Procedure

To create a JDBC data source, complete the following steps.

1. Log in to the WebLogic administration console. Use this URL:
   http://<host>:<listen port>/console/login/LoginForm.jsp.
2. Navigate the domain structure tree to Services/JDBC/Data Sources.
3. Click New to create the new data source. Enter the following required information.
   - Name: Select any name for the data source,
   - JNDI name: This field must be set to jdbc/RetailWebServiceDs. The generated code for the service uses this JNDI name to look up the data source.
4. Select the transaction options for the data source. Click Next.
5. Enter the database name and user information for the data source. Click Next.
6. The connection information for the data source is displayed. Click Test Configuration to ensure the connection information is correct. If the information is correct, the following message is displayed: "Connect test succeeded."
7. Click Next. Select a server to which to deploy the data source. (This step is not required at this point in the procedure if you want to deploy the data source to a server at a later time.)
8. Click Finish to complete the data source setup. The data sources page is displayed, including the new data source.
9. Click the new data source to see the properties page. A default connection pool is created for the data source. Click the Connection Pool tab to view the connection pool properties.
10. The generated JDBC connection URL for the data source is displayed in the following format:
    jdbc:oracle:thin:@<hostname>:<port>:<sid>
    For example:
    jdbc:oracle:thin:@localhost:1521:orc
11. If the database is a RAC database, the URL should be in the following format:

   
   \[ \text{dbc:oracle:thin:@(DESCRIPTION = (ADDRESS_LIST=(ADDRESS = (PROTOCOL = TCP)(HOST = <host>)(PORT = <port>))|(ADDRESS = (PROTOCOL = TCP)(HOST = <host>)(PORT = <port>))|(LOAD_BALANCE = yes))(CONNECT_DATA =(SERVICE_NAME = <sid>)))} \]

   For example:

   \[ \text{jdbc:oracle:thin:@(DESCRIPTION = (ADDRESS_LIST=(ADDRESS = (PROTOCOL = TCP)(HOST = mspvip72)(PORT = 1521))|(ADDRESS = (PROTOCOL = TCP)(HOST = mspvip73)(PORT = 1521))|(LOAD_BALANCE = yes))(CONNECT_DATA =(SERVICE_NAME = dvolr02)))} \]

12. In the Configuration > Connection Pool tab of the data source, set the following properties.

   - Initial capacity: Set the value to 20 connections. This value should be increased or decreased based on the expected load on the server.
   - Maximum capacity: Set the value to 100 connections. This value should be increased or decreased based on the expected load on the server.
   - Capacity Increment: Set the value to 20 connections. This value should be increased or decreased based on the expected load on the server.
   - Inactive Connection Time-out: This property is available in the advanced section of the connection pool configuration. Set the value of this property to 60 seconds.
   - Remove Infected Connections Enabled: This check box must be unchecked.

13. Restart the WebLogic instance to reflect the data source changes.
