About This Reference

This document of gives detailed instructions on the use of the following Sun Java™ System Calendar Server 6 2004Q2 (Calendar Server), formerly Sun™ ONE Calendar Server, APIs and protocol that you may use to customize your server installation:

- Calendar Server Application Program Interface (CSAPI), to modify server functionality.
- Proxy Authentication SDK (authSDK), an external plugin to use a portal authenticaion service.
- Web Calendar Access Protocol (WCAP), to access calendar services.

Topics covered in this chapter include:

- Who Should Read This Book
- What You Need to Know
- How This Book is Organized
- Document Conventions
- Accessing Sun Documentation Online
- Related Third-Party Web Site References

Who Should Read This Book

This guide is for programmers who want to customize applications in order to implement Calendar Server.

What You Need to Know

This book assumes that you are a programmer with a knowledge of C / C++ and that you have a general understanding of the following:

- The Internet and the World Wide Web
- Calendaring concepts
- LDAP
- RFC 2445, RFC 2446, RFC 2447

  These RFCs describe in detail the format and definition for times, strings, parameters, etc. used in WCAP commands, unless otherwise specified.

  The RFC's may be found at the IETF web site:

  - `http://www.ietf.org/rfc/rfc2445.txt`
  - `http://www.ietf.org/rfc/rfc2446.txt`
  - `http://www.ietf.org/rfc/rfc2447.txt`

How This Book is Organized

This book documents three APIs, an SDK, and a protocol inside Calendar Server, as well as containing an overall architecture discussion of the product. For each interface there is an overview chapter, followed by a reference chapter, where available.

A list of the chapters follows:

- About This Reference (this chapter)
- Part 1 Non-WCAP APIs
  - Chapter 1, "Calendar Server API (CSAPI) Overview"

    This API allows programmers to customize server functionality in five areas: access control, authentication, calendar lookup, data format translation, and user attribute access.
  - Chapter 2, "CSAPI Reference"

    This chapter describes the CSAPI interfaces and their methods.There are two types of interfaces: client and server.
  - Chapter 3, "Proxy Authentication SDK Overview"

This chapter discusses one of the three authentication schemes shipped with the server. This API allows you to integrate your portal service with Calendar Server.

- Chapter 4, “Proxy Authentication SDK Reference”

  This chapter describes the five functions that make up the SDK.

- Part 2 WCAP API
  - Chapter 5, “Web Calendar Access Protocol Overview”

    This chapter give an introduction to the WCAP protocol. WCAP is a command based system for transmitting calendar data.

  - Chapter 6, “WCAP Common Topics” on page 73

    Covers topics of common interest that span multiple commands.

  - Chapter 7, “WCAP Command Reference”

    This chapter details the individual commands.

- Glossary

Document Conventions

Monospaced Font

`Monospaced font` is used for any text that appears on the computer screen or text that you should type. It is also used for filenames, distinguished names, functions, and examples.

Italicized Font

Italicized font is used to represent text that you enter using information that is unique to your installation (for example, variables). It is used for server paths and names.

For example, throughout this document you will see path references of the form:

`cal_svr_base/...`

The Calendar Server Base (*cal_svr_base*) represents the directory path in which you install the server. The default value of the *cal_svr_base* is `/opt/SUNWics5/cal`.

Square or Straight Brackets

Square (or straight) brackets [] are used to enclose optional parameters.

Platform-specific Syntax

All paths specified in this manual are in UNIX® format.

Accessing Sun Documentation Online

The following Calendar Server documents are available online in PDF and HTML formats:

- *Sun Java System Calendar Server 6 2004Q2 Release Notes*
- *Sun Java System Calendar Server 6 2004Q2 Administration Guide*
- *Sun Java System Calendar Server 6 2004Q2 Developer's Guide*
- *Sun Java System Communications Services 6 2004Q2 Event Notification Service Guide*
- *Sun Java System Communications Services 6 2004Q2 Schema Reference*
- *Sun Java System Communications Services 6 2004Q2 Schema Migration Guide*
- *Sun Java System Communications Services 6 2004Q2 User Management Utility Administration Guide*
- *Sun Java System Communications Express 6 2004Q2 Administration Guide*
- *Sun Java System Communications Express 6 2004Q2 Customization Guide*

To find this book and all Calendar Server 6 2004Q2 documentation, use the following URL:

`http://docs.sun.com/coll/CalendarServer_4q2`

In addition, both graphical user interfaces, Calendar Express and Communications Express, have online help.

Related Third-Party Web Site References

Third-party URLs are referenced in this document and provide additional, related information.

Sun will not be responsible or liable for any actual or alleged damage or loss caused by or in connection with the use of or reliance on any such content, goods, or services that are available on or through such sites or resources.

Part I

Non-WCAP APIs

Chapter 1, "Calendar Server API (CSAPI) Overview"

Chapter 2, "CSAPI Reference"

Chapter 3, "Proxy Authentication SDK Overview"

Chapter 4, "Proxy Authentication SDK Reference"

Chapter 1

Calendar Server API (CSAPI) Overview

This chapter gives an overview of the Calendar Server API (CSAPI), a set of high performance programmatic interfaces that enables you to modify or enhance the feature set of Sun Java™ System Calendar Server 6 2004Q2 (Calendar Server), formerly Sun™ ONE Calendar Server. CSAPI allows you to create very fast runtime shared objects that outperform both system executables and scripts in any language, with respect to speed, memory footprint, and load. All of these factors contribute to scalability issues in high-end systems.

This chapter has the following sections:

- CSAPI Architecture
  - Thread Safe Requirement
  - Dependencies
- Using CSAPI
  - Loading CSAPI Modules
  - Plug-in Interfaces
  - Client and Server APIs
- CSAPI Samples

CSAPI Architecture

The CSAPI is a group of shared-object runtime interfaces to Calendar Server functions. You can use plug-in CSAPI modules to manipulate server data for incoming requests and for responses. This architecture allows the server to act as a simple gateway to data it knows nothing about. It also allows for dynamic logging and statistics tracking, external authentication schemes, user attribute manipulation, and a variety of other functions.

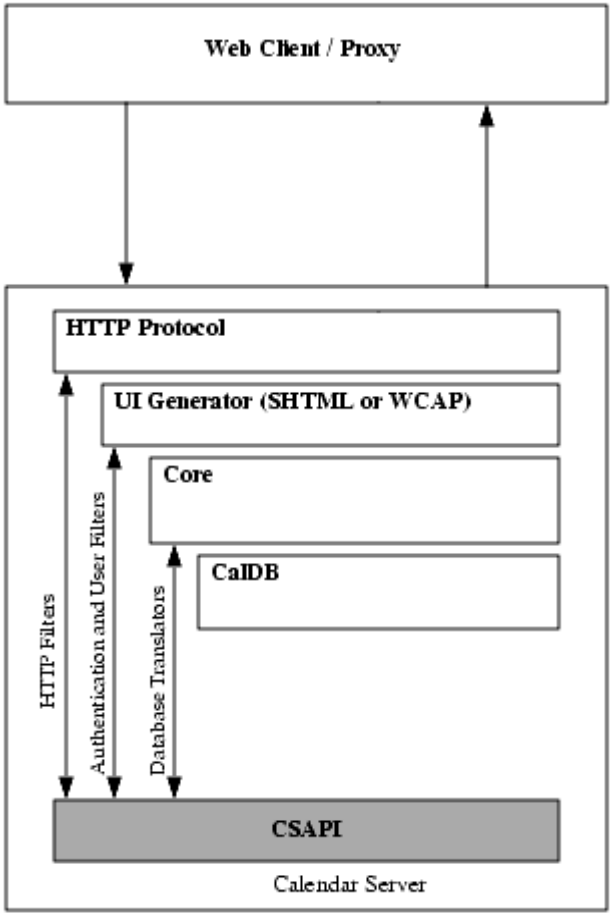
Figure 1-1, which follows, shows the relationship of CSAPI modules to other subsystems within Calendar Server. Depending on which functional group or groups a CSAPI module supports, it can interact with one or more areas of Calendar Server functionality, such as data formatting, authentication, and directory services.

A module is a shared object (`.so` file) on Unix, or dynamic linked library (`.dll` file) on Windows NT. Each module that you provide implements one or more of the CSAPI interfaces (or pure virtual base classes) defined in this document; see Chapter 2, "CSAPI Reference." Each client-side interface addresses a functional area of Calendar Server. The implementation contained in a module can either augment or override the native Calendar Server functionality in its area.

A set of server-side APIs allows CSAPI modules to get the server's version information, and use the server's fast memory allocation mechanism.

The installation contains plug-ins for each of the CSAPI interfaces with the default code, which you can use as templates to create your own plug-ins, along with all supporting libraries and headers.

Figure 1-1 CSAPI Relationship to Other Subsystems



Thread Safe Requirement

CSAPI module plug-ins must be thread safe, as many thousands of threads can access a module at any time. For those plug-ins that cannot be thread-aware, use simple monitors at the function-call level in the plug-in itself. For more information on Netscape™ Portable Runtime (NSPR) threads, refer to the NSPR reference manual at mozilla.org. For the URL, see the "Dependencies" section later in this chapter.

Dependencies

CSAPI is a C and C++ interface for Unix and Windows NT systems. It uses Netscape Portable Runtime (NSPR), a part of the mozilla.org source code that is a platform independent API to operating system services, and XPCOM for Interface Dispatch.

For documentation on NSPR see the Mozilla™ technical documentation site:

`http://www.mozilla.org/projects/nspr/reference/html/index.html`

For documentation on XPCOM, see:

`http://www.mozilla.org/projects/xpcom`

You must use NSPR for platform-independent C data types and runtime functions in implementations that need to run on different platforms. Calendar Server uses the XPCOM C++ API (`QueryInterface`) to discover the exact interfaces a specific module implements.

Using CSAPI

The following section describes how the system loads and uses the plug-ins you provide. Default plug-ins ship with the system. You may choose to augment or override any or all of them.

Loading CSAPI Modules

Calendar Server loads CSAPI modules from the `cal/bin/plugins` directory at startup and unloads them at server shutdown. All plug-in modules must reside in this directory and have filenames that are prefaced with `cs_`.

The server checks `ics.conf` for the modules to be dynamically loaded at server startup. If the value of the preference `csapi.plugin.loadall` is `y`, the server loads all shared objects in the `cal/bin/plugins` directory whose names begin with the prefix `cs_`. Otherwise, if the value is `n`, various preferences exist for the various plug-ins. For more information on the preferences in `ics.conf`, see the *Calendar Server Administration Guide.*

To specify the loading of a specific plug-in, `csapi.plugin.loadall` must be set to `n`. In addition, two preferences must be used: `csapi.plugin.`*`plugin name`*, with a value of `y`, and `csapi.plugin.`*`plugin name`*`.name`, with the value being the name of the plug-in. For example, for the calendar-lookup plug-in, the preferences are:

```
csapi.plugin.loadall = "n"

csapi.plugin.calendarlookup = "n"

csapi.plugin.calendarlookup.name = " "
```

Note that the `plugin name` part of the preference must match on both preferences, but that it does not have to be the same as the value of the `.name` preference. Thus, if you wanted to create a plug-in called `cs_myown_plugin`, you could call the preferences `csapi.plugin.anyname`, and `csapi.plugin.anyname.name`. The value of `csapi.plugin.anyname.name` would be "`cs_myown_plugin`".

Calendar Server uses the NSPR function `PR_LoadLibrary()` to load the shared object at startup, the function `PR_UnloadLibrary` to unload the shared image at shutdown. Once a shared object is loaded into memory, Calendar Server uses the function `PR_FindSymbol` to find entry points to known API implementations.

Plug-in Interfaces

All CSAPI plug-ins support one and only one exported symbol, *NSGetFactory*, as required by the XPCOM specification. From this entry point, Calendar Server calls the XPCOM method `QueryInterface` to find an object implementing the `csIPlugin` interface. This allows the server to query the plug-in for version, description, and vendor information. This interface is optional; however, it is highly recommended that you implement it so the server can ensure version control.

Plug-in Version Numbers

Each default plug-in interface can have a different version number. Version numbers increment by a whole number when the API is updated by Sun Microsystems, Inc. All custom plug-ins must use the methods in the current version of the default plug-in API.

If you created a custom plug-in based on an earlier default plug-in version, you must update your custom plug-in to use the new version of all updated methods, and you must increment its version number to reflect the current version number of the default plug-in.

The system will not load plug-ins with version numbers below the current default version number. Your plug-in must have a version number greater than the current default plug-in, but less than the next whole number. For example, if you are writing, or have created in the past, a custom plug-in for `csIDatabaseLookup`, which is currently at version 2.0, your plug-in version number must be greater than 2.0 and less than 3.0.

Table 1-1 lists the current version of each plug-in API.

Table 1-1 Current Plug-in API Versions

Plug-in API	Current Version of Default Plug-in
csIAccessControl	1.0
csIAuthentication	1.0
csICalendarLookup	2.0
csIDataTranslator	2.0
csIPlugin	1.0
csIQualifiedCalidLookup	1.0
csIUserAttributes	2.0
csICalendarServer	1.0
csIMalloc	1.0

Client and Server APIs

The CSAPIs fall into two categories, client and server APIs.

Table 1-2 lists the CSAPI client interfaces, which may be implemented by one or more plug-ins.

Table 1-2 CSAPI Client APIs

CSAPI Module Interface	Description
csIAccessControl	Augments or overrides the default access control mechanism.
csIAuthentication	Augments or overrides the login authentication mechanism.
csICalendarLookup	Augments or overrides the default calendar lookup mechanism.
csIDataTranslator	Augments or overrides the format translation of incoming and outgoing data.
csIPlugin	Provides version control and descriptive information about the module.
csIQualifiedCalidLookup	Retrieves a calendar ID for the specified qualified URL.
csIUserAttributes	Augments or overrides the mechanism for storing and retrieving user attributes.

The interfaces are described in detail in Chapter 2, “CSAPI Reference.”

All interfaces have the following initialization method that you must implement:

```
Init (nsISupports * aServer);
```

The server invokes this method immediately after it registers the interface in a newly loaded module. In the module, you can bind the parameter that the server returns, `aServer`, and use it to refer to the server instance. Your custom plug-in can use the `QueryInterface` method to find the server interfaces, listed in Table 1-3:

Table 1-3 CSAPI Server APIs

Server Interface	Description
csICalendarServer	Provides general server information, including version number.
csIMalloc	Allows access to server's memory allocation mechanism.

Server Query Example

The following example checks the version of Calendar Server. It demonstrates how to do the following:

- Bind the returned reference from the Init method.
- Query the server for an interface.
- Call a server method in that interface.
- Release the server reference.

```
NS_IMETHODIMP csDataTranslator :: Init(nsISupports * aServer)
{
nsresult res = NS_COMFALSE ;
PRUint32 min, maj;
csICalendarServer * cs;
/* QueryInterface for CalendarServer. If call succeeds, server
increments reference count */
if (aServer)
  res = aServer->QueryInterface(kICalendarServerIID,(void**)&cs);
/* If succeeded in getting reference to server, check version */
if (NS_SUCCEEDED(res)) {
  cs->GetVersion(maj,min);
  if (min > 0 && maj >= 1)
    res = NS_OK;
  else
    res = NS_COMFALSE;
/* Release this reference to the server instance */
```

```
  cs->Release();
  }
return res;
}
```

CSAPI Samples

The distribution includes sample code for three of the CSAPI interfaces in the `csapi/samples` directory. You can use these files as templates in building your own CSAPI modules.

The following sample modules are provided:

Table 1-4 CSAPI Interface Samples

CSAPI Module Sample	Description
`Authentication`	This sample overrides the default login authentication mechanism, using local authentication to validate users. The sample works on Solaris™ and on Window NT: On Solaris, it uses the `pam` library to authenticate against the `local /etc/passwd` file or NIS. On Windows NT, it uses the WIN32 API `LogonUser`, which authenticates against Microsoft clients. In order for this sample to work properly on NT, the administrator must enable the privilege for users to log on via batch jobs. You can do this from within the UserManager Administrative Tool, under the Policies/User Rights section.
`DataTranslator`	This sample overrides the default format translation of incoming and outgoing data. It shows how to convert `icalendar` data into Microsoft Outlook CSV format. CSV format is a simple line-oriented file, where each entry has its own line and properties are separated by commas.
`UserAttributes`	This sample overrides the default mechanism for storing and retrieving user attributes. It shows how to use the Berkeley database to store local user preferences. This code works on all supported platforms. The database is a simple table-driven key/value pair. The key for storing user preferences is a string stored as `$user.$pref`. The key must be unique.

Chapter 2

CSAPI Reference

This section details the nine CSAPI interfaces each of which is an API. The APIs are divided between client and server side.

Use the APIs listed in Table 2-1 and Table 2-2 to augment or override Calendar Server's default behavior:

Table 2-1 Client APIs

csIAccessControl	Augments or overrides the access control mechanism.
csIAuthentication	Augments or overrides the login authentication mechanism.
csICalendarLookup	Augments or overrides the default calendar lookup mechanism.
csIDataTranslator	Augments or overrides the format translation of incoming and outgoing data.
csIPlugin	Provides version control and descriptive information about the module.
csIUserAttributes	Augments or overrides the mechanism for storing and retrieving user attributes.
csIQualifiedCalidLookup	Retrieves a calendar ID for the specified qualified URL.

Table 2-2 Server APIs

csICalendarServer	Provides general server information, including version number.
csIMalloc	Allows access to server's memory allocation mechanism.

csIAccessControl

Implement the methods in this interface to augment or override the default access control behavior of Calendar Server.

Methods

The csIAccessControl interface implements two methods:

CheckAccess	Sets access control criteria for users.
Init	Confirms that the interface was found and registered.

Description

Defines the types of access allowed. You must set the return code to specify whether you are using the default access control or overriding the default.

CheckAccess

Purpose

Sets users' calendar access.

Syntax

```
PRUint32 CheckAccess (char* aUser, char* aCalid, PRInt32 *aAccessRequest,
                      PRInt32 *aAccessAllowed, PRInt32 *aReturnCode) = 0;
```

Parameters

The method has the following five parameters:

aUser	The authenticated user making the request. For anonymous access, pUserID is "anonymous".
aCalid	calid for the calendar being accessed.
aAccessRequest	A set of bit flags representing the requested access type.
aAccessAllowed	Output parameter. A set of bit flags representing the allowed accesses. The method checks only the bits specified in aAccessRequest.
aReturnCode	On return, contains a constant that determines whether the server should continue with the default authentication procedure. One of the following constants: NS_CONTINUE_DEFAULT_PROCESSING NS_OVERRIDE_DEFAULT_PROCESSING

Returns

NS_OK on success. A non-zero error code on failure.

Description

Use this method to request access types for this user. You send in the name of the user in the aUser parameter, and the access types requested in the aAccessRequest parameter (bitmask).The system checks for only those access types specified in the aAccessRequest bitmask. The returned bitmask, aAccessAllowed, represents the user's allowed access for the types you requested.

For anonymous access, the user ID is "anonymous".

ICS_ACCESSTYPE constants (bitmaps) that define available access types are as follows:

Access Types	Bitmaps
ICS_ACCESSTYPE_NONE	0x00000000
ICS_ACCESSTYPE_READCOMPONENT	0x00000001
ICS_ACCESSTYPE_WRITECOMPONENT	0x00000002
ICS_ACCESSTYPE_CREATECOMPONENT	0x00000008
ICS_ACCESSTYPE_DELETECOMPONENT	0x00000010
ICS_ACCESSTYPE_READCALENDAR	0x00000020
ICS_ACCESSTYPE_WRITECALENDAR	0x00000040
ICS_ACCESSTYPE_CREATECALENDAR	0x00000080
ICS_ACCESSTYPE_DELETECALENDAR	0x00000100
ICS_ACCESSTYPE_SCHEDULE	0x00000200
ICS_ACCESSTYPE_FREEBUSY	0x00000400
ICS_ACCESSTYPE_SELF_ADMIN	0x00000800
ICS_ACCESSTYPE_ALL	0xFFFFFFFF

Use this method to specify your own access control procedure. You can augment the native access control mechanism, performing your own processing first, then continuing with the default process, or you can completely replace the native access control mechanism.

Init

Purpose

Confirms that the interface has been registered, and provides a reference to the server.

Syntax

```
PRUint32 Init (nsISupports *a Server) = 0;
```

Parameters

The method has the following parameter:

aServer	On return, this location contains a reference to the server with which the module is registered.

Returns

NS_OK on success. A non-zero error code on failure.

Description

The server calls this method, after finding and registering the interface on module load, to confirm that the operation was successful. You can use the pointer returned in aServer to make calls out to the server.

csIAuthentication

All plug-ins wishing to augment or override the default authentication behavior of the calendar server must implement this interface.

Methods

The csIAuthentication interface implements five methods:

ChangePassword	Change a user's password.
Init	Confirms that the interface was found and registered.
Logon	Logs in a user.
Logout	Logs out a user.
VerifyUserExists	Verify a user's existence.

Description

Allows you to define logon, logoff, verification, and password methods that implement the authentication technique of your choice. You may replace a method and still continue to use the default for the others. Each method uses the return code parameter (`aReturnCode`) to tell the server whether to continue with the default access control process after executing the method. The return code value must be one of the following constants:

`NS_CONTINUE_DEFAULT_PROCESSING`	Indicates that the server is to continue default access control processing.
`NS_OVERRIDE_DEFAULT_PROCESSING`	Indicates that this method overrides the server's native access control mechanism.

ChangePassword

Purpose

Changes the password for the specified user.

Syntax

```
PRUint32 Init (char* aUser, char* aOldPassword, char* aNewPassword, PRInt32
               *aReturnCode) = 0;
```

Parameters

The method has the following four parameters:

`aUser`	The user's name.
`aOldPassword`	The old password.
`aNewPassword`	The new password.
`aReturnCode`	On return, contains a constant that determines whether the server should continue with the default authentication procedure. One of the following constants: • `NS_CONTINUE_DEFAULT_PROCESSING` • `NS_OVERRIDE_DEFAULT_PROCESSING`

Returns

On success, `NS_AUTHENTICATION_CHANGEPASSWORD_SUCCESS`. On failure, `NS_AUTHENTICATION_CHANGEPASSWORD_FAILURE`.

Description

Changes the password of the specified user.

Init

Purpose

Confirms that the interface has been registered, and provides a reference to the server.

Syntax

```
PRUint32 Init (nsISupports *aServer) = 0;
```

Parameters

The method has the following parameter:

aServer	On return, this location contains a reference to the server with which the module is registered.

Returns

NS_OK on success. A non-zero code on failure.

Description

The server calls this method after finding and registering the interface on module load, to confirm that the operation was successful. You can use the pointer returned in aServer to make calls out to the server.

Logon

Purpose

Augment or override the authentication procedure for plain text login.

Syntax

```
PRUint32 Login (char* aUser, char* aPassword, PRInt32 *aReturnCode) = 0;
```

Parameters

The method has the following three parameters:

aUser	The user's login name.
aPassword	The plain text password.

aReturnCode	On return, contains a constant that determines whether the server should continue with the default authentication procedure. One of the following constants: • NS_CONTINUE_DEFAULT_PROCESSING • NS_OVERRIDE_DEFAULT_PROCESSING

Returns

On success, NS_AUTHENTICATION_LOGON_SUCCESS. On failure, NS_AUTHENTICATION_LOGON_FAILURE.

Description

Use this method to specify your own authentication procedure on login to Calendar Server. You can augment the native authentication mechanism, performing your own processing first, then continuing with the default process, or you can completely replace the native authentication mechanism

Logout

Purpose

Logout a user.

Syntax

```
PRUint32 Init (char* aUser,PRInt32 *aReturnCode) = 0;
```

Parameters

The method has the following two parameters:

aUser	The user ID of the user to be logged out.
aReturnCode	On return, contains a constant that determines whether the server should continue with the default authentication procedure. One of the following constants: • NS_CONTINUE_DEFAULT_PROCESSING • NS_OVERRIDE_DEFAULT_PROCESSING

Returns

NS_OK on success. A non-zero error code on failure.

Description

None.

VerifyUserExists

Purpose

Verify that the user ID is in the LDAP directory.

Syntax

```
PRUint32 Init (char* aUser,PRInt32 *aReturnCode) = 0;
```

Parameters

The method has the following two parameters:

`aUser`	The user ID of the user to be logged out.
`aReturnCode`	On return, contains a constant that determines whether the server should continue with the default authentication procedure. One of the following constants: • `NS_CONTINUE_DEFAULT_PROCESSING` • `NS_OVERRIDE_DEFAULT_PROCESSING`

Returns

`NS_OK` on success. A non-zero error code on failure.

Description

None.

csICalendarLookup

Implement the methods in this interface to augment or override the default calendar lookup (LDAP). There are two types of calendar lookup provided in Calendar Server: algorithmic or LDAP. LDAP is the default type. Some of the methods in this plug-in are used only by the LDAP-type lookup.

The table that follows lists the methods for this plug-in, tells which type of lookup it supports: Algorithmic (Alg), or LDAP, and gives a description of the method.

Methods

The csICalendarLookup implements the following methods:

Method	Type	Description
DeleteHostnameForCalid	LDAP only	Removes the host name entry from the calendar lookup database for a specific calendar.
FreeCalid	both Alg and LDAP	Frees a previously allocated, fully qualified calid.
FreeType	both Alg and LDAP	Frees a previously allocated type.
GetHostnameForCalid	LDAP only	Gets the hostname from the calendar lookup database associated with the calendar specified by the calid
Init	both Alg and LDAP	Confirms that the interface was found and registered.
QualifyCalid	both Alg and LDAP	Returns the name of the qualified calid.
QueryType	both Alg and LDAP	Queries the type of plug-in.
SetHostnameForCalid	LDAP only	Sets the host name for a calendar user associated with a calid being created.

Description

Allows you to control calendar lookup by implementing one or more of the methods.

piReturnCode Values

There are four possible return codes for the piReturnCode parameter:

- Cannot connect to LDAP server
- Insufficient privileges to modify LDAP entry
- Invalid credentials to connect to LDAP
- No value for back end host

DeleteHostnameForCalid

Purpose

Removes the hostname in LDAP associated with the specified `calid`.

Syntax

```
PRInt32 GetHostnameForCalid(char* psCalid, PRInt32 *piReturnCode) = 0;
```

Parameters

The following are the parameters and definitions for this method:

`psCalid`	`calid` for which the hostname is requested.
`piReturnCode`	`0`= successful, non-zero indicates failure.

Returns

Returns zero for success; a non-zero code for failure. See piReturnCode Values.

Description

Removes the hostname associated with the specified calendar in the calendar lookup database. This is a no-op for the algorithmic implementation.

FreeCalid

Purpose

Frees a previously allocated, fully qualified calendar ID (`calid`).

Syntax

```
PRUint32 FreeCalid(char** aQualifiedCalid,PRInt32 *aReturnCode) = 0;
```

Parameters

The method has the following parameters:

`aQualifiedCalid`	`calid` to free.
`aReturnCode`	`NS_OK` if successful. Normal processing will not continue if unsuccessful.

Returns

`NS_OK` on success, non-zero error code on failure.

Description
Used by both implementations of lookup.

FreeType

Purpose
Frees a previously allocated database plug-in type.

Syntax
```
PRUint32 FreeType(char* aType,PRInt32 *aReturnCode) = 0;
```

Parameters
The method has the following parameters:

aType	The database plug-in type to free
aReturnCode	NS_OK if successful. Normal processing will not continue if unsuccessful.

Returns
NS_OK on success, non-zero error code on failure.

Description
Frees the string allocated in QueryType method. Used by both implementations.

GetHostnameForCalid

Purpose
Retrieves the hostname associated with the specified calid.

Syntax
```
PRInt32 GetHostnameForCalid(char* psCalid, char** ppsHost, PRInt32
                            *piReturnCode) = 0;
```

Parameters
The following are the parameters and definitions for this method:

psCalid	calid for which the hostname is requested.
ppsHost	The hostname to be returned.
piReturnCode	0= successful, non-zero indicates failure.

Returns

Returns zero for success; a non-zero code for failure. See piReturnCode Values.

Description

Gets the hostname associated with a calendar in the calendar lookup database. This is a no-op for the algorithmic implementation.

Init

Purpose

Confirms that the interface has been registered, and provides a reference to the server.

Syntax

```
PRUint32 Init(nsISupports *aServer) = 0;
```

Parameters

The method has the following parameter:

aServer	On return, contains a reference to the server with which the module is registered.

Returns

NS_OK on success, non-zero error code on failure.

Description

The server calls this method after finding and registering the interface on module load, to confirm that the operation was successful. You can use the pointer returned in aServer to make calls out to the server.

QualifyCalid

Purpose

Qualifies the relative calid.

Syntax

```
PRUint32 QualifyCalid(char* psCalid, char** ppsQualifiedCalid, PRInt32
                      *piReturnCode) = 0;
```

Parameters

The method has the following parameters:

psCalid	The calid to be qualified.
ppsQualifiedCalid	On return, contains the URL of the qualified calid.
piReturnCode	0= successful, non-zero indicates failure.

Returns

Zero on success, non-zero error code on failure.

Description

Returns the name of the qualified calid. The qualified calid format is:

dwp://*back-end host*[:port]/psCalid

QueryType

Purpose

Query type of database plug-in.

Syntax

```
PRUint32 QueryType(char* aType,PRInt32 *aReturnCode) = 0;
```

Parameters

The method has the following parameters:

aType	The type of CLD (Calendar Lookup Database).
aReturnCode	NS_OK if successful. Normal processing will not continue if unsuccessful.

Returns

NS_OK on success, non-zero error code on failure.

Description

This function retrieves a string representing the type of CLD the plugin implements.

The only supported type is “algorithmic”, which supports regular expressions.

SetHostnameForCalid

Purpose

Not currently used. Sets the host name for a calendar user.

Syntax

```
PRInt32 SetHostnameForCalid(char* psCalid, char* ppsHost, PRInt32
                            *piReturnCode) = 0;
```

Parameters

This method uses the following parameters:

`psCalid`	`calid` for which the hostname is to be set.
`ppsHost`	The hostname to be set.
`piReturnCode`	`0`= successful, non-zero indicates failure.

Returns

Zero for success; non-zero for failure. See

Description

Sets the hostname for a `calid` that is about to be created. This is a no-op for the algorithmic implementation.

csIDataTranslator

This is the interface for data translator plug-ins. All parameters should be allocated by the plug-in.

Methods

The `csIDataTranslator` interface implements three methods:

`GetSupportedContentTypes`	Informs the server about the content types that this database translator supports.
`Init`	Confirms that the interface was found and registered.
`Translate`	Translates calendar data to the specified MIME format.

Description

This interface allows you to manipulate or change the HTML Body content of calendar data flowing to, or from, the database, or between various data translators. The data translator manipulates the output format (`fmt-out`) component of a WCAP response.

Calendar Server supports the following MIME-types for translating calendar data:

MIME Type	Description
`text/calendar`	iCalendar
`text/xml`	iCalendar in XML

A CSAPI Data Translation module registers with the server for a specific MIME-type using the `GetSupportedContentType` method. The translator can request that the incoming data be provided in any of the supported MIME-types.

When incoming data is in the MIME-type that the module takes as input, the server passes the data to the module's `Translate` method. The translator converts the data to its supported MIME-type and passes it back to the server, which proceeds to update the database.

GetSupportedContentTypes

Purpose

Gets the content type this database translator supports.

Syntax

```
PRUint32 GetSupportedContentTypes (char** aSupportedInContentTypes, char**
                                   aSupportedOutContentType, char**
                                   aPreferredInContentType, PRInt32
                                   *aReturnCode) = 0;
```

Parameters

The method has the following parameters:

`aSupportedInContentTypes`	A list of content-types that the server can send as input to translator. An array of `NULL`-terminated strings.
`aSupportedOutContentType`	The content type the plug-in will convert data to.
`aPreferredInContentType`	The content type the plug-in would prefer to receive. It must be one of the supported content types passed in the first parameter.

aReturnCode	On return, contains a constant that determines whether the server should continue with the default authentication procedure. One of the following constants: NS_CONTINUE_DEFAULT_PROCESSING NS_OVERRIDE_DEFAULT_PROCESSING

Returns

NS_OK on success. A non-zero on failure.

Description

Get the content type this database translator supports.

Init

Purpose

Confirm that the interface has been registered and obtain a reference to the server.

Syntax

```
PRUint32 Init (nsISupports *aServer) = 0;
```

Parameters

The method has the following parameter:

aServer	On return, this location contains a reference to the server with which the module is registered.

Returns

NS_OK on success, non-zero error code on failure.

Description

The server calls this method after finding and registering the interface on module load, to confirm that the operation was successful. You can use the pointer returned in aServer to make calls out to the server.

Translate

Purpose

Implement the translation from one content type to another.

Syntax

```
PRUint32 Translate (char* aInContentType, char* aOutContentType, char**
aInBuffer, char** aOutBuffer, PRInt32 *aInSize, PRInt32 *aOutsize, PRInt32
*aReturncode) = 0;
```

Parameters

The method has the following parameters:

`aInContentType`	The incoming content type.
`aOutContentType`	The outgoing content type.
`aInBuffer`	The input data buffer.
`aOutBuffer`	The output data buffer.
`aInSize`	The input buffer size.
`aOutSize`	The output buffer size.

`aReturnCode`	On return, contains a constant that determines whether the server should continue with the default authentication procedure.
	One of the following constants:
	`NS_CONTINUE_DEFAULT_PROCESSING`
	`NS_OVERRIDE_DEFAULT_PROCESSING`

Returns

`NS_OK` on success, non-zero on failure.

Description

This method retrieves content of the specified input type from the specified buffer, translates the content from its original format to the output format, stores the translated content in the specified output buffer, and stores the size of the output buffer at the specified location.

csIPlugin

You should implement the methods in this interface in order to provide the server with information about your plug-in module on startup.

Methods

The `csIPlugin` interface implements four methods:

GetDescription	Gets a textual description of what the plug-in does.
GetVendorName	Gets a textual description of the vendor supplying this plug-in.
GetVersion	Gets the major and minor version of the plug-in. This value must be greater than or equal to 1.0. For a list of the current version numbers for each plug-in API, see Table 1-1 Current Plug-in API Versions in Chapter 1, "Calendar Server API (CSAPI) Overview.".
Init	Confirms that the interface was found and registered.

Description

This interface is not required, but it is highly recommended that you implement it in each module to provide version information to the server when it loads that module. The methods return descriptive information to the server.

GetDescription

Purpose

Retrieve a text description of the module.

Syntax

```
PRUint32 GetDescription (nsString& aDescription) = 0;
```

Parameters

The method has the following parameter:

`aDescription`	On return, contains the text description of the module.

Returns

`NS_OK` on success, non-zero error code on failure.

Description

Use this method to provide a text description of the module.

GetVendorName

Purpose
Retrieve a text description of the vendor supplying the module.

Syntax
```
PRInt32 GetVendorName (nsString& aVendorName) = 0;
```

Parameters
The method has the following parameter:

aVendorName	On return, contains the text description of the vendor.

Returns
NS_OK on success, non-zero error code on failure.

Description
Use this method to identify the module's supplier.

GetVersion

Purpose
Provide server with version information on startup.

Syntax
```
PRUint32 GetVersion (PRUint32& aMajorValue, PRUint32& aMinorValue) = 0;
```

Parameters
The method has the following two parameters:

aMajorValue	On return, contains the major version number.
aMinorValue	On return, contains the minor version number.

Returns
NS_OK on success, non-zero error code on failure.

Description
Use this method to identify the module's major and minor version number. The number must be greater than or equal to 1.0.

Init

Purpose

Confirm that the interface has been registered and obtains a reference to the server.

Syntax

```
PRUint32 Init (nsISupports *aServer) = 0;
```

Parameters

The method has the following parameter:

aServer	On return, this location contains a reference to the server with which the module is registered.

Returns

NS_OK on success, non-zero error code on failure.

Description

The server calls this method, after finding and registering the interface on module load, to confirm that the operation was successful. You can use the pointer returned in aServer to make calls out to the server.

csIQualifiedCalidLookup

Implement the methods in this interface to augment or override the default method of retrieving the calendar ID of the qualified URL passed in.

Methods

The csICalendarLookup implements two methods:

FindCalid	Returns a calendar ID for the qualified URL.
Init	Confirms that the interface was found and registered.

Description

Retrieves the calendar ID of the qualified URL passed in to it. If the calid is not found, the command returns an error.

FindCalid

Purpose
Finds the calendar ID for the URL specified.

Syntax
```
PRUint32 FindCalid (char* pQualifiedURL, char** ppCalidOut, PRInt32
*piCalidSize, PRInt32 *aReturnCode) = 0;
```

Parameters
The method has the following parameters:

pQualifiedURL	The URL to search on.
ppCalidOut	A pointer to the address of the calid found.
piCalidSize	Size of the calid returned.
aReturnCode	On return, contains a constant that determines whether the server should continue with the default, or with the override processing. One of the following constants: NS_CONTINUE_DEFAULT_PROCESSING NS_OVERRIDE_DEFAULT_PROCESSING

Returns
The calid for the qualified URL passed in.

Description
Uses the qualified URL pointer passed to it to perform a search of the calendar ID database. If it finds a match, it returns a pointer to the address of the calid and an integer with the size of the calid.

Init

Purpose
Confirms that the interface has been registered, and provides a reference to the server.

Syntax
```
PRUint32 Init (nsISupports *aServer) = 0;
```

Parameters

The method has the following parameter:

aServer	On return, contains a reference to the server with which the module is registered.

Returns

NS_OK on success, non-zero error code on failure.

Description

The server calls this method after finding and registering the interface on module load, to confirm that the operation was successful. You can use the pointer returned in aServer to make calls out to the server.

csIUserAttributes

Implement the methods in this interface to override the procedure for setting or retrieving user attributes.

Methods

The csIUserAttributes interface implements four methods:

FreeAttribute	Free the memory used to store a retrieved attribute.
GetAttribute	Retrieve an attribute value for a user.
Init	Confirm that the interface was found and registered.
SetAttribute	Set an attribute value for a user.

Description

The User Attributes interface allows a CSAPI module to maintain or manipulate all requests coming in for setting and retrieving user attribute values. You provide methods that retrieve and set attributes using the technique of your choice.

FreeAttribute

Purpose

Free the memory associated with your local attribute storage.

Syntax

```
PRint32 FreeAttribute (char* aValue, PRInt32 *aReturnCode) = 0;
```

Parameters

The method has the following two parameters:

aValue	The location you allocated to contain the retrieved attribute value.
aReturnCode	On return, contains a constant that determines whether the server should continue with the default, or with the override processing. One of the following constants: • NS_CONTINUE_DEFAULT_PROCESSING • NS_OVERRIDE_DEFAULT_PROCESSING

Returns

NS_OK on success, non-zero error code on failure.

Description

When you retrieve the value of an attribute using the GetAttribute method, the value is stored at a location that you have allocated, using the memory management technique of your choice. Use the FreeAttribute method to free that memory when it is no longer needed, using the same memory management technique. (See csIMalloc.)

GetAttribute

Purpose

Retrieve an attribute value for a user.

Syntax

```
PRUint32 GetAttribute (char* aUser, char* aKey, char** aValue, PRInt32
                       *aReturnCode) = 0;
```

Parameters

The method has the following four parameters:

aUser	The name of the user.
aKey	The attribute key.
aValue	On return, this location contains a pointer to the retrieved attribute value.

aReturnCode	On return, contains a constant that determines whether the server should continue with the default, or with the override processing. One of the following constants: • NS_CONTINUE_DEFAULT_PROCESSING • NS_OVERRIDE_DEFAULT_PROCESSING

Returns

NS_OK on success, non-zero error code on failure.

Description

Retrieves the value of the specified attribute for the specified user, and stores it at the location pointed to by aValue. You are responsible for allocating storage space for the returned attribute, and for freeing it (using the FreeAttribute method) when it is no longer needed.

Init

Purpose

Confirm that the interface has been registered and obtain a reference to the server.

Syntax

```
PRUint32 Init (nsISupports *aServer) = 0;
```

Parameters

The method has the following parameter:

aServer	On return, this location contains a reference to the server with which the module is registered.

Returns

NS_OK on success, non-zero error code on failure.

Description

The server calls this method, after finding and registering the interface on module load, to confirm that the operation was successful. You can use the pointer returned in aServer to make calls out to the server.

SetAttribute

Purpose

Set an attribute value for a user.

Syntax

```
PRUint32 SetAttribute (char* aUser, char* aKey, char* aValue, PRInt32
                       *aReturnCode) = 0;
```

Parameters

The method has the following parameters:

aUser	The name of the user.
aKey	The attribute key.
aValue	The value.
aReturnCode	On return, contains a constant that determines whether the server should continue with the default, or with the override processing. One of the following constants: • NS_CONTINUE_DEFAULT_PROCESSING • NS_OVERRIDE_DEFAULT_PROCESSING

Returns

NS_OK on success, non-zero error code on failure.

Description

Sets the specified attribute for the specified user to the specified value.

csICalendarServer

Provides server version information to a plug-in module.

Methods

The csICalendarServer interface implements two methods:

GetVersion	Get the calendar server version.
Init	Confirms that the interface was found and registered.

Description

Plug-in modules can query the `csICalendarServer` interface to get version information about the running instance of Calendar Server. The object is valid for the full lifetime of the client, so `Init` does not return a reference.

GetVersion

Purpose

Provide plug-in module with server version information.

Syntax

```
PRUint32 GetVersion (PRUint32& aMajorValue, PRUint32& aMinorValue) = 0;
```

Parameters

The method has the following two parameters:

`aMajorValue`	On return, contains the major version number.
`aMinorValue`	On return, contains the minor version number.

Returns

`NS_OK` on success, non-zero error code on failure.

Description

Use this method to identify the server's major and minor version number. The number is always greater than or equal to `1.0`.

Init

Purpose

Confirm that the interface has been registered.

Syntax

```
PRUint32 Init() = 0;
```

Parameters

The method has no parameters.

Returns

`NS_OK` on success, non-zero error code on failure.

Description

The server calls this method to confirm that the interface was found and registered successfully.

csIMalloc

Allocates and frees memory.

Methods

The `csIMalloc` interface implements six methods:

Calloc	Allocates and initializes memory for a number of objects.
Free	Frees memory that is no longer in use.
FreeIf	Frees memory, allowing a `NULL` pointer.
Init	Confirms that the interface was found and registered.
Malloc	Allocates an amount of memory.
Realloc	Reallocates previously allocated memory.

Description

Plug-in modules can use this object to take advantage of the server's efficient memory allocation technique.The object is valid for the full lifetime of the client, so `Init` does not return a reference.

Calloc

Purpose

Allocates, and initializes to zero, memory for a number of objects.

Syntax

```
void* Calloc (PRUint32 aSize, PPRUint32 aNum) = 0;
```

Parameters

The method has the following two parameters:

`aSize`	The size in bytes of each object.
`nNum`	The number of objects.

Returns
A pointer to the allocated memory on success, or NULL on failure.

Description
This method allocates enough memory for the specified number of objects of the specified size, and initializes the memory to zero.

Free

Purpose
Free memory previously allocated by the Malloc method.

Syntax
```
PRUint32 Free (void * aPtr) = 0;
```

Parameters
The method has the following parameter:

aPtr	A pointer to the memory to be freed.

Returns
NS_OK on success, non-zero error code on failure.

Description
Use this method in the same way as its C/C++ counterpart to free previously allocated memory.

FreeIf

Purpose
Free memory previously allocated by the Malloc method, allowing a NULL pointer.

Syntax
```
PRUint32 FreeIf (void * aPtr) = 0;
```

Parameters
The method has the following parameter:

aPtr	A pointer to the memory to be freed or NULL.

Returns
`NS_OK` on success, non-zero error code on failure.

Description
Frees the memory at the specified location, if `aPtr` is not `NULL`.

Init

Purpose
Confirm that the interface has been registered.

Syntax
```
PRUint32 Init() = 0;
```

Parameters
The method has no parameters.

Returns
`NS_OK` on success, non-zero error code on failure.

Description
The server calls this method to confirm that the interface was found and registered successfully.

Malloc

Purpose
Allocate a specified amount of memory.

Syntax
```
void* Malloc (PRUint32 nBytes) = 0;
```

Parameters
The method has the following parameter:

`nBytes`	The size in bytes of the memory to be allocated.

Returns
A pointer to the allocated memory on success, or `NULL` on failure.

Description

Use this method in the same way as its C/C++ counterpart.

Realloc

Purpose

Reallocates memory that was previously allocated.

Syntax

```
void* Realloc (void* aPtr,PRUint32 nBytes) = 0;
```

Parameters

The method has the following parameter:

`aPtr`	A pointer to previously allocated memory.
`nBytes`	The size in bytes of the memory to be allocated.

Returns

A pointer to the allocated memory on success, or `NULL` on failure.

Description

Use this method in the same way as its C/C++ counterpart to reallocate memory that was previously allocated.

Chapter 3

Proxy Authentication SDK Overview

This chapter describes the Calendar Server Proxy Authentication SDK (authSDK). It addresses the following topics:

- Who Will Use the authSDK?
- What Is the authSDK?
- Architecture
- Functions Overview

Who Will Use the authSDK?

Programmers, whose installation has a portal service, can use authSDK to integrate the portal with Calendar Server. When a portal system authenticates a user, authSDK functions notify Calendar Server, which then allows the user access to various services without reauthentication.

What Is the authSDK?

The authSDK consists of a DLL / shared-object that exports five functions.

The install package includes the following, located in *cal_svr_base*/bin/authsdk:

- libicsexp10.so/DLL. The SDK library.
- expapi.h. Header file for API users.

Architecture

The authSDK is pretty simple. It consists of initialization, lookup, and cleanup. Additionally, one other function, `CEXP_SetHttpPort`, allows the authSDK to use a non-standard port, and another, `CEXP_GetVersion`, gets the authSDK version number should you need to contact customer or technical support. For a complete description of the API functions, see Chapter 4, "Proxy Authentication SDK Reference."

Initialization

Call `CEXP_Init` for initialization. If you pass it LDAP information, it initializes an LDAP connection used during the lookup phase for discovering on which calendar server the user resides. This connection is set up for a threaded environment. All threads share this connection, but since the locking is done in the LDAP, it is fast enough in most environments. The connection is kept open so there is no setup / teardown cost per lookup.

Other things set up by initialization include the programmer supplied attribute to use for matching the lookup user name in LDAP queries.

Lookup

Use the lookup function, `CEXP_GenerateLoginURL`, when you want to generate a new session for a user. Lookup performs no authentication. It simply uses the user name and IP address to generate an entry in the session table for them and returns a URL associated with that session. If you pass the hostname of a calendar server, the function will contact that server to generate the session. If not, it will query the LDAP server to determine the host. In order for it to generate a session without actually authenticating the user, you must provide the proxy administrator's ID and password.

Cleanup

If you are in a threaded environment and you wish to cleanup resources such as memory, open LDAP connections, etc., use `CEXP_Shutdown`.

Functions Overview

There are five functions in the SDK, as listed in Table 3-1.

Table 3-1 Proxy Authentication SDK Functions

Function	Description
CEXP_GenerateLoginURL	Generates a URL with the valid session ID.
CEXP_GetVersion	Generates the version ID string.
CEXP_Init	Initializes the SDK.
CEXP_SetHttpPort	Specify the port over which you will contact the calendar server.
CEXP_Shutdown	Performs all shutdown procedures, including freeing memory and shutting down connections.

Chapter 4

Proxy Authentication SDK Reference

This chapter describes the Calendar Server Proxy Authentication SDK (authSDK) API. The chapter is divided into two parts: Proxy Authentication SDK Functions, and How to Use the authSDK.

Proxy Authentication SDK Functions

There are five authSDK functions. They are presented below in alphabetical order, not in order of use:

- CEXP_GenerateLoginURL

  Generates a URL with the valid session ID.

- CEXP_GetVersion

  Generates the version ID string.

- CEXP_Init

  Initializes the SDK.

- CEXP_SetHttpPort

  Specifies the port over which you will contact the calendar server.

- CEXP_Shutdown

  Performs all shutdown procedures, including freeing memory and shutting down connections.

CEXP_GenerateLoginURL

Purpose

Returns a login URL with a valid session ID for a given user.

Syntax

```
int CEXP_GenerateLoginURL (char * pszUser,
                           char * pszClientAddress,
                           char * pszCalendarHost,
                           char * pszURL);
```

Parameters

There are four parameters:

`pszUser`	A string containing the user name.
`pszClientAddress`	A string containing the client host IP-address.
`pszCalendarHost`	A string containing the hostname (no IP-address) of the calendar server.
`pszURL`	A pointer to a buffer to place the URL

Returns

Returns `0` on success, `-1` on failure. On success, the `pszURL` buffer contains a valid URL string.

CEXP_GetVersion

Purpose

Gets the version ID string.

Syntax

```
char * CEXP_GetVersion(void);
```

Parameters

There are no parameters:

Returns

A reference to the version ID string.

CEXP_Init

Purpose

Initializes the SDK.

Syntax

```
int CEXP_Init (char * pszLdapHost,
               char * pszLdapMatchAttrib,
               char * pszLdapDN,
               unsigned int iLdapPort,
               char * pszLdapBindUser,
               char * pszLdapBindPass,
               char * pszAdminUser,
               char * pszAdminPassword);
```

Parameters

There are eight parameters:

`pszLdapHost`	A string containing the hostname of the directory server.
`pszLdapMatchAttrib`	A string containing the attribute name. Used to match against the user name.
`pszLdapDN`	A string containing the base DN to search for user records. “DN”, for Distinguished Name, is a string representation of an LDAP directory entry’s name and location.
`iLdapPort`	An integer specifying the directory server’s port number.
`pszLdapBindUser`	A string specifying the DN to bind as.
`pszLdapBindPass`	A string containing the password for the bind DN.
`pszAdminUser`	A string containing the Calendar Server administrator’s LDAP user ID.
`pszAdminPassword`	A string containing the Calendar Server administrator’s password.

Returns

Returns `0` on success, `-1` on failure.

Comment

If the bind DN (`pszLdapBindUser`) and password (`pszLdapBindPass`) are `NULL`, anonymous searching will be attempted.

CEXP_SetHttpPort

Purpose
Sets the HTTP port used to contact the calendar server.

Syntax
```
void CEXP_SetHttpPort (int iHttpPort);
```

Parameters
There is one parameter:

`iHttpPort`	An integer specifying the port.

Returns
Nothing.

CEXP_Shutdown

Purpose
Cleans up all global memory, shuts down connections, and other clean-up functions when the user is finished using the SDK.

Syntax
```
int CEXP_Shutdown (void);
```

Parameters
There are no parameters:

Returns
Returns `0` on success, `-1` on failure.

Comments
Call this only after all threads using the SDK complete.

How to Use the authSDK

To implement authSDK in your installation, follow these steps:

1. Link the authSDK to your code.

   To integrate the authSDK into your existing code, simply include the `expapi.h` header file in the calling code and link with the DLL / shared-object. On some platforms you may also be required to link with other system libraries the authSDK requires.

2. Authenticate your user with your portal authentication program.

3. Call `CEXP_Init`.

   This function initializes the authSDK configuration information. This is necessary before any other authSDK function is called.

4. Optionally, call `CEXP_SetHttpPort`.

   By default, the authSDK contacts the standard HTTP port, 80. Use this function to tell the authSDK to contact a non-standard port when connecting to generate a session.

CAUTION This function is not thread safe and sets a global value. If you want to use it in a threaded environment, you must lock around this call and the `CEXP_GenerateLoginURL` call.

5. Call `CEXP_GenerateLoginURL`.

   This function generates a session handle for the user and client-ip address. It returns a string, in a buffer you allocate, containing a login URL to be used when connecting to Calendar Server. The string is a kind of token providing proof of identity. It is given to the client in the form of a cookie or URL via HTTP headers or JavaScript™. The client will then connect to Calendar Server, presenting the token as proof of identity.

6. Optionally, call `CEXP_Shutdown`.

   Call this function to shutdown and cleanup any resources used by the authSDK. It is not necessary to call this function in some environments (a simple CGI login, for example), but plug-ins using the API may want to reclaim resources and continue running.

Other Tips

There are a few other things that must be done to assure success in using the AuthSDK:

- The value of `service.http.allowadminproxy` in the `ics.conf` file must be “yes”.
- The parameter `caladmin`, passed in the `init` method, must have the same value as `service.admin.calmaster.userid` in the `ics.conf` file.
- The parameter `calpass`, passed in the `init` method, must have the same value as `service.admin.calmaster.cred` in the `ics.conf` file.
- The two parameters `caladmin` and `calpass` must be defined in your directory service.
- If your calendar server is not listening on the default port 80, you must use the `SetHttpPort` method with the correct port value.

WCAP API

Chapter 5, “Web Calendar Access Protocol Overview”

Chapter 6, “WCAP Common Topics”

Chapter 7, “WCAP Command Reference”

Chapter 5

Web Calendar Access Protocol Overview

This chapter describes the Web Calendar Access Protocol (WCAP), which is a high level command-based protocol used to communicate with the Calendar Server. This chapter has the following sections:

- Introduction
- Command Overview
- Command Formats

Introduction

The default client UI protocol for Calendar Server is an SHTML protocol, and is private. To retrieve calendar data in `text/calendar` and `text/xml` formats, use WCAP commands with the `fmt-out` parameter set to `text/calendar` or `text/xml`.

WCAP is a command based system consisting of client requests and server responses for transmitting calendaring data. WCAP returns calendaring data via HTTP. In most cases, Calendar Server receives data through URL-encoded arguments.

WCAP returns output in an HTTP message. The returned content body of the HTTP messages can consist of calendar data in the following formats:

- `text/calendar` format.
- `text/xml` format.

NOTE In order to start the Calendar Server user interface (Calendar Express), you must specify `fmt-out=text/html` in the `login` command. This is the only instance of this format type.

WCAP commands consist of four general categories of usage:

- User Configuration Information
- Web Calendaring Data
- Communication-sending for group scheduling
- Miscellaneous commands

Command Overview

Table 5-1 describes the high level list of commands supported in WCAP. For a detailed description of each command, see Chapter 7, "WCAP Command Reference."

Table 5-1 WCAP Command Overview

WCAP Command	Description
addlink	Add event links from one calendar to another.
change_password	Change the user's password.
check_id	Administrator only: Check if user's session ID is valid.
createcalendar	Create a new calendar.
deletecalendar	Delete an existing calendar.
deletecomponents_by_range	Delete both events and todos in a calendar(s) over a specific time period.
deleteevents_by_id	Delete events given a specific calid and uid/recurrence-ID pair.
deleteevents_by_range	Delete events in a calendar(s) over a specific time period.
deletetodos_by_id	Delete todos given a specified calid and userid/recurrence-ID pair.
deletetodos_by_range	Deletes todos in a calendar(s) over a specific time period.
export	Exports a calendar to a file.
fetchcomponents_by_alarmrange	Queries for components that have alarms to trigger over a specific time period.

Table 5-1 WCAP Command Overview *(Continued)*

WCAP Command	Description
fetchcomponents_by_attendee_error	Queries for components that had errors while sending group scheduling messages.
fetchcomponents_by_lastmod	Queries for components that have changed, during the specified time range.
fetch_deletedcomponents	Queries the `deletelog` database for deleted components.
fetchcomponents_by_range	Queries for components over a specific time period, with filtering attributes.
fetchevents_by_id	Queries for one or more events by a unique identifier (UID, Recurrence ID, modifier).
fetchtodos_by_id	Queries for one or more todos by a unique identifier (UID, Recurrence ID, modifier).
get_all_timezones	Returns all the timezones the server supports.
get_calprops	Returns calendar properties.
get_freebusy	Returns calendar freebusy time.
get_guids	Returns a set of random UIDs.
gettime	Returns the server times for the requested `calids`.
get_userprefs	Returns user preferences and some server settings.
import	Imports a calendar from a file to a user's calendar.
list	Lists all calendars owned by a user.
list_subscribed	Lists all calendars subscribed to by a user.
login	Authenticates a user and redirects to first HTML view.
logout	Terminates the current user's session and return to login screen.
ping	Administrator only: Pings the calendar server.
search_calprops	Searches for a calendar with the specified parameter values.
set_calprops	Sets calendar properties.
set_userprefs	Sets user preferences.
storeevents	Stores events that are specified in application/urlencoded manner. For storing an even by passing properties in a URL.
storetodos	Stores todos that are specified in the application/urlencoded manner.
subscribe_calendars	Adds calendars to a users subscription list.
unsubscribe_calendars	Removes calendars from a user's subscription list.
verifyevents_by_ids	Fetches events and returns the uid/rid of events not in the database.

Table 5-1 WCAP Command Overview *(Continued)*

WCAP Command	Description
verifytodos_by_ids	Fetches todos and returns the uid/rid of events not in the database.
version	Returns the WCAP version that the server supports.

Session Identifiers

For many WCAP commands, you must specify the session identifier (`id`) that is returned by the `login` command. The session identifier ensures that data is accessible only to authenticated users with the required level of privilege or ownership.

When logging into the system, a user provides authentication of identity. The default authentication mechanism uses plain-text passwords and user names. Calendar Server generates the session identifier only when authentication is successful. The identifier then serves as proof of authentication in subsequent calendaring operations.

You can customize the authentication mechanism to use a local or external authentication scheme. See Chapter 2, "CSAPI Reference," for the section "csIAccessControl."

Hosted (Virtual) Domain Mode

If your LDAP is set up to use hosted (virtual) domains, all WCAP commands you issue must have fully qualified user IDs and calendar IDs (`calid`), for example `jdoe@example.com`.

In order to be in hosted domain mode, the following `ics.conf` parameter must be set as shown:

```
service.virtualdomain.support="y"
```

See your Calendar Server administrator if you do not know whether you are using hosted domains.

The following two example WCAP commands demonstrate the difference between `calid` values for non-hosted domain mode and hosted domain mode.

Not in hosted domain mode:

```
http://webcalendarserver/get_userprefs.wcap?id=b5q2o8ve2rk02nv9t6&
calid=jdoe&fmt-out=text/calendar
```

In hosted domain mode:

```
http://webcalendarserver/get_userprefs.wcap?id=b5q2o8ve2rk02nv9t6&
calid=jdoe@example.com&fmt-out=text/calendar
```

Command Formats

The plug-in architecture of Calendar Server allows it to support multiple command formats. Both client and server can use a variety of data formats to meet various ISP needs.

The command protocol uses HTTP, and follows the standards defined by the WC3 URL specifications.

WCAP in Calendar Server consists calendar data formatted as XML or iCalendar, communicated as HTML documents over HTTP on both the client and server side. Refer to the *Calendar Server Release Notes* for recommended browser versions for client interfaces.

NOTE There is a limit to the number of characters that may be passed in for each parameter. The limit per parameter is 1024 characters.

Client Request Formats

Clients submit command requests to the Calendar Server in either Universal Resource Identifier (URI) data format, or with one of three HTML forms.

Command Format	Description
URI	Requests from client submitted using standard URI syntax.
HTML Form - `urlencoded`	Requests from client submitted as encoded URLs.
HTML Form - `text/xml`	Requests from client submitted using objects formatted as XML.
HTML Form - `text/calendar`	Requests from client submitted using objects formatted as iCalendar.

URI Format

Use the following format to submit a URI request:

```
http://webcalenderserver/COMMAND?PARAM=VAL&PARAM=VAL...
```

Multiple items are delimited by semicolons. If a string contains a semicolon character, replace the semicolon with its quoted-printable equivalent, `%3B`. For example, to represent the string “gh;i” in a list of IDs, use the following:

`http://webcalendarserver/fetchcomponents_by_range.wcap?uid=abc;def;gh%3bi;jkl`

See also Chapter 6, “WCAP Common Topics.”

HTML Form

Submit a form with `method=[GET|POST]` and `action=`*command* (where *command* is the command to execute). Parameters need to be formatted as specified in the encoding.

NOTE The maximum length for WCAP parameters is 1024 characters.

Client Side Event Notification

All client side JavaScript code in the parent frame of the response page is required to implement a method called `Cal`*command*`Callback()`, where *command* is the name of the command requested. This callback will be invoked when the HTML response is completed loading.

The above commands when used with HTTP `GET` are simply for data retrieval.

The above commands when used with HTTP `POST` are for data modifications (including creation / deletion).

Server Response Formats

Calendar Server responds to client requests by serving HTML containing JavaScript objects. You can configure a response format preference for a server, a user, or an individual request.

The client may request output in either text / calendar or text / xml formats. The following table gives a brief description of each response format:

Response Format	Description
text/calendar	Responses are in HTML, containing data formatted as iCalendar objects. This is the default format.
text/xml	Responses are formatted as XML objects

Chapter 6

WCAP Common Topics

This chapter contains topics of common interest that span multiple commands.

The topics are listed in alphabetical order. The table that follows lists and contains links to these topics:

Access Control Entries

Application IDs (appid parameter)

Changing Language or Character Set

Encoded Characters

Error Handling

Fetching Component Data

Fetching Component State Data

Fetching Deleted Data

Fetching Recurrence Data

Formatting Standards

Freebusy Calendars

Freebusy Calculation for Private Events

Group Scheduling

Output Format

Recurring Components – Overview

Recurring Components – Creating, Modifying

Recurring Components – Deleting

Recurring Components – Fetching

Time Zones

Updating Parameter Values

X-Tokens

Access Control Entries

Access Control Entries (ACE strings) determine access control for calendars. There may be multiple ACE strings that apply to a single calendar. Collectively, all the ACE strings that apply to a calendar are called an Access Control List (ACL). As the system searches the ACL list for a calendar, the first ACE encountered that either grants of denies access will be used. Thus, the ordering of an ACL is significant. ACE strings should be ordered such that the more specific ones appear before the more general ones.

Some access is “built-in”. For example, primary owners have access to everything in their calendars. The system does not need to perform access control checks for primary owners accessing their own calendars.

The `set_calprops` command uses the `acl` parameter to facilitate storing of ACE strings to a calendar. The `acl` parameter is a semicolon-separated list of ACE strings. You may set the default `acl` in the `ics.conf` file by changing the `calstore.calendar.default.acl` preference, or by using the `cscal` command line utility. See the *Calendar Server Administration Guide* for further information on configuration settings.

The `get_userprefs` command will fail if any node does not have “allow anyone” access rights for reading and searching. For example, the following LDAP modify record for an ACI entry gives the correct privileges to make the command work correctly.

```
dn:  o=usergroup
changetype: modify
add: aci
aci: (targetattr="icscalendar || cn || givenName || sn || uid ||
mail")(targetfilter=(objectClass=icscalendaruser))(version 3.0; acl "Allow
calendar administrators to proxy - product=ics,class=admin,num=2,version=1";
allow (proxy) groupdn = "ldap:///cn=Calendar
Administrators,ou=Groups,o=usergroup";)
```

Due to a limitation on the user interface, do not add ACE strings for more than 75 users per calendar.

Here is an example of an ACE string:

```
jdoe^c^wd^g
```

The string has four elements separated by three “^” characters. The four elements are:

1. The first element of an ACE tells who the ACE applies to.

This could be an individual user (specified by user ID), a domain, or a class-type of user. There are four types of classes for users:

- All users, represented by the string “@”.
- Primary owners of a calendar, represented by the string “@@p”.
- Owners of a calendar, represented by the string “@@o”.
- Non-owners of a calendar, represented by the string “@@n”.

2. The second element of an ACE indicates what the ACE applies to.

The ACE can be applied to:

- The entire calendar.

  Applies to both components and calendar properties. To indicate the entire calendar, pass in the value a.

- The components of the calendar only.

  Applies to calendar components (i.e events / todos). To indicate just the components, pass in the value c.

- The calendar properties of the calendar only.

  Applies to calendar properties (i.e display name, ownerlist). To indicate calendar properties only, pass in the value p.

3. The third element of an ACE indicates what access values the ACE applies to.

Multiple values may be specified at the same time. To do this, the caller must pass in a string to indicate which bits to check.

Table 6-1 lists the Access Control characters used in ACE strings. The third element contains a string with one or more of the Access Control characters.

Table 6-1 Access Control Characters

Access Control Characters	Description
c	(not implemented)Grants the user act-on-behalf-of cancel access. With cancel access, a user has the right to cancel components to which attendees have been invited on behalf of the calendar’s primary owner.
d	Grants the user delete access.
e	(not implemented)Grants the user act-on-behalf-of reply access. This grants a user the rights to accept or decline invitations on behalf of the calendar’s primary owner.
f	Grants the user free-busy access.

Table 6-1 Access Control Characters

i	(not implemented) Grants the user act-on-behalf-of invite access. This grants a user the right to create and modify components in which other attendees have been invited on behalf of the calendar's primary owner
r	Grants the user read access.
s	Grants the user schedule access. This means that requests can be made, replies will be accepted, and other ITIP scheduling interactions will be honored.
w	Grants the user write access. This includes adding new items, deleting items, and modifying existing items.

For example, to grant read access, the value `r` is passed in. To grant write and delete access, the value `wd` is passed in.

4. The fourth element of an ACE indicates whether to grant or deny access.

   The ACE can either grant or deny access.

   - To grant access, set the value to `g`.
   - To deny access, set the value to `d`.

ACE Summary

Here is a quick summary of the order of an ACE:

who ^ flags ^ how ^ grant

Where:

- who = A string, type (str).
- flags = One of the characters `c`, `p`, or `a`.
- how = An access-string composed of one or more of the access control characters described earlier in Table 6-1.
- grant = One of the characters `g`, or `d`

Extended Examples

Here are some examples of circumstances and how the ACE would be set in the `acl` parameter for `jdoe`'s calendar:

- To grant john read access to both components and calendar properties (acl=john a r g), and to grant susan write and delete access to components only (acl=susan c wd g), the entire command is:

```
set_calprops.wcap?id=${SESSIONID}&calid=jdoe&acl=john^a^r^g;
susan^c^wd^g
```

- To grant all users in a domain schedule, freebusy, and read access to a calendar (*@domainname* a sfr g), to grant owners write and delete access to components only (@@o c wd g), to grant owners self-admin, schedule, freebusy, and read access to both components and calendar properties (@@o a zsfr g), to deny susan all access to both components and calendar properties (susan a zsfdwr d), and to grant read access to all users (@ c r g), the entire command is:

```
set_calprops.wcap?id=${SESSIONID}&calid=jdoe&acl=@domainname^a^sfr^g;@
@o^c^wd^g;@@o^a^zsfr^g;susan^a^zfsdwr^d;@^c^r^g
```

NOTE An administrator can override the access control of all WCAP commands if he is logged in as administrator and the server configuration preference service.admin.calmaster.overrides.accesscontrol is set to “yes” in the ics.conf file.

Mapping User Interface Operations to ACLs

Table 6-2 shows the ACLs necessary to achieve the desired user interface operation.

Table 6-2 Mapping User Interface Operations to ACLs

User Interface Operation	ACL Required	Example	Description
Delete Events and Todos	Modify Events and Todos + Delete Components or Delete Calendar	c^d^g or, a^d^g	To delete events or todos, you need modify permission, and either delete components or delete calendar permission.
Freebusy	Freebusy Components or Freebusy Calendar	c^f^g a^f^g	To view a freebusy representation of a calendar (the events and todos), you need freebusy components or freebusy calendar permission.

Table 6-2 Mapping User Interface Operations to ACLs

User Interface Operation	ACL Required	Example	Description
Modify Events and Todos	Read Events and Todos + Write Components or Write Calendar	c^w^g a^w^g	To modify components of a calendar (events and todos), you need read permission, and either write components or write calendar permission.
Read Events on a Calendar	Read Calendar	a^r^g	To read components, you must have read calendar permission. Note that read components permission (c^r^g) will not work.
Schedule (Invite)	Schedule Calendar	a^s^g	To invite someone, you need schedule calendar permission.
Subscribe	Read Properties	p^r^g	To subscribe to a calendar, you must have read properties permission.

Application IDs (appid parameter)

The following WCAP commands accept the `appid` parameter:

- `deletecomponents_by_range` – (ENS notifications not yet implemented)
- `deleteevents_by_id`
- `deleteevents_by_range` – (ENS notifications not yet implemented)
- `deletetodos_by_id`
- `deletetodos_by_range` – (ENS notifications not yet implemented)
- `import` – (ENS notifications not yet implemented)
- `storeevents`
- `storetodos`

This WCAP command parameter is used to set the value of an X-Token that ENS returns with notifications.

Applications passing this parameter in with the appropriate WCAP command can detect which ENS notifications they originated by checking the value of the X-Token `X-NSCP-COMPONENT-SOURCE`. Note that this X-Token is not returned by WCAP commands, only ENS notifications.

This parameter is a runtime parameter. That is, nothing is stored in the database.

If appid is present, the Event Notification Service (ENS) returns the value of appid as the value of the X-Token X-NSCP-COMPONENT-SOURCE. If the appid parameter is missing, ENS assigns one of the standard values to the X-Token (WCAP, CALENDAR EXPRESS, ADMIN). (Note that ADMIN is not yet implemented.)

Table 6-3 shows the effect of the presence of the appid parameter on the value of the X-Token X-NSCP-COMPONENT-SOURCE. For more information about ENS, see the *Sun Java System Communications Services Event Notification Service Guide*.

Table 6-3 Presence of appid and Value of X-Token X-NSCP-COMPONENT-SOURCE

appid Present?	Value of X-Token X-NSCP-COMPONENT-SOURCE (with Request Origin)
no	WCAP (default) CALENDAR EXPRESS (from UI) ADMIN (from Admin tools) – Not yet implemented
yes	Value of appid

NOTE For the Calendar Server, ENS notifications are only returned for some of the commands (as noted earlier). The other commands will be implemented in a later release.

Changing Language or Character Set

To insert a request for data to be returned in a language other than the system default, set either the lang or charset parameter. Note that the system default for language is now a server preference that you set in the ics.conf file. See the *Calendar Server Administration Guide* for details. The login command uses only the lang parameter.

For the set_calprops command, in most cases, specifying the lang parameter is enough. However, it may be necessary, in some instances, to use the charset parameter instead of the lang parameter. For example, if the user wants the requested data returned in a specified character set, then the user must specify it using charset. One possible charset value is: iso-8859-1. For more information on formatting specifications, see the RFCs referenced in "Formatting Standards" on page 88 in this chapter.

Please note that when the user requests data in iCalendar or XML format, data always returns in UTF-8 format, per the RFC specification. Setting `charset` will not change this.

Here is a list of the valid `lang` values:

`de`	German
`en`	English (the default)
`es`	Spanish
`fr`	French
`it`	Italian
`ja`	Japanese
`ko`	Korean
`ru`	Russian
`sv`	Swedish
`zh_CN`	Chinese/Simplified Chinese
`zh_TW`	Taiwanese

NOTE This does not mean that all of these languages are currently supported by the server. Please check with your Sun Java Enterprise System representative to find out which languages are currently supported by the server.

For example, enter the following if you want to insert an event into the calendar:

```
storeevents.wcap?id=${SESSIONID}&calid=id&summary=summary&
location=location&desc=desc&charset=euc-jp
```

As another example, suppose that the location value is two Japanese characters whose unicode values are \u3068\u30889. In this case, the location value is %A4%C8%A4%E9. Note that all non-ASCII characters should be URL-encoded according to the charset parameter, which in this case is euc-jp. The following command is an example of same data sent in Shift_JIS:

```
storeevents.wcap?id=${SESSIONID}&calid=id&summary=summary&
location=location&desc=desc&charset=Shift_JIS
```

In the above example, the *location* value is %82%C6%82%E7.

WCAP uses the value of the `charset` parameter to convert the data from the URL-encoded value into UTF-8 before storing it into the database. It is stored internally in UTF-8.

The `charset` parameter in this command have the same role as in the `storeevents.wcap` because the `set_calprops` command takes non-ASCII data. The `charset` parameter in this command does not have any other special meaning.

If `charset` is not specified, WCAP expects the data to be URL-encoded in UTF-8.

Encoded Characters

In the example, the encoded list of parameters for `cal` includes some encoded characters. Here are some examples of encoded characters:

%3D = '='

%26 = '&'

%22 = '"'

The %XX is the hexadecimal ASCII value of the character. For example, the '&' character is 26 in hex (38 in ASCII).

Error Handling

Each call to a WCAP command that returns component data (fetch, delete, and store commands) also returns an error number.

Error String

The error string, `errno`, returns the non-zero error number for the transaction. The value is `0` if the command succeeded.

Error Codes

Table 6-4 list some of the error codes returned in the error number array.

Table 6-4 Error Names, Values, and Meanings

Error Name	Value	Meaning
LOGOUT	-1	Logout successful.
OK	0	Command successful.
LOGIN_FAILED	1	Login failed, session ID timed out. Invalid session ID
LOGIN_OK_DEFAULT_CALENDAR_NOT_FOUND	2	`login.wcap` was successful, but the default calendar for this user was not found. A new default calendar set to the userid was created.
DELETE_EVENTS_BY_ID_FAILED	6	Command failed.
SETCALPROPS_FAILED	8	Command failed.
FETCH_EVENTS_BY_ID_FAILED	9	Command failed.
CREATECALENDAR_FAILED	10	Command failed.
DELETECALENDAR_FAILED	11	Command failed.
ADDLINK_FAILED	12	Command failed.
FETCHBYDATERANGE_FAILED	13	Command failed.
STOREEVENTS_FAILED	14	Command failed.
STORETODOS_FAILED	15	Command failed.
DELETE_TODOS_BY_ID_FAILED	16	Command failed.
FETCH_TODOS_BY_ID_FAILED	17	Command failed.
FETCHCOMPONENTS_FAILED_BAD_TZID	18	Command failed to find correct `tzid`. Applies to `fetchcomponents_by_range`, `fetchevents_by_id`, `fetchtodos_by_id`.
SEARCH_CALPROPS_FAILED	19	Command failed.
GET_CALPROPS_FAILED	20	Command failed.
DELETECOMPONENTS_BY_RANGE_FAILED	21	Command failed.
DELETEEVENTS_BY_RANGE_FAILED	22	Command failed.
DELETETODOS_BY_RANGE_FAILED	23	Command failed.
GET_ALL_TIMEZONES_FAILED	24	Command failed.
CREATECALENDAR_ALREADY_EXISTS_FAILED	25	`createcalendar.wcap` failed; calendar with that name already exists in the database.
SET_USERPREFS_FAILED	26	Command failed.
CHANGE_PASSWORD_FAILED	27	Command failed.

Table 6-4 Error Names, Values, and Meanings *(Continued)*

Error Name	Value	Meaning
ACCESS_DENIED_TO_CALENDAR	28	Command failed; user denied access to a calendar.
CALENDAR_DOES_NOT_EXIST	29	Command failed; calendar does not exist in the database.
ILLEGAL_CALID_NAME	30	`createcalendar.wcap` failed; `calid` passed in was invalid.
CANNOT_MODIFY_LINKED_EVENTS	31	`storeevents.wcap` failed; event to modify was a linked event.
CANNOT_MODIFY_LINKED_TODOS	32	`storetodos.wcap` failed; todo to modify was a linked todo.
CANNOT_SENT_EMAIL	33	Command failed; the email notification failed. Usually caused by the server not being properly configured to send email. This can occur in `storeevents`, `storetodos`, `deleteevents_by_id`, `deletetodos_by_id`.
CALENDAR_DISABLED	34	Command failed; calendar is disabled in the database.
WRITE_IMPORT_FAILED	35	Import failed when writing files to the server.
FETCH_BY_LAST_MODIFIED_FAILED	36	Command failed.
CAPI_NOT_SUPPORTED	37	Failed trying to read from CS&T calendar data.
CALID_NOT_SPECIFIED	38	Calendar ID was not specified.
GET_FREEBUSY_FAILED	39	Command failed.
STORE_FAILED_DOUBLE_BOOKED	40	If double booking is not allowed in this calendar, `storeevents` or `storetodos` will fail with this error when attempting to store an event/todo in a time slot that was already filled.
FETCH_BY_ALARM_RANGE_FAILED	41	Command failed.
FETCH_BY_ATTENDEE_ERROR_FAILED	42	Command failed.
ATTENDEE_GROUP_EXPANSION_CLIPPED	43	An LDAP group being expanded was too large and exceeded the maximum number allowed in an expansion. The expansion stopped at the specified maximum limit. The maximum limit defaults to 200. To change the maximum limit, set the server configuration preference `calstore.group.attendee.maxsize`.
USERPREFS_ACCESS_DENIED	44	Either the server does not allow this administrator access to get/modify user preferences, or the requester is not an administrator.

Table 6-4 Error Names, Values, and Meanings *(Continued)*

Error Name	Value	Meaning
NOT_ALLOWED_TO_REQUEST_PUBLISH	45	The requester was not an organizer of the event, and, therefore, is not allowed to edit the component using the PUBLISH or REQUEST method.
INSUFFICIENT_PARAMETERS	46	The caller tried to invoke verifyevents_by_ids, or verifytodos_by_ids with insufficient arguments (mismatched number of uids and rids).
MUSTBEOWNER_OPERATION	47	The user needs to be an owner or co-owner of the calendar in questions to complete this operation. (Probably related to private or confidential component.)
AC_ERR_DWP_CONNECTION_FAILED	48	GSE scheduling events failed to make connection to DWP.
AC_ERR_DWP_MAX_CONNECTION_REACHED	49	Reached the maximum number of connections. When some of the connections are freed, users can successfully connect. Same as 11001.
AC_ERR_DWP_CANNOT_RESOLVE_CALENDAR	50	Front end can't resolve to a particular back end. Same as 11002.
AC_ERR_DWP_BAD_DATA	51	Generic response. Check all DWP servers; one might be down. Same as 11003.
AC_ERR_BAD_COMMAND	52	The command sent in was not recognized. This is an internal only error code. It should not appear in the error logs.
AC_ERR_NOT_FOUND	53	Returned for all errors from a write to the Berkeley DB. This is an internal only error code. It should not appear in the error logs.
AC_ERR_WRITE_IMPORT_CANT_EXPAND_CALID	54	Can't expand `calid` when importing file.
GETTIME_FAILED	55	Get server time failed.
FETCH_DELETEDCOMPONENTS_FAILED	56	Fetch deleted components failed.
FETCH_DELETEDCOMPONENTS_PARTIAL_RESULT	57	Success but partial result.
WCAP_NO_SUCH_FORMAT	58	Returned in any of the commands when supplied fmt-out is not a supported format.
COMPONENT_NOT_FOUND	59	Returned when a fetch or delete is attempted that does not exist.
AC_ERR_BAD_ARGUMENTS	60	Currently used when attendee or organizer specified does not have a valid email address.

Table 6-4 Error Names, Values, and Meanings *(Continued)*

Error Name	Value	Meaning
GET_USERPREFS_FAILED	61	get_userprefs.wcap failed. The following error conditions will return error code 61: • ldap access denied • no results found • ldap limit exceeded • ldap connection failed
WCAP_MODIFY_NO_EVENT	62	storeevents.wcap issued with storeytype set to 2 (WCAP_STORE_TYPE_MODIFY) and the event doesn't exist.
WCAP_CREATE_EXISTS	63	storeevents.wcap issued with storetype set to 1 (WCAP_STORE_TYPE_CREATE) and the event already exists.
WCAP_MODIFY_CANT_MAKE_COPY	64	storevents.wcap issued and copy of event failed during processing.
STORE_FAILED_RECUR_SKIP	65	One instance of a recurring event skips over another
STORE_FAILED_RECUR_SAMEDAY	66	Two instances of a recurring event can't occur on the same day
BAD_ORG_ARGUMENTS	67	Bad organizer arguments. orgCalid or orgEmail must be passed if any other org parameter is sent. That is, orgUID can't be sent alone on a storeevents or a storetodos command if it is trying about to "create" the event or task. Note, if no org information is passed, the organizer defaults to the calid being passed with the command.
STORE_FAILED_RECUR_PRIVACY	68	Error returned if you try to change the privacy or transparency of a single instance in a recurring series.
LDAP_ERROR	69	For get_calprops, when there is an error is getting LDAP derived token values (X-S1CS-CALPROPS-FB-INCLUDE, X-S1CS-CALPROPS-COMMON-NAME).
GET_INVITE_COUNT_FAILED	70	Error in getting invite count (for get_calprops.wcap and fetchcomponents_by_range.wcap commands)
LIST_FAILED	71	list.wcap failed
LIST_SUBSCRIBED_FAILED	72	list_subscribed.wcap failed
SUBSCRIBE_FAILED	73	subscribe.wcap failed
UNSUBSCRIBE_FAILED	74	unsubscribe.wcap failed

Table 6-4 Error Names, Values, and Meanings *(Continued)*

Error Name	Value	Meaning
ANONYMOUS_NOT_ALLOWED	75	Command cannot be executed as anonymous. Used only for `list.wcap`, `list_subscribed.wcap`, `subscribe.wcap`, and `unsubscribe.wcap` commands.
ACCESS_DENIED	76	Generated f a non-admin user tries to read or set the calendar-owned list or the calendar-subscribed list of some other user, or if the option is not turned on in the server
AC_ERR_BAD_IMPORT_ARGUMENTS	77	Incorrect parameter received by `import.wcap`
CDWP_ERR_MAX_CONNECTION_REACHED	11000	Maximum connections to back end database reached. As connections are freed up users will be allowed to connect to back end.
CDWP_ERR_CANNOT_CONNECT	11001	Cannot connect to back end. Back end machine may be down or DWP server is not up and running.
CDWP_ERR_CANNOT_RESOLVE_CALENDAR	11002	Front end cannot resolve calendar to a particular back end.
CDWP_ERR_BAD_DATA	11003	Bad data received from DWP connection. This is a generic response formatting error. Check all DWP servers. One might be down.
CDWP_ERR_DWPHOST_CTX_DOES_NOT_EXIST	11004	For the back end host, context doesn't exist in the context table. Solution is to add back end host to ics.conf and restart front end.
CDWP_ERR_HOSTNAME_NOT_RESOLVABLE	11005	DNS/NIS/files or hostname resolver is not set up properly or machine does not exist.
CDWP_ERR_NO_DATA	11006	No data was received from reading the calprops from the DWP connection.
CDWP_ERR_AUTH_FAILED	11007	DWP authentication failed.
CDWP_ERR_CHECKVERSION_FAILED	11008	DWP version check failed.

Fetching Component Data

The `component_type` parameter directs WCAP to return either only events, only todos, or both events and todos. The keyword arguments, respectively, are: `event`, `todo`, or `all`. The parameter is not required. Its default is `all`, returning both events and todos. If an unrecognized value is passed in, the default value is used.

This parameter is found in all the fetchcomponents_by_* commands.

In addition, deleted components can be retrieved from the `deletelog.db` in the calendar store using the `fetch_deletedcomponents` command.

Fetching Component State Data

All fetch commands, except `fetchcomponents_by_attendee_error`, have the ability to fetch by component state, using the parameter `compstate`. The default (`compstate=ALL`) is to fetch all component states, Use this parameter to limit the type of components fetched.

If the parameter is not specified, the default value is `ALL`.

Table 6-5 lists component state values. A component state pertains either to the attendee or the organizer.

Table 6-5 Component State Values for `compstate` Parameter

Value	Organizer/ Attendee	Comment
`REPLY-DECLINED`	Attendee	The event or todo is an invitation from another user and the current user has declined the invitation.
`REPLY-ACCEPTED`	Attendee	The event or todo is an invitation from another user and the current user has accepted the invitation.
`REQUEST-COMPLETED`	Organizer	The event or todo is an invitation from the current user to other invitees, and all invities have replied.
`REQUEST_NEEDS-ACTION`	Attendee	The event or todo is an invitation from another user and the current user has not replied to it yet.
`REQUEST-NEEDSNOACTION`	Attendee	The event or todo is an invitation from another user and the current user is not required to reply.
`REQUEST-PENDING`	Organizer	The event or todo is an invitation from the current user to other invitees, and is currently in the process of sending out invitations.
`REQUEST-WAITFORREPLY`	Organizer	The event or todo is an invitation from the current user to other invitees, and is currently awaiting replies from all invitees.
`ALL`	N/A	(Default) All event and todo component states.

Fetching Deleted Data

If you have deleted component data and need to reconstruct it, you can use the `fetch_deletedcomponents` command, which causes the system to process the Delete Log Database (ics50deletelog.db in the csdb directory). However, it is not possible to recreate the entire component data since not all of it is logged.

When non-recurring components are deleted, the server removes it from the component database and writes it to the Delete Log database.

When individual instances of a recurring event or task are deleted, the server writes each deleted instance to the Delete Log database. When all instances of the recurring event or todo are deleted, the server deletes the master entry for the component from the component database and writes it to the Delete Log database. A master entry in the Delete Log database contains the `rrules`, `exrules`, and `exdates` recurrence parameters.

In a single `fetch_deletedcomponents` command, either individual instances can be retrieved, or the master entry with its exceptions, but not both.

For more information on the Delete Log database, see the *Calendar Server Administration Guide*.

Fetching Recurrence Data

The `compressed` parameter allows you to retrieve a reduced amount of recurrence data. The parameter defaults (`compressed=0`) to the compressed format, which returns data without the `rrule`, `rdate`, `exrule`, and `exdate` properties as the default. To receive all the recurrence data back from the following commands, use `compressed=1`.

This parameter is used by all the `fetchcomponents_by_*` commands, the `fetchevents_by_id` and `fetchtodos_by_id` commands, and the `store*` commands.

NOTE This parameter has been deprecated for the current release and may be removed from the future releases.

Formatting Standards

Find the exact format and definition for all times, strings, parameters, etc. by referring to RFC 2445, RFC 2446, and RFC 2447. Unless otherwise noted, all WCAP commands follow these specifications.

The RFC's may be found at the IETF web site:

- `http://www.ietf.org/rfc/rfc2445.txt`
- `http://www.ietf.org/rfc/rfc2446.txt`
- `http://www.ietf.org/rfc/rfc2447.txt`

NOTE As a reminder, the maximum parameter value length is 1024 characters.

For more information on time zones, see "Time Zones,"which follows later in this section.

Freebusy Calendars

Calendars can be displayed in freebusy format instead of showing details of scheduled events and todos. Freebusy calendars are used to facilitate scheduling of events or todos in the event and todo creation dialogs in the user interface. They can also be used by calendar owners to prevent other users from viewing the details of their calendars.

This can be accomplished in two separate ways that are not mutually exclusive:

- Freebusy access rights can be granted to users in the calendar's properties.
- Freebusy access can be assigned to the calendar as a whole using the calendar property `fbinclude`.

  If `fbinclude` is set to `0`, it overrides any access rights granted to users. That is, if fbinclude=`0`, then the calendar will not be included in freebusy calculations, no matter what the `acl` parameter specifies.

  If the `fbinclude` is set to `1`, which allows the use of the calendar for freebusy calculations, then the `acl` access rights will be used to determine if the user can see the details of the calendar, the freebusy representation only, or neither.

In freebusy calendars, instead of event or todo details, just the word "Busy" appears by the time block. Blocks of time without any scheduled events are listed also, with the word "Free" next to them.

For example, a calendar called `jdoe` has the following events:

100:00-11:00 first meeting

12:00-1:00	lunch
3:00-4:00	second meeting

If user `john` has only freebusy access to the calendar `jdoe`, user `john` will get only a freebusy version of the calendar. The freebusy time for `jdoe` (from 9:00 to 6:00) would appear as the following:

9-10		Free
10-11		Busy
11-12		Free
12-1	:	Busy
1-3	:	Free
3-4	:	Busy
4-6	:	Free

Notice that `john` does not know the details of why the user is busy, but simply knows when the user is busy.

The `get_freebusy` command allows selection of which calendars to use in the calculation in two ways: using the `calid` parameter, or the `mail` parameter. One of the parameters is required, but not both. If both are present, the `calid` value is used.

When an email address is passed in using the `mail` parameter, all calendars, for which this user is the primary owner and which have `fbinclude=1` in their calendar properties settings, will be included in the freebusy calculation.

When the `calid` parameter is used, specific calendars can be named rather than using all of owners calendars. Note that the `calid` parameter can take an email address (by specifying `mailto:`*`ref822address`*, where *`rfc822address`* is any valid email address that maps to a single calendar in the local LDAP directory).

The command returns the busy data only. The rest of the time slots are presumed to be free.

Freebusy Calculation for Private Events

When a freebusy calendar rendition is requested using the `get_freebusy` command, private events and todos will be included or excluded depending on the value of the `transparent` parameter stored with the events and todos when they were created or modified.

Using the `store*` commands, set the event or todo `transparent` parameter to `1` to keep the event truly private, and set it to `0` to allow it to be included in the freebusy calculation.

As opposed to regular events, all-day events (`isAllDay` parameter is set to `1`) default to private and opaque (`transparent=1`). For the all-day event to be included in the freebusy calculation, the `transparent` parameter must be set to `0`.

Group Scheduling

When you are using the `storeevents` command for scheduling a group event, there are two parameters that are required:

- Attendee Parameter
- Method Parameter

Attendee Parameter

The two most important parameters for creating a group-scheduled event are `attendee` and `method`. The `attendee` parameter is a semicolon separated list of attendee entries. The attendee entry is explained in the section below.

Each attendee entry may contain several parameters, such as invitation participation status, whether attendance is required or not, etc. All such parameters are encapsulated in a syntax very similar to the `ATTENDEE` property defined in the iCalendar Specification (RFC 2445). Reading the entire document is recommended in order to have the necessary background information to understand the WCAP attendee syntax. There are some differences, such as, WCAP uses a different delimiter, "^", to set apart these parameters. (However, WCAP uses the standard iCalendar semicolon delimiter for separating attendees.)

For example, where iCalendar would have the following:

```
PARSTAT=ACCEPTED;RSVP=TRUE:mailto:abc@xyz.com
```

WCAP would format it this way:

```
PARSTAT=ACCEPTED^RSVP=TRUE^mailto:abc@xyz.com
```

Examples of WCAP Attendee Entries

If attendee A (attA) accepts an invitation, the WCAP command would contain:

```
PARTSTAT=ACCEPTED^RSVP=TRUE^attA
```

If attendee B (attB) declines an invitation, the WCAP command would contain:

```
PARTSTAT=DECLINED^RSVP=TRUE^attB
```

If the email attendee `jdoe@xyz.com` has not yet decided to attend and is not required to respond, the WCAP command would contain:

```
PARTSTAT=NEEDS-ACTION^RSVP=FALSE^mailto:jdoe@xyz.com
```

An attendee in an existing meeting can be marked for deletion by assigning `X-NSCP-WCAP-ATTENDEE-DELETE` to `PARTSTAT`. For example, if you want to delete attendee `jdoe`, the `attendee` parameter of the `storeevents` command would contain the following:

```
PARTSTAT=X-NSCP-WCAP-ATTENDEE-DELETE^jdoe
```

Table 6-6 lists the parameters in the iCalendar ATTENDEE property understood by WCAP. Most of the parameters are optional. Not all are fully supported by Calendar Server, although the information will be stored. For group scheduling, only the PARTSTAT and RSVP parameters are relevant.

Table 6-6 iCalendar ATTENDEE parameters understood by WCAP

Parameters	Purpose
PARTSTAT	The only required parameter. This shows the attendees participation status.
CUTYPE	Calendar user type.
MEMBER	List of groups the attendee is part of. WCAP has no understanding of these groups.
ROLE	Role of the attendee in this meeting.

Table 6-6 iCalendar ATTENDEE parameters understood by WCAP

Parameters	Purpose
RSVP	Attendee response required or not.
DELEGATED-TO	To whom the attendee delegates attendance.
DELEGATED-FROM	Attendee is a delegate for this person.
SENT-BY	The calendar user acting on behalf of the specified user.
CN	Display name of attendee.
DIR	Directory entry reference.
LANG	Language of the entry.

In addition, WCAP allows the optional use of an additional parameter, SENT-STATUS, which is specific to Calendar Server and is not part of the iCalendar specification. Possible values for SENT-STATUS are: NOT-SENT, and SENT-SUCCEEDED. The default is NOT-SENT. The Group Scheduling Engine inside Calendar Server will not process an attendee with a SENT-STATUS value of SENT-SUCCEEDED.

Method Parameter

The method parameter describes the type of message used: invitation, response, cancellation.

For group scheduling, specify one of the following ITIP methods:

1	PUBLISH	Used only by the organizer.
2	REQUEST	Used only by the organizer.
4	REPLY	Used only by attendees.
8	CANCEL	Used only by the organizer.

NOTE Even though the method parameter has a default value, it is a required parameter if you are trying to do anything other than PUBLISH. Leaving the parameter off the storeevents or storetodos commands will cause the default (PUBLISH) to be the presumed action.

In an invitation, three types of messages may occur:

- An organizer invites attendees.

  When an organizer creates a meeting, there are two ways to invite people:

  - Send a PUBLISH message, creating or modifying a meeting. The method parameter is set to “1”. Note that everthing except the attendee information is sent. (Attendees can see the event but not the other attendees.)
  - Send a REQUEST message, creating or modifying a meeting, and requesting a response to the invitation from attendees. The method parameter is set to “2”.

  Only the organizer of the meeting can send a PUBLISH or REQUEST message.

- Attendees respond to invitation.

  An attendee sends a REPLY message, either accepting or declining the invitation. (The method parameter is set to “4”.)

- Organizer cancels the meeting.

  When an organizer cancels a meeting, attendees are notified by sending a CANCEL using one of the deleteevents commands. The method parameter is set to “8”.

NOTE The preferred way to handle a cancellation is to use one of the deleteevents commands, rather than storeevents.

The following set of examples demonstrates the WCAP commands for an organizer “org” to invite attendees “attA” and “attB” to a meeting. Attendee “attA” accepts the invitation; attendee “attB” declines it. The uid for the meeting is “event_u1”. The event will be created on both attendees’ calendars. Each will respond to the event on their own calendar. The response will be sent back to the organizer’s calendar by the Calendar Server Group Scheduling Engine.

The following is an example of an invitation:

```
storeevents.wcap?id=${SESSIONID of org}&calid=org&dtstart=
   20020201T200200Z&dtend=20020201T210000Z&summary=invite_attA_attB
   &method=2&attendees=PARTSTAT=ACCEPTED^RSVP=TRUE^org;PARTSTAT=
   NEEDS-ACTION^RSVP=TRUE^attA;PARTSTAT=NEEDS-ACTION^RSVP=
   TRUE^attB&fmt-out=text/xml
```

The following is an example of the acceptance:

```
storeevents.wcap?id=${SESSIONID ofattA}&calid=attA&uid=event_u1
   &method=4&attendees=PARTSTAT=ACCEPTED^RSVP=TRUE^attA
   &fmt-out=text/xml
```

The following is an example of a declined meeting:

```
storeevents.wcap?id=${SESSIONID ofattB}&calid=attB&uid=event_u1
   &method=4&attendees=PARTSTAT=DECLINED^RSVP=TRUE^attA
   &comments=I_cannot_make_it_Sorry&fmt-out=text/xml
```

Output Format

WCAP commands can request the output format in two content types:

1. `text/calendar` - iCalendar
2. `text/xml` - iCalendar XML

To change the output format, set `fmt-out` to the target value. If `fmt-out` is not specified, the default format of `text/calendar` will be returned.

Recurring Components – Overview

Recurrence handling occurs as follows:

- A recurring series of events or todos has a master entry plus entries for exceptions.
- Changing the `rrules` of a single instance returns an error. When `rrules` are modified for a recurring series, the whole series is deleted and recreated.
- Changing `dtstart` of a recurring series entry causes the whole series to be recreated with the new dtstart, thereby losing all exceptions.
- Inserting a `rid` that was not part of the original rule is not supported.
- Multiple `rrules` for any component are not supported.

Recurring Components – Creating, Modifying

The following parameters are used with the `storeevents` and `storetodos` commands to create and modify components:

- `rrules` - Semicolon-separated list of quoted recurrence-rule strings for recurring events.
- `rdates` – Semicolon-separated list of ISO 8601 date strings listing recurrence dates.
- `exrules` – Semicolon-separated list of quoted recurrence-rule strings for dates to exclude.
- `exdates` – Semicolon-separated list of ISO 8601 date strings listing dates to exclude.
- `rid` – ISO 8601 DateTimeString giving the recurrence ID of an event.
- `mod` – Modifier telling which instances of the event to store.
- `rchange` – A boolean specifying whether or not to replace the `rrules` parameter. If `rchange=1`, the store commands map all `mod` settings (`2-4`) are mapped to 4. This means that you can not change an `rrule` for only some of the components in a recurring series. To change the `rrules` parameter, all components in the recurring series must be changed.

NOTE The rrules, rdates, exrules, and exdates parameters always function in replace mode. That is, no matter what the replace parameter value is set to, the values passed in always replace the parameter value, rather being appended to it.

This means you can not have multiple rrules for the same component.

For more information on the replace parameter, see Updating Parameter Values.

rrules

The `rrules` parameter takes a semicolon-separated list of quoted recurrence rule strings. Each string represents a recurrence rule of the event. Each string must be enclosed in quotes. There are many parameters possible for recurrence rules. See RFC 2445 for a complete description of the syntax.

Three very useful parameters for specifying recurrence are `freq`, `count` and `until`:

- The freq parameter in a rule defines the periodicity of the event, and has the following possible values:

DAILY	The event recurs daily.
WEEKLY	The event recurs weekly.
MONTHLY	The event recurs monthly.
YEARLY	The event recurs yearly.

- The count parameter in a rule defines how many times the meeting will repeat. If you do not specify the count, the default is the maximum number of recurrences allowed.The default maximum is 60. To change the maximum number, set the server configuration preference calstore.recurrence.bound.
- The until parameter in a rule specifies using an end date as opposed to using the count to limit the number of instances created. Instances will be created up to the end date or until 60 instances are created, whichever occurs first.

In the event that neither the count nor the until parameter are specified, the default is 60 instances.

NOTE Using the storeevents.wcap command to create an event with only exdate or rdate values, without specifying a rrule results in no events being created. The same behavior can be observed with the storetodos.wcap command.

The following example shows an rrules parameter that specifies the event is to occur daily for 10 instances:

```
rrules="count%3D10%3Bfreq%3Ddaily" (COUNT=10;FREQ=DAILY)
```

The following example URL passes the example rrules parameter:

```
http://webcalendarserver/storecomponents.wcap?id=b5q2o8ve2rk02nv9t6
&calid=jdoe&uid=333&dtstart=20020301T112233Z
&rrules="count%3D10%3Bfreq%3Ddaily"&dtend=20020301T112233&summary=uuuu
```

rdates

The rdates parameter takes a semicolon-separated list of date-time specifications where each date-time gives a recurrence date of the event.

For example, the following rdates parameter specifies a recurring event with two recurrence dates (3/31/02 11:22:33 and 5/31/02 11:22:33):

```
rdates=20020331T112233;20020531T112233
```

The following example URL passes the example rdates parameter:

```
http://webcalendarserver/storecomponents.wcap?id=b5q2o8ve2rk02nv9t6
&calid=jdoe&uid=333&dtstart=20020301T112233Z
&rdates=20020331T112233;20020531T112233
&dtend=20020301T112233&summary=uuuu
```

If you want to the change the recurrence rule after a certain date, you must set rchange to 1.

exrules

The exrules parameter takes a semicolon-separated list of quoted recurrence rule strings where each rule is an excluded recurrence of the event.

For example, the following exrules parameter specifies a recurring event that does not recur at the times specified by the two rules:

```
exrules="count%3D10%3Bfreq%3Ddaily";"freq%3Dweekly%3Bcount%3D4"
(COUNT=10;FREQ=DAILY and FREQ=WEEEKLY;COUNT=4 encoded)
```

The first rule is for the event not to occur daily for 10 instances. The second rule is for the event not to occur weekly for 4 instances.

The following example URL passes the example exrules parameter:

```
http://webcalendarserver/storecomponents.wcap?id=b5q2o8ve2rk02nv9t6
&calid=jdoe&uid=333&dtstart=20020301T112233Z
&exrules="count%3D10%3Bfreq%3Ddaily";"freq%3Dweekly%3Bcount%3D4"
&rrules="count%3D100%3Bfreq%3Ddaily"&dtend=20020301T112233&summary=uuuu
```

exdates

The exdates parameter takes a semicolon-separated list of date-time specifications. Each date-time represents an excluded date of the event.

For example, the following exdates parameter specifies a recurring event that does not occur on the two specified dates (3/31/02 11:22:33 and 5/31/02 11:22:33):

```
exdates=20020331T112233;20020531T112233
```

The following example URL passes the example exdates parameter:

```
http://webcalendarserver/storecomponents.wcap?id=b5q2o8ve2rk02nv9t6
&calid=jdoe&uid=333&dtstart=20020301T112233Z
&exdates=20020331T112233;20020531T112233
&rrules="COUNT%3D200%3BFREQ=DAILY";dtend=20020301T112233&summary=uuuu
```

rid

This parameter specifies a unique recurrence date of an event or todo. Use rid in conjunction with the mod parameter to specify a range of events and todos to be modified.

For example:

```
http://webcalendarserver/storecomponents.wcap?id=b5q2o8ve2rk02nv9t6
&calid=jdoe&uid=333&dtstart=20020301T112233Z
&rid=20020331T112233;dtend=20020301T112233&summary=uuuu&mod=1
```

For a non-recurring event or todo, the rid is 0.

mod

When modifying recurring components, this parameter specifies whether to apply the changes to one or more instances of the event or todo. The following settings are mapped, but currently only the values 1 and 4 are honored. If 2 or 3 are specified, in certain cases they are mapped to 4.

Value	Option
1	This instance only.
2	This and all future instances.
3	This and all prior instances.
4	This and all instances.

When creating or modifying a recurring component, if changing rrules is allowed (rchange is set to 1), the system assumes a setting of 4, which causes the entire series of events or todos to be deleted and rewritten. If 2 or 3 are specified when trying to change rules or start times, it will be mapped to 4 anyway. If 2 0r 3 is specified for changing a summary or description, the setting will be honored, but no exceptions will be created for errors.

rchange

The rchange parameter specifies whether recurrences are expanded in storeevents, and storetodos. Normally, events and todos calendar components are not expanded, so the parameter defaults to 0, which implies the series is recreated.

However, you might not want to expand recurrences when you are modifying multiple events. For example, suppose a meeting recurs every Friday starting Jan. 1, 2002. Use the following URL to change the summary of each event after Feb. 1, 2002 to changed-event.

The following example sets the rchange parameter to 0, to make the modification without adding additional events:

```
http://webcalendarserver/storeevents.wcap?id=b5q2o8ve2rk02nv9t6
&calid=jdoe&uid=abcxyz&dtstart=20020201T112233Z
&rrules="byday%3Dfr%3Bfreq%3Dweekly"&summary=changed-event
&rid=20020201T112233Z&mod=2&rchange=0
```

Note that when you are modifying a recurrence series, do not pass in rrule unless you are trying to recreate the series with a new rule.

Recurring Components – Deleting

When you delete a recurring component, specify the recurrence ID and whether to delete the recurrences as well as the original event or todo.

Use the mod parameter to choose which option you want:

Value	Option
1	Delete/modify this instance only.
2	Delete/modify this and all future recurrences.
3	Delete/modify this and all prior recurrences.
4	Delete/modify all instances.

A setting of 2 will delete only as many instances as exist on the server.

Examples Using deleteevents_by_id

To delete just the single instance of the event, the `mod` parameter should be set to `1`. For example, this URL would delete just the event that occurs on the date March 1, 2002 11:22:33 AM GMT.

```
http://webcalendarserver/deleteevents_by_id.wcap?id=23423423434abc&calid=j
doe&uid=001&rid=20020301T112233Z&mod=1
```

To delete the event and all future instances of the event, the `mod` parameter should be set to 2. For example, this URL would delete the event that occurs on the date March 1, 2002 11:22:33 AM GMT and all future instances of this event (`uid 001`).

```
http://webcalendarserver/deleteevents_by_id.wcap?id=23423423434abc&
calid=jdoe&uid=001&rid=20020301T112233Z&mod=2
```

To delete the event and all prior instances of the event, the `mod` parameter should be set to 3.

For example, this URL would delete the event that occurs on the date March 1, 200211:22:33 AM GMT and all prior instances of this event (`uid 001`).

```
http://webcalendarserver/deleteevents_by_id.wcap?id=23423423434abc&
calid=jdoe&uid=001&rid=20020301T112233Z&mod=3
```

To delete all instances of the event, the `mod` parameter should be set to 4. For example, this URL would delete ALL instances of the event (`uid` 001).

```
http://webcalendarserver/deleteevents_by_id.wcap?id=23423423434abc&
calid=jdoe&uid=001&rid=20020301T112233Z&mod=4
```

Recurring Components – Fetching

The following parameters are found in the `fetchcomponents_by_*` commands, and the `fetchevents_by_id` and `fetchtodos_by_id` commands:

- `compressed` – A boolean specifying whether to return all of the recurring entry's data, or to exclude the following parameters:`rrules`, `rdate`, `exrule`, `exdate`.

  Note that this parameter is deprecated in the current release and may be removed from future releases.

- recurring – A boolean parameter specifying whether or not to return all components in compressed form (master entry and exceptions). This parameter is also present in the fetch_deletedcomponents command.

Time Zones

To support a universal standard, Calendar Server uses the date and time strings in Greenwich Mean Time (GMT) or Coordinated Universal Time (UTC), called Zulu time. The server stores and returns all date and time strings from the database in Zulu time. WCAP converts the Zulu times to the appropriate time zone settings depending upon the value of the tzid and tzidout parameters.

The tzid parameter is used for date and time strings passed in with the dtstart, dtend, and rid parameters, which are not already in Zulu time. WCAP uses the value of the tzid parameter to calculate the Zulu time. If the tzid parameter is not passed in, the server's default time zone is used to calculate Zulu time.

For commands that return events and todos, the data will be returned in Zulu time, unless the tzidout parameter is passed in. In this case the Zulu time is translated into the time zone specified in the tzidout parameter.

For example, if the fetch_components_by range command specifies a date range of 20020506T100000 to 20020507T100000, with a tzid=America/Los_Angeles, WCAP will translate that to Zulu time for database lookup. If the tzidout parameter was also passed in (for our example, tzidout=America/New_York), then the resulting output would be translated to that time zone and returned. If the tzidout parameter is missing, the component data is returned in Zulu time.

The tzidout parameter can be used with the storeevents and storetodos command when the fetch parameter is set to 1 (fetch=1).

The time zones information is kept in a plain text file (timezones.ics) in VTIMEZONE format.

The server never uses the system time zone information to calculate the current date and time. It uses the time elapsed in seconds since the Epoch (00:00:00 UTC, January 1, 1970) to calculate current date and time. Then depending on the user's time zone settings, the date is displayed to reflect the correct time zone.

The following commands use both the tzid and tzidout parameters:

- fetchcomponents_by_alarmrange
- fetchcomponents_by_lastmod
- fetchcomponents_by_range

- fetchevents_by_id
- fetchtodos_by_id
- storeevents
- storetodos

In addition, the following commands use the tzid parameter (but not the tzidout):

- deleteevents_by_id
- deletetodos_by_id
- get_freebusy
- set_calprops

Updating Parameter Values

Two commands, storeevents and storetodos, allow you to update (replace, append, or delete) parameter values. When updating current values for a component, you can either replace the current values with the new ones being passed in, append the new values to the current values, or pass in empty parameter values to delete the parameter.

The ability to append parameter values applies only to parameters that can accommodate multiple values (that is, parameters that use semicolon-separated values, such as the attendees parameter). The default is to append (replace=0) the new values to the current values. If you want to replace the current values with the new values being passed in, include the replace parameter in the command, with the value set to 1 (replace=1). If you do not include the replace parameter in the command, the system assumes the default setting (replace=0) and appends the new values to the old values.

With one exception, the recurrence and alarm parameters can only be replaced, not appended. Specifically, the parameters are: rrules, rdates, exrules, exdates, alarmAudio, alarmDescription,alarmFlashing, alarmPopup, and alarmStart. The alarmEmails parameter is the only one that allows multiple values, and thus is the only exception. Therefore you can append an alarm email recipient to the list by specifying replace=0.

In all cases, a parameter can be deleted by passing in an empty parameter and setting `replace` to `1`. For example, to delete the `alarmPopup` parameter, pass in the following: `alarmPopup=&replace=1`. Using `replace=1` can also be used to delete string fields. For example, to delete the description, you would use `desc=&replace=1`.

X-Tokens

Table 6-7 lists the X-tokens returned by WCAP commands.

Table 6-7 X-Tokens Returned by WCAP Commands

Token Name	Type	WCAP Command	Description
X-NSCP-ATTENDEE-GSE-STATUS	integer	all fetch commands	Attendee status for group scheduled components.
X-NSCP-CALPROPS-ACCESS-CONTROL-ENTRY	string	all fetch commands	ACL for this calendar.
X-NSCP-CALPROPS-CALMASTER	string	all fetch commands	`Calmaster`
X-NSCP-CALPROPS-CATEGORIES	string	all fetch commands	
X-NSCP-CALPROPS-CHARSET	string	all fetch commands	Character Set used by calendar.
X-NSCP-CALPROPS-CHILDREN	string	all fetch commands	Child calendars if present.
X-NSCP-CALPROPS-CREATED	string	all fetch commands	Date the component was created.
X-NSCP-CALPROPS-DESCRIPTION	string	all fetch commands	Calendar description.
X-NSCP-CALPROPS-LANGUAGE	string	all fetch commands	Language used by calendar.
X-NSCP_CALPROPS-LAST-MODIFIED	string	all fetch commands	Date string of last modification to properties.
X-NSCP-CALPROPS-NAME	string	all fetch commands	Name of calendar.
X-NSCP-CALPROPS-OWNERS	string	all fetch commands	Owners for this calendar.
X-NSCP-CALPROPS-PARENT-CALID	string	all fetch commands	Parent `calid` if present.
X-NSCP-CALPROPS-PRIMARY-OWNER	string	all fetch commands	Calendar's primary owner.
X-NSCP-CALPROPS-READ	integer	all fetch commands	Permission to read properties.
X-NSCP-CALPROPS-RELATIVE-CALID	string	`get_freebusy`, all fetch commands	Calendar identifier of user.
X-NSCP-CALPROPS-RESOURCE	string	all fetch commands	Resource rather than a regular calendar.

Table 6-7 X-Tokens Returned by WCAP Commands *(Continued)*

Token Name	Type	WCAP Command	Description
X-NSCP-CALPROPS-TZID	string	all fetch commands	Time date string for calendar creation.
X-NSCP-CALPROPS-WRITE	integer	all fetch commands	Permission to write properties.
X-NSCP-CHARSET	string	all fetch commands	Character Set.
X-NSCP-DTEND-TZID	string	all fetch commands	End time string.
X-NSCP-DTSTART-TZID	string	all fetch commands	Start time string.
X-NSCP-DUE-TZID	string	all fetch commands	Due date time string.
X-NSCP-GSE-COMMENT	string	all fetch commands	Comment.
X-NSCP-GSE-COMPONENT-STATE	string	all fetch commands	Component state.
X-NSCP-GUID	GUID integer	get_guids	Globally unique identifier.
X-NSCP-LANGUAGE	string	all fetch commands	Returns the lang string (for example, en for English)
X-NSCP-LINK-CALID	string	all fetch commands	Calendar ID.
X-NSCP-ONGOING	integer	all fetch commands	
X-NSCP-ORGANIZER-EMAIL	string	all fetch commands	Organizer's email address.
X-NSCP-ORGANIZER-SENT-BY-UID	string	all fetch commands	uid for who created the component for the organizer.
X-NSCP-ORGANIZER-UID	string	all fetch commands	Organizer's uid.
X-NSCP-ORIGINAL-DTSTART	Date Time Z string	fetch commands	
X-NSCP-REQUEST-STATUS	string	deleteevents_by_range, deletetodos_by_range	Error message string returned from WCAP commands.
X-NSCP-TOMBSTONE	integer	all fetch commands	Dead events (those in the past).
X-NSCP-WCAP-CALENDAR-ID	string		calendar ID of logged-in user
X-NSCP-WCAP-ERRNO	integer	all	Error number generated from WCAP command

Table 6-7 X-Tokens Returned by WCAP Commands *(Continued)*

Token Name	Type	WCAP Command	Description
X-NSCP-WCAP-PREF-	varies by preference	get_userprefs	User preferences: cn, givenName, preferredLanguage, sn, nswcalCALID, cefontSizeDelta, ceTableSpacing, ceColorSet, ceBgcolor, ceCalList, ceAgendaList, ceAgendaTZMode_Personal, ceCursorColor
X-NSCP-WCAP-SERVER-PREF-	varies by preference	get_userprefs	Server preferences: allowchangepassword, allowcreatecalendars allowdeletecalendars
X-NSCP-WCAP-SESSION-ID	string	check_id	Session identifier of logged-in user
X-NSCP-WCAP-USER-ID	string		user ID of logged-in user
X-NSCP-WCAP-VERSION	string		WCAP version the server currently supports (current version is 3.0)
X-S1CS-ATTENDEE-EXDATELIST	string	all fetch commands	Attendee exceptions for each date.
X-S1CS-ATTENDEE-RDATELIST	string	all fetch commands	Attendees for each date.
X-S1CS-CALID	string	all fetch commands	Calendar ID.
X-S1CS-CALPROPS-ALLOW-DOUBLEBOOKING	string	get_calprops set_calprops	Doublebooking allowed.
X-S1CS-CALPROPS-COMMON-NAME	string	get_calprops	Common name. Set by querying LDAP cn attribute.
X-S1CS-CALPROPS-FB-INCLUDE	integer	get_calprops	0=not included in free/busy calculation. 1= included in free/busy calculation.
X-S1CS-CALPROPS-INVITATION-COUNT	string	get_calprops	Invoke command with invitecount=1 to return total number of open invitations.
X-S1CS-CALPROPS-OWNED-CALENDAR	string	list	Full calids of all calendars owned for this user.. For example: jdoe@example.com jdoe@example.com:Vacation

Table 6-7 X-Tokens Returned by WCAP Commands *(Continued)*

Token Name	Type	WCAP Command	Description
X-S1CS-CALPROPS-SUBSCRIBED-CALENDAR	string	list_subscribed	Full calids of all calendars this user subscribes to, including all owned by the user. For example: jdoe@example.com jdoe@example.com:Vacation fred@example.com jane@example.com:ProjectX
X-NSCP-COMPONENT-SOURCE	string	all fetch commands	
X-S1CS-EMAIL	string	all fetch commands	Email address.
X-S1CS-EXPORTVERSION	string	all fetch commands	Export version.
X-S1CS-RECURRENCE-COUNT	integer	all fetch commands	Count of the number of components in the recurring series.
X-S1CS-RECURRENCE-EXDATELIST	string	all fetch commands	Exception list for recurring master.
X-S1CS-RECURRENCE-RDATELIST	string	all fetch commands	List of recurrence dates.
X-S1CS-RECURRENCE-UNTIL	string	all fetch commands	Date string for end date.
X-NSCP-TRIGGERED_BY	string	all fetch commands	
X-S1CS-TZID-ALIAS	string	all fetch commands	Alias for time zone.

Chapter 7

WCAP Command Reference

This chapter contains the WCAP command reference. Each command accepts various parameters, which are defined for each command in this chapter.

Unless otherwise noted, the maximum length value for any parameter accepted by WCAP commands is 1024 characters. While no input length checking is performed by WCAP, any parameter value longer than 1024 can produce unpredictable results.

For all commands that allow the `id` parameter (session ID), it is a required parameter. There are two exceptions to this rule. It is not required in order to grant anonymous access to a calendar, nor is it required in order to grant read access to a public calendar. In all other situations, you must provide the session ID in the `id` parameter.

NOTE The server supports “anonymous” as a special principal name. The anonymous user can log in with any password. It is not associated with any particular domain.

The following is a list of the available WCAP commands:

addlink – deprecated

change_password

check_id

createcalendar

deletecalendar

deletecomponents_by_range

deleteevents_by_id

deleteevents_by_range

deletetodos_by_id

deletetodos_by_range

export

fetchcomponents_by_alarmrange

fetchcomponents_by_attendee_error

fetchcomponents_by_lastmod

fetch_deletedcomponents

fetchcomponents_by_range

fetchevents_by_id

fetchtodos_by_id

get_all_timezones

get_calprops

get_freebusy

get_guids

gettime

get_userprefs

import

list

list_subscribed

login

logout

ping

search_calprops

set_calprops

set_userprefs

storeevents

storetodos

subscribe_calendars

unsubscribe_calendars

verifyevents_by_ids

verifytodos_by_ids

version

addlink

Purpose

This command has been deprecated. It is not used in the current version of Calendar Server and may be removed from the product in a future version.

Add links from one calendar's events or todos to another calendar.

Parameters

Table 7-1 lists `addlink` parameters:

Table 7-1 `addlink` Parameters

Parameter	Types	Purposes	Required	Default
`id`	unique identifier string	The session identifier.	Y	N/A
`destCal`	string	The calendar containing the events or todos. You must have read access to this calendar.	Y	N/A
`rid`	semicolon separated list of strings.	A list of event and/or todo recurrence identifiers to which to create links.	Y	N/A
`srcCal`	string	The calendar receiving the links. You must have write access to this calendar.	Y	N/A
`uid`	semicolon separated list of strings.	A list of event and/or todo identifiers to which to create links.	Y	N/A

Description

Use this command to add links in the destination calendar to the specified events and / or todos in the source calendar.

You must specify the `id` parameter with the command unless the specified calendar is a public calendar.

The number of items in the `uid` and `rid` lists must match exactly, with each `rid` corresponding to the `uid` in the same position in the list. If an event or todo has no recurrence ID, use `0` in the `rid` list.

Unless the following three requirements are met, the transaction will fail:

- The source calendar and destination calendar parameters must be valid calendar ID's.
- The user must have write access to the destination calendar and read access to the source calendar.

- The uid and rid lists must have the same number of elements.

Returns

If the transaction fails, an error of ADDLINK_FAILED(12) returns; otherwise, the return code is 0.

Example

This example shows how to add two event links to the calendar jdoe. The links should point to events in the pub calendar. The events are 1111 and 2222, (their uids). Neither event is recurring, so their recurrence-id is 0.

This URL executes the above transaction.

```
http://webcalendarserver/addlink.wcap?id=b5q2o8ve2rk02nv9t6&destCal=jdoe&s
rcCal=pub&uid=1111;2222&rid=0;0
```

change_password

Purpose

Change the password of the current user. This command is deprecated. It is here only for backward compatibility. See the "Administration Guide" for details on changing a password.

Parameters

Table 7-2 lists change_password parameters:

Table 7-2 change_password Parameters

Parameter	Type	Purpose	Required	Default
id	string	The session identifier.	Y	N/A
newPassword	string	The new user password.	Y	N/A
oldPassword	string	The previous user password.	Y	N/A
fmt-out	string	The format for the returned data. The three format types: text/calendar text/xml	N	text/calendar

Purpose

This command changes a user's password. Passwords are passed as plain text. Only users with administrative privilege may use this command unless the service.wcap.allowchangepassword preference is set.

You must specify the id parameter with the command unless the specified calendar is a public calendar.

Returns

A failure of the command will return the error CHANGE_PASSWORD_FAILED(27).

Example

This example URL requests a password change:

```
http://webcalendarserver/change_password.wcap?id=b5q2o8ve2rk02nv9t6&oldPas
sword=abc&newPassword=def
```

check_id

Purpose

This administrator only command allows the administrator to verify that a session is still valid.

Parameters

Table 7-2 lists check_id parameters:

Table 7-3 check_id Parameters

Parameter	Type	Purpose	Required	Default
id	string	The session identifier.	Y	N/A
fmt-out	string	The format for the returned data. The three format types: text/calendar text/xml	N	text/calendar

Purpose

This command allows the administrator to verify that the session is still valid.

Returns

The server returns the property X-NSCP-WCAP-CHECK-ID. If the value of this property is 1 the session is valid. If a zero (0) is returned, the session is invalid. It has either timed out or is unrecognized.

Example

The following command returns whether the specified session is valid or not:

http://*webcalendarserver*/check_id.wcap?id=n3l0eeu6s3n3o3b8v&fmt-out=text/calendar

The output returned is:

```
HTTP/1.1 200
Date: Thu, 14 Dec 2002 19:48:17 GMT
Content-type: text/calendar; charset=UTF-8
Content-length: 131
Last-modified: Thu, 14 Dec 2002 19:48:17 GMT
```

```
Pragma: no-cache
Expires: 0
Cache-Control: no-cache
Connection: Keep-Alive

BEGIN:VCALENDAR
PRODID:-//SunJavaSystem/Calendar Hosting Server//EN
METHOD:PUBLISH
VERSION:6.0
X-NSCP-WCAP-CHECK-ID:1
END:VCALENDAR
```

createcalendar

Purpose

Create a new calendar.

Parameters

Table 7-4 lists createcalendar parameters:

Table 7-4 createcalendar Parameter

Parameter	Types	Purposes	Required	Default
calid	string	The user's calid, used to generate the new calendar's calid.	Y	N/A
id	unique identifier string	The session identifier.	Y	N/A
fmt-out	string	The format for the returned data. The three format types: text/calendar text/xml	Y	text/calendar
set_calprops	integer (0,1)	A boolean indicating whether to set the properties of the new calendar. 1 = Set properties. 0 = Do not set properties.	N	0
subscribe	integer (0 or 1)	Allows a user to specify if the newly created calendar should be added to the user's subscribed calendar list. 1 = Subscribe to the calendar 0 = Do not subscribe to the calendar	N	0

Description

Use this command to create a new calendar for the current user. To enable users who do not have administrative privileges to use this command, set the service.wcap.allowcreatecalendars preference in the ics.conf file.

Creating a Valid Calid

The new calid of the created calendar is a combination of the user's userid and the calid parameter passed in. The system retrieves the userid by doing a lookup on the session specified with the id parameter. The format for the new calendar's calid is userid:calid. For example, if the user is jdoe, and the calid parameter is tv, the new calendar's calid is jdoe:tv.

The server will attempt to truncate calid parameters that are too long or contain any illegal characters. If the server is unable to truncate the calid parameter, the error returned is ILLEGAL_CALID_NAME(30).

Valid characters for the calid parameter are:

- Alphabet characters (A-Z, a-z)
- Numeric characters (0-9)
- Three special characters
  - Dash (-)
  - Underscore (_)
  - Period (.)

For example, these are legal values for the calid parameter: calendar1, calendar-1, calendar_1, calendar.1

Setting Calendar Properties

You can set the calendar properties during creation. Pass in the set_calprops parameter with a value of 1. You can then pass in any additional parameters as defined for the set_calprops command for setting calendar properties.

For more information on calendar properties you can set, see the set_calprops command.

Note that at calendar creation, if you do not specify calendar properties, the defaults set in the ics.conf file will be used.

Returns

The returned output shows the calendar properties (retrieved with a call to the fetchcomponents_by_range command) formatted according to the fmt-out value.

Error Codes

If the operation is successful, the error number of 0 is appended to the error string. If the newly created calid already exists in the database, an error code returns: CREATECALENDAR_ALREADY_EXISTS_FAILED(25)

Example

The following example URL creates a calendar with the ID jdoe:newcal for the user jdoe, sets the name to New-Calendar, and the categories to business and work:

```
http://webcalendarserver/createcalendar.wcap?id=b5q2o8ve2rk02nv9t6&calid=newcal&set_calprops=1&name=New-Calendar&categories=business;work
```

deletecalendar

Purpose

This command deletes a user's calendar.

Parameters

Table 7-5 lists deletecalendar parameters:

Table 7-5 deletecalendars Parameter

Parameter	Types	Purposes	Required	Default
calid	string	The name of the calendar to delete.	Y	N/A
id	unique identifier string	The session identifier.	Y	N/A
fmt-out	string	The format for the returned data. The three format types: text/calendar text/xml	Y	text/calendar
unsubscribe	integer (0 or 1)	Allows an administrator to specify if deleted calendars should be removed from the users subscribed calendar list. 1 = Unsubscribe the calendar. 0 = Do not unsubscribe the calendar.	N	1

Description

Use this command to delete a user's calendar. You must pass in the calid, which is the name of the calendar to delete.

Only users with administrative privilege may use this command unless the service.wcap.allowdeletecalendars preference is set.

Returns

The returned output is the formatted output from a call to fetchcomponents_by_range.

Error Codes

If the operation is successful, the error number of 0 is appended to the error string. If the calid doesn't exist in the database, the delete_layer_errno[x] value is set to 1, where x is the calendar's index in the passed calid list. In addition, the errno variable contains the error: CALENDAR_DOES_NOT_EXIST(29).

Example

For example, sending this URL deletes the calendar named `newcal`.

```
http://webcalendarserver/deletecalendar.wcap?id=b5q2o8ve2rk02nv9t6&calid=newcal
```

deletecomponents_by_range

Purpose

Delete events and todos from a calendar in a specified range.

NOTE ENS notifications for `appid` are not yet implemented.

Parameters

Table 7-6 lists `deletecomponents_by_range` parameters:

Table 7-6 `deletecomponents_by_range` Parameters

Parameter	Type	Purpose	Required	Default
`appid`	string	A runtime parameter (not stored in the database) that specifies which application is making the request. ENS uses this parameter to determine which X-Tokens to return. Does not affect WCAP command output. For more information on the ENS X-Tokens, see the *Sun Java System Communications Services Event Notification Service Guide*	N	N/A
`calid`	string	Semicolon-separated list of calendar identifiers from which to delete events and todos. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to "mailto:". The address is mapped to a user with an LDAP lookup, and then the user's default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	N	Current user's `calid`.
`dtend`	Date Time string	End time and date of events or todos to be deleted. A value of `0` means delete all events and todos up to the end of time. This value must be in coordinated universal time.	N	`0`
`dtstart`	DateTime string)	Start time and date of events or todos to be deleted. A value of `0` means delete all events and todos from the beginning of time. This value must be in coordinated universal time.	N	`0`

Table 7-6 deletecomponents_by_range Parameters *(Continued)*

Parameter	Type	Purpose	Required	Default
fmt-out	string	The format for the returned data. The three format types: text/calendar text/xml	N	text/calendar
id	unique identifier string	The session identifier.	Y	N/A
smtp	integer (0, 1)	Send email cancellation to user without calendar. 0—No 1—Yes	N	1

Description.

Use this command to delete the events and todos that fall completely within the specified range from the specified calendars. If a range is not specified, it deletes all events and todos. The range parameters, dtstart and dtend, should be specified in UTC time (the 'Z' must be on the end). Otherwise, results are unpredictable.

Error Codes

If the operation is successful, the error number of 0 is appended to the error string, If an error occurs while deleting from the calendar, the delete_layer_errno[x] value is set to 1, where x is the calendar's index in the passed calid list. In addition, errno contains the error: DELETECOMPONENTS_BY_RANGE_FAILED(21).

Example

For example, assuming the user has read access to the calendars jdoe and john, the following URL deletes all events and todos from those two calendars:

```
http://deletecomponents_by_range.wcap?id=2342347923479asdf
  &calid=jdoe;john&dtstart=0&dtend=0
```

deleteevents_by_id

Purpose

Deletes one or more events from a calendar by event identifier.

Parameters

Table 7-7 lists `deleteevents_by_id` parameters:

Table 7-7 `deleteevents_by_id` Parameters

Parameter	Type	Purpose	Required	Default
`appid`	string	A runtime parameter (not stored in the database) that specifies which application is making the request. ENS uses this parameter to determine which X-Tokens to return. Does not affect WCAP command output. For more information on the ENS X-Tokens, see the *Sun Java System Communications Services Event Notification Service Guide*	N	N/A
`calid`	string	Calendar identifier of event to delete. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to “mailto:”. The address is mapped to a user with an LDAP lookup, and then the user’s default calendar ID is used.. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	Y	N/A

`fmt-out`	string	The format for the returned data.
		The two format types:
		`text/calendar`
		`text/xml`
			N	text/ calendar

`id`	unique identifier string	The session identifier. Required unless the calendar is public.	Y	`NULL`
`mod`	integer 1,2,3,4	A modifier indicating which recurrences to delete, or semicolon-separated list of modifiers. If a list, it must have same number of elements as `uid` list. One of the following values: 1 = `THISINSTANCE` 2 = `THISANDFUTURE` 3 = `THISANDPRIOR` 4 = `THISANDALL`	Y	N/A

Table 7-7 `deleteevents_by_id` Parameters *(Continued)*

Parameter	Type	Purpose	Required	Default
`notify`	integer `0`,`1`	A boolean indicating whether or not to notify attendees of this change. `1` = Notify attendees. `0` = Do not notify attendees.	N	`0`
`rid`	string	Recurrence identifier of the event, or semicolon-separated list of recurrence identifiers. If a list, it must have same number of elements as the `uid` list. If there are no recurrences, the value is `0`.	Y	N/A
`smtp`	integer (0, 1)	Send email cancellation to user without calendar. 0—No 1—Yes	N	1
`tzid`	time zone ID string	Default time zone to use if the `rid` parameter does not have a time zone specified. For example, “America/Los_Angeles”	N	server’s default time zone
`uid`	string	Unique Identifier of an event to be deleted, or semicolon-separated list of unique identifiers.	Y	N/A

Description.
Use this command to delete the specified event or events from the specified calendar.

Error Codes
If the operation is successful, the error number of `0` is appended to the error string. If the `uid` does not exist, the server returns error code `59`. See also, “Error Handling.”

Notify
The `notify` parameter specifies whether or not to send an IMIP `CANCEL` message to the email attendees of the event. To send the cancellation message, set the `notify` value to `1`.

For example, here’s a URL that sends the IMIP `CANCEL` message to all attendees of the event with `uid=001`.

`http://webcalendarserver/deleteevents_by_id.wcap?id=3423423asdfasf&calid=jdoe&uid=001&notify=1`

Recurrences

If the rid parameter is passed, the command also deletes recurrences, as specified by the mod parameter. (See "Recurring Components – Deleting.".) To delete multiple events, specify a semicolon-separated list for the uid, rid, and mod parameters. The three lists must have the same number of elements. Each list element corresponds to the same element in the other two lists.

Example

For example, there are two non-recurring events in the database with UIDs of uid-EVENT1 and uid-EVENT2. Since the events are non-recurring, the rid value for each event is set to 0 and mod value for each event is set to 1.

The following URL deletes the two events:

```
http://webcalendarserver/deleteevents_by_id.wcap?id=br6p3t6bh5po35r
  &uid=uid-EVENT1;uid-EVENT2&rid=0;0&mod=0;0&fmt-out-text/calendar
```

The resulting data would look like this:

```
BEGIN:VCALENDAR
PRODID:-//SunJavaSystem/Calendar Hosting Server//EN
METHOD:PUBLISH
VERSION:6.0
BEGIN:VEVENT
UID:uid-EVENT1
REQUEST-STATUS:2.0;Success.  Delete successful.
END:VEVENT
BEGIN:VEVENT
UID:uid-EVENT2
REQUEST-STATUS:2.0;Success.  Delete successful.
END:VEVENT
X-NSCP-WCAP-ERRNO:0
END:VCALENDAR
```

deleteevents_by_range

Purpose

Delete events from a calendar in a specified range.

NOTE ENS notifications for `appid` are not yet implemented.

Parameters

Table 7-8 lists `deleteevents_by_range` parameters:

Table 7-8 `deleteevents_by_range` Parameters

Parameter	Type	Purpose	Required	Default
`appid`	string	A runtime parameter (not stored in the database) that specifies which application is making the request. ENS uses this parameter to determine which X-Tokens to return. Does not affect WCAP command output. For more information on the ENS X-Tokens, see the *Sun Java System Communications Services Event Notification Service Guide.*	N	N/A
`calid`	string	Semicolon-separated list of calendar identifiers from which to delete events. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to “mailto:”. The address is mapped to a user with an LDAP lookup, and then the user’s default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	N	Current user’s `calid`.
`dtend`	DateTime string	End time and date of events to be deleted. A value of `0` means delete all events until the end of time.	N	`0`
`dtstart`	DateTime string	Start time and date of events to be deleted. A value of `0` means delete all events from the beginning of time.	N	`0`

Table 7-8 `deleteevents_by_range` Parameters *(Continued)*

Parameter	Type	Purpose	Required	Default

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`id`	unique identifier string	The session identifier.	Y	N/A
`smtp`	integer (0, 1)	Send email invitation to user without calendar. 0—No 1—Yes	N	1

Description.

Use this command to delete the events that fall completely within the specified range from the specified calendars. If a range is not specified (`dtstart` and `dtend`), it deletes all events from the specified calendars.

You must specify the `id` parameter with the command unless the specified calendar is a public calendar. The server returns data in the format specified by the `fmt-out` parameter. If this parameter is not passed, the data returns in the default `text/calendar` format.

Error Codes

If the operation is successful, the error number of `0` is appended to the error string, `errno`. If the operation is not successful, the `errno` variable contains the error: `DELETEEVENTS_BY_RANGE_FAILED(22)`.

See also, "Error Handling."

Example

For example, assuming the user has read access to the calendars `jdoe` and `john`, the following URL would result in deleting *all* events from the calendars `jdoe` and `john`:

```
http://webcalendarserver/deleteevents_by_range.wcap?id=2342347923479asdf&calid=jdoe;john&dtstart=0&dtend=0
```

deletetodos_by_id

Purpose

Delete one or more todos from a calendar.

Parameters

Table 7-9 lists deletetodos_by_id parameters:

Table 7-9 deletetodos_by_id Parameters

Parameter	Type	Purpose	Required	Default
appid	string	A runtime parameter (not stored in the database) that specifies which application is making the request. ENS uses this parameter to determine which X-Tokens to return. Does not affect WCAP command output. For more information on the ENS X-Tokens, see the *Sun Java System Communications Services Event Notification Service Guide*.	N	N/A
calid	string	Calendar identifier of the todos to delete. The calid can be supplied in two formats: • *string* - calendar identifier • mailto:*rfc822addr* - An email address appended to "mailto:". The address is mapped to a user with an LDAP lookup, and then the user's default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	Y	N/A
fmt-out	string	The format for the returned data. The three format types: text/calendar text/xml	N	text/calendar
id	unique identifier string	The session identifier.	Y	N/A
mod	integer	A modifier indicating which recurrences to delete, or semicolon-separated list of modifiers. If a list, must have same number of elements as uid list. One of the following values: 1 = THISINSTANCE 2 = THISANDFUTURE 3 = THISANDPRIOR 4 = THISANDALL	Y	N/A

Table 7-9 `deletetodos_by_id` Parameters *(Continued)*

Parameter	Type	Purpose	Required	Default
`notify`	integer (0,1)	A boolean telling whether or not to notify attendees of this change. `1` = Notify attendees. `0` = Do not notify attendees.	N	`0`
`rid`	string	The recurrence identifier of the todo, or a semicolon-separated list of recurrence identifiers. If a list, it must have the same number of elements as the `uid` list. If there are no recurrences, the value is `0`.	Y	N/A
`tzid`	time zone ID string	Default time zone to use if `dtstart`, or `dtend` parameters do not have a time zone specified. For example, “America/Los_Angeles”	N	server’s default time zone
`uid`	string	The unique identifier of a todo to be deleted, or a semicolon-separated list of unique identifiers.	Y	N/A

Description.
Use this command to delete the specified todo from the specified calendar.

You must specify the `id` parameter with the command unless the specified calendar is a public calendar. The server returns data in the format specified by the `fmt-out` parameter. If this parameter is not passed, the data returns in the default `text/calendar` format.

Error Codes
If the `uid` does not exist, returns error `59`.

See also, “Error Handling.”

Notify
The `notify` parameter specifies whether or not to send an IMIP `CANCEL` message to the email attendees of the todo. If `notify` is `1`, an email cancellation message is sent.

For example, here’s a URL that sends the IMIP `CANCEL` message to all attendees of the todo with `uid=001`.

`http://webcalendarserver/deletetodos_by_id.wcap?id=3423423asdfasf&calid=jdoe&uid=001&notify=1`

Recurrences

If the rid parameter is passed, the command also deletes recurrences, as specified by the mod parameter. See "Recurring Components – Deleting."

To delete multiple todos, specify a semicolon-separated list for the uid, rid, and mod parameters. The three lists must have the same number of elements. Each list element corresponds to the same element in the other two lists.If the rid parameter is passed, the command also deletes recurrences, as specified by the mod parameter.

Example

For example, there are two non-recurring todos in the database with UIDs of uid-TODO1 and uid-TODO2. Since the todos are non-recurring, the rid value for each todo is set to 0 and mod value for each todo is set to 1.

The following URL deletes the two todos:

```
http://webcalendarserver/deletetodos_by_id.wcap?id=br6p3t6bh5po35r
  &uid=uid-TODO1;uid-TODO2&rid=0;0&mod=1;1&fmt-out=text/calendar
```

The resulting data would look like this:

```
BEGIN:VCALENDAR
PRODID:-//SunJavaSystem/Calendar Hosting Server//EN
METHOD:PUBLISH
VERSION:6.0
BEGIN:VTODO
UID:uid-TODO1
REQUEST-STATUS:2.0;Success.  Delete successful.
END:VTODO
BEGIN:VTODO
UID:uid-TODO2
REQUEST-STATUS:2.0;Success.  Delete successful.
END:VTODO
X-NSCP-WCAP-ERRNO:0
END:VCALENDAR
```

deletetodos_by_range

Purpose

Delete todos in a range from a calendar.

NOTE ENS notifications for `appid` are not yet implemented.

Parameters

Table 7-10 lists `deletetodos_by_range` parameters:

Table 7-10 `deletetodos_by_range` Parameters

Parameter	Type	Purpose	Required	Default
`appid`	string	A runtime parameter (not stored in the database) that specifies which application is making the request. ENS uses this parameter to determine which X-Tokens to return. Does not affect WCAP command output. For more information on the ENS X-Tokens, see the *Sun Java System Communications Services Event Notification Service Guide.*	N	N/A
`calid`	string	Semicolon-separated list of calendar identifiers from which to delete todos. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to "mailto:". The address is mapped to a user with an LDAP lookup, and then the user's default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	N	Current user's `calid`
`dtstart`	DateTime string	Start time and date of todos to be deleted. A value of `0` means delete all todos from the beginning of time.	N	`0`
`dtend`	DateTime string	End time and date of todos to be deleted. A value of `0` means delete all todos up to the latest time.	N	`0`
`id`	unique identifier string	The session identifier.	Y	N/A

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

Description.

Use this command to delete the todos that fall completely within the specified range from the specified calendars. If a range is not specified, it deletes all todos. For example, the following URL would delete just the todo that occurs on the date March 1, 2002 11:22:33 AM GMT.

```
http://webcalendarserver/deletetodos_by_id.wcap?id=23423423434abc&calid=jdoe&uid=001&rid=20020301T112233Z&mod=1
```

You must specify the `id` parameter with the command unless the specified calendar is a public calendar. The server returns data in the format specified by the `fmt-out` parameter. If this parameter is not passed, the data is returned in the default `text/calendar`.

Error Codes

If the operation is successful, the error number of `0` is appended to the error string. If an error occurs, the `errno` variable contains the error: `DELETETODOS_BY_RANGE_FAILED(23)`.

See also, "Error Handling."

export

Purpose

Export events and todos from a calendar to a file.

Parameters

Table 7-11 lists `export` parameters:

Table 7-11 `export` Parameters

Parameter	Type	Purpose	Required	Default
`calid`	string	A semicolon-separated list of calendar identifiers from which to export events and todos. The user must have read access to all calendars in the list. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to "mailto:". The address is mapped to a user with an LDAP lookup, and then the user's default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	N	Current user's `calid`.

`content-out`	string	Content type for output file. One of the following:
		`text/calendar`
		`text/xml`
			Y	N/A

`dtend`	DateTime string.)	End time and date of the events and todos to export. A value of `0` means export all components from the start date to the latest date.	N	`0`
`dtstart`	DateTime string.	Start time and date of events and todos to export. A value of `0` means export all components from the earliest date to the end date.	N	`0`
`id`	unique identifier string	The session identifier.	N	`NULL`

Description.

Use this command to export events and todos from one or more specified calendars to a file. The contents of the file can later be imported to a calendar using the `import` command. The command creates a file called `export.ics` or `export.xml`, depending on the value of the `content-out` parameter.

Range

If you do not specify either the starting or ending date, all events and todos in the calendars are added to the file. If you specify a starting and ending date, the command exports only events and todos in the calendars that fall within the time range. Specify starting and ending dates in UTC time (indicated by `Z` at the end of the datetime).

HTTP Post Examples

You must use this command with an HTTP `POST` (unlike other commands, which can be used with an HTTP `GET`).

Example 1

The following HTTP `POST` message exports all components of the calendars `jdoe` and `john` to an iCalendar file named `export.ica`:

```
POST
/export.wcap?id=t95qm0n0es3bo35r&calid=jdoe;john&dtstart=0&dtend=0
  &content-out=text/calendar
Content-type: multipart/form-data;
boundary=---------------------------41091400621290
Content-Length: 47
-----------------------------41091400621290--
WinNT; U)
Host: jdoe:12345
Accept: image/gif, image/x-xbitmap, image/jpeg, image/pjpeg, image/png
*/*
Accept-Encoding: gzip
Accept-Language: en
Accept-Charset: iso-8859-1,*,utf-8
```

Example 2

The following HTML generates a `POST` message using the `export` command, producing files in both iCalendar and XML formats:

```
<form METHOD=POST ENCTYPE="multipart/form-data" NAME="john.ics"
ACTION="http://webcalendarserver:12345/export.wcap?id=t9u9m0eh8x5pu9b
  &calid=jdoe;john&dtstart=0&dtend=0&content-out=text/calendar">
<ul>
```

```
<li>Press Export ICAL Now:<input type="submit" value="Export ICAL now">
</li> </ul> </form>
<form METHOD=POST ENCTYPE="multipart/form-data" NAME="john.xml"
ACTION="http://webcalendarserver:12345/export.wcap?id=t9u9m0eh8x5pu9b
  &calid=jdoe;john&dtstart=0&dtend=0&content-out=text/xml">
<ul>
<li>Press Export XML Now:<input type="submit" value="Export XML now”>
</ul> </form>
```

This is the output generated:

```
HTTP/1.0 200
Date: Thu, 03 Jun 2002 22:15:52 GMT
Content-type: text/calendar
Content-disposition: attachment; filename="export.ics"
Content-length: 7004

fetchcomponents_by_alarmrange

Purpose

Retrieve calendar events and todos with alarm triggers.

Parameters

Table 7-12 lists `fetchcomponents_by_alarmrange` parameters:

Table 7-12 `fetchcomponents_by_alarmrange` Parameters

Parameter	Type	Purpose	Required	Default
`calid`	string	A semicolon-separated list of calendar identifiers. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to "mailto:". The address is mapped to a user with an LDAP lookup, and then the user's default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	N	Current user's `calid`.
`component-type`	keyword (`event`, `todo`, `all`)	Indicates which components to return: `event` returns only events `todo` returns only todos (tasks) `all` returns both events and todos If an invalid value is passed in, the system assumes `all`.	N	`all`

`compressed`	integer (`0`,`1`)	This parameter is deprecated in this release and may be deleted in future releases.
		For `compressed=0`, returns less data. Specifically, it does not return the following parameters:
		`rrules`
		`rdate`
		`exrule`
		`exdate`
		For `compressed=1`, all recurrence data is returned.
			N	`0`

`compstate`	semicolon-separated list of component state keywords	The list of component states to fetch. For `compstate` values, see Table 6-5 on page 87.	N	`ALL`

Table 7-12 `fetchcomponents_by_alarmrange` Parameters *(Continued)*

Parameter	Type	Purpose	Required	Default
`dtend`	DateTime string	End time and date of events and todos to be returned. A value of `0` means fetch all events.	N	`0`
`dtstart`	DateTime string	Start time and date of events/todos with alarms ready to go off during the specified time. A value of `0` means fetch all events from the beginning of time.	N	`0`
`emailorcalid`	integer (`0`, `1`)	`0` = The `calid` is returned in the cal-address part of the ATTENDEE and ORGANIZER properties. The X-Token X-S1CS-EMAIL has the RFC 822 email address of the invitee or organization. `1` = The email address is returned in the cal-address part of the ATTENDEE and ORGANIZER properties. The X-Token X-S1CS-CALID contains the `calid` value.	N	`0`

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`id`	unique identifier string	The session identifier.	Y	N/A
`maxResults`	integer	The maximum number of events and todos to be returned. When `0`, no maximum is applied and the command returns all events and todos found.	N	`0`
`recurring`	integer (`0`, `1`)	Whether to return all components in compressed form (1) or not (0). (Compressed form has master entry plus exceptions.)	N	0 (not compressed)
`relativealarm`	integer (0, 4)	Return the alarm as relative or absolute. 0—Return alarm values as absolute. 4—Return alarms as originally created.	N	0 (absolute)
`tzid`	time zone ID string	If `dtstart` and `dtend` parameters are not already in Zulu time, the time zone to use for translating them to Zulu time. For example, “America/Los_Angeles”	N	server’s default time zone
`tzidout`	time zone ID string	Time zone to report returned data in.	N	Zulu time

Description.
This command returns a list of events and todos having alarms that are about to go off during the specified time.

Output Format
The server returns data in the format specified by the `fmt-out` parameter. If this parameter is not passed, the data is returned in the default `text/calendar` format.

maxResults Value
If you specify a maximum `n`, the command returns up to the first `n` events and first `n` todos in the specified range. For example, if you specify a `maxResults` value of `75`, the returned data would contain the following variables

```
var maxResults=75 /* maximum cap passed in */
var size=75       /* event size is capped to 75 */
var todosize=28 /* todo size not affected since it is less than 75 */
```

If the `maxResults` parameter is set to `0` or is not passed, then the returned data does not contain the `var maxResults` statement.

Returns
For each calendar specified in `calid`, the server returns the calendar's events and todos having alarms about to go off within the range specified by `dtstart` and `dtend`.

If the times specified in the `dtstart` and `dtend` parameters is not Zulu time, the system uses the time zone specified in the `tzid` parameter to translate the times into Zulu time for data retrieval. If the `tzid` parameter is missing, the system uses the server's default time zone.

The system uses the `tzidout` parameter to determine what time zone to translate retrieved data into before returning it. If the `tzidout` parameter is missing, the system returns the data in Zulu time.

If neither the starting nor ending date-time is specified, the server returns all events and todos with alarms, up to the specified maximum.

Error Codes
If the operation is successful, the error number of `0` is appended to the error string. If a calendar cannot be accessed or is missing, `errno` is `FETCH_BY_ALARM_RANGE_FAILED(41)`.

Example
For example, suppose there are 3 events:

- eventA: alarm on Dec. 25, 2001, 12:30 PM GMT

- eventB: alarm on Feb. 10, 2002, 10:00 AM GMT
- todoA: alarm on Jan. 20, 2002, 1:15 PM GMT

Here are two queries and their return values:

Example 1

This query fetches all events and todos that have alarms about to go off between Dec. 1, 2001 and Jan. 31, 2002.

```
http://webcalendarserver/fetchcomponents_by_alarmrange.wcap?id=abcdefg&dts
tart=20011201T112233Z&dtend=20020131T112233Z&fmt-out=text/calendar
```

It returns eventA and todoA:

```

fetchcomponents_by_attendee_error

Purpose.

Fetch a list of components that had errors while sending group scheduling messages.

Parameters.

Table 7-13 lists `fetchcomponents_by_attendee_error` parameters

Table 7-13 `fetchcomponents_by_attendee_error` Parameters

Parameter	Type	Purpose	Required	Default
`attendee`	string	The attendee's `calid` to search on. The command searches the calendars specified in the `calid` parameter for all errors in events for this attendee. If this parameter is not specified, the command searches the primaryOwner's calendars for all event errors for any attendee.	N	N/A
`calid`	string	A semicolon-separated list of calendar identifiers. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to "mailto:". The address is mapped to a user with an LDAP lookup, and then the user's default calendar ID is use. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	N	Current user's `calid`.
`component-type`	keyword (`event`, `todo`, `all`)	Indicates which components to return: `event` returns only events `todo` returns only todos (tasks) `all` returns both events and todos If an invalid value is passed in, the system assumes `all`.	N	`all`

Table 7-13 `fetchcomponents_by_attendee_error` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default

`compressed`	integer (`0`,`1`)	This parameter is deprecated in this release and may be deleted in future releases.
		For `compressed=0`, returns less data. Specifically, it does not return the following parameters:
		`rrules`
		`rdate`
		`exrule`
		`exdate`
		For `compressed=1`, all recurrence data is returned.
			N	`0`

`emailorcalid`	integer (`0`, `1`)	`0` = The `calid` is returned in the cal-address part of the ATTENDEE and ORGANIZER properties. The X-Token X-S1CS-EMAIL has the RFC 822 email address of the invitee or organization. `1` = The email address is returned in the cal-address part of the ATTENDEE and ORGANIZER properties. The X-Token X-S1CS-CALID contains the `calid` value.	N	`0`

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`id`	unique identifier string	The session identifier.	Y	N/A
`maxResults`	integer	The maximum number of events and todos to be returned. When `0`, no maximum is applied and the command returns all events and todos found.	N	`0`
`recurring`	integer (`0`, `1`)	Whether to return all components in compressed form (1) or not (0). (Compressed form has master entry plus exceptions.)	N	0 (not compressed)
`relativealarm`	integer (`0`, `4`)	Return the alarm as relative or absolute. 0—Return alarm values as absolute. 4—Return alarms as originally created.	N	0 (absolute)
`tzidout`	standard time zone string	The time zone returned data is translated to.	N	Returns data in Zulu time

Description.
Use this command to retrieve a list of events and todos that had errors when sending group scheduling messages. This command works almost like `fetchcomponents_by_range`.

Output Format
The server returns data in the format specified by the `fmt-out` parameter. If this parameter is not passed, the data is returned in the default `text/calendar` format.

maxResults Value
If you specify a maximum `n`, the command returns up to the first `n` events and first `n` todos in the specified range. For example, if you specify a `maxResults` value of `75`, the returned data would contain the following variables

```
var maxResults=75 /* maximum cap passed in */
var size=75       /* event size is capped to 75 */
var todosize=28 /* todo size not affected since it is less than 75 */
```

If the `maxResults` parameter is set to `0` or is not passed, then the returned data does not contain the `var maxResults` statement.

Returns
For each calendar specified in `calid`, the server returns the events and todos that had errors for the specified attendee while sending group scheduling messages.

For example, if the `calid` parameter specifies calendars `cal1` and `cal2`, and the `attendee` parameter specifies `jdoe`, then both `cal1` and `cal2` would be searched for events with errors that had `jdoe` as an attendee. In the table that follows, `cal1` and `cal2` each have four events with associated attendees:

cal1 Events	**cal2 Events**
event - 1c1	event - 1c2
attendee: `jdoe`	attendee: `john`
status: error	status: OK
event - 2c1	event - 2c2
attendee: `susan`	attendee: `jdoe`
status: error	status: error
event - 3c1	event - 3c2
attendee: `jdoe`	attendee: `susan`
status: OK	status: OK

cal1 Events	cal2 Events
event - 4c1	event - 4c2
attendee: john	attendee: susan
status: OK	status: error

For attendee jdoe, the command returns: events 1c1 and 2c2.

The system uses the tzidout parameter to determine what time zone to translate retrieved data into before returning it. If the tzidout parameter is missing, the system returns the data in Zulu time.

Error Codes

If the operation is successful, the error number of 0 is appended to the error string. If the command fails for any reason, errno is FETCH_BY_ATTENDEE_ERROR_FAILED(42).

fetchcomponents_by_lastmod

Purpose.

Fetch a list of components that have changed during a specified time period.

Parameters.

Table 7-14 lists `fetchcomponents_by_lastmod` parameters

Table 7-14 `fetchcomponents_by_lastmod` Parameters

Parameter	Type	Purpose	Required	Default
`calid`	string	A semicolon-separated list of calendar identifiers. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to "mailto:". The address is mapped to a user with an LDAP lookup, and then the user's default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	N	Current user's `calid`.
`component-type`	keyword (`event`, `todo`, `all`)	Indicates which components to return: `event` returns only events `todo` returns only todos (tasks) `all` returns both events and todos If an invalid value is passed in, the system assumes `all`.	N	`all`

`compressed`	integer (`0`,`1`)	This parameter is deprecated in this release and may be deleted in future releases.
		For `compressed=0`, returns less data. Specifically, it does not return the following parameters:
		`rrules`
		`rdate`
		`exrule`
		`exdate`
		For `compressed=1`, all recurrence data is returned.
			N	`0`

`compstate`	semicolon-separated list of component state keywords	The list of component states to fetch. For `compstate` values, see Table 6-5 on page 87.	N	`ALL`

Table 7-14 `fetchcomponents_by_lastmod` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`dtend`	DateTime string	End time and date of events to be returned. A value of `0` means fetch all events.	N	`0`
`dtstart`	DateTime string	Start time and date of events to be returned. A value of `0` means fetch all events from the beginning of time.	N	`0`
`emailorcalid`	integer (`0`, `1`)	`0` = The `calid` is returned in the cal-address part of the `ATTENDEE` and `ORGANIZER` properties. The `X-Token` `X-S1CS-EMAIL` has the RFC 822 email address of the invitee or organization. `1` = The email address is returned in the cal-address part of the `ATTENDEE` and `ORGANIZER` properties. The `X-Token` `X-S1CS-CALID` contains the `calid` value.	N	`0`

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`id`	unique identifier string	The session identifier.	Y	N/A
`maxResults`	integer	The maximum number of events and todos to be returned. When `0`, no maximum is applied and the command returns all events and todos found.	N	`0`
`recurring`	integer (`0`, `1`)	Whether to return all components in compressed form (1) or not (0). (Compressed form has master entry plus exceptions.)	N	0 (not compressed)
`relativealarm`	integer (`0`, `4`)	Return the alarm as relative or absolute. 0—Return alarm values as absolute. 4—Return alarms as originally created.	N	0 (absolute)
`tzid`	time zone ID string	Time zone to use if `dtstart`, or `dtend` parameters are not in Zulu time. For example, “America/Los_Angeles”	N	server’s default time zone
`tzidout`	time zone ID string	Time zone to report returned data in.	N	Zulu time

Description.
Use this command to retrieve a list of events and todos that have changed during a specific time period. This command works almost like fetchcomponents_by_range.

Output Format
The server returns data in the format specified by the fmt-out parameter. If this parameter is not passed, the data is returned in the default text/calendar format.

maxResults Value
If you specify a maximum n, the command returns up to the first n events and first n todos in the specified range. For example, if you specify a maxResults value of 75, the returned data would contain the following variables

```
var maxResults=75 /* maximum cap passed in */
var size=75       /* event size is capped to 75 */
var todosize=28 /* todo size not affected since it is less than 75 */
```

If the maxResults parameter is set to 0 or is not passed, then the returned data does not contain the var maxResults statement.

Returns
For each calendar specified in calid, the server returns the calendar's the events and todos that changed during the range specified by dtstart and dtend.

If the times specified in the dtstart and dtend parameters is not Zulu time, the system uses the time zone specified in the tzid parameter to translate the times into Zulu time for data retrieval. If the tzid parameter is missing, the system uses the server's default time zone.

The system uses the tzidout parameter to determine what time zone to translate retrieved data into before returning it. If the tzidout parameter is missing, the system returns the data in Zulu time.

If neither the starting nor ending date-time is specified, the server returns all events and todos that have changed, up to the specified maximum.

Error Codes
If the operation is successful, the error number of 0 is appended to the error string. If a calendar cannot be accessed or is missing, the error number is appended to the error string.

Example
For example, the calendar jdoe has these three events:

- eventA: last-modified on Feb. 10, 2002, 10:00 AM GMT.

- eventB: last-modified on Dec. 25, 2001, 12:30 PM GMT.
- todoA: last-modified on Jan. 20, 2002, 1:15 PM GMT.

Here are some queries and their return values:

```
http://webcalendarserver/fetchcomponents_by_lastmod.wcap?id=jdoe
&dtstart=0&dtend=0
```

The above query would fetch all events and todos that have ever been modified. Thus eventA, eventB, and todoA would be returned.

```
http://webcalendarserver/fetchcomponents_by_lastmod.wcap?id=jdoe
&dtstart=20011201T112233Z&dtend=20020131T112233Z
```

The above query would fetch all modified events and todos between 12/1/2001 and 1/31/2002. Thus eventB and todoA would be returned.

```
http://webcalendarserver/fetchcomponents_by_lastmod.wcap?id=jdoe
&dtstart=20020101T112233Z&dtend=20020601T112233Z
```

The above query would fetch all events and todos that have been modified between 1/1/2002 and 6/1/2002. Thus eventA and todoA would be returned.

fetchcomponents_by_range

Purpose

Retrieve calendar events and todos.

Parameters

Table 7-15 lists `fetchcomponents_by_range` parameters:

Table 7-15 `fetchcomponents_by_range` Parameters

Parameter	Type	Purpose	Required	Default

`attrset`	integer (`0`, `1`, `2`)	Indicates to the server to retrieve the complete vEvent or vTask data, or if they just want a subset of the data for each matching component. (This can reduce the amount of processing a client must do.)
		`2` = Returns the full event and is the default.
		`1` = Returns the following fields only: `UID`, `RRULE`, `DTSTART`, `DTEND`, `SUMMARY`, `CLASS`, `LOCATION`, `VALARM`
		`0` = Returns the following fields only: `UID`, `DTSTART`, `DTEND`, `SUMMARY`
			N	2

`calid`	string	A semicolon-separated list of calendar identifiers. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to “mailto:”. The address is mapped to a user with an LDAP lookup, and then the user’s default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	N	Current user’s `calid`.
`component-type`	keyword (`event`, `todo`, `all`)	Indicates which components to return: `event` returns only events `todo` returns only todos (tasks) `all` returns both events and todos If an invalid value is passed in, the system assumes `all`.	N	`all`

Table 7-15 `fetchcomponents_by_range` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default

`compressed`	integer (`0`,`1`)	This parameter is deprecated in this release and may be deleted in future releases.
		For `compressed=0`, returns less data. Specifically, it does not return the following parameters:
		`rrules`
		`rdate`
		`exrule`
		`exdate`
		For `compressed=1`, all recurrence data is returned.
			N	`0`

`compstate`	semicolon-separated list of component state keywords	The list of component states to fetch. For `compstate` values, see Table 6-5 on page 87.	N	`ALL`
`dtend`	DateTime string	End time and date of events to be returned. A value of `0` means fetch all events.	N	`0`
`dtstart`	DateTime string	Start time and date of events to be returned. A value of `0` means fetch all events from the beginning of time.	N	`0`
`emailorcalid`	integer (`0`, `1`)	`0` = The `calid` is returned in the cal-address part of the ATTENDEE and ORGANIZER properties. The X-Token X-S1CS-EMAIL has the RFC 822 email address of the invitee or organization. `1` = The email address is returned in the cal-address part of the ATTENDEE and ORGANIZER properties. The X-Token X-S1CS-CALID contains the `calid` value.	N	`0`

Table 7-15 `fetchcomponents_by_range` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`filter`	string	Name/value pair that represents a filter for an event. The left side is any valid property of an event or todo from RFC 2445. Only single valued filters are currently supported. For example: `filter=(ATTENDEE=jdoe@sesta.com)` where the left side of the value is a property from RFC 2445 and the right side is the value to match in the events and todos. The following are the only supported properties for filtering: • ATTENDEE • ORGANIZER • SUMMARY • DESCRIPTION • LOCATION • CLASS • CATEGORY	N	`NULL`

`fmt-out`	string	The format for the returned data. Either:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`id`	unique identifier string	The session identifier.	Y	N/A
`invitecount`	integer (`0`, `1`)	`1` = Requests the server to return the open invitations count, that is, events where `PARSTAT`=needs-action. The integer count is returned in the X-Token `X-S1CS-CALPROPS-INVITATION-COUNT`. if more than one `calid` is specified in the `calid` parameter, the open invitation count for each calendar is returned in the corresponding iCal or iCal XML block. 0 = Count not requested.	N	0
`maxResults`	integer	(currently not implemented) The maximum number of events and todos to be returned. When `0`, no maximum is applied and the command returns all events and todos found.	N	`0`
`recurring`	integer (`0`, `1`)	Whether to return all components in compressed form (1) or not (0). (Compressed form has master entry plus exceptions.)	N	0 (not compressed)

Table 7-15 `fetchcomponents_by_range` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`relativealarm`	integer (0, 4)	Return the alarm as relative or absolute. 0—Return alarm values as absolute. 4—Return alarms as originally created.	N	0 (absolute)

`searchOpts`	integer
	0,1,2,3
		How to perform the search. One of the following:
		`0 = CONTAINS`
		`1 = BEGINS_WITH`
		`2 = ENDS_WITH`
		`3 = EXACT`
			N	`0`

`tzid`	time zone ID string	Default time zone to use if `dtstart`, or `dtend` parameters are not in Zulu time. For example, “America/Los_Angeles”	N	server’s default time zone
`tzidout`	time zone ID string	Time zone to report returned data in.	N	Zulu time

Description.
Use this command to retrieve properties, events, and todos from one or more specified calendars.

Output Format
The server returns data in the format specified by the `fmt-out` parameter. If this parameter is not passed, the data is returned in the default `text/calendar` format.

Returns
For each calendar specified in `calid`, the server returns the calendar's properties and the events and todos of that calendar that fall within the range specified by `dtstart` and `dtend`.

Tasks returned by this command:

- Tasks due within the date range
- Overdue tasks
- Tasks completed within the date range
- Tasks that are never due but have a start date within the range

If the times specified in the `dtstart` and `dtend` parameters is not Zulu time, the system uses the time zone specified in the `tzid` parameter to translate the times into Zulu time for data retrieval. If the `tzid` parameter is missing, the system uses the server’s default time zone.

The system uses the tzidout parameter to determine what time zone to translate retrieved data into before returning it. If the tzidout parameter is missing, the system returns the data in Zulu time.

If neither the starting nor ending date-time is specified, the server returns all events and todos, up to the specified maximum.

Error Codes

If the operation is successful, the error number of 0 is appended to the error string. If a calendar cannot be accessed or is missing, the error number is appended to the error string.

Output Format

The server returns data in the format specified by the fmt-out parameter. If this parameter is not passed, the data is returned in the default text/calendar format.

maxResults Value

If you specify a maximum n, the command returns up to the first n events and first n todos in the specified range. For example, if you specify a maxResults value of 75, the returned data would contain the following variables

```
var maxResults=75 /* maximum cap passed in */
var size=75       /* event size is capped to 75 */
var todosize=28 /* todo size not affected since it is less than 75 */
```

If the maxResults parameter is set to 0 or is not passed, then the command does not cap the number of returned components, and the returned data does not contain the var maxResults statement.

Error Codes

If the operation is successful, the error number of 0 is appended to the error string. If a calendar cannot be accessed or is missing, the error number is appended to the error string.

Example

Example 1

This example fetches components for the current user from Dec. 1, 2001 to Jan. 31, 2002, using the following URL:

```
http://webcalendarserver/fetchcomponents_by_range.wcap?id=bes6bbe2mu98uw9&
dtstart=20011201T000000Z&dtend=20020131T000000Z&fmt-out=text/calendar
```

It returns one event and one todo for this period:

```

fetch_deletedcomponents

Purpose.

Returns a list of deleted components from the `deletelog.db` for a specified time period.

Parameters.

Table 7-14 lists `fetch_deletedcomponents` parameters

Table 7-16 `fetch_deletedcomponents` Parameters

Parameter	Type	Purpose	Required	Default
`calid`	string	A semicolon-separated list of calendar identifiers. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to "mailto:". The address is mapped to a user with an LDAP lookup, and then the user's default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	N	Current user's `calid`.
`component-type`	keyword (`event`, `todo`, `all`)	Indicates which components to return: `event` returns only events `todo` returns only todos (tasks) `all` returns both events and todos If an invalid value is passed in, the system assumes `all`.	N	`all`
`dtend`	DateTime string	End time and date of events to be returned. A value of `0` means fetch all deleted components in the deletelog database until the end of time. The return value has the server time that will be used in the next fetch.	N	`0`
`dtstart`	DateTime string	Start time and date of events to be returned. A value of `0` means fetch all deleted components in the deletelog database from the beginning of time.	N	`0`

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

Table 7-16 `fetch_deletedcomponents` Parameters *(Continued)*

Parameter	Type	Purpose	Required	Default
`id`	unique identifier string	The session identifier.	Y	N/A
`maxResults`	integer	The maximum number of events and todos to be returned. When `0`, no maximum is applied and the command returns all events and todos found.	N	`0`
`recurring`	integer (`0`, `1`)	Whether to return all components in compressed form (1) or not (0). For `recurring=0`, it does not return the master entry. For `recurring=1`, it does not return the expanded instances of the recurring components; it returns the master entry. If all the instances of the recurring series have been deleted, it returns `dtStart`, `dtEnd`, `rrules`, `rdate`, `exrule`, `exdate`, and `uid`.	N	0 (not compressed)
`tzid`	time zone ID string	Time zone to use if `dtstart`, or `dtend` parameters are not in Zulu time. For example, “America/Los_Angeles”	N	server’s default time zone
`tzidout`	time zone ID string	Time zone to report returned data in.	N	Zulu time

Description.

Use this command to retrieve a list of events and todos that have been deleted during a specific time period. For recurring format components, this command should be used in conjunction with `fetchcomponents_by_lastmod` in order to return recurring instances that are still active.

Output Format

The server returns data in the format specified by the `fmt-out` parameter. If this parameter is not passed, the data is returned in the default `text/calendar` format.

maxResults Value

If you specify a maximum `n`, the command returns up to the first `n` events and first `n` todos in the specified range. For example, if you specify a `maxResults` value of 75, the returned data would contain the following variables

```
var maxResults=75 /* maximum cap passed in */
var size=75       /* event size is capped to 75 */
var todosize=28 /* todo size not affected since it is less than 75 */
```

If the maxResults parameter is set to 0 or is not passed, then the returned data does not contain the var maxResults statement.

Returns

When this command is called in compressed mode (with recurring =1), the query interface goes through the Delete Log database and returns all the non-repeating entries and the master components deleted that match the criteria. This pass ignores the recurring instances that are stored in the database. This will not return any master entries associated with the deleted recurring instances that are still active. Those active master entries will be returned using the fetchcomponents_by_lastmod command. If all the instances in a recurring chain are deleted, the master component will return dtstart, dtend, rrules, rdate, exrule, exdate and uid.

When the command is called in expanded mode (with recurring=0), the query interface goes through the Delete Log database and returns all instances of recurring components. Specifically, it does not return the master component.

Error Codes

If the operation is successful, the error number of 0 is appended to the error string. If a calendar cannot be accessed or is missing, the error number is appended to the error string.

The following failure codes can be returned:

- X-NSCP-WCAP-ERRNO:1 - Session ID timed out or Invalid session ID
- X-NSCP-WCAP-ERRNO:28 - Command failed; user denied access to a calendar
- X-NSCP-WCAP-ERRNO:29 - Command failed; calendar does not exist in the database
- X-NSCP-WCAP-ERRNO:56 - Fetch deleted components failed
- X-NSCP-WCAP-ERRNO:57 - Success but partial result

Example

Fetching Deleted Components (recurring defaults to 0)

fetchevents_by_id

Purpose

Retrieve specific calendar events.

Parameters

Table 7-17 lists `fetchevents_by_id` parameters:

Table 7-17 `fetchevents_by_id` Parameters

Parameter	Type	Purpose	Required	Default
`calid`	string	A semicolon-separated list of calendar identifiers. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to "mailto:". The address is mapped to a user with an LDAP lookup, and then the user's default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	N	Current user's `calid`.

`compressed`	integer (`0`,`1`)	This parameter has been deprecated for this release and may be removed from future versions.
		For `compressed=0`, returns less data. Specifically, it does not return the following parameters:
		`rrules`
		`rdate`
		`exrule`
		`exdate`
		For `compressed=1`, all recurrence data is returned.
			N	`0`

`compstate`	semicolon-separated list of component state keywords	The list of component states to fetch. For `compstate` values, see Table 6-5 on page 87.	N	`ALL`

Table 7-17 `fetchevents_by_id` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`emailorcalid`	integer (`0`, `1`)	`0` = The `calid` is returned in the cal-address part of the `ATTENDEE` and `ORGANIZER` properties. The `X-Token` `X-S1CS-EMAIL` has the RFC 822 email address of the invitee or organization. `1` = The email address is returned in the cal-address part of the `ATTENDEE` and `ORGANIZER` properties. The `X-Token` `X-S1CS-CALID` contains the `calid` value.	N	`0`

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`id`	unique identifier string	The session identifier.	Y	N/A
`mod`	integer	A modifier indicating which recurrences to retrieve. One of the following values: 1 = `THISINSTANCE` 2 = `THISANDFUTURE` 3 = `THISANDPRIOR` 4 = `THISANDALL`	N	`1` (`THISINSTANCE`)
`recurring`	integer (`0`, `1`)	Whether to return all components in compressed form (1) or not (0). (Compressed form has master entry plus exceptions.)	N	0 (not compressed)
`relativealarm`	integer (0, 4)	Return the alarm as relative or absolute. 0—Return alarm values as absolute. 4—Return alarms as originally created.	N	0 (absolute)
`rid`	ISO 8601 DateTime string	The recurrence identifier for the event. For a nonrecurring event, set to `0`.	N	`0`
`tzid`	time zone ID string	Time zone to use if the `rid` parameter is not in Zulu time. For example, “America/Los_Angeles”	N	server’s default time zone
`tzidout`	time zone ID string	Time zone that returned data should be translated to.	N	Returns data in Zulu time
`uid`	sting	The unique identifier for the event.	Y	N/A

Description.
Use this command to retrieve the specified events and recurrences from the specified calendar. You must specify the `id` parameter with the command unless the specified calendar is a public calendar. The command returns recurrences as specified by the `mod` parameter. See "Recurring Components – Overview."

Output Format
The server returns data in the format specified by the `fmt-out` parameter. If this parameter is not passed, the data is returned in the default format.

Returns
The system uses the `tzidout` parameter to determine what time zone to translate retrieved data into before returning it. If the `tzidout` parameter is missing, the system returns the data in Zulu time.

Error Codes
If the operation is successful, the error number of `0` is appended to the error string. If a calendar cannot be accessed or is missing, the error number is appended to the error string.

Example
This query retrieves an event with a specific id.

```
http://webcalendarserver/fetchevents_by_id.wcap?id=bes6bbe2mu98uw9&calid=j
doe&uid=3c11625900005ffe00000011000010b7
&fmt-out=text/calendar
```

It returns one event:

fetchtodos_by_id

Purpose

Retrieve specific calendar todos.

Parameters

Table 7-18 lists `fetchtodos_by_id` parameters:

Table 7-18 `fetchtodos_by_id` Parameters

Parameter	Type	Purpose	Required	Default
`calid`	string	A semicolon-separated list of calendar identifiers. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to “mailto:”. The address is mapped to a user with an LDAP lookup, and then the user’s default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	N	Current user’s `calid`.

`compressed`	integer (`0`,`1`)	This parameter has been deprecated for the current release and may be removed from future releases.
		For `compressed=0`, returns less data. Specifically, it does not return the following parameters:
		`rrules`
		`rdate`
		`exrule`
		`exdate`
		For `compressed=1`, all recurrence data is returned.
			N	`0`

`compstate`	semicolon-separated list of component state keywords	The list of component states to fetch. For `compstate` values, see Table 6-5 on page 87.	N	`ALL`

Table 7-18 `fetchtodos_by_id` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`emailorcalid`	integer (`0`, `1`)	`0` = The `calid` is returned in the cal-address part of the `ATTENDEE` and `ORGANIZER` properties. The X-Token `X-S1CS-EMAIL` has the RFC 822 email address of the invitee or organization. `1` = The email address is returned in the cal-address part of the `ATTENDEE` and `ORGANIZER` properties. The X-Token `X-S1CS-CALID` contains the `calid` value.	N	`0`

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`id`	unique identifier string	The session identifier.	Y	N/A
`mod`	integer	A modifier indicating which recurrences to retrieve. One of the following values: 1 = THISINSTANCE 2 = THISANDFUTURE 3 = THISANDPRIOR 4 = THISANDALL	N	`1` (`THISINSTANCE`)
`recurring`	integer (`0`, `1`)	Whether to return all components in compressed form (1) or not (0). (Compressed form has master entry plus exceptions.)	N	0 (not compressed)
`relativealarm`	integer (0, 4)	Return the alarm as relative or absolute. 0—Return alarm values as absolute. 4—Return alarms as originally created.	N	0 (absolute)
`rid`	ISO 8601 DateTime string	The recurrence identifier for the todo. For a nonrecurring todo, set to `0`.	N	`0`
`tzid`	time zone ID string	Time zone to use if the `rid` parameter is not in Zulu time. For example, “America/Los_Angeles”	N	server’s default time zone
`tzidout`	time zone ID string	Time zone the returned data should be translated to.	N	Returns data in Zulu time
`uid`	sting	The unique identifier for the todo.	Y	N/A

Description

Use this command to retrieve the specified todo and its recurrences from the specified calendar. You must specify the `id` parameter with the command unless the specified calendar is a public calendar.

Output Format

The server returns data in the format specified by the `fmt-out` parameter. If this parameter is not passed, the data is returned in the default `text/calendar` format.

Returns

For each calendar specified in `calid`, the server returns the calendar's todos of that calendar. If the todo has recurrences, it returns them as specified by the `rid` and `mod` parameters. See "Recurring Components – Overview."

If the times specified in the `rid` parameter is not Zulu time, the system uses the time zone specified in the `tzid` parameter to translate the times into Zulu time for data retrieval. If the `tzid` parameter is missing, the system uses the server's default time zone.

The system uses the `tzidout` parameter to determine what time zone to translate retrieved data into before returning it. If the `tzidout` parameter is missing, the system returns the data in Zulu time.

Error Codes

If the operation is successful, the error number of `0` is appended to the error string. If a calendar cannot be accessed or is missing, the error number is appended to the error string.

Example

For example, a todo "weekly todo B" that's due weekly at 5:00pm starting on Feb 1, 2002 and ending on Mar 1, 2002.

Example 1

This query fetches just the first todo, on Feb 1, 2002, because the recurrence ID of the first item is specified (`rid=20020201T170000Z`) but no modifier is specified, so it defaults to 1 (`THISINSTANCE`):

```
http://webcalendarserver/fetchtodos_by_id.wcap?
id=n3o3m05sx9v6t98t8u2p&uid=3c15309d0000370200200021400003189&
rid=20020201T170000Z&fmt-out=text/calendar
```

The following output is generated:

```
BEGIN:VCALENDARPRODID:-//SunONE/Calendar Hosting Server//EN
```

```

Example 2

This query fetches the last two recurrences by specifying the recurrence ID of the second to last recurrence on Feb. 22, 2002 (`rid=20020222T170000Z`) and a modifier of 2 (`mod=2`) which means `THISANDFUTURE` recurrences:

```
http://webcalendarserver/fetchtodos_by_id.wcap?
id=n3o3m05sx9v6t98tu2p&uid=3c15309d0000370200200021400003189&
rid=20020222T170000Z&mod=2&fmt-out=text/calendar
```

The results of the query are as follows:

```

get_all_timezones

Purpose

Retrieve data about all timezones supported by the server.

Parameters

Table 7-19 lists `get_all_timezones` parameters:

Table 7-19 `get_all_timezones` Parameters

Parameter	Type	Purpose	Required	Default
`dtend`	DateTime string	End date of the crossover values to retrieve. A value of `0` means get all crossover dates until the last known year (2087).	N	`0`
`dtstart`	DateTime string	Start date of crossover values to retrieve. A value of `0` means get all crossover dates from the first known year (1987).	N	`0`

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`id`	unique identifier string	The session identifier.	Y	N/A

Description.

Use this command to retrieve data about all timezones that are supported by the server. The crossover values are defined to be the dates when the timezone enters/exits daylight savings time. The odd index dates are the beginning of daylight-savings. The even index dates are the end of daylight-savings. If the timezone does not have daylight-savings, then this value will be set to the empty-string.

Returns

If you specify a range of years with the `dtstart` and `dtend` parameters, the command returns only the crossover dates for the years within the range. Otherwise, it returns all crossover dates from the first to the last known year (1987-2087).

The server returns data in the format specified by the `fmt-out` parameter. If you do not pass in the `fmt-out` parameter, the server uses the default `text/calendar` format.

Error Codes

If there was an error in getting the timezones, the server returns the error GET_ALL_TIMEZONES_FAILED(24).

Example

The first example shows the command output. The second example is a crossover array.

Example 1

This query gets all time zones.

```
http://calendarserver/get_all_timezones.wcap?
id=2m2ns6w9x9h2mr6p3b&fmt-out=text/calendar
```

This is the result of the query:

```

TZNAME:TOT
TZNAME:PHOT
END:STANDARD
END:VTIMEZONE
X-NSCP-WCAP-ERRNO:0
END:VCALENDAR
```

Example 2

The following is an example of a timezone array element where crossover dates have been limited to the years from mid-1998 to 2006:

```
timezoneList[20] = new TZ('America/Los_Angeles',
'PST',
'PDT',
'-0800',
'-0700',
new Array
('19981025T090000Z','20020404T100000Z','20021031T090000Z',
'20020402T100000Z','20021029T090000Z','20020401T100000Z',
'20021028T090000Z', '20020407T100000Z', '20021027T090000Z',
'20030406T100000Z', '20031026T090000Z', '20040404T100000Z',
'20041031T090000Z', '20050403T100000Z', '20051030T090000Z',
'20060402T100000Z', '20061029T090000Z'))
```

The "America/Phoenix" timezone does not have daylight-savings. Thus the daylight elements exactly equal the standard elements. Also, the crossover strings are set to the empty string.

```
timezoneList[23] = new TZ('America/Phoenix',
'MST',
'MST',
'-0700',
'-0700',
new Array())
```

get_calprops

Purpose

Retrieve calendar properties.

Parameters

Table 7-20 lists `get_calprops` parameters:

Table 7-20 `get_calprops` Parameters

Parameter	Type	Purpose	Required	Default
`calid`	semicolon-separated list of strings	Semicolon-separated list of calendar identifiers from which to retrieve properties. The calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to "mailto:". The address is mapped to a user with an LDAP lookup, and then the user's default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	N	Current user's `calid`.

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`id`	unique identifier string	The session identifier.	Y	N/A
`invitecount`	integer (`0`, `1`)	`1` = Requests the server to return the open invitations count, that is, events where PARSTAT=needs-action. The integer count is returned in the X-Token `X-S1CS-CALPROPS-INVITATION-COUNT`. if more than one `calid` is specified in the `calid` parameter, the open invitation count for each calendar is returned in the corresponding iCal or iCal XML block. 0 = Count not requested.	N	0

Description.

Use this command to retrieve the calendar properties for the specified calendars.

Returns

The command returns a page with the following X-Tokens containing property information for the specified calendars:

```
X-NSCP-CALPROPS-ACCESS-CONTROL-ENTRY
X-NSCP-CALPROPS-CALMASTER
X-NSCP-CALPROPS-CATEGORIES
X-NSCP-CALPROPS-CHARSET
X-NSCP-CALPROPS-CHILDREN
X-NSCP-CALPROPS-CREATED
X-NSCP-CALPROPS-DESCRIPTION
X-NSCP-CALPROPS-LANGUAGE
X-NSCP-CALPROPS-LAST-MODIFIED
X-NSCP-CALPROPS-NAME
X-NSCP-CALPROPS-OWNERS
X-NSCP-CALPROPS-PRIMARY-OWNER
X-NSCP-CALPROPS-READ
X-NSCP-CALPROPS-RELATIVE-CALID
X-NSCP-CALPROPS-RESOURCE
X-NSCP-CALPROPS-TZID
X-NSCP-CALPROPS-WRITE
X-S1CS-CALPROPS-ALLOW-DOUBLEBOOKING
X-S1CS-CALPROPS-COMMON-NAME
X-S1CS-CALPROPS-FB-INCLUDE
X-S1CS-CALPROPS-INVITATION-COUNT
```

Error Codes

If the calendar exists, but the user does not have `READ` access to it, `errno` is set to `ACCESS_DENIED_TO_CALENDAR` (28).

If the fetch fails for any calendar, its error number, `errno`, is set to `GET_CALPROPS_FAILED(20)`.

Example

In the following example, you want to retrieve the calendar properties for the calendars `jdoe`, `jsmith`, and `susan`, in that order.

This is the URL:

```
http://webcalendarserver/get_calprops.wcap?id=2mu95r5so0hq68ts6q3
&calid=jdoe;jsmith;susan&fmt-out=text/calendar
```

This is the returned data:

```
BEGIN:VCALENDAR
```

```

get_freebusy

Purpose

Get the freebusy information for users.

Parameters

Table 7-21 lists `get_freebusy` parameters:

Table 7-21 `get_freebusy` Parameters

Parameter	Type	Purpose	Required	Default
`busyonly`	Integer (`0`, `1`)	`0` = return both busy and free periods `1` = return only busy periods	N	`1`
`calid`	string	The calendar identifier. he calid can be supplied in two formats: • *string* - calendar identifier • `mailto:`*rfc822addr* - An email address appended to "mailto:". The address is mapped to a user with an LDAP lookup, and then the user's default calendar ID is used. Returns: X-SICS-EMAIL and X-NSCP-CALPROPS-RELATIVE-CALID	Y	Current user's default calendar.
`dtstart`	DateTime string	Start time of freebusy search.	Y	N/A
`dtend`	DateTime string	End time of freebusy search.	Y	N/A
`duration`	Integer	Freebusy duration time in number of days.	N	60 or Default taken from `ics.conf`

`fmt-out`	string	The format for the returned data.
		Format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`
				Default taken from `ics.conf`

`freebusybegin`	integer	Offset in number of days from the value of `ics.conf` setting `service.wcap.freebusybegin`. Backs off the date range by the value of this parameter. For example, a value of 30 would start the freebusy range 30 days before the current time found in the `ics.conf` parameter.	N	Default `ics.conf` value is 30.

Table 7-21 `get_freebusy` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`freebusyend`	integer	Offset in number of days from the value of `ics.conf` setting `service.wcap.freebusyend` to calculate the end of the freebusy range. Extends the date found in the `ics.conf` parameter. For example, a value of 30 would put the end date 30 days beyond the current setting.	N	Default `ics.conf` value is 30 days.
`id`	unique identifier string	The session identifier.	Y	N/A
`mail`	email address	An email address used to compute free/busy time. The address must be present in the LDAP. When an email address is passed in, all calendars of the specified user (that is calendars for which this user is the primary owner) that have `fbinclude=1`, are used in computing free/busy time.	Y/N	Either `calid` or `mail` must be specified.
`tzid`	timezone-ID string	Default time zone to use if `dtstart`, or `dtend` parameters do not have a time zone specified. For example, “America/Los_Angeles”	N	Server’s default timezone.
`tzidout`	time zone ID string	Time zone to report returned data in.	N	Zulu time

Description.

This command to retrieve the freebusy information for specified users. Freebusy information tells whether or not a user’s time has been scheduled. It does not indicate why the user is busy.

The component freebusy time will be calculated for a time period that can be specified in one of three ways:

- `duration` parameter

  The default value of the `duration` parameter is taken from the `ics.conf` setting `service.wcap.freebusyduration`. The standard default is `60` days. This is the default taken if none of the time period parameters are passed in.

- `dtstart` and `dtend` parameters

  The absolute start and end times to use for this freebusy calculation. There is no default for these parameters.

- `freebusybegin` and `freebusyend` parameters.

  The relative beginning and end times to include in the freebusy calculation. If these are specified with no value, the default is `30` for each.

If conflicting parameters are passed in, the `duration` parameter overrides the other two types.

For further information about how freebusy calendars are specified, see Freebusy Calendars and Freebusy Calculation for Private Events.

Error Codes

If this command fails for any reason, `errno` is set to `GET_FREEBUSY_FAILED(39)`.

Example

For example, a calendar called `jdoe` has the following events:

10:00-11:00	first meeting
12:00-1:00	lunch
3:00-4:00	second meeting

The freebusy time for `jdoe` (from 9:00 to 6:00) would be the following:

9-10	:	Free
10-11	:	Busy
11-12	:	Free
12-1	:	Busy
1-3	:	Free
3-4	:	Busy
4-6	:	Free

The following URL generates freebusy information found in the calendar `jdoe` between May 1 2002 and July 1 2002.

The output is returned in `text/calendar` format.

```
http://webcalendarserver/get_freebusy.wcap?id=2mu95r5so0hq68ts6q3&calid=jsun&dtstart=20020501T112233Z&dtend=20020701T112233Z&fmt-out=text/calendar
```

Here is the output:

get_guids

Purpose

Generate a set of globally unique identifiers.

Parameters

Table 7-22 lists get_guids parameters:

Table 7-22 get_guids Parameters

Parameter	Type	Purpose	Required	Default
guidCount	integer	Number of GUIDs to return.	N	1
fmt-out	string	The format for the returned data. The three format types: text/calendar text/xml	N	text/calendar

Description.

This command returns the specified number of globally unique identifiers (GUIDs). The client need not be authenticated to call this command.

Example

```
http://webcalendarserver/get_guids.wcap?guidCount=10
&fmt-out=text/calendar
```

```

gettime

Purpose

Gets the server time for the requested calendars.

Parameters

Table 7-21 lists `gettime` parameters:

Table 7-23 `gettime` Parameters

Parameter	Type	Purpose	Required	Default
`calid`	semicolon-separated list of strings	A list of calendar identifiers.	N	Current user's calid.

`fmt-out`	string	The format for the returned data.
		Format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`id`	unique identifier string	The session identifier.	Y	N/A
`tzidout`	time zone ID string	Time zone to report returned data in.	N	Zulu time

Description

Calendars must have given read permission to the user requesting the server time. Returns the server time of the server where the calendar is stored.

Error Codes

- `X-NSCP-WCAP-ERRNO:1` - Session ID timed out or Invalid session ID
- `X-NSCP-WCAP-ERRNO:28` - Command failed; user denied access to a calendar
- `X-NSCP-WCAP-ERRNO:29` - Command failed; calendar does not exist in the database
- `X-NSCP-WCAP-ERRNO:55` - Get Server time Failed

Example

Valid session with tzidout

```
http://webcalendarserver/gettime.wcap?id=br6e8vx9ek02n2ow9&
calid=jdoe&tzidout=America/Los_Angeles
```

```

get_userprefs

Purpose

Retrieve the calendar preferences for the current user.

Parameters

Table 7-24 lists `get_userprefs` parameters:

Table 7-24 `get_userprefs` Parameters

Parameter	Type	Purpose	Required	Default

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`id`	unique identifier string	The session identifier.	Y	N/A
`userid`	string	Indicates which user's preferences to get.	N	N/A

Description.

This command retrieves all the calendar preferences for the current user, and the following server preferences relating to this user:

- `allowchangepassword`. Users can change the password.
- `allowcreatecalendars`. Users can create calendars.
- `allowdeletecalendars`. Users can delete calendars.
- `allowpublicwritablecalendars`. Users can have publicly writable calendars.
- `validateowners`. If set to `1`, the server must validate that each owner of a calendar exists in the directory (whether the directory is LDAP or a CSAPI compatible user mechanism).
- allowsetprefs. If set to `1`, allow `set_userprefs.wcap` to modify the user preferences.

See the *Sun Java System Calendar Server Administration Guide* for more information about server preferences.

Access Control Information (ACI)

The Calendar Server configuration program adds new ACIs. If you are upgrading from an earlier version of Java Enterprise System, you must rerun the configuration program to have the new ACIs added. Or you can use the Directory Server `ldapmodify` command to add them yourself as follows.

On the root suffix (`o=usergroup`):

```
dn:  o=usergroup
changetype: modify
add: aci
aci: (targetattr="icscalendar || cn || givenName || sn || uid ||
mail")(targetfilter=(objectClass=icscalendaruser))(version 3.0; acl "Allow
calendar administrators to proxy - product=ics,class=admin,num=2,version=1";
allow (proxy) groupdn = "ldap:///cn=Calendar
Administrators,ou=Groups,o=usergroup";)
```

On the domain basedn node (`o=sesta.com,o=usergroup`):

```
dn:  o=sesta.com,o=usergroup
changetype: modify
add: aci
aci:(targetattr="icscalendar || cn || givenName || sn || uid ||
mail")(targetfilter=(objectClass=icscalendaruser))(version 3.0; acl "Allow
calendar users to read and search other users -
product=ics,class=admin,num=3,version=1"; allow (search,read) userdn =
"ldap:///uid=*, ou=People, o=sesta.com, o=usergroup";)
```

Note that if there is no domain basedn node, add the preceding ACI to the root suffix itself (change the `dn:` value to `o=usergoup`).

NOTE All nodes under the basedn must be set to allow anyone read and search access rights in order for this command to work. For more information, see the Common Topic "Access Control Entries" on page 74.

Example

The following URL retrieves user preferences for the current user:

`http://`*`webcalendarserver`*`/get_userprefs.wcap?id=b5q2o8ve2rk02nv9t6&calid=jdoe&fmt-out=text/calendar`

This is the data returned:

import

Purpose

Import events and todos from a file to a calendar.

Parameters

Table 7-25 lists `import` parameters:

Table 7-25 `import` Parameters

Parameter	Type	Purpose	Required	Default
`appid`	string	A runtime parameter (not stored in the database) that specifies which application is making the request. ENS uses this parameter to determine which X-Tokens to return. Does not affect WCAP command output. For more information on the ENS X-Tokens, see the *SunONE Messaging and Collaboration Event Notification Service Manual*.	N	N/A
`calid`	string	Identifier of a calendar to which to import event.	Y	N/A

`content-in`	string	Content type of input data. One of the following values:
		`text/calendar`
		`text/xml`
			Y	N/A

`dtend`	DateTime string	End time and date of the events and todos to import. A value of `0` means import all components from the start date to the last date in the file.	N	`0`
`dtstart`	DateTime string	Start time and date of events and todos to import. A value of `0` means import all components from the earliest date in the file to the end date.	N	`0`
`id`	unique identifier string	The session identifier. Required unless the calendar is public.	Y	N/A

Description.

Use this command to import to the specified calendar events and todos that have previously been exported to a file using the `export` command. You must specify the file's MIME content type in the `content-in` parameter.

If you do not specify either the starting or ending date, or you pass in `0` as the value for `dtstart` and `dtend`, the command adds all events and todos in the file to the specified calendar. If you specify a starting and ending date, the command imports only events and todos in the file that fall within the time range. Specify starting and ending dates in UTC time (indicated by `Z` at the end of the datetime).

You must use this command with an HTTP POST message (unlike other commands, which can be used with an HTTP GET message). You attach the file containing the exported events and todos to the POST message. This file must be in either iCalendar (.ics) or XML (.xml) format.

Example

The following POST message imports the attached iCalendar file to the calendar jdoe using the import command (The session id is required.):

```
POST /import.wcap?id=t95qm0n0es3bo35r&calid=jdoe&dtstart=0&dtend=0
Content-type: multipart/form-data;
boundary=---------------------------33111928916708
Content-Length: 679
-----------------------------33111928916708
Content-Disposition: form-data; name="Upload";
filename="C:\TEMP\ical1.ics"
BEGIN:VCALENDAR

X-S1CS-CALPROPS-SUBSCRIBED-CALENDAR:jdoe@example.com:Vacation
X-S1CS-CALPROPS-SUBSCRIBED-CALENDAR:jdoe@example.com:ProjectX
END:VCALENDAR
```

login

Purpose

Authenticate a specific user.

Parameters

Table 7-28 lists `login` parameters:

Table 7-28 `login` Parameters

Parameter	Type	Purpose	Required	Default

`fmt-out`	string	Specifies the desired output format.
		Specify `text/html` to log in to the Calendar Express user interface. This format type is invalid in all other commands.
		If you are not logging into the Calendar Express user interface, choose one of the other output format types that follows:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`lang`	enum	The user's preferred language.	N	`NULL`
`password`	string	The user's password.	N	N/A
`proxyauth`	string	Used by calendar administrators to perform proxy authorization.	N	N/A
`user`	string	The user's name.	N	`NULL`

Description.

This command logs a specific user into Calendar Server, authenticating the user to the server with a user name and password convention.

The user name is a plain text string that uniquely identifies the user to the server. This user name could, for example, be the same as a user's email address. The password is also plain text.

fmt-out=text/html

This data type is allowed in only one command in WCAP, `login`. It is for the express purpose of logging into the SHTML user interface. When `fmt-out=text/html` occurs in `login`, the command is redirected to `command.shtml`, which connects the user to the Calendar Server user interface. Since this data type is not the default for the parameter, you must specify it explicitly when logging in to the Calendar Server interface.

Authentication

Do internal authentication using either the default LDAP authentication, or your own CSAPI plug-in to link to an existing user authentication method (For more information on CSAPI authentication, see "csIAccessControl" on page 25). For more information on the Proxy Authentication SDK, see Chapter 3, "Proxy Authentication SDK Overview" for the overview and Chapter 4, "Proxy Authentication SDK Reference" for the API Reference.

If the user fails to authenticate correctly, the login window reappears with an error noting a failure to log in.

Example

For example, the following URL attempts to login user `jdoe`:

```
http://webcalendarserver/login.wcap?user=jdoe&password=mypword
```

Returns

The `login` command returns the information shown in this example:

```
HTTP/1.0 302 OK
Date: Tue, 11 May 2002 22:38:33 GMT
Pragma: no-cache
Expires: 0
Cache-Control: no-cache
Content-Length: 0
Last-modified: Tue, 11 May 2002 22:38:33 GMT
Location:
http://webcalendarserver/en/main.html?id=er6en05tv6n3bv9&lang=en
 &host=http://webcalendarserver/
```

logout

Purpose

Terminate the current user's session.

Parameters

Table 7-29 lists `logout` parameters:

Table 7-29 `logout` Parameters

Parameter	Type	Purpose	Required	Default

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text calendar`

`id`	unique identifier string	The session identifier.	Y	N/A

Description.

This command ends the specified session of the current user, and deletes the session instance of the user in the session table. The user is returned to the login screen.

The following is an example of a URL using this command:

`http://`*`webcalendarserver`*`/logout.wcap?id=bu9p3eb8x5p2nm0q3`

ping

Purpose

Determine whether the calendar server is active.

Parameters

This command takes no parameters.

Description.

This command returns a minimal HTML page to indicate that the server responded.

Only users with administrative privilege can use this command.

Returns

For this example, the administrator's `userid` and `calid` are both `adminX`.

```
HTTP/1.0 200
Date: Thu, 03 Jun 2002 21:31:42 GMT
Content-type: text/html; charset=iso-8859-1
Content-length: 190
Last-modified: Thu, 03 Jun 2002 21:31:42 GMT
Pragma: no-cache
Expires: 0
Cache-Control: no-cache
```

search_calprops

Purpose

Search for a calendar's properties.

Parameters

Table 7-30 lists search_calprops parameters:

Table 7-30 search_calprops Parameters

Parameter	Type	Purpose	Required	Default
calid	integer (0,1)	A boolean indicating whether or not to search the calid property. 1 = Search the calid property 0 = Do not search it.	N	0, unless both primaryOwner and name are 0
id	unique identifier string	The session identifier.	Y	N/A
maxResults	integer	The maximum number of results to return.	N	200
name	integer (0,1)	A boolean indicating whether or not to search the name property. 1 = Search the name property 0 = Do not search it.	N	0
primaryOwner	integer (0,1)	A boolean indicating whether or not to search the primaryOwner property. 1 = Search the primaryOwner property. 0 = Do not search it.	N	0
searchOpts	integer 0,1,2,3	How to perform the search. One of the following: 0 = CONTAINS 1 = BEGINS_WITH 2 = ENDS_WITH 3 = EXACT	N	0
search-string	string	The string to search for in calendars.	Y	N/A

Description.

This command searches for a calendar using the query type specified by searchOpts. It returns the calendar properties for all calendars where a string in the specified properties (primaryOwner, calid, name), matches the search-string, using the specified seachOpts, up to the specified maximum number of matches (maxResults).

Search Properties

This command searches for a matching string in one of three properties:

- `calid`. The calendar's unique identifier.
- `name`. The calendar's common name (text).
- `primaryOwner`. The calendar's primary owner.

To search for the value of a specific property, set that parameter to `1`. If both `primaryOwner` and `name` are set to `0`, `calid` defaults to `1` and the server assumes the `search-string` is a `calid`, regardless of the `calid` parameter setting.

Search Options

There are four search options:

- Return the calendar properties that contain the `search-string` (`CONTAINS`).
- Return the calendar properties that begin with the `search-string` (`BEGINS_WITH`).
- Return the calendar properties that ends with the `search-string` (`ENDS_WITH`).
- Return the calendar properties that exactly match the `search-string` (`EXACT`).

Example

The following example URL searches the primary owner property (primaryOwner=1) in all calendars to see if it contains (searchOpts=0) the string "jdoe"

http://*webcalendarserver*/search_calprops.wcap?id=n3o3m05sx9v6t98t8u2p&search-string=jdoe&primaryOwner=1&searchOpts=0&maxResults=50&fmt-out=text/calendar

The following data is a result of the example URL above:

set_calprops

Purpose

Set the calendar properties of a calendar.

Parameters

Table 7-31 lists `set_calprops` parameters:

Table 7-31 `set_calprops` Parameters

Parameter	Type	Purpose	Required	Default
acl	string	A semicolon-separated list of strings specifying the new value of the access control entries.	N	,,,,
`cal`	encoded string	A list of parameters to decode. There can be multiple instances of this parameter.	N	N/A
`calid`	string	Identifier of the calendar to modify.	Y	N/A
`categories`	string	A semicolon-separated list of strings containing the new categories the calendar belongs to.	N	N/A
`charset`	string	The character set for the calendar.	N	N/A
`description`	string	The description of the calendar.	N	N/A
`doublebooking`	integer	Allow or disallow doublebooking. `1` = Allow doublebooking. `0` = Disallow doublebooking.	N	N/A
`fbinclude`	integer	Specifies whether the calendar can be used in any free/busy lookup. `1` = Include the calendar. `0` = Do not include the calendar. If you want to remove the calendar from the free/busy lookup list, pass in `fbinclude=0`.	N	N/A

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`id`	unique identifier string	The session identifier.	Y	N/A
`lang`	string	The language of the calendar.	N	N/A
`master`	string	The email contact for the calendar.	N	N/A

Table 7-31 `set_calprops` Parameters *(Continued)*

Parameter	Type	Purpose	Required	Default
`multiple`	integer	The number of calendars for which to set these preferences.	N	`0`
`name`	string	The new text name of the calendar.	N	N/A
`owners`	string	A semicolon-separated list of strings containing he new list non-primary owners.	N	N/A
`tzid`	string	The new timezone identifier for this calendar.	N	,,,,

Description.

This command is an update command, that is, it only changes the values of the parameters you specify. It is not necessary to supply all parameters in the command, only the ones you wish to change. Calendar properties are special states of a calendar, which includes the calendar's name, read and write permission values (`acl` parameter), the list of owners, and the list of categories.

Use `set_calprops` to do the following:

- Change the name of the calendar.
- Change owner of calendar.
- Change category of calendar.
- Change read permission of calendar’s event.
- Change write permission of calendar’s event.
- Change description of calendar.
- Change character set of calendar.
- Change language of calendar.
- Change email contact of this calendar.
- Change the timezone-identifier of the calendar.

Single Calendar Example

Here is a sample URL that sets calendar properties: (The `calid` parameter is required.)

```
http://webcalendarserver?set_calprops.wcap?id=dfasdfzd3ds&calid=jdoe&categ
ories=business;meeting&name=John%39s%32Calendar
```

Multiple Calendars Example

To set properties of several calendars at one time, set the `multiple` parameter to the number of calendars to be set, then pass a `cal` parameter for each calendar. The cal parameter contains an encoded string with the complete property parameter list for the identified calendar. In this string, replace all special characters with a percent character (%), followed by the hexadecimal ASCII code for the special character. ASCII hex codes for common special characters are as follows:

Character	Code
=	%3D
&	%26
"	%22

For example, the following URL modifies three calendars with IDs xxxx, yyyy, and zzzz, setting the descriptions to `X-Calendar`, `Y-Calendar`, and `Z-Calendar`, respectively:

```
http://webcalendarserver?id=fasdfzd3ds
     &multiple=3
     &cal=calid%3Dxxxx%26description%3DX-Calendar
     &cal=calid%3Dyyyy%26description%3DY-Calendar
     &cal=calid%3Dzzzz%26description%3DZ-Calendar
```

This is the equivalent of the following three URLs:

```
http://webcalendarserver?id=fasdfzd3ds&calid=xxxx&desc=X-Calendar
```

```
http://webcalendarserver?id=fasdfzd3ds&calid=yyyy&desc=Y-Calendar
```

```
http://webcalendarserver?id=fasdfzd3ds&calid=zzzz&desc=Z-Calendar
```

In the example, notice that since the `multiple` parameter is set to 3, there are three instances of the `cal` parameter. The value of each `cal` parameter is an encoded list of parameters and their values. The server will decode each `cal` parameter and set the properties appropriately.

Access Control Entries

See "Access Control Entries" on page 74, in the Common Topics section at the front of this chapter. Note that due to limitations of the user interface, it is advisable to limit the number of individuals listed in the ACEs to a maximum of 75 per calendar.

Freebusy Access

See “Freebusy Calendars” on page 89, in the Common Topics section at the front of this chapter.

Choosing a Different Language or Character Set

See “Changing Language or Character Set” on page 79, in the Common Topics section at the front of this chapter.

set_userprefs

Purpose

Modify the preferences or password for a session.

Parameters

Table 7-32 lists set_userprefs parameters:

Table 7-32 set_userprefs Parameters

Parameter	Type	Purpose	Required	Default
add_attrs	string	Add a new preference.	N	N/A
convertCalid	integer (0,1)	When set to 1 and setting the preferences icsSet or icsSubscribed, indicates to the server to convert the character "^" to ":" when storing the calid. When set to 0, the parameter is ignored.	N	0
del_attrs	string	Delete an existing preference.	N	N/A
fmt-out	string	The format for the returned data. The three format types: text/calendar text/xml	Y	text/calendar
id	unique identifier string	The session identifier.	Y	N/A
set_attrs	string	Modify a preference value.	N	N/A
userid	string	Used only by administrators. Indicates which user's preferences to set.	N	N/A

Description.

This command modifies the preferences for the current user. You may also modify the user's password through LDAP.

Use of this parameter is only necessary when setting the subscribed list of calendars (icsSubscribed), or the subscribed list of groups (icsSet). The calid on incoming commands must have the colon, ":", replaced with a caret, "^". For example, if the calid is jdoe:personal, then WCAP must receive it as jdoe^personal in order for the command to work properly.

If the value of convertCalid is 1, then WCAP will convert the "^" back to a ":". If the value of the convertCalid is 0, the conversion will not be done

When the administrator is logged in, and the ics.conf file preference `service.admin.calmaster.wcap.allowgetmodifyuserprefs` is set to “yes”, the `userid` parameter specifies which user’s preferences to set.

Returns

The function returns the text of `get_userprefs`.

Examples

For example, the following URL adds a new preference, `ceBgcolor`, to the calendar and sets it to `black`:

`http://`*`webcalendarserver`*`/set_userprefs.wcap?id=b5q2o8ve2rk02nv9t6&add_attrs=ceBgcolor=black`

This URL deletes the calendar preference `ceBgcolor` from the user’s preferences.

`http://`*`webcalendarserver`*`/set_userprefs.wcap?id=b5q2o8ve2rk02nv9t6&del_attrs=ceBgcolor`

This URL would modify the calendar preference `ceBgcolor` to have the value `white`:

`http://`*`webcalendarserver`*`/set_useprefs.wcap?id=b5q2o8ve2rk02nv9t6&set_attrs=ceBgcolor=white`

This URL would allow the logged-in administrator to modify the calendar preference `ceBgcolor` to have the value `black` for user `jdoe`:

`http://`*`webcalendarserver`*`/set_userprefs.wcap?id=b5q2o8ve2rk02nv9t6&userid=jdoe&set_attrs=ceBgcolor=black`

storeevents

Purpose

Add events to a calendar.

Parameters

Table 7-33 lists `storeevents` parameters:

Table 7-33 `storeevents` Parameters

Parameter	Type	Purpose	Required	Default
`alarmAudio`	ISO 8601 Date Time string	The time at which to sound an audio alarm.	N	N/A
`alarmDescription`	string	The message sent out with the alarm	N	“This is the alarm description”
`alarmEmails`	semicolon-separated list of email addresses	Recipients of alarm notifications for the event.	N	N/A
`alarmFlashing`	ISO 8601 Date Time string	The time at which to run flashing alarm.	N	N/A
`alarmPopup`	ISO 8601 Date Time string, or ISO 8601 Duration string	The time at which to pop up a dialog alarm.	N	N/A
`alarmStart`	ISO 8601 Date Time string, or ISO 8601 Duration string	The time at which to send the event alarm notification.	N	N/A
`appid`	string	A runtime parameter (not stored in the database) that specifies which application is making the request. ENS uses this parameter to determine which X-Tokens to return. Does not affect WCAP command output. For more information on the ENS X-Tokens, see the *SunONE Messaging and Collaboration Event Notification Service Manual*.	N	N/A
`attachments`	semicolon-separated list of strings	This is for iCalendar interoperability only. The strings are URLs.	N	N/A

Table 7-33 `storeevents` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`attendees`	semicolon-separated list of strings	An event's iCalendar RFC 2445 attendee properties. For a list of the properties understood by Calendar Server, see Table 6-6. There is one optional property that is specific only to Calendar Server: `SENT-STATUS`, which can have the value of: `NOT-SENT` or `SENT-SUCCEEDED`. The default for this property is `NOT-SENT`. If this property is set to `SENT-SUCCEEDED`, the the Group Scheduling Engine (GSE) will not process this attendee.	N	N/A
`calid`	string	Calendar identifier (or email address of `calid`) in which to store the event.	Y	N/A
`categories`	semicolon-separated list of strings	The event categories.	N	N/A
`charset`	string	The character set for the calendar.	N	N/A

`compressed`	integer (`0`,`1`)	This parameter has been deprecated for this release and may be removed from future releases.
		
		For `compressed=0`, returns less data. Specifically, it does not return the following parameters:
		`rrules`
		`rdate`
		`exrule`
		`exdate`
		
		For `compressed=1`, all recurrence data is returned.
			N	`0`

`contacts`	semicolon-separated list of strings	Contacts for the event.	N	N/A
`desc`	string	Event purpose description. A string of any length. If not passed, `desc` is set to the `summary` value. To include spaces in the string, use the code `%20`.	N	Value of `summary` parameter.
`dtend`	Date Time string	Event end time and date.	N	N/A

Table 7-33 `storeevents` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`dtstart`	Date Time string	Event start time and date. Required to create or modify events.	 Y	N/A
`duration`	ISO 8601 duration string	Event duration. If an event has both a `duration` and a `dtend`, the duration is ignored.	N	N/A
`exdates`	semicolon-separated list of ISO 8601 Date Time Z strings	Event exclusionary recurrence dates. To successfully create events, the `rrules` parameter must be used in conjunction with this parameter.	N	N/A
`exrules`	semicolon-separated list of ISO 8601 Date Time Z strings	Event exclusionary recurrence rules. A semicolon-separated list of recurrence-rule strings. Each rule value must be enclosed in quotes. See "Recurring Components – Overview."	N	N/A
`fetch`	integer (`0`,`1`)	A boolean indicating whether or not to fetch and return newly stored todos. `1` = Fetch and return newly stored todos. `0` = Do not fetch.	N	`0`

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`geo`	two semicolon-separated floats	Semicolon-separated string of two float numbers representing the event's geographical location (latitude and longitude). For example, `37.31;-123.2`.	N	`0;0`

`icsClass`	string	Event class.
		One of the following values:
		`PUBLIC`
		`PRIVATE`
		`CONFIDENTIAL`
			N	`PUBLIC`

`icsUrl`	string	Event URL.	N	`""`
`id`	unique identifier string	The session identifier.	Y	N/A
`isAllDay`	integer (0,1)	A boolean indicating whether or not the event lasts all day. `1` = Lasts all day. `0` = Does not last all day.	N	`0`

Table 7-33 `storeevents` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`language`	string	Language of event. (For example, “en”, “fr”, “de”)	N	N/A
`location`	string	Event location.	N	“”
`method`	integer (1,2,4,8)	ITIP method for group scheduling.	Y	`1` (`PUBLISH`)
		`1` = `PUBLISH` (organizer only uses this) `2` = `REQUEST` (organizer only uses this) `4` = `REPLY` (attendees only use this) `8` = `CANCEL` (organizer only uses this)		
`mod`	integer	Specifies the recurrences to modify.		N/A
		Not required for creating events.	N	
		Required to modify events.	Y	
		One of the following values:		

		`1 = THISINSTANCE`
		`2 = THISANDFUTURE`
		`3 = THISANDPRIOR`
		`4 = THISANDALL`		

`orgCalid`	string	Calendar identifier of organizer.	N	N/A
		One of the following parameters must be specified: orgCalid, orgEmail, or orgUID.		
`orgCN`	string	Common name of the organizer.	N	N/A
`orgEmail`	email address	Email address of the event contact (usually the organizer).	N	N/A
		One of the following parameters must be specified: orgCalid, orgEmail, or orgUID.		
`orgUID`	`userid`	The `userid` of the organizer.	N	N/A
		One of the following parameters must be specified: orgCalid, orgEmail, or orgUID.		
`priority`	integer (0-9)	Event priority.	N	`0`
		`0` = lowest `9`= highest		
`rchange`	integer (`0`,`1`)	A boolean indicating whether or not to expand a recurring event.	N	`0`
		`1` = expand `0` = do not expand		

Table 7-33 `storeevents` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`rdates`	semicolon-separated list of ISO 8601 Date Time Z strings	Event recurrence dates. To successfully create events, the `rrules` parameter must also be specified.	N	N/A
`relatedTos`	semicolon-separated list of quoted strings	Other events to which this event is related.	N	N/A
`replace`	Integer (0,1)	A boolean. For parameters with semicolon-separated values: `1` = update (replace the old values with the new passed-in values) `0` = append (add the new passed-in values to the old ones)	N	`0`
`resources`	semicolon-separated list of strings	The resources associated with the event.	N	N/A
`rid`	ISO 8601 DateTime string	Event recurrence identifier. Not required to create events. If this parameter is not set when trying to modify events, the whole series of events is modified.	 N N	N/A
`rrules`	semicolon-separated list of strings	Event recurrence rules. A semicolon-separated list of recurrence-rule strings. Each rule value must be enclosed in quotes. See “Recurring Components – Overview.”	N	N/A
`seq`	integer	(Not implemented) Event sequence number.	N	`0`
`smtp`	integer (0, 1)	Clients that send out invitations themselves set the value to 0. Clients that require the server to send out invitations set the value to 1. 0—No 1—Yes	N	`1`

Table 7-33 `storeevents` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`status`	integer	The event status code. One of the following values: `0` CONFIRMED `1` CANCELLED `2` TENTATIVE `3` NEEDS_ACTION `4` COMPLETED `5` IN_PROCESS `6` DRAFT `7` FINAL	N	N/A
`storetype`	integer	Designates whether an explicit “create” or “modify” is attempted on an event. An error results if an attempt is made to create an event that already exists, or to modify an event that does not exist. The error returned is `STOREEVENTS_FAILED (14)` The following values are valid: 0 WCAP_STORE_TYPE_NONE 1 WCAP_STORE_TYPE_CREATE 2 WCAP_STORE_TYPPE_MODIFY If the attribute is not passed or has a value of `0`, no error conditions are reported.	N	0
`summary`	string	Event summary. A string of any length. Required for new events; not required for modifying events. To include spaces in the string, use the code `%20`.	Y/N	Default `summary` available for new events
`transparent`	integer (`0`, `1`)	Is the event transparent (`1`), or opaque (`0`)? If it is transparent, exclude this event from freebusy calculations. If opaque, then include it in freebusy calculations. If the isAllDay parameter is set to `1`, the default is transparent instead of opaque.	N	`0` (opaque) `1` (transparent, if `isAllDay=1`)
tzid	time zone ID string	The time zone used to translate dates to Zulu time for storage. If this parameter is missing, and the time string has no Z after it, the calendar server time zone ID is used.	N	Calendar server time zone ID.
tzidout	time zone ID string	Time zone returned data should be translated to.	N	Returns data in Zulu time

Table 7-33 `storeevents` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`uid`	string	Unique identifier of the event to be stored. System generated for new events. Required to modify events.	 N Y	`Default uid` available for new events.
`X-`*property name*	string	One or more X properties, in iCalendar 2445 format (note that WCAP uses ^ as the separator)	N	N/A

Description.

Use this command to creates or modify events with the specified attributes and stores them in the specified calendar in the database.

The command creates and stores recurrences as specified by the `rrules`,`exrules`, `rid`, `mod`, and `rchange` parameters. See "Recurring Components – Overview."

When the `notify` value is `1`, it sends an IMIP `PUBLISH` message to all attendees of the event.

Use the `language` parameter to specify the language of the event. See "Changing Language or Character Set" on page 79 for a list of possible language codes.

For an explanation of how to use the `attendee` and `method` parameters to do group scheduling, see the Common Topics section "Group Scheduling" on page 91.

For an explanation of how to replace, append or delete a parameter, see the explanation in the Common Topics section "Updating Parameter Values" on page 103.

The server does not support attachments. The `attachments` parameter exists to support iCalendar interoperability only, and is not functional.

It is possible to delete an attendee in an existing meeting by assigning the value `X-NSCP-WCAP-ATTENDEE-DELETE` to the `attendee` parameter `PARTSTAT`. For example, to delete attendee jdoe, the attendee parameter would contain the following:

```
PARTSTAT=X-NSCP-WCAP-ATTENDEE-DELETE^jdoe
```

Required Parameters

This command creates new events and modifies existing events. You can not add and modify events in the same command. You must do one or the other.

There is a different set of parameter requirements for both cases:

- To create new events requires only the dtstart parameter.

  Every other parameter is optional. The server generates the uid.

- To modify existing events requires two parameters:

  - uid
  - mod

  All other parameters are optional. If a parameter is not specified, the event will retain the previous value of the property.

Duration and Dtend

The ending date (dtend) overrides duration. If you specify both duration and dtend, the command ignores duration.

Duration strings can be used in three parameters: duration, alarmPopup and alarmStart.

Specify the duration in iCal format. For example:

- P1Y2M3DT1H30M10S represents a duration of 1 year, 2 months, 3 days, 1 hour, 30 minutes, 10 seconds
- PT1H30M represents a duration of 1 hour, 30 minutes
- P1D represents a duration of 1 day
- PT15M represents a duration of 15 minutes

Notice that the T in the string separates the date information (year, month, day) from the time information (hour, minute, second).

Returns

The command returns the error value. To have the command return the stored todo data, specify the fetch parameter (fetch=1). In addition, use the tzidout parameter to specify the time zone the returned data should be translated to. If the tzidout parameter is missing, the data will be returned in Zulu time.

Error Codes

This command cannot modify a linked event. The command will fail and return CANNOT_MODIFY_LINKED_EVENTS(31) in the errno array.

The command fails, and returns the error STORE_FAILED_DOUBLE_BOOKED(40), when it tries to store an event in a time slot that is already scheduled (double booking).

Example

For example, this URL would call `storeevents.wcap` and would result in storing an event in the calendar `john`,

```
http://webcalendarserver/storeevents.wcap?id=3423423asdfasf
&calid=john&dtstart=20020101T103000&dtend=20020101T113000&uid=001
&summary=new%20year%20event
```

The above example results in the following entry in an iCalendar database:

```
BEGIN:VEVENT
DTSTART:20020101T183000Z
DTEND:20020101T193000Z
UID:001
SUMMARY:new year event
END:VEVENT
```

storetodos

Purpose

Add one or more todos to a calendar.

Parameters

Table 7-34 lists storetodos parameters:

Table 7-34 storetodos Parameters

Parameter	Type	Purpose	Required	Default
alarmAudio	ISO 8601 Date Time string	The time at which to sound an audio alarm.	N	N/A
alarmDescription	string	The message send out with the alarm	N	“This is the alarm description”
alarmEmails	semicolon-separated list of email addresses	Recipients of alarm notifications for the todo.	N	N/A
alarmFlashing	ISO 8601 Date Time string	The time at which to run a flashing alarm.	N	N/A
alarmPopup	ISO 8601 Date Time string ISO 8601 Duration string	The time at which to pop up a dialog alarm.	N	N/A
alarmStart	ISO 8601 Date Time string ISO 8601 Duration string	The time at which to send an alarm notification of the todo.	N	N/A
appid	string	A runtime parameter (not stored in the database) that specifies which application is making the request. ENS uses this parameter to determine which X-Tokens to return. Does not affect WCAP command output. For more information on the ENS X-Tokens, see the *SunONE Messaging and Collaboration Event Notification Service Manual*.	N	N/A
attachments	semicolon-separated list of strings	This parameter exists to support iCalendar interoperability only. The strings are URLs.	N	N/A
attendees	semicolon-separated list of strings	A todo’s iCalendar RFC 2445 attendee properties. For a list of the properties understood by Calendar Server, see Table 6-6	N	N/A

Table 7-34 `storetodos` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`calid`	string	Calendar identifier (or email address of `calid`) in which to store the todo.	Y	N/A
`categories`	semicolon-separated list of strings	The todo categories.	N	N/A
`charset`	string	The character set for the calendar.	N	N/A
`completed`	ISO 8601 Date Time string	Completion date of the todo. A value of `0` means the todo is not yet completed.	N	`0`

`compressed`	integer (`0`,`1`)	This parameter has been deprecated in this release and may be removed in future releases.
		For `compressed=0`, returns less data. Specifically, it does not return the following parameters:
		`rrules`
		`rdate`
		`exrule`
		`exdate`
		For `compressed=1`, all recurrence data is returned.
			N	`0`

`contacts`	semicolon-separated list of strings	Contacts for the todo.	N	N/A
`desc`	string	Purpose of the todo. A string of any length. If not passed, `desc` is set to the `summary` value. To include spaces in the string, use the code `%20`.	N	Value in `summary` parameter.
`dtstart`	ISO 8601 Date Time string	Start time and date of the todo. Not required to modify todos. Required to create todos.	 N Y	N/A
`due`	ISO 8601 Date Time string	End time and date of the todo.	N	N/A
`duration`	ISO 8601 duration string	Todo duration.	N	N/A
`exdates`	semicolon-separated list of ISO 8601 TimeDate strings	Exclusionary recurrence dates of the todo. To successfully create todos, the `rrules` parameter must also be specified.	N	N/A

Table 7-34 `storetodos` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`exrules`	semicolon-separated list strings	Todo exclusionary recurrence rules. A semicolon-separated list of recurrence-rule strings. Each rule value must be enclosed in quotes. See "Recurring Components – Overview."	N	N/A
`fetch`	integer (`0`,`1`)	A boolean indicating whether or not to fetch and return newly stored todos. `1` = Fetch and return newly stored todos. `0` = Do not fetch todos.	N	`0`

`fmt-out`	string	The format for the returned data.
		
		The three format types:
		
		`text/calendar`
		`text/xml`
			N	`text/calendar`

`geo`	two semicolon-separated floats	Semicolon-separated string of two float numbers representing the todo's geographical location (latitude and longitude). For example, 37.31;-123.2.	N	`0;0`

`icsClass`	string	Todo class. One of the following values:
		
		`PUBLIC`
		`PRIVATE`
		`CONFIDENTIAL`
			N	`PUBLIC`

`icsUrl`	string	Todo URL.	N	""
`id`	unique identifier string	The session identifier.	Y	N/A
`isAllDay`	integer (`0`,`1`)	A boolean indicating whether or not it is an all day todo. `1` = An all day todo. `0` = Not an all day todo.	N	`0`
`language`	string	The language of the todo. (For example, "en", "fr", "de".)	N	N/A
`location`	string	Todo location.	N	""
`method`	integer (1,2,4,8,16,32)	ITIP method for group scheduling. One of the following: 1 = `PUBLISH` 2 = `REQUEST` 4 = `REPLY` 8 = `CANCEL` 16 = `MOVE` 32 = `COUNTER` (only attendees use this)	Y	1 (`PUBLISH`)

Table 7-34 `storetodos` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`mod`	integer	Specifies the recurrences to store/modify.		N/A
		Not required for new todos.	N	
		Required to modify todos.	Y	

		One of the following values:
		`1 = THISINSTANCE`
		`2 = THISANDFUTURE`
		`3 = THISANDPRIOR`
		`4 = THISANDALL`		

`notify`	integer 0,1	This parameter has been deprecated. It remains to provide backward compatibility. The Group Scheduling Engine (GSE) handles sending of email notifications.	N	`0`
		A boolean indicating whether or not to notify attendees of a changed todo. `1` = Notify attendees of the change. `0` = Do not notify attendees.		
`orgCalid`	string	Calendar identifier of organizer.	N	N/A
		One of the following parameters must be specified: `orgCalid`, `orgEmail`, or `orgUID`.		
`orgCN`	string	Common name of the organizer.	N	N/A
`orgEmail`	email address	The email address contact for the todo. (Usually the organizer's email.)	N	N/A
		One of the following parameters must be specified: `orgCalid`, `orgEmail`, or `orgUID`.		
`orgUID`	`userid`	The `userid` of the organizer.	N	N/A
		One of the following parameters must be specified: `orgCalid`, `orgEmail`, or `orgUID`.		
`percent`	integer (`0`-`100`)	Percentage completion of the todo.	N	`0`
`priority`	integer (`0`-`9`)	The priority of the todo. `0` = Lowest priority. `9`= Highest priority.	N	`0`
`rchange`	integer (0,1)	A boolean indicating whether or not to replace the rrule: `1` = Replace the rule. `0` = Do not replace it.	N	`0`
`rdates`	semicolon-separated list of ISO 8601 TimeDate Z strings	Recurrence dates of the todo. To successfully create todos, the `rrules` parameter must also be specified.	N	N/A

Table 7-34 `storetodos` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`relatedTos`	semicolon-separated list of quoted strings	Other todos to which this todo is related.	N	N/A
`replace`	Integer (0,1)	A boolean. For parameters with semicolon-separated values: `1` = update (replace the old values with the new passed-in values) `0` = append (add the new passed-in values to the old ones)	N	`0`
`resources`	semicolon-separated list of strings	The resources associated with the todo.	N	N/A
`rid`	ISO 8601 TimeDate string	Recurrence identifier of the todo. Not required for new todos. If this parameter is not specified the whole series is modified.	N	N/A
`rrules`	semicolon-separated list of strings	Todo recurrence rules. A semicolon-separated list of recurrence-rule strings. Each rule value must be enclosed in quotes. See “Recurring Components – Overview.”	N	N/A
`seq`	integer	Sequence number of the todo.	N	`0`

`status`	integer	A code for the status of the todo. One of the following values:
		`0 CONFIRMED`
		`1 CANCELLED`
		`2 TENTATIVE`
		`3 NEEDS_ACTION`
		`4 COMPLETED`
		`5 IN_PROCESS`
		`6 DRAFT`
		`7 FINAL`
		Note: Setting `status=4` sets the `status` as `COMPLETED`, but does not set the `COMPLETED_TIME_STAMP` and `PERCENT` properties. All three parameters must be set if a task is completed.
			N	N/A

Table 7-34 `storetodos` Parameters *(Continued) (Continued)*

Parameter	Type	Purpose	Required	Default
`storetype`	integer	Designates whether an explicit “create” or “modify” is attempted on a todo. An error results if an attempt is made to create a todo that already exists, or to modify a todo that does not exist. The error returned is `STORETODOS_FAILED (15)` The following values are valid: 0 WCAP_STORE_TYPE_NONE 1 WCAP_STORE_TYPE_CREATE 2 WCAP_STORE_TYPPE_MODIFY If the attribute is not passed or has a value of `0`, no error conditions are reported.	N	0
`summary`	string	Todo summary. A string of any length. Required for new todos; not required for modifying todos. To include spaces in the string, use the code `%20`.	Y/N	Default `summary` available for new todos
`transparent`	integer (`0`, `1`)	Is the private todo transparent (`1`), or opaque (`0`)? If it is transparent, exclude this private todo from freebusy calculations. If opaque, then include it in freebusy calculations.	N	0 (opaque)
`tzid`	time zone ID string,	The timezone used to convert time parameter values to Zulu time for storage. If this parameter is not present, and the string does not end in Z, then the calendar server tim zone ID is used.	N	Calendar server time zone ID
`tzidout`	time zone ID string	Time zone returned data should be translated to. Only valid when the `fetch` parameter is set to `1` (`fetch=1`).	N	Returns data in Zulu time
`uid`	string	Unique identifier of the todo to be stored. System generated for new todos; required to modify todos.	N/Y	Default `uid` for new todos

Description.

Use this command to create and modify todos with the specified attributes and stores them in the specified calendar in the database.

The command creates and stores recurrences as specified by rrules, exrules, rid, mod, and rchange parameters. See "Recurring Components – Overview."

When the notify value is 1, it sends an IMIP PUBLISH message to the email attendees of the todo.

For group scheduling, used the attendee and method parameters as explained in the Common Topics section "Group Scheduling" on page 91.

For an explanation of how to replace, append or delete a parameter, see the explanation in the Common Topics section "Updating Parameter Values" on page 103.

The server does not support attachments. The attachments parameter exists to support iCalendar interoperability only, and is not functional.

Required Parameters

This command creates new todos and modifies existing todos. There is a different set of parameter requirements for both cases:

- To create new todos requires the dtstart parameter.

  Every other parameter is optional. The server generates the uid.

- To modify existing todos requires two parameters:

  - uid
  - mod

  All other parameters are optional. If a parameter is not specified, the todo will retain the previous value of the property.

Duration and Due

The due date (due) overrides duration. If you specify both duration and due, the command ignores duration.

Specify the duration in the ISO 8601 format. For example:

- P1Y2M3DT1H30M10S represents a duration of 1 year, 2 months, 3 days, 1 hour, 30 minutes, 10 seconds
- PT1H30M represents a duration of 1 hour, 30 minutes
- P1D represents a duration 1 day
- PT15M represents a duration of 15 minutes

Notice that the T in the string separates the date information (year, month, day) from the time information (hour, minute, second).

Returns

The command returns the error value. To have the command return the stored todo data, specify the `fetch` parameter (`fetch=1`). In addition, use the `tzidout` parameter to specify the time zone the returned data should be translated to. If the `tzidout` parameter is missing, the data will be returned in Zulu time.

Error Codes

This command cannot modify a linked todo. The command will fail and return an error of `CANNOT_MODIFY_LINKED_TODOS(32)` in `errno`.

The command fails, and returns the error `STORE_FAILED_DOUBLE_BOOKED(40)`, when it tries to store a todo in a time slot that is already scheduled (double booking).

subscribe_calendars

Purpose

Add the specified calendars to the user's calendar subscription list.

Parameters

Table 7-25 lists subscribe_calendars parameters:

Table 7-35 subscribe_calendars Parameters

Parameter	Type	Purpose	Required	Default
calid	string	A semi-colon separated list of calendar identifiers.	Y	N/A
id	unique identifier string	The session identifier. Required unless the calendar is public.	Y	N/A
userid	string	Specifies which user is subscribing.. Can only be used by an administrator, and only if the option is configured on the server.	N	N/A

Description

Adds the calendars specified in the calid parameter to the user's subscription list. A check is made to see if the calendar exists. If not, an error code is returned.

Example

```
http://calendar.sesta.com/subscribe_calendars.wcap?id=br6p3t6bh5po35r&
calid=john@sesta.com;william@sesta.com:baseball
```

unsubscribe_calendars

Purpose

Remove the specified calendars to the user's calendar subscription list.

Parameters

Table 7-25 lists `subscribe_calendars` parameters:

Table 7-36 `subscribe_calendars` Parameters

Parameter	Type	Purpose	Required	Default
`calid`	string	A semi-colon separated list of calendar identifiers.	Y	N/A
`id`	unique identifier string	The session identifier. Required unless the calendar is public.	Y	N/A
`userid`	string	Specifies which user is subscribing. Can only be used by an administrator, and only if the option is configured on the server.	N	N/A

Description

Removes the calendars specified in the `calid` parameter to the user's subscription list. No check is made to see if the calendar exists.

Example

```
http://calendar.sesta.com/unsubscribe_calendars.wcap?id=br6p3t6bh5po35r&
calid=john@sesta.com;william@sesta.com:baseball
```

verifyevents_by_ids

Purpose

This command is used to verify if the event specified with the uid and rid pair exists in the database.

Parameters

Table 7-39 lists verifyevents_by_ids parameters:

Table 7-37 verifyevents_by_ids Parameters

Parameter	Type	Purpose	Required	Default
calid	string	Calendar from which to fetch events.	N	User's default calendar
fmt-out	string	The format for the returned data. The three format types: text/calendar text/xml	N	text/calendar
id	string	Uniquely identifies the session (session ID).	N*	null
rid	ISO 8601 DateTime string	Corresponding set of comma separated event rids. If this is a non-recurring event, rid=0.	Y	N/A
tzid	time zone ID string	Time zone, such as "America/Los_Angeles"	N	Server's default time zone
uid	string	Comma separated set of event uids.	Y	N/A

* The id must be specified with the command unless the calendar to fetch from is public calendar.

Description.

This command tries to fetch events matching the passed in uid-rid pairs.

Returns

If the events are found, the data is returned in the format specified by the fmt-out parameter. If no format was specified, the output defaults to text/calendar.

If the events are not found, if the rids were not zero (0), then the uids and rids are returned.

If the events are not found and the rids were zero (0), then only the uids are returned.

Example

Example 1 is in text/calendar format, and example 2 is in text/xml output.

Example 1

```
verifyevents_by_ids.wcap?id=$n3o2m05sx9v6t98t8u2p&calid=jdoe&uid=3bd9e72f0

verifytodos_by_ids

Purpose

This command is used to verify if the todo specified with the uid and rid pair exists in the database.

Parameters

Table 7-38 lists verifytodos_by_ids parameters:

Table 7-38 verifytodos_by_ids Parameters

Parameter	Type	Purpose	Required	Default
calid	string	Calendar from which to fetch todos.	N	User's default calendar
fmt-out	string	The format for the returned data. The three format types: text/calendar text/xml	N	text/calendar
id	string	Uniquely identifies the session (session ID).	N*	null
rid	ISO 8601 DateTime string	Corresponding set of comma separated todo rids. If this is a non-recurring todo, rid=0.	Y	N/A
tzid	time zone ID string	Time zone, such as "America/Los_Angeles"	N	Server's default time zone
uid	string	Comma separated set of todo uids.	Y	N/A

* The id must be specified with the command unless the calendar to fetch from is public calendar.

Description.

This command tries to fetch todos matching the passed in uid-rid pairs.

Returns

If the todos are found, the data is returned in the format specified by the fmt-out parameter. If no format was specified, the output defaults to text/calendar.

If the todos are not found, if the rids were not zero (0), then the uids and rids are returned.

If the todos are not found and the rids were zero (0), then only the uids are returned.

Example

```
verifytodos_by_ids.wcap?id=bo35r2pr3e5po35r&calid=jdoe&uid=3bde188f0000472
d0000000b00000399&rid=20021029T200200Z&fmt-out=text/xml
```

```
<?xml version="1.0" encoding="UTF-8"?>
<iCalendar>
<iCal version="6.0" prodid="-//SunONE/Calendar Hosting Server//EN">
<TODO>
<UID>3bde188f0000472d0000000b00000399</UID>
<RECURID>20021029T200200Z</RECURID>
</TODO>
</iCal>
</iCalendar>
```

version

Purpose

To get the current WCAP version.

Parameters

Table 7-39 lists the `version` parameter:

Table 7-39 `version` Parameters

Parameter	Type	Purpose	Required	Default

`fmt-out`	string	The format for the returned data.
		The three format types:
		`text/calendar`
		`text/xml`
			N	`text/calendar`

Description.

This command gets the current WCAP version. (Note: this is different from the server version as well as the HTTP version.)

Returns

The commands supports output types of iCal and XML, the variable *X-NSCP-WCAPVERSION* contains the WCAP version number.

Example

The following examples are for each of output data types.

- iCalendar: (URL: `/version.wcap?fmt-out=text/calendar`)

```
BEGIN:VCALENDAR
PRODID:-//iPlanet/Calendar Hosting Server//EN
METHOD:PUBLISH
VERSION:2.0
X-NSCP-WCAPVERSION:2.0.0
END:VCALENDAR
```

- XML: (URL: /version.wcap?fmt-out=text/xml)

```
<?xml version="1.0" encoding="UTF-8"?>
<iCalendar>
<iCal version="2.0" prodid="-//iPlanet/Calendar Hosting Server//EN">
<X-NSCP-WCAPVERSION>2.0.0</X-NSCP-WCAPVERSION>
</iCal>
</iCalendar>
```
