

Sun Java System Web Proxy Server 4.0.8 Configuration File Reference

Sun Microsystems, Inc.
4150 Network Circle
Santa Clara, CA 95054
U.S.A.

Part No: 820-5724
August 2008

Copyright 2008 Sun Microsystems, Inc. 4150 Network Circle, Santa Clara, CA 95054 U.S.A. All rights reserved.

Sun Microsystems, Inc. has intellectual property rights relating to technology embodied in the product that is described in this document. In particular, and without limitation, these intellectual property rights may include one or more U.S. patents or pending patent applications in the U.S. and in other countries.

U.S. Government Rights – Commercial software. Government users are subject to the Sun Microsystems, Inc. standard license agreement and applicable provisions of the FAR and its supplements.

This distribution may include materials developed by third parties.

Parts of the product may be derived from Berkeley BSD systems, licensed from the University of California. UNIX is a registered trademark in the U.S. and other countries, exclusively licensed through X/Open Company, Ltd.

Sun, Sun Microsystems, the Sun logo, the Solaris logo, the Java Coffee Cup logo, docs.sun.com, Java, and Solaris are trademarks or registered trademarks of Sun Microsystems, Inc. or its subsidiaries in the U.S. and other countries. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. in the U.S. and other countries. Products bearing SPARC trademarks are based upon an architecture developed by Sun Microsystems, Inc.

The OPEN LOOK and Sun™ Graphical User Interface was developed by Sun Microsystems, Inc. for its users and licensees. Sun acknowledges the pioneering efforts of Xerox in researching and developing the concept of visual or graphical user interfaces for the computer industry. Sun holds a non-exclusive license from Xerox to the Xerox Graphical User Interface, which license also covers Sun's licensees who implement OPEN LOOK GUIs and otherwise comply with Sun's written license agreements.

Products covered by and information contained in this publication are controlled by U.S. Export Control laws and may be subject to the export or import laws in other countries. Nuclear, missile, chemical or biological weapons or nuclear maritime end uses or end users, whether direct or indirect, are strictly prohibited. Export or reexport to countries subject to U.S. embargo or to entities identified on U.S. export exclusion lists, including, but not limited to, the denied persons and specially designated nationals lists is strictly prohibited.

DOCUMENTATION IS PROVIDED "AS IS" AND ALL EXPRESS OR IMPLIED CONDITIONS, REPRESENTATIONS AND WARRANTIES, INCLUDING ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT, ARE DISCLAIMED, EXCEPT TO THE EXTENT THAT SUCH DISCLAIMERS ARE HELD TO BE LEGALLY INVALID.

Copyright 2008 Sun Microsystems, Inc. 4150 Network Circle, Santa Clara, CA 95054 U.S.A. Tous droits réservés.

Sun Microsystems, Inc. détient les droits de propriété intellectuelle relatifs à la technologie incorporée dans le produit qui est décrit dans ce document. En particulier, et ce sans limitation, ces droits de propriété intellectuelle peuvent inclure un ou plusieurs brevets américains ou des applications de brevet en attente aux Etats-Unis et dans d'autres pays.

Cette distribution peut comprendre des composants développés par des tierces personnes.

Certains composants de ce produit peuvent être dérivées du logiciel Berkeley BSD, licenciés par l'Université de Californie. UNIX est une marque déposée aux Etats-Unis et dans d'autres pays; elle est licenciée exclusivement par X/Open Company, Ltd.

Sun, Sun Microsystems, le logo Sun, le logo Solaris, le logo Java Coffee Cup, docs.sun.com, Java et Solaris sont des marques de fabrique ou des marques déposées de Sun Microsystems, Inc., ou ses filiales, aux Etats-Unis et dans d'autres pays. Toutes les marques SPARC sont utilisées sous licence et sont des marques de fabrique ou des marques déposées de SPARC International, Inc. aux Etats-Unis et dans d'autres pays. Les produits portant les marques SPARC sont basés sur une architecture développée par Sun Microsystems, Inc.

L'interface d'utilisation graphique OPEN LOOK et Sun a été développée par Sun Microsystems, Inc. pour ses utilisateurs et licenciés. Sun reconnaît les efforts de pionniers de Xerox pour la recherche et le développement du concept des interfaces d'utilisation visuelle ou graphique pour l'industrie de l'informatique. Sun détient une licence non exclusive de Xerox sur l'interface d'utilisation graphique Xerox, cette licence couvrant également les licenciés de Sun qui mettent en place l'interface d'utilisation graphique OPEN LOOK et qui, en outre, se conforment aux licences écrites de Sun.

Les produits qui font l'objet de cette publication et les informations qu'il contient sont régis par la législation américaine en matière de contrôle des exportations et peuvent être soumis au droit d'autres pays dans le domaine des exportations et importations. Les utilisations finales, ou utilisateurs finaux, pour des armes nucléaires, des missiles, des armes chimiques ou biologiques ou pour le nucléaire maritime, directement ou indirectement, sont strictement interdites. Les exportations ou réexportations vers des pays sous embargo des Etats-Unis, ou vers des entités figurant sur les listes d'exclusion d'exportation américaines, y compris, mais de manière non exclusive, la liste de personnes qui font objet d'un ordre de ne pas participer, d'une façon directe ou indirecte, aux exportations des produits ou des services qui sont régis par la législation américaine en matière de contrôle des exportations et la liste de ressortissants spécifiquement désignés, sont rigoureusement interdites.

LA DOCUMENTATION EST FOURNIE "EN L'ETAT" ET TOUTES AUTRES CONDITIONS, DECLARATIONS ET GARANTIES EXPRESSES OU TACITES SONT FORMELLEMENT EXCLUES, DANS LA MESURE AUTORISEE PAR LA LOI APPLICABLE, Y COMPRIS NOTAMMENT TOUTE GARANTIE IMPLICITE RELATIVE A LA QUALITE MARCHANDE, A L'APTITUDE A UNE UTILISATION PARTICULIERE OU A L'ABSENCE DE CONTREFACON.

Preface

This guide describes how to configure and administer the Sun Java™ System Web Proxy Server 4, formerly known as Sun ONE™ Web Proxy Server and iPlanet™ Web Proxy Server (and hereafter referred to as the Sun Java System Web Proxy Server or the Proxy Server).

Who Should Use This Book

This book is intended for information technology administrators in production environments. The guide assumes familiarity with the following areas:

- Performing basic system administration tasks
- Installing software
- Using web browsers
- Issuing commands in a terminal window

Before You Read This Book

The Sun Java System Web Proxy Server can be purchased by itself or as a component of the Sun Java Enterprise System, a software infrastructure that supports enterprise applications distributed across a network or Internet environment. If you purchased the Sun Java System Web Proxy Server as a component of the Java Enterprise System, you should be familiar with the system documentation at <http://docs.sun.com/coll/1286.2>.

How This Book Is Organized

The guide is divided into chapters, each of which addresses specific areas and tasks. The following table lists the chapters of the guide and their contents.

TABLE P-1 Guide Organization

Chapter	Description
Chapter 1, “Basics of Server Operation”	This chapter introduces the major configuration files that control the Sun Java System Web Proxy Server and describes how to activate and edit them.
Chapter 2, “Server Configuration Elements in the <code>server.xml</code> file”	This chapter discusses the <code>server.xml</code> file, which controls most aspects of server operation.
Chapter 3, “Syntax and Use of the <code>magnus.conf</code> File”	This chapter discusses the directives you can set in the <code>magnus.conf</code> file to configure the Sun Java System Web Proxy Server during initialization.
Chapter 4, “Syntax and Use of the <code>obj.conf</code> File”	This chapter discusses the SAFs you can set in the <code>obj.conf</code> configuration file to configure the Sun Java System Web Proxy Server during initialization.
Chapter 5, “Predefined SAFs in the <code>obj.conf</code> File”	This chapter describes the predefined SAFs used in the <code>obj.conf</code> file.
Chapter 6, “MIME Types”	This chapter discusses the MIME types file, which maps file extensions to file types.
Chapter 7, “Other Server Configuration Files”	This chapter lists other important configuration files and provides a quick reference of their contents.
Appendix A, “Configuration Changes Between iPlanet Web Proxy Server 3.6 and Sun Java System Web Proxy Server 4”	This appendix describes the changes in configuration files between the iPlanet Web Proxy Server 3.6 and the Sun Java System Web Proxy Server 4.
Appendix B, “Time Formats”	This appendix describes the format strings used for dates and times in the server log.
Appendix C, “Server Configuration Elements”	This appendix provide an alphabetical list for easy lookup of elements in the <code>server.xml</code> file and directives in the <code>magnus.conf</code> file.
Appendix D, “List of Predefined SAFs”	This appendix provide an alphabetical list for easy lookup of directives in the <code>obj.conf</code> file.

Proxy Server Documentation Set

The documentation set lists the Sun documents that are related to Proxy Server. The URL for Proxy Server documentation is <http://docs.sun.com/coll/1311.8>. For an introduction to Proxy Server, refer to the books in the order in which they are listed in the following table.

TABLE P-2 Sun Java System Web Proxy Server Documentation

Document Title	Contents
<i>Sun Java System Web Proxy Server 4.0.8 Release Notes</i>	<p>The Proxy Server release:</p> <ul style="list-style-type: none"> ■ Late-breaking information about the software and the documentation ■ New features ■ Supported platforms and environments ■ System requirements ■ Known issues and workarounds
<i>Sun Java System Web Proxy Server 4.0.8 Installation and Migration Guide</i>	<p>Performing installation and migration tasks:</p> <ul style="list-style-type: none"> ■ Installing the Sun Java System Web Proxy Server ■ Migrating from version 3.6 to version 4
<i>Sun Java System Web Proxy Server 4.0.8 Administration Guide</i>	<p>Performing administration and management tasks:</p> <ul style="list-style-type: none"> ■ Using the administration and command-line interfaces ■ Configuring server preferences ■ Managing users and groups ■ Monitoring and logging server activity ■ Using certificates and public key cryptography to secure the server ■ Controlling server access ■ Proxying and routing URLs ■ Caching ■ Filtering content ■ Using a reverse proxy ■ Using SOCKS
<i>Sun Java System Web Proxy Server 4.0.8 Configuration File Reference</i>	Editing configuration files
<i>Sun Java System Web Proxy Server 4.0.8 NSAPI Developer's Guide</i>	Creating custom Netscape Server Application Programmer's Interface (NSAPI) plugins

Related Books

The URL for all documentation about Sun Java Enterprise System (Java ES) and its components is <http://docs.sun.com/prod/entsys.5>.

Default Paths and File Names

The following table describes the default paths and file names that are used in this book.

TABLE P-3 Default Paths and File Names

Placeholder	Description	Default Value
<i>install-dir</i>	Represents the base installation directory for the Sun Java System Web Proxy Server.	Solaris and Linux installations: /opt/sun/proxyserver40 Windows installations: \\Sun\\ProxyServer40

Typographic Conventions

The following table describes the typographic changes that are used in this book.

TABLE P-4 Typographic Conventions

Typeface	Meaning	Example
AaBbCc123	The names of commands, files, and directories, and onscreen computer output	Edit your <code>.login</code> file. Use <code>ls -a</code> to list all files. <code>machine_name% you have mail.</code>
AaBbCc123	What you type, contrasted with onscreen computer output	<code>machine_name% su</code> Password:
<i>AaBbCc123</i>	A placeholder to be replaced with a real name or value	The command to remove a file is <code>rm filename</code> .
<i>AaBbCc123</i>	Book titles, new terms, and terms to be emphasized (note that some emphasized items appear bold online)	Read Chapter 6 in the <i>User's Guide</i> . A <i>cache</i> is a copy that is stored locally. Do <i>not</i> save the file.

Shell Prompts in Command Examples

The following table shows default system prompts and superuser prompts.

TABLE P-5 Shell Prompts

Shell	Prompt
C shell on UNIX and Linux systems	machine_name%
C shell superuser on UNIX and Linux systems	machine_name#
Bourne shell and Korn shell on UNIX and Linux systems	\$
Bourne shell and Korn shell superuser on UNIX and Linux systems	#
Microsoft Windows command line	C:\

Symbol Conventions

The following table explains symbols that might be used in this book.

TABLE P-6 Symbol Conventions

Symbol	Description	Example	Meaning
[]	Contains optional arguments and command options.	ls [-l]	The -l option is not required.
{ }	Contains a set of choices for a required command option.	-d {y n}	The -d option requires that you use either the y argument or the n argument.
\${ }	Indicates a variable reference.	\${com.sun.javaRoot}	References the value of the com.sun.javaRoot variable.
-	Joins simultaneous multiple keystrokes.	Control-A	Press the Control key while you press the A key.
+	Joins consecutive multiple keystrokes.	Ctrl+A+N	Press the Control key, release it, and then press the subsequent keys.
→	Indicates menu item selection in a graphical user interface.	File → New → Templates	From the File menu, choose New. From the New submenu, choose Templates.

Documentation, Support, and Training

The Sun web site provides information about the following additional resources:

- Documentation (<http://www.sun.com/documentation/>)
- Support (<http://www.sun.com/support/>)
- Training (<http://www.sun.com/training/>)

Searching Sun Product Documentation

Besides searching Sun product documentation from the docs.sun.comSM web site, you can use a search engine by typing the following syntax in the search field:

```
search-term site:docs.sun.com
```

For example, to search for “broker,” type the following:

```
broker site:docs.sun.com
```

To include other Sun web sites in your search (for example, java.sun.com, www.sun.com, and developers.sun.com), use sun.com in place of docs.sun.com in the search field.

Third-Party Web Site References

Third-party URLs are referenced in this document and provide additional, related information.

Note – Sun is not responsible for the availability of third-party web sites mentioned in this document. Sun does not endorse and is not responsible or liable for any content, advertising, products, or other materials that are available on or through such sites or resources. Sun will not be responsible or liable for any actual or alleged damage or loss caused or alleged to be caused by or in connection with use of or reliance on any such content, goods, or services that are available on or through such sites or resources.

Sun Welcomes Your Comments

Sun is interested in improving its documentation and welcomes your comments and suggestions. To share your comments, go to <http://docs.sun.com> and click Send Comments. In the online form, provide the full document title and part number. The part number is a 7-digit or 9-digit number that can be found on the book's title page or in the document's URL. For example, the part number of this book is 820-5724.

Basics of Server Operation

The configuration and behavior of the Sun Java System Web Proxy Server is determined by a set of configuration files. When you use the Administration interface, you change the settings in these configuration files. You can also manually edit these files.

This chapter contains the following sections:

- “Configuration Files” on page 21
- “Directory Structure” on page 23
- “Dynamic Reconfiguration” on page 24

Configuration Files

The configuration and operation of the Sun Java System Web Proxy Server is controlled by configuration files. The configuration files reside in the directory *instance-directory/config*. This directory contains various configuration files for controlling different components. The exact number and names of configuration files depend on which components have been enabled or loaded into the server.

This directory always contains four configuration files that are essential for the server to operate. These files are:

- “*server.xml* File” on page 21 - Contains most of the server configuration
- “*magnus.conf* File” on page 22 - Contains global server initialization information
- “*obj.conf* File” on page 22 - Contains instructions for handling HTTP requests from clients
- “*mime.types* File” on page 22 - Contains information for determining the content type of requested resources

server.xml File

This file contains most of the server configuration. A schema file, *sun-web-proxy-server_4_0.dtd*, defines its format and content.

For more information about how the server uses `sun-web-proxy-server_4_0.dtd` and `server.xml`, see [Chapter 2, “Server Configuration Elements in the `server.xml` file.”](#)

`magnus.conf` File

This file sets values of variables that configure the server during initialization. The server looks at this file and executes the settings on startup. The server does not look at this file again until it is restarted.

See [Chapter 3, “Syntax and Use of the `magnus.conf` File,”](#) for a list of all the variables that can be set in `magnus.conf`.

`obj.conf` File

This file contains instructions for the Sun Java System Web Proxy Server about how to handle HTTP requests from clients and how to handle proxy requests to the origin server that services the content. The server looks at the configuration defined by this file every time it processes a request from a client.

This file contains a series of instructions (directives) that tell the Sun Java System Web Proxy Server what to do at each stage in the request-response process. You can modify and extend the request handling process by adding or changing the instructions in `obj.conf`.

All `obj.conf` files are located in the *instance-directory/config* directory.

The `obj.conf` file is essential to the operation of the Sun Java System Web Proxy Server. When you make changes to the server through the Administration interface, the system automatically updates `obj.conf`.

For information about how the server uses `obj.conf`, see [Chapter 4, “Syntax and Use of the `obj.conf` File.”](#)

`mime.types` File

This file maps file extensions to MIME types to enable the server to determine the content type of a requested resource. For example, requests for resources with `.html` extensions indicate that the client is requesting an HTML file, while requests for resources with `.gif` extensions indicate that the client is requesting an image file in GIF format.

For more information about how the server uses `mime.types`, see “MIME Types.”

Other Configuration Files

For information about other important configuration files, see [Chapter 7, “Other Server Configuration Files.”](#)

Directory Structure

The following section describes the directory structure created when you first install the Sun Java System Web Proxy Server 4.

Default Directory Structure

The default directory structure of the proxy server environment consists of the following items:

- *install-root/alias* - Contains the key-pair files for all server instances installed in this installation directory
- *install-root/bin* - Contains the binary executables for the Proxy Server itself
- *install-root/extra* - Contains the command-line utilities for the Proxy Server
- *install-root/httpacl* - Contains the access control list (ACL) files for all server instances installed in this installation directory
- *install-root/manual* - Contains the HTML documentation for the Proxy Server
- *install-root/ns-icons* - Contains graphical images for proxied FTP browsing
- *install-root/plugin* - Contains plug-ins installed for this installation of the Proxy Server
- *install-root/proxy-admserv* - Contains an HTTP server instance used to manage the Proxy and SOCKS servers for this installation

Proxy Server Directory Structure

The default directory structure of the Proxy Server instance immediately after installation consists of the following items:

- *instance-directory/cache* - Contains the initial cache file system for this instance of the Proxy Server
- *instance-directory/conf_bk* - Contains backup versions of the Proxy Server configuration files
- *instance-directory/config* - Contains the current versions of the Proxy Server configuration files
- *instance-directory/logs* - Contains the errors and access log files for the Proxy Server instance

- *instance-directory/pac* - Contains the proxy autoconfiguration files
- *instance-directory/reconfig* Command-line script to perform dynamic reconfiguration of the Proxy Server configuration files
- *instance-directory/start-sockd* Command-line script to start the SOCKS daemon
- *instance-directory/start* Command-line script to start the Proxy Server

Dynamic Reconfiguration

Dynamic reconfiguration enables you to make configuration changes to a live Proxy Server without having to stop and restart the Proxy Server for the changes to take effect. You can dynamically change all configuration settings and attributes in the `server.xml` file as well as many other configuration files without having to restart the server.

Server Configuration Elements in the `server.xml` file

The `server.xml` file contains most of the server configuration. The encoding is UTF-8 to maintain compatibility with regular UNIX text editors. The `server.xml` file is located in the `<instance-directory>/config` directory. A schema file, `sun-web-proxy-server_4_0.dtd`, determines the format and content of the `server.xml` file.

This chapter describes the `server.xml` and `sun-web-proxy-server_4_0.dtd` file in the following sections:

- “`sun-web-proxy-server_4_0.dtd` File” on page 25
- “Elements in the `server.xml` File” on page 27
- “Core Server Elements” on page 27
- “Listener Elements” on page 34
- “Cache Elements” on page 40
- “Sun Java System LDAP Schema” on page 44
- “Variables” on page 46
- “Sample `server.xml` File” on page 47

sun-web-proxy-server_4_0.dtd File

The `sun-web-proxy-server_4_0.dtd` file defines the structure of the `server.xml` file, including the elements it can contain and the subelements and attributes these elements can have. The `sun-web-proxy-server_4_0.dtd` file is located in the `<Install_Directory>/bin/proxy/dtds` directory.

Each element defined in a DTD file (which may be present in the corresponding XML file) can contain the following:

- “Subelements” on page 26
- “Data” on page 26
- “Attributes” on page 27

Subelements

Elements can contain subelements. For example, the following file fragment defines the VSCLASS element:

```
<!ELEMENT LS (DESCRIPTION?, SSLPARAMS?)>
```

The ELEMENT tag specifies that a LSCLASS element can contain DESCRIPTION, and SSLPARAMS elements in that order.

The following table shows how optional suffix characters of subelements determine the requirement rules, or number of allowed occurrences, for the subelements.

TABLE 2-1 Requirement Rules and Subelement Suffixes

Subelement Suffix	Requirement Rule
<i>element*</i>	Can contain <i>zero or more</i> of this subelement
<i>element?</i>	Can contain <i>zero or one</i> of this subelement
<i>element+</i>	Must contain <i>one or more</i> of this subelement
<i>element</i> (no suffix)	Must contain <i>only one</i> of this subelement

If an element cannot contain other elements, you see EMPTY or (#PCDATA) instead of a list of element names in parentheses.

Data

Some elements contain character data instead of subelements. These elements have definitions of the following format:

```
<!ELEMENT element-name (#PCDATA)>
```

For example:

```
<!ELEMENT DESCRIPTION (#PCDATA)>
```

In the server.xml file, white space is treated as part of the data in a data element. Therefore, no extra white space should appear before or after the data delimited by a data element. For example:

```
<DESCRIPTION>myserver</DESCRIPTION>
```

Attributes

Elements that have ATTLIST tags contain attributes (name-value pairs). For example:

```
<!ATTLIST ACLFILE
  id ID #REQUIRED
  file CDATA #REQUIRED
```

An ACLFILE element can contain `id`, and `file` attributes.

The `#REQUIRED` label means that a value must be supplied. The `#IMPLIED` label means that the attribute is optional, and that the Sun Java System Web Proxy Server generates a default value. Wherever possible, explicit defaults for optional attributes (such as “`true`”) are listed.

Attribute declarations specify the type of the attribute. For example, `CDATA` means character data, and `%boolean` is a predefined enumeration.

Elements in the server.xml File

This section describes the XML elements in the `server.xml` file. Elements are grouped as follows:

- “Core Server Elements” on page 27
- “Listener Elements” on page 34
- “Cache Elements” on page 40

Note – Subelements must be defined in the order in which they are listed under each Subelements heading unless otherwise noted.

For an alphabetical listing of elements in `server.xml`, see [Appendix C, “Server Configuration Elements.”](#)

Core Server Elements

General elements are as follows:

- “SERVER” on page 28
- “PROPERTY” on page 29
- “DESCRIPTION” on page 30
- “LOG” on page 30
- “EVENT” on page 31

- “EVENTTIME” on page 32
- “EVENTACTION” on page 33

SERVER

The SERVER element defines a server. SERVER is the root element. Only one SERVER element can exist in a server.xml file.

Subelements

The following table describes subelements for the SERVER element.

TABLE 2-2 SERVER subelements

Element	Required	Description
“PROPERTY” on page 29	Zero or more	Specifies a property of the server
“LS” on page 34	One or more	Defines one or more HTTP listen sockets
“MIME” on page 37	Zero or one	Defines mime type
“ACLFILE” on page 38	Zero or one	References one or more ACL files
“USERDB” on page 39	Zero or more	Defines the user database used
“FILECACHE” on page 40	Only one	Configures NSFC parameters
“CACHE” on page 42	Zero or one	Configures the disk cache parameters
“LOG” on page 30	Zero or one	Configures the system logging service
“EVENT” on page 31	Zero or more	Configures events

Attributes

The following table describes attributes for the SERVER element.

TABLE 2-3 SERVER attributes

Attribute	Default	Description
objectfile	obj.conf	Specifies the obj.conf file for the server.

TABLE 2-3 SERVER attributes (Continued)

Attribute	Default	Description
rootobject	default	(optional) Tells the server which object loaded from an obj . conf file is the default. The default object is expected to have all the name translation (NameTrans) directives for the server. Any server behavior that is configured in the default object affects the entire server. If you specify an object that does not exist, the server does not report an error until a client tries to retrieve a document.

PROPERTY

The PROPERTY element specifies a property, or a variable that is defined in server . xml and referenced in obj . conf. For information about variables, see [“Variables” on page 46](#).

A property adds configuration information to its parent element that meets one or both of the following requirements:

- Optional with respect to the Sun Java System Web Proxy Server
- Needed by a system or object that the Sun Java System Web Proxy Server doesn't have knowledge of, such as an LDAP server or a Java class

For example:

```
<PROPERTY name="accesslog" value="<install-root>/<instance-directory>/logs/access"/>
```

Subelements

The following table describes subelements for the PROPERTY element.

TABLE 2-4 PROPERTY subelements

Element	Required	Description
“DESCRIPTION” on page 30	Zero or one	Contains a text description of the property

Attributes

The following table describes attributes for the PROPERTY element.

TABLE 2-5 PROPERTY attributes

Attribute	Default	Description
name	None	Specifies the name of the property or variable
value	None	Specifies the value of the property or variable

DESCRIPTION

Contains a text description of the parent element.

Subelements

None

Attributes

None

LOG

Configures the system logging service, which includes the following log files:

- The `errors` log file stores messages from the server. The default name is `errors`.
- The `access` log file stores HTTP access messages from the server. The default name is `access.log`. To configure the access log, you use server application functions in the `obj.conf` files.

Subelements

The following table describes subelements for the LOG element.

TABLE 2-6 LOG subelements

Element	Required	Description
“PROPERTY” on page 29	Zero or more	Specifies a property or a variable

Attributes

The following table describes attributes for the LOG element.

TABLE 2-7 LOG attributes

Attribute	Default	Description
file	errors	Specifies the file that stores messages from the server.
loglevel	info	Controls the default type of messages logged by other elements to the error log. Allowed values are as follows, from highest to lowest: finest, finer, fine, info, warning, failure, config, security, and catastrophe.
logstdout	true	(optional) If true, redirects stdout output to the errors log. Valid values are on, off, yes, no, 1, 0, true, false.
logstderr	true	(optional) If true, redirects stderr output to the errors log. Valid values are on, off, yes, no, 1, 0, true, false.
logtoconsole	true	(optional, UNIX only) If true, redirects log messages to the console.
createconsole	false	(optional, Windows only) If true, creates a Windows console. Valid values are on, off, yes, no, 1, 0, true, false.
usesyslog	false	(optional) If true, uses the UNIX syslog service or Windows Event Logging to produce and manage logs. Valid values are on, off, yes, no, 1, 0, true, false.

EVENT

An event can be scheduled to run at specific times, either on days of the week or on days of the month, or when the server starts up or shuts down.

Subelements

The following table describes subelements for the EVENT element.

TABLE 2-8 EVENT subelements

Element	Required	Description
“DESCRIPTION” on page 30	Zero or one	Descriptive text about the event. Used for informational purposes. This element is optional.

TABLE 2-8 EVENT subelements (Continued)

Element	Required	Description
“EVENTTIME” on page 32	Only one	Container element that specifies the time at which the event is to be executed. This element is required.
“EVENTACTION” on page 33	Only one	Container element that specifies the event action to be executed. This element is required.
“PROPERTY” on page 29	Zero or more	Specifies a property or a variable.

Attributes

The following table describes attributes for the EVENT element.

TABLE 2-9 EVENT attributes

Attribute	Default	Description
enabled	true	Indicates whether the specified event is to be scheduled
name	None	Specifies the name of the event

EVENTTIME

Container element that specifies the time at which the event is to be executed. This is a required element.

Subelements

The following table describes subelements for the EVENTTIME element.

TABLE 2-10 EVENTTIME subelements

Element	Required	Description
TIMEOFDAY	Only one	<p>A space-separated list of times (in 24 hour hh:mm notation) at which the event should be run. This element is required. If neither DAYOFWEEK or DAYOFMONTH is specified then the event will be scheduled at these times every day of the week.</p> <p>For example:</p> <pre><TIMEOFDAY>00:30 6:30 12:30 18:30</TIMEOFDAY></pre>

TABLE 2-10 EVENTTIME subelements (Continued)

Element	Required	Description
DAYOFWEEK	Zero or one	A space-separated list of weekday names on which the event should be run at the time specified by the TIMEOFDAY value. A value for either this element or the DAYOFMONTH element must be specified. The valid names for weekdays are Mon, Tue, Wed, Thu, Fri, Sat, Sun. For example: <code><DAYOFWEEK>Mon Wed Fri</DAYOFWEEK></code>
DAYOFMONTH	Zero or one	A space-separated list of integers from 1-31 that denotes the day of the month on which the event is to be run. The TIMEOFDAY value specifies the time at which the event will be run. A value for either this element or the TIMEOFDAY element must be specified. For example: <code><DAYOFMONTH>1 15</DAYOFMONTH></code>
ONSTARTUP	Only one	The event is scheduled to occur when the server starts up.
ONSHUTDOWN	Only one	The event is scheduled to occur when the server shuts down.

EVENTACTION

Container element that specifies the event action to be executed.

Subelements

The following table describes subelements for the EVENTACTION element.

TABLE 2-11 EVENTACTION subelements

Element	Required	Description
RESTART	Zero or one	If specified, this event will restart the server at the specified times
RECONFIG	Zero or one	If specified, this event will dynamically reconfigure the server at the specified times.
ROTATELOGS	Zero or one	If specified, this event will rotate the server access and error log files at the specified times.

TABLE 2-11 EVENTACTION subelements *(Continued)*

Element	Required	Description
COMMAND	Zero or one	The command line of the executable to run at the scheduled times. This element is an optional subelement of EVENTACTION.

Listener Elements

The Listener elements are as follows:

- “LS” on page 34
- “SSLPARAMS” on page 36
- “MIME” on page 37
- “ACLFILE” on page 38
- “USERDB” on page 39

LS

Defines an HTTP listen socket.

Note – When you create a secure listen socket through the Server Manager, security is automatically turned on globally in `magnus.conf`. When you create a secure listen socket manually in `server.xml`, security must be turned on by editing `magnus.conf`.

Subelements

The following table describes subelements for the LS element.

TABLE 2-12 LS subelements

Element	Required	Description
“DESCRIPTION” on page 30	Zero or one	Contains a text description of the listen socket
“SSLPARAMS” on page 36	Zero or one	Defines Secure Socket Layer (SSL) parameters

Attributes

The following table describes attributes for the LS element.

TABLE 2-13 LS attributes

Attribute	Default	Description
id	None	(optional) The socket family type. A socket family type cannot begin with a number. When you create a secure listen socket in the <code>server.xml</code> file, security must be turned on in <code>magnus.conf</code> . When you create a secure listen socket in the Server Manager, security is automatically turned on globally in <code>magnus.conf</code> .
ip	Any	Specifies the IP address of the listen socket. The value can be in dotted-pair or IPv6 notation. The value can also be any for <code>INADDR_ANY</code> .
port	None	Port number on which to create the listen socket. Legal values are 1 - 65535. On UNIX, creating sockets that listen on ports 1 - 1024 requires superuser privileges. Configuring an SSL listen socket to listen on port 443 is recommended. Two different IP addresses can't use the same port.
security	false	(optional) Determines whether the listen socket runs SSL. Valid values are <code>on</code> , <code>off</code> , <code>yes</code> , <code>no</code> , <code>1</code> , <code>0</code> , <code>true</code> , <code>false</code> . You can turn SSL2 or SSL3 on or off and set ciphers using an <code>SSLPARAMS</code> subelement for this listen socket. The <code>Security</code> setting in the <code>magnus.conf</code> file globally enables or disables SSL by making certificates available to the server instance. Therefore, <code>Security</code> in <code>magnus.conf</code> must be turned on or <code>security</code> in <code>server.xml</code> does not work. For more information, see Chapter 3, "Syntax and Use of the <code>magnus.conf</code> File."
acceptorthreads	1	(optional) Number of acceptor threads for the listener. The recommended value is the number of processors in the machine. Valid values are 1 - 1024.
family	None	(optional) The socket family type. Valid values are <code>inet</code> , <code>inet6</code> , and <code>nca</code> . Use the value <code>inet6</code> for IPv6 listen sockets. When using the value of <code>inet6</code> , IPv4 addresses will be prefixed with <code>::ffff:</code> in the log file. Specify <code>nca</code> to make use of the Solaris Network Cache and Accelerator.

TABLE 2-13 LS attributes (Continued)

Attribute	Default	Description
blocking	false	(optional) Determines whether the listen socket and the accepted socket are put into blocking mode. Use of blocking mode may improve benchmark scores. Valid values are on, off, yes, no, 1, 0, true, false.
servername	None	Tells the server what to put in the host name section of any URLs it sends to the client. This affects URL values that the server automatically generates. This value does not affect the URLs for directories and files stored in the server. This name should be the alias name if your server uses an alias. If you append a colon and port number, that port will be used in URLs the server sends to the client.

SSLPARAMS

Defines SSL (Secure Socket Layer) parameters.

Subelements

none

Attributes

The following table describes attributes for the SSLPARAMS element.

TABLE 2-14 SSLPARAMS attributes

Attribute	Default	Description
servercertnickname	Server-Cert	The nickname of the server certificate in the certificate database or the PKCS#11 token. In the certificate, the name format is <i>tokenname:nickname</i> . Including the <i>tokenname</i> : part of the name in this attribute is optional.
ssl2	false	(optional) Determines whether SSL2 is enabled. Valid values are on, off, yes, no, 1, 0, true, and false. If both SSL2 and SSL3 are enabled for a virtual server, the server tries SSL3 encryption first. If that encryption fails, the server tries SSL2 encryption.

TABLE 2-14 SSLPARAMS attributes (Continued)

Attribute	Default	Description
ssl2ciphers	None	(optional) A space-separated list of the SSL2 ciphers used with the prefix + to enable or - to disable, for example, +rc4. Allowed values are rc4, rc4export, rc2, rc2export, idea, des, desede3.
ssl3	true	(optional) Determines whether SSL3 is enabled. Valid values are on, off, yes, no, 1, 0, true and false. If both SSL2 and SSL3 are enabled for a virtual server, the server tries SSL3 encryption first. If that encryption fails, the server tries SSL2 encryption.
ssl3tlsciphers	none	(optional) A space-separated list of the SSL3 ciphers used with the prefix + to enable or - to disable, for example, +rsa_des_sha. Allowed SSL3 values are rsa_rc4_128_md5, rsa_3des_sha, rsa_des_sha, rsa_rc4_40_md5, rsa_rc2_40_md5, rsa_null_md5. Allowed TLS values are rsa_des_56_sha, rsa_rc4_56_sha.
tls	true	(optional) Determines whether TLS is enabled. Valid values are on, off, yes, no, 1, 0, true, and false.
tlsrollback	true	(optional) Determines whether TLS rollback is enabled. Valid values are on, off, yes, no, 1, 0, true, and false. TLS rollback should be enabled for Microsoft Internet Explorer 5.0 and 5.5.
clientauth	false	(optional) Determines whether SSL3 client authentication is performed on every request, independent of ACL-based access control. Valid values are on, off, yes, no, 1, 0, true, and false.

MIME

The MIME element defines MIME types.

The most common way that the server determines the MIME type of a requested resource is by invoking the type-by-extension directive in the ObjectType section of the obj.conf file. The type-by-extension function does not work if no MIME element has been defined in the “SERVER” on page 28 element.

Subelements

The following table lists the subelements for the MIME element.

TABLE 2-15 Mime subelements

Element	Required	Description
TYPE	Zero or more	Specifies the mime type of the requested resource.

Attributes

The following table describes attributes for the MIME element.

TABLE 2-16 MIME attributes

Attribute	Default	Description
id	None	Internal name for the MIME types listing. The MIME types name cannot begin with a number.
file	None	The name of a MIME types file. For more information, see Chapter 6, “MIME Types”

TYPE

Defines the type of the requested resource.

Subelements

None

Attributes

The following table describes attributes for the TYPE element.

TABLE 2-17 TYPE attributes

Attribute	Default	Description
type	None	Defines the type of the requested resource
language	None	Defines the content language
encoding	None	Defines the content-encoding
extensions	None	Defines the file extensions associated with the specified resource

ACLFILE

References one ACL file.

Subelements

The following table describes subelements for the ACLFILE element.

TABLE 2-18 ACLFILE subelements

Element	Required	Description
“DESCRIPTION” on page 30	Zero or one	Contains a text description of the ACLFILE element

Attributes

The following table describes attributes for the ACLFILE element.

TABLE 2-19 ACLFILE attributes

Attribute	Default	Description
id	None	Internal name for the ACL file listing. An ACL file listing name cannot begin with a number.
file	None	A space-separated list of ACL files. Each ACL file must have a unique name. For information about the format of an ACL file, see the Sun Java System Web Proxy Server 4.0.2 <i>Administration Guide</i> . The name of the default ACL file is <code>generated.https-server-id.acl</code> , and the file resides in the <code>server_root/server-id/httpacl</code> directory. To use this file, you must reference it in <code>server.xml</code> .

USERDB

Defines the user database used by the server.

Subelements

The following table describes subelements for the USERDB element.

TABLE 2-20 USERDB subelements

Element	Required	Description
“DESCRIPTION” on page 30	Zero or one	Contains a text description of this element

Attributes

The following table describes attributes for the USERDB element.

TABLE 2-21 USERDB attributes

Attribute	Default	Description
id	None	The user database name in the server's ACL file. A user database name cannot begin with a number.
database	None	The user database name in the <code>dbswitch.conf</code> file.
basedn	None	(optional) Overrides the base DN lookup in the <code>dbswitch.conf</code> file. However, the <code>basedn</code> value is still relative to the base DN value from the <code>dbswitch.conf</code> entry.
certmaps	None	(optional) Specifies which certificate mapped to LDAP entry mappings defined in <code>certmap.conf</code> to use. If the certificate is not present, all mappings are used. All lookups based on mappings in <code>certmap.conf</code> are relative to the final base DN of the server.

Cache Elements

Cache elements are as follows:

- [“FILECACHE” on page 40](#)
- [“CACHE” on page 42](#)
- [“PARTITION” on page 42](#)
- [“GC” on page 43](#)

FILECACHE

Configures the in-memory cache.

Subelements

The following table describes subelements for the FILECACHE element.

TABLE 2-22 FILECACHE subelements

Element	Required	Description
“DESCRIPTION” on page 30	Zero or one	Contains a text description of this element

Attributes

The following table describes attributes for the FILEACHE element.

TABLE 2-23 FILECACHE attributes

Attribute	Default	Description
<code>enabled</code>	<code>true</code>	Select this option, if not already selected.
<code>transmitfile</code>	<code>false</code>	When you enable <code>transmitfile</code> , the server caches open file descriptors for files in the file cache, rather than caching the file contents. <code>PR_transmitfile</code> is used to send the file contents to a client. When <code>transmitfile</code> is enabled, the distinction normally made by the file cache between small, medium, and large files no longer applies, because only the open file descriptor is being cached.
<code>contentcache</code>	<code>true</code>	Enables caching file content.
<code>tempdir</code>		Specifies the directory to store temporary files.
<code>maxage</code>	30	The maximum age in seconds of a valid cache entry. This setting controls how long cached information will continue to be used once the file is cached. An entry older than <code>maxage</code> is replaced by a new entry for the same file, if the same file is referenced through the cache.
<code>mediumfilesizelimit</code>	537600	Size in bytes of the largest (non-small) file that is considered to be medium size. The contents of medium files are cached by mapping the file into virtual memory (currently only on UNIX platforms). The contents of "large" files (larger than "medium") are not cached, although information about large files is cached.
<code>mediumfilespace</code>	10485760	Specifies how much virtual memory will be used to map all medium-sized files.
<code>smallfilesizelimit</code>	2048	Size in bytes of the largest file that is considered to be "small". The contents of small files are cached by allocating heap space and reading the file into that space.
<code>smallfilespace</code>	1048576	Specifies how much heap space will be used for the cache, including heap space used to cache small files.
<code>maxfiles</code>	1024	The maximum number of files that may be in the cache at once.
<code>hashinitsize</code>	0	Initial number of hash buckets.

CACHE

Configures the disk cache.

Subelements

The following table describes subelements for the CACHE element.

TABLE 2-24 CACHE subelements

Element	Required	Description
“DESCRIPTION” on page 30	Zero or one	Contains a text description of this element.
“PARTITION” on page 42	One or more	The cache partition is a reserved part of disk or memory that is set aside for caching purposes.
“GC” on page 43	Zero or one	The cache garbage collector is used to delete files from the cache. Garbage collection can be done in either the automatic mode or the explicit mode.

Attributes

The following table describes attributes for the CACHE element.

TABLE 2-25 CACHE attributes

Attribute	Default	Description
enabled	true	Select this option, if not already selected.
cachedir	<i>install-root/instance-directory/cache</i>	Specifies the directory for caching.
cachecapacity	2000 Mbytes	The cache capacity should be set equal to or greater than the cache size. Setting the capacity larger than the cache size can be helpful if you know that you plan to increase the cache size later, such as by adding an external disk.

PARTITION

Configures the storage area on a disk that you set aside for caching. If you want to have your cache span several disks, you need to configure at least one cache partition for each disk. Each partition can be independently administered, so you can enable, disable, and configure a partition independently of all other partitions.

Subelements

The following table describes subelements for the `PARTITION` element.

TABLE 2-26 `PARTITION` subelements

Element	Required	Description
“DESCRIPTION” on page 30	Zero or one	Contains a text description of this element.

Attributes

The following table describes attributes for the `PARTITION` element.

TABLE 2-27 `PARTITION` attributes

Attribute	Default	Description
<code>enabled</code>	<code>true</code>	Select this option, if not already selected.
<code>partitiondir</code>	<i>install-root/instance-directory/cache</i>	Specify the directory where the partition is to be created.
<code>partitionname</code>	<code>part1</code>	Specify a name for the partition.
<code>maxsize</code>	1600 Mbytes	(Optional) Number for the maximum size to which you want to allow the cache partition to grow, listed in megabytes.
<code>minspace</code>	5 Mbytes	The minimum amount of available space, in megabytes, on the physical partition. This partition is the actual disk on which the cache partition resides. If less space is available, the proxy stops caching to that cache partition, even if the cache has not reached the maximum size (<code>maxsize</code>). The proxy server continues to write to other partitions that are not full.

GC

Configures the cache garbage collector that deletes files from the cache. Garbage collection can be done in either the automatic mode or the explicit mode.

Subelements

The following table describes subelements for the `GC` element.

TABLE 2-28 CACHE subelements

Element	Required	Description
“DESCRIPTION” on page 30	Zero or one	Contains a text description of this element.

Attributes

The following table describes attributes for the GC element.

TABLE 2-29 CACHE attributes

Attribute	Default	Description
enabled	true	Select this option, if not already selected
gchimargin	80	Controls the percentage of the maximum cache size that, when reached, triggers garbage collection
gclomargin	70	Controls the percentage of the maximum cache size that the garbage collector targets
gcleavefsfull	60	Determines the percentage of the cache partition size below which garbage collection will not go
gcextramargin	30	Sets the percentage of the cache to be removed by the garbage collector

Sun Java System LDAP Schema

This section describes the Sun Java System LDAP Schema that defines a set of rules for directory data.

You can use the `dcsuffix` attribute in the `dbswitch.conf` file if your LDAP database meets the requirements outlined in this section. For more information about the `dbswitch.conf` file, see “[dbswitch.conf](#)” on page 253.

The subtree rooted at an ISP entry, for example, `o=isp` is called the *convergence tree*. It contains all directory data related to organizations (customers) served by an ISP.

The subtree rooted at `o=internet` is called the *domain component tree*, or *dc tree*. It contains a sparse DNS tree with entries for the customer domains served. These entries are links to the appropriate location in the convergence tree where the data for that domain is located.

The directory tree may be single rooted, which is recommended. For example, `o=root` may have `o=isp` and `o=internet` under it. The tree may also have two separate roots, one for the convergence tree and one for the dc tree.

Convergence Tree

The top level of the convergence tree must have one organization entry for each customer or organization, and one for the ISP itself.

Underneath each organization must be two `organizationalUnit` entries: `ou=People` and `ou=Groups`. A third, `ou=Devices`, can be present if device data is to be stored for the organization.

Each user entry must have a unique `uid` value within a given organization. The namespace under this subtree can be partitioned into various `ou` entries that aggregate user entries in convenient groups, for example, `ou=eng`, `ou=corp`. User `uid` values must still be unique within the entire `People` subtree.

User entries in the convergence tree are of type `inetOrgPerson`. The `cn`, `sn`, and `uid` attributes must be present. The `uid` attribute must be a valid email name, specifically a valid local-part as defined in RFC822. The `cn` must contain *name initial sn*. The RDN of the user entry be the `uid` value. User entries must contain the auxiliary class `inetUser` if they are to be considered enabled for service or valid.

User entries can also contain the auxiliary class `inetSubscriber`, which is used for account management purposes. If an `inetUserStatus` attribute is present in an entry and has a value of `inactive` or `deleted`, the entry is ignored.

Groups are located under the `Groups` subtree and consist of LDAP entries of type `groupOfUniqueNames`.

Domain Component (dc) Tree

The `dc` tree contains hierarchical `domain` entries, each of which is a DNS name component.

Entries that represent the domain name of a customer are overlaid with the LDAP auxiliary class `inetDomain`. For example, the two LDAP entries `dc=customer1,dc=com,o=Internet,o=root` and `dc=customer2,dc=com,o=Internet,o=root` contain the `inetDomain` class, but `dc=com,o=Internet,o=root` does not. The latter is present only to provide structure to the tree.

Entries with an `inetDomain` attribute are called virtual domains. The attribute `inetDomainBaseDN` for these domains must be filled with the DN of the top-level organization entry where the data of this domain is stored in the convergence tree. For example, the virtual domain entry in `dc=cust2,dc=com,o=Internet,o=root` would contain the attribute `inetDomainBaseDN` with value `o=Cust2,o=isp,o=root`.

If an `inetDomainStatus` attribute is present in an entry and has a value of `inactive` or `deleted`, the entry is ignored.

Variables

Some variables are defined in `server.xml` for use in the `obj.conf` file. The following file fragment defines a `docroot` variable:

```
<PROPERTY name="accesslog" value="install-root/instance-directory/logs/access"/>
```

The variable is then used in the `obj.conf` file. For example:

```
Init fn="flex-init" access="$accesslog" format.access="%Ses->client.ip%
- %Req->vars.auth-user% [%SYSDATE%] '%Req->reqpb.clf-request%'
%Req->srvhdrs.clf-status% %Req->srvhdrs.content-length%"
```

Using this `accesslog` variable enables you to define different document roots for different virtual servers within the same virtual server class.

Format of a Variable

A variable is found in the `obj.conf` file when the following regular expression matches:

```
\\$[A-Za-z][A-Za-z0-9_]*
```

This expression represents a `$` followed by one or more alphanumeric characters. A delimited version (“`${property}`”) is not supported. To use a regular `$` character, use `$$` to have variable substitution.

Other Important Variables

In a default installation, the following variables are used to configure various aspects of the server’s operation.

General Variables

The following table lists general `server.xml` variables. The left column lists variables, and the right column lists descriptions of those variables.

TABLE 2-30 General Variables

Property	Description
<code>accesslog</code>	The access log file for the server.

Variable Evaluation

Variables are evaluated when generating specific objectsets. Evaluation is recursive; meaning that variable values can contain other variables.

Sample server.xml File

```
<?xml version="1.0" encoding="UTF-8"?>

Syntax and Use of the `magnus.conf` File

At startup, the Sun Java System Web Proxy Server looks in a file called `magnus.conf` in the `server-id/config` directory to establish a set of global variable settings that affect the server's behavior and configuration. The Sun Java System Web Proxy Server executes all the directives defined in `magnus.conf`. The order of the directives is not important.

Note – When you edit the `magnus.conf` file, you must restart the server for the changes to take effect.

This chapter describes the global settings that can be specified in `magnus.conf` in the Sun Java System Web Proxy Server 4. The setting categories are:

- “Server Information” on page 49
- “DNS Lookup” on page 51
- “Process Directive” on page 52
- “Error Logging and Statistic Collection” on page 52
- “Security” on page 53
- “Summary of Directives in the `magnus.conf` File” on page 54

For an alphabetical list of directives, see [Appendix C, “Server Configuration Elements.”](#)

Server Information

This section lists the directives in `magnus.conf` that specify information about the server, which are:

- “Server Name Directive” on page 50
- “Server ID Directive” on page 50
- “User Directive” on page 50
- “NetsiteRoot” on page 51

Server Name Directive

Specifies the server name.

Server ID Directive

Specifies the server ID.

User Directive

Windows: The User directive specifies the user account the server runs with. By using a specific user account other than LocalSystem, you can restrict or enable system features for the server. For example, you can use a user account that can mount files from another machine.

UNIX: The User directive specifies the UNIX user account for the server. If the server is started by the superuser or root user, the server binds to the port you specify and then switches its user ID to the user account specified with the User directive. This directive is ignored if the server isn't started as root. The user account you specify should have read permission to the server's root and subdirectories. The user account should have write access to the logs directory and execute permissions to any CGI programs. The user account should not have write access to the configuration files. This restriction ensures that in the unlikely event that someone compromises the server, that person will not be able to change configuration files and gain broader access to your machine. Specifying the nobody user is not recommended.

Syntax

User *name*

name is the login name for the UNIX user account, which can be a maximum of eight characters long.

Default

If there is no User directive, the server runs with the user account it was started with.

Examples

User http

User server

User nobody

NetsiteRoot

Specifies the server root. This directive is set during installation and is commented out. Unlike other directives, the server expects this directive to start with #. Do not change this directive.

Syntax

```
#NetsiteRoot path
```

Example

```
#ServerRoot <install-root>/<instance-directory>
```

DNS Lookup

This section lists the directives in `magnus.conf` that affect DNS (Domain Name System) lookup. The directives are:

- [“AsyncDNS” on page 51](#)
- [“DNS Directive” on page 51](#)

AsyncDNS

Specifies whether asynchronous DNS is allowed. This directive is ignored. Even if the value is set to on, the server does not perform asynchronous DNS lookups.

DNS Directive

The DNS directive specifies whether the server performs DNS lookups on clients that access the server. When a client connects to your server, the server receives the client's IP address but not its host name. For example, the server identifies the client as `198.95.251.30`, rather than its host name `www.a.com`. The server will resolve the client's IP address into a host name for operations like access control, CGI, error reporting, and access logging.

If your server responds to many requests per day, you might or need to stop host name resolution. Limiting resolution can reduce the load on the DNS or NIS (Network Information System) server.

Syntax

```
DNS [on|off]
```

Default

DNS host name resolution is off as a default

Example

DNS on

Process Directive

This section describes UNIX only `MaxProcs` directive in `magnus.conf` that affect the number and timeout of threads, processes, and connections. `MaxProcs` specifies the maximum number of processes that the server can have running simultaneously. If you don't include `MaxProcs` in your `magnus.conf` file, the server defaults to running a single process.

One process per processor is recommended if you are running in multi process mode. In Sun Java System Web Proxy Server 4, a basic process is always running in addition to the number of active processes specified by this setting.

Default

1

Error Logging and Statistic Collection

This section lists the directives in `magnus.conf` that affect error logging and the collection of server statistics, which are:

- [“ErrorLogDateFormat” on page 52](#)
- [“PidLog” on page 53](#)

ErrorLogDateFormat

Syntax

`ErrorLogDateFormat` *format*

The *format* can be any format valid for the C library function `strftime`. See [Appendix B, “Time Formats”](#)

Default

`%d/%b/%Y:%H:%M:%S`

PidLog

PidLog specifies a file in which to record the process ID (pid) of the base server process. Some of the server support programs assume that this log is in the server root, in `logs/pid`.

To shut down your server, kill the base server process listed in the `pidLog` file by using a `-TERM` signal. To tell your server to reread its configuration files and reopen its log files, use `kill` with the `-HUP` signal.

If the `PidLog` file isn't writable by the user account that the server uses, the server does not log its process ID anywhere. The server won't start if it can't log the process ID.

Syntax

`PidLog file`

file is the full path name and file name where the process ID is stored.

Example

```
PidLog /home/xx12345/builds/install1/proxy-server1/logs/pid
```

Security

This section describes the security directive in `magnus.conf`, which affects server access and security issues for Sun Java System Web Proxy Server 4.

Security Directive

The Security directive globally enables or disables SSL by making certificates available to the server instance. This directive must be on for the server to use SSL. If this directive enabled, the user is prompted for the administrator password in order to access certificates, and so on.

When you create a secure listen socket through the Server Manager, security is automatically turned on globally in `magnus.conf`. When you create a secure listen socket manually in `server.xml`, security must be turned on by editing `magnus.conf`.

Syntax

```
Security [on|off]
```

Default

```
off
```

Example

Security off

Summary of Directives in the magnus.conf File

Purpose

The magnus.conf file contains global variable settings that affect server functioning. This file is read only at server startup.

Directives have the following syntax:

directive value

The following table lists the directives in the magnus.conf file.

TABLE 3-1 magnus.conf Directives

Directive	Allowed Values	Default Value	Description
AcceptLanguage	on, off	off	Determines whether the server parses the Accept-Language header sent by the client to indicate which languages the client accepts.
AcceptTimeout	Any number of seconds	30 for servers that don't use hardware encryption devices and 300 for those that do	Specifies the number of seconds the server waits for data to arrive from the client. If data does not arrive before the timeout expires then the connection is closed.
ACLCacheLifetime	Any number of seconds	120	Determines the number of seconds before cache entries expire. Each time an entry in the cache is referenced, its age is calculated and checked against ACLCacheLifetime. The entry is not used if its age is greater than or equal to the ACLCacheLifetime. If this value is set to 0, the cache is turned off.
ACLUserCacheSize		200	Determines the number of users in the User Cache.

TABLE 3-1 `magnus.conf` Directives (Continued)

Directive	Allowed Values	Default Value	Description
<code>ACLGroupCacheSize</code>		4	Determines how many group IDs can be cached for a single UID/cache entry.
<code>AsyncDNS</code>	on, off	off	Specifies whether asynchronous DNS is allowed.
<code>Address</code>	IP address	not enabled	When <code>Address</code> is enabled, proxy will bind all connect sockets (sockets used to connect to the web server) to the IP address specified in the directive. If <code>Address</code> is "0.0.0.0", then proxy does not perform any bind operation and lets the operating system handle the binding of socket when <code>connect()</code> is called.
<code>CanonicalizeURI</code>	0 (off), 1 (on)	1 (on)	Enable/disable URI canonicalization.
<code>CGIExpirationTimeout</code>	Any number of seconds	300 (5 minutes) recommended	Specifies the maximum time in seconds that CGI processes are allowed to run before being killed.
<code>CGIStubIdleTimeout</code>	Any number of seconds	30	Causes the server to kill any CGIStub processes that have been idle for the number of seconds set by this directive. Once the number of processes is at the <code>MinCGIStubs</code> level, the server does not kill any more processes.
<code>CGIWaitPid</code>	on, off	on	(UNIX only) Makes the action for the <code>SIGCHLD</code> signal the system default action for the signal. Makes the SHTML engine wait explicitly for its <code>exec cmd</code> child processes.
<code>ChildRestartCallback</code>	on, off, yes, no, true, false	no	Forces the callback of NSAPI functions that were registered using the <code>daemon_atrestart</code> function when the server is restarting or shutting down.

TABLE 3-1 `magnus.conf` Directives (Continued)

Directive	Allowed Values	Default Value	Description
<code>Chroot</code>	A path	(none)	(UNIX only) Enables the UNIX system administrator to restrict the server so that it only has access to files in the “Chroot” directory.
<code>ChunkedRequestBufferSize</code>	Any number of bytes	8192	Determines the default buffer size for restate request data.
<code>ChunkedRequestTimeout</code>	Any number of seconds	60 (1 minute).	Determines the default timeout for restate request data.
<code>ConnQueueSize</code>	Any number of connections (including 0)	4096	Specifies the number of outstanding connections that the web proxy server can have.
<code>DefaultLanguage</code>	en (English), fr (French), de (German), ja (Japanese)	en	Specifies the default language for the server. The default language is used for both the client responses and administration.
<code>DNS</code>	on, off	on	Specifies whether the server performs DNS lookups on clients that access the server.
<code>ErrorLogDateFormat</code>	See the manual page for the C library function <code>strftime</code>	%d/%b/%Y:%H:%M:%S	The date format for the error log.
<code>ExtraPath</code>	A path	(none)	Appends the specified directory name to the <code>PATH</code> environment variable. This is used for configuring the Java™ application environment on Windows NT. No default value is assigned. You must specify a value.
<code>Favicon</code>	On, off	on	Enables the server administrator to disable or change the icon that appears in the web address book or favorites list on Internet Explorer browsers “favorite icon”.

TABLE 3-1 `magnus.conf` Directives (Continued)

Directive	Allowed Values	Default Value	Description
<code>flushTimer</code>	Any number of milliseconds	3000 (3 seconds).	If the interval in milliseconds between subsequent write operations for an application is greater than this value, further buffering is disabled.
<code>HeaderBufferSize</code>	Any number of bytes	8192 (8 KB)	The size in bytes of the buffer used by each of the request processing threads for reading the request data from the client. The maximum number of request processing threads is controlled by the <code>RqThrottl</code> setting.
<code>HTTPVersion</code>	<i>m.n</i> ; <i>m</i> is the major version number and <i>n</i> the minor version number	1.1	The current HTTP version used by the server.
<code>KeepAliveQueryMaxSleepTime</code>		100 On lightly loaded systems that primarily service keep-alive connections, you can lower this number to enhance performance. However doing so can increase CPU usage.	This directive specifies an upper limit to the time slept in milliseconds after polling keep-alive connections for further requests.
<code>KeepAliveQueryMeanTime</code>		100 is appropriate for almost all installations. CPU usage will increase with lower <code>KeepAliveQueryMeanTime</code> values.	This directive specifies the desired keep-alive latency in milliseconds.
<code>KeepAliveIdleTime</code>	Any number of milliseconds	200	Specifies the idle time between polls within each thread in the keep-alive subsystem.

TABLE 3-1 `magnus.conf` Directives (Continued)

Directive	Allowed Values	Default Value	Description
<code>KeepAlivePollTimeout</code>	Any number of milliseconds	1000	Specifies the timeout to the <code>poll()</code> call within each thread in the keep-alive subsystem.
<code>KeepAliveThreads</code>	Any number of threads	1	Specifies the number of threads in the keep-alive subsystem. This number should be a small multiple of the number of processors on the system.
<code>KeepAliveTimeout</code>	300 seconds maximum	30	Determines the maximum time that the server holds open an HTTP keep-alive connection or a persistent connection between the client and the server.
<code>KernelThreads</code>	0 (off), 1 (on)	0 (off)	If on, ensures that the server uses only kernel-level threads, not user-level threads. If off, uses only user-level threads.
<code>ListenQ</code>	Ranges are platform-specific	4096 (AIX), 200 (NT), 128 (all others)	Defines the number of incoming connections for a server socket.
<code>LogFlushInterval</code>	Any number of seconds	30	Determines the log flush interval, in seconds, of the log flush thread.
<code>MaxCGIStubs</code>	Any number of CGI stubs	10	Controls the maximum number of CGIStub processes the server can spawn. This value is the maximum concurrent CGIStub processes in execution, not the maximum number of pending requests.
<code>MaxKeepAliveConnections</code>	0 - 32768		Specifies the maximum number of keep-alive and persistent connections that the server can have open simultaneously.
<code>MaxProcs</code>		1	(UNIX only) Specifies the maximum number of processes that the server can have running simultaneously.
<code>MaxRqHeaders</code>	1 - 512	64	Specifies the maximum number of header lines in a request.

TABLE 3-1 `magnus.conf` Directives (Continued)

Directive	Allowed Values	Default Value	Description
<code>MinCGIStubs</code>	Any number less than <code>MaxCGIStubs</code>	2	Controls the number of processes that are started by default.
<code>NativePoolMaxThreads</code>	Any number of threads		Determines the maximum number of threads in the native (kernel) thread pool.
<code>NativePoolMinThreads</code>	Any number of threads	1	Determines the minimum number of threads in the native (kernel) thread pool.
<code>NativePoolQueueSize</code>	Any nonnegative number	0	Determines the number of threads that can wait in the queue for the thread pool.
<code>NativePoolStackSize</code>	Any nonnegative number	0	Determines the stack size of each thread in the native (kernel) thread pool.
<code>PidLog</code>	A valid path to a file	(none)	Specifies a file in which to record the process ID (pid) of the base server process.
<code>PostThreadsEarly</code>	1 (on), 0 (off)	0 (off)	If on, checks whether the minimum number of threads is available at a socket after accepting a connection but before sending the response to the request.
<code>RcvBufSize</code>	Range is platform-specific	0 (uses platform-specific default)	Controls the size of the receive buffer at the server's sockets.
<code>RqThrottle</code>	Any number of requests (including 0)		Specifies the maximum number of simultaneous request processing threads that the server can handle simultaneously per socket. This setting can have performance implications. For more information, see the Sun Java System Web Proxy Server 4 <i>Performance Tuning, Sizing, and Scaling Guide</i> .

TABLE 3-1 magnus.conf Directives (Continued)

Directive	Allowed Values	Default Value	Description
RqThrottleMin	Any number less than RqThrottle		Specifies the number of request processing threads that is created when the server is started. As the load on the server increases, more request processing threads are created up to a maximum of RqThrottle threads.
Security	on, off	off	Globally enables or disables SSL by making certificates available to the server instance. Must be on for virtual servers to use SSL.
SndBufSize	Range is platform-specific	0 (uses platform-specific default)	Controls the size of the send buffer at the server's sockets.
SSL3SessionTimeout	5 - 86400	86400 (24 hours)	The number of seconds until a cached SSL3 session becomes invalid.
SSLCacheEntries	A non-negative integer	10000 (used if 0 is specified)	Specifies the number of SSL sessions that can be cached with no upper limit.
SSLClientAuthDataLimit	Number of bytes	1048576 (1MB)	Specifies the maximum amount of application data that is buffered during the client certificate handshake phase.
SSLClientAuthTimeout	Any number of seconds	60	Specifies the number of seconds after which the client certificate handshake phase times out.
SSLSessionTimeout	5 - 100	100	Specifies the number of seconds until a cached SSL2 session becomes invalid.
StackSize	Number of bytes	The most favorable machine-specific stack size	Determines the maximum stack size for each request handling thread.
StrictHttpHeaders	on, off	off	If on, rejects connections that include inappropriately duplicated headers.

TABLE 3-1 `magnus.conf` Directives (Continued)

Directive	Allowed Values	Default Value	Description
<code>TempDir</code>	A path	<code>/tmp</code> (UNIX) <code>TEMP</code> (environment variable for Windows NT)	Specifies the directory the server uses for its temporary files. On UNIX, this directory should be owned by, and writable by, the user the server runs as.
<code>TempDirSecurity</code>	<code>on</code> , <code>off</code>	<code>on</code>	Determines whether the server checks if the <code>TempDir</code> directory is secure. On UNIX, specifying <code>TempDirSecurity off</code> allows the server to use <code>/tmp</code> as a temporary directory.
<code>TerminateTimeout</code>	Any number of seconds	<code>30</code>	Specifies the time in seconds that the server waits for all existing connections to terminate before it shuts down.
<code>ThreadIncrement</code>	Any number of threads	<code>10</code>	The number of additional or new request processing threads created to handle an increase in the load on the server.
<code>Umask</code>	A standard UNIX umask value	(none)	UNIX only: Specifies the umask value used by the NSAPI functions <code>System_fopenWA()</code> and <code>System_fopenRW()</code> to open files in different modes.
<code>UseNativePoll</code>	<code>1 (on)</code> , <code>0 (off)</code>	<code>1 (on)</code>	Uses a platform-specific poll interface when set to <code>1 (on)</code> . Uses the NSPR poll interface in the <code>KeepAlive</code> subsystem when set to <code>0 (off)</code> .
<code>UseOutputStreamSize</code>	Any number of bytes	<code>8192 (8 KB)</code>	Determines the default output stream buffer size for the <code>net_read</code> and <code>netbuf_grab</code> NSAPI functions.

TABLE 3-1 magnus.conf Directives (Continued)

Directive	Allowed Values	Default Value	Description
User	A login name, 8 characters or less	(none)	<p>(Windows NT) Specifies the user account the server runs with, allowing you to restrict or enable system features for the server.</p> <p>(UNIX) If the server is started by the superuser or root user, the server binds to the Port you specify and then switches its user ID to the user account specified with the User directive. This directive is ignored if the server isn't started as root.</p>
WinCgiTimeout	Any number of seconds	60	WinCGI processes that require more time this value are terminated when this timeout expires.

Syntax and Use of the `obj.conf` File

The `obj.conf` configuration file contains directives that instruct the Sun Java System Web Proxy Server how to handle HTTP and HTTPS requests from clients. You can modify and extend the request-handling process by adding or changing the instructions in `obj.conf`.

All `obj.conf` files are located in the *instance-dir/config* directory, where *instance-dir* is the path to the installation directory of the server instance.

By default, the `obj.conf` file for the server is named `obj.conf`.

This chapter discusses server instructions in `obj.conf`, the use of OBJECT tags, the use of variables, the flow of control in `obj.conf`, the syntax rules for editing `obj.conf`, and a note about example directives.

Note – For detailed information about the standard directives and predefined Server Application Functions (SAFs) that are used in the `obj.conf` file, see [Chapter 5, “Predefined SAFs in the `obj.conf` File.”](#)

This chapter contains the following sections:

- “How the Proxy Server Functions” on page 64
- “Dynamic Reconfiguration” on page 66
- “Server Instructions in `obj.conf`” on page 67
- “Configuring HTTP Compression” on page 70
- “Object and Client Tags” on page 71
- “Variables Defined in `server.xml`” on page 75
- “Flow of Control in the `obj.conf` File” on page 75
- “Changes in Function Flow” on page 83
- “Syntax Rules for Editing `obj.conf`” on page 84
- “About `obj.conf` Directive Examples” on page 86

How the Proxy Server Functions

“Proxy” is a general term that means “to act on behalf of a user in an authorized capacity.” A web proxy server intercepts client connections and obtains the requested content from an origin server, the owner of the content on behalf of the client.

A typical web proxy accepts connections from clients, makes decisions as to whether the clients are permitted to use the proxy or access the requested resources, and then completes connections on behalf of the clients to the various origin servers. In this manner, the web proxy acts as both a server as well as a client of the requested resource.

The two basic types of web proxy server are: a forward proxy and a reverse proxy. While they share much of the same functionality, some definite differences exist between the two types.

Forward Proxy Scenario

A Forward proxy provides internal clients access through a firewall to resources on the Internet. This service is often provided as part of a larger intranet security strategy. Forward proxying allows clients to access resources outside of the firewall without compromising the integrity of the private network.

A forward proxy can be configured to keep copies of content within their local cache. Subsequent requests for that content can then be serviced from the local cache rather than obtaining the content from the origin server. Caching increases performance by decreasing the time involved in traversing the network.

Most proxy servers have the capability to filter requests from users. Administrators can choose to limit access to certain resources that might not be appropriate for the workplace and therefore deny such access.

In a forward proxy scenario, the client is aware of the proxy server and is configured to use it for various requests. The firewall can then be configured to allow only certain traffic from the proxy server rather than permitting such access to all internal clients.

Reverse Proxy Scenario

A proxy server can also provide external clients with access to internal resources the reside behind the corporate firewall. When a proxy server is used to handle connections into a private network, the process is called reverse proxying. The term “reverse” refers to the fact that traffic flows in the opposite direction from normal proxy traffic flow.

A forward proxy is best used to filter content, increase performance, and log user accesses. A reverse proxy provides these benefits and more. You can use a reverse proxy to load balance across multiple servers, provide failover capabilities, and provide access to corporate resources in a safe and secure manner.

In a reverse proxy scenario, the client is not even aware that it is using a proxy server. This transparency is one of the key differences between a forward and reverse proxy server scenario.

URL Mapping

The URL Mapping feature enables the Proxy Server to function as a reverse proxy or a junction by acting as a front-end server. Based on the client's URI, access is provided to the back-end application servers.

The features included in URL Mapping are:

- URL Mapping
- URL rewriting in HTTP headers, HTML content, JavaScript, and Style Sheets
- Per-application cookie management
- Pass-through cookies, including cookie renaming
- Junction selection based on a last-seen cookie

For information on the Server Application Functions (SAFs) used in URL Mapping, see [“Server Application Functions \(SAFs\)” on page 88](#).

NSAPI Filters

The NSAPI API enables multiple Server Application Functions (SAFs) to interact in request processing. For example, one SAF can be used to authenticate the client after which a second SAF would generate the content.

Request-Handling Process

At startup, the server performs some initialization and then waits for a request from a client, such as a browser.

The `obj.conf` file for the server specifies how the request is handled.

1. **Init** - Loads and initializes server modules and plugins, and initializes log files.
2. **AuthTrans** (authorization translation) - Verifies any authorization information (such as name and password) sent in the request.
3. **NameTrans** (name translation) - Translates the logical URI into a local file system path.
4. **PathCheck** (path checking) - Checks the local file system path for validity and checks that the requestor has access privileges to the requested resource on the file system.
5. **ObjectType** (object typing) - Determines the MIME-type (Multi-purpose Internet Mail Encoding) of the requested resource (for example, `text/html`, `image/gif`, and so on).
6. **Input** (prepare to read input) - Selects filters that will process incoming request data read by the `Service` step.

7. **Output** (prepare to send output) - Selects filters that will process outgoing response data generated by the **Service** step.
8. **Service** (generate the response) - Generates and returns the response to the client.
9. **AddLog** (adding log entries) - Adds entries to log file(s).
10. **Error** (service) - Executes only if an error occurs in the previous steps. If an error occurs, the server logs an error message and aborts the process.
11. **Connect** - Calls the connect function you specify.
12. **DNS** - Calls either the `dns - config` built-in function or a DNS function that you specify.
13. **Filter** - Runs an external command and then sends the data through the external command before processing that data in the proxy.
14. **Route** - Specifies information about where the proxy server should route requests.

Directives for Handling Requests

The `obj.conf` file contains a series of instructions, known as directives, that tell the Sun Java System Web Proxy Server what to do at each stage in the request-handling process. Each directive invokes a Server Application Function (SAF) with one or more arguments. Each directive applies to a specific stage in the request-handling process. The stages are `Init`, `AuthTrans`, `NameTrans`, `PathCheck`, `ObjectType`, `Input`, `Output`, `Service`, `AddLog`, `Connect`, `DNS`, `Filter`, and `Route`.

Dynamic Reconfiguration

You do not need to restart the server for changes to certain configuration files to take effect (for example, `obj.conf`, `mime.types`, and `server.xml`). All you need to do is apply the changes by clicking the **Apply** link and then clicking the **Load Configuration Files** button on the **Apply Changes** screen. If there are errors in installing the new configuration, the previous configuration is restored.

When you edit `obj.conf` and apply the changes, a new configuration is loaded into memory that contains all of the information from the dynamically configurable files.

Every new connection references the newest configuration. Once the last session referencing a configuration ends, the now unused old configuration is deleted.

Server Instructions in obj.conf

The obj.conf file contains directives that instruct the server how to handle requests received from clients such as browsers. These directives appear inside OBJECT tags.

Each directive calls a function, indicating when to call it and specifying arguments for it.

The syntax of each directive is:

Directive `fn=func-name name1="value1" . . . nameN="valueN"`

For example:

```
Init fn="flex-init" access="$accesslog" format.access="%Ses->client.ip%
- %Req->vars.auth-user% [%SYSDATE%] '%Req->reqpb.clf-request%'
%Req->srvhdrs.clf-status% %Req->srvhdrs.content-length%"
```

Directive indicates when this instruction is executed during the request-handling process. The value is one of `Init`, `AuthTrans`, `NameTrans`, `PathCheck`, `ObjectType`, `Service`, `AddLog`, `Error`, `Connect`, `DNS`, `Filter`, and `Route`.

The value of the `fn` argument is the name of the SAF to execute. All directives must supply a value for the `fn` parameter; if there's no function, the instruction won't do anything.

The remaining parameters are the arguments needed by the function, and they vary from function to function.

The Sun Java System Web Proxy Server is shipped with a set of built-in Server Application Functions (SAFs) that you can use to create and modify directives in obj.conf.

Summary of the Directives

Following are the categories of server directives and a description of what each does. Each category corresponds to a stage in the request-handling process. The section [“Flow of Control in the obj.conf File” on page 75](#) explains how the server decides which directives to execute in each stage.

- [“Init Directive” on page 75](#) - Loads and initializes server modules and plugins, and initializes log files.
- [“AuthTrans Directive” on page 76](#) - Verifies any authorization information that is normally sent in the `Authorization` header provided in the HTTP request; and translates it into a user or a group. Server access control occurs in two stages. `AuthTrans` verifies the authenticity of the user. Later, `PathCheck` tests the user's access privileges for the requested resource.

```
AuthTrans fn=basic-auth userfn=ntauth auth-type=basic userdb=none
```

This example calls the `basic-auth` function, which calls a custom function (in this case `ntauth`) to verify authorization information sent by the client. The `Authorization` header is sent as part of the basic server authorization scheme.

- [“NameTrans Directive” on page 76](#) - Translates the URL specified in the request from a logical URL to a physical file system path for the requested resource. This process might also result in redirection to another site.
- [“PathCheck Directive” on page 77](#) - Performs tests on the physical path determined by the `NameTrans` step. These tests determine whether the path is valid and whether the client is allowed to access the requested resource. For example:

```
PathCheck fn="find-index" index-names="index.html,home.html"
```

This example calls the `find-index` function with an `index-names` argument of `index.html,home.html`. If the requested URL is a directory, this function instructs the server to look for a file called either `index.html` or `home.html` in the requested directory.

- [“ObjectType Directive” on page 78](#) - Determines the MIME type of the requested resource. The MIME type has attributes `type`, which indicates content type, encoding, and language. The MIME type is sent in the headers of the response to the client. The MIME type also helps determine which `Service` directive the server should execute.

The resulting type might be:

- A common document type such as `text/html` or `image/gif`. For example, the file name extension `.gif` translates to the MIME type `image/gif`.
- An internal server type. Internal types always begin with `magnus-internal`.

For example:

```
ObjectType fn="type-by-extension"
```

This example calls the `type-by-extension` function, which causes the server to determine the MIME type according to the requested resource’s file extension.

- [“Input Directive” on page 80](#) - Selects filters that will process incoming request data read by the `Service` step. The `Input` directive allows you to invoke the `insert-filter` SAF in order to install filters that process incoming data. All `Input` directives are executed when the server or a plugin first attempts to read entity body data from the client. The `Input` directives are executed at most once per request. For example:

```
Input fn="insert-filter" filter="http-decompression" This directive instructs the insert-filter function to add a filter named http-decompression to the filter stack, which would decompress incoming HTTP request data before passing it to the Service step.
```

- [“Output Directive” on page 80](#) - Selects filters that will process outgoing response data generated by the `Service` step. The `Output` directive enables you to invoke the `insert-filter` SAF to install filters that process outgoing data. All `Output` directives are

executed when the server or a plug-in first attempts to write entity body data from the client. The `Output` directives are executed at most once per request. For example:

```
Output fn="insert-filter" filter="http-compression"
```

This directive instructs the `insert-filter` function to add a filter named `http-compression` to the filter stack, which would compress outgoing HTTP response data generated by the `Service` step.

- [“Service Directive” on page 80](#) - Generates and sends the response to the client. This process sets the HTTP result status, sets up response headers such as `Content-Type` and `Content-Length`, and generates and sends the response data. The default response is to invoke the `send-file` function to send the contents of the requested file along with the appropriate header files to the client.

The default `Service` directive is:

```
Service method="(GET|HEAD|POST)" fn="send-file"
```

This directive instructs the server to call the `send-file` function in response to any request whose method is `GET`, `HEAD`, or `POST`.

Another example:

```
Service method="(GET|HEAD)" fn="imagemap"
```

In this case, if the method of the request is either `GET` or `HEAD`, the function `imagemap` is called.

- [“AddLog Directive” on page 82](#) - Adds an entry to a log file to record information about the transaction. For example:

```
AddLog fn="flex-log" name="access"
```

This example calls the `flex-log` function to log information about the current request in the log file named `access`.

- [“Error Directive” on page 83](#) - Handles an HTTP error. This directive is invoked if a previous directive results in an error. Typically the server handles an error by sending a custom HTML document to the user describing the problem and possible solutions.

For example:

```
Error fn="send-error" reason="Unauthorized" path="D:/Sun/ProxyServer40/Server1/errors/unauthorized.html"
```

In this example, the server sends the file in `D:/Sun/ProxyServer40/Server1/errors/unauthorized.html` whenever a client requests a resource that it is not authorized to access.

- [“Connect Directive” on page 83](#) - Calls the `connect` function you specify.

Only the first applicable `Connect` function is called, starting from the most restrictive object. Occasionally you might want to call multiple functions until a connection is established. The function returns `REQ_NOACTION` if the next function should be called. If it fails to connect, the return value is `REQ_ABORT`. If it connects successfully, the connected socket descriptor will be returned.

- “[DNS Directive](#)” on page 83 - Calls either the `dns-config` built-in function or a DNS function that you specify.
- “[Filter Directive](#)” on page 83 - Runs an external command and then pipes the data through the external command before processing that data in the proxy by using the `pre-filter` function.
- “[Route Directive](#)” on page 83 - Specifies information about where the proxy server should route requests.

Configuring HTTP Compression

When compression is enabled in the server, an entry gets added to the `obj.conf` file. A sample entry is shown below:

```
Output fn="insert-filter" filter="http-compression" type="text/*"
```

Depending on the options specified, this line might also contain these options:

```
vary="on" compression-level="9"
```

To restrict compression to documents of only a particular type, or to exclude browsers that don't work well with compressed content, you would need to edit the `obj.conf` file, as discussed below.

The option that appears as `type="text/*"` restricts compression to documents that have a MIME type of `text/*`. For example, `text/ascii`, `text/css`, `text/html`, and so on. This can be modified to compress only certain types of documents. If you want to compress only HTML documents, for example, you would change the option to:

```
type="text/html"
```

Alternatively, you can specifically exclude browsers that are known to misbehave when they receive compressed content by using the `<Client>` tag as follows:

```
<Client match="none" \
  browser="*MSIE [1-3]*" \
  browser="*MSIE [1-5]*Mac*" \
  browser="Mozilla/[1-4]*Nav*">
Output fn="insert-filter" filter="http-compression" type="text/*"
</Client>
```

This example restricts compression to browsers other than the following browsers:

- Internet Explorer for Windows earlier than version 4
- Internet Explorer for Macintosh earlier than version 6
- Netscape Navigator/Communicator earlier than version 6

Internet Explorer on Windows earlier than version 4 may request compressed data at times, but does not correctly support it. Internet Explorer on Macintosh earlier than version 6 does the same. Netscape Communicator version 4.x requests compression, but only correctly handles compressed HTML. It will not correctly handle linked CSS or JavaScript code from the compressed HTML, so administrators often simply prevent their servers from sending any compressed content to that browser or earlier versions.

For more information about the `<Client>` tag, see [“Client Tag” on page 73](#).

Object and Client Tags

This section discusses the use of `<Object>` and `<Client>` tags in the `obj.conf` file.

`<Object>` tags group directives that apply to requests for particular resources, while `<Client>` tags group directives that apply to requests received from specific clients.

These tags are described in the following topics:

- [“Object Tag” on page 71](#)
- [“Client Tag” on page 73](#)

Object Tag

Directives in the `obj.conf` file are grouped into objects that begin with an `<Object>` tag and end with an `</Object>` tag. The default object provides instructions to the server about how to process requests by default. Each new object modifies the default object's behavior.

An `Object` tag may have a `name` attribute or a `ppath` attribute. Either parameter may be a wildcard pattern. For example:

```
<Object name="cgi">
```

```
<Object ppath="/usr/sun/proxyserver40/server1/private/*">
```

The server always starts handling a request by processing the directives in the default object. However, the server switches to processing directives in another object after the `NameTrans` stage of the default object if either of the following conditions is true:

- The successful NameTrans directive specifies a name argument
- The physical path name that results from the NameTrans stage matches the ppath attribute of another object

When the server has been alerted to use an object other than the default object, the server processes the directives in the other object before processing the directives in the default object. For some steps in the process, the server stops processing directives in that particular stage such as the Service stage as soon as one is successfully executed. For other stages the server processes all directives in that stage, including the ones in the default object as well as those in the additional object. For more details, see [“Flow of Control in the obj . conf File” on page 75](#)

Objects that Use the name Attribute

If a NameTrans directive in the default object specifies a name argument, the server switches to processing the directives in the object of that name before processing the remaining directives in the default object.

For example, the following NameTrans directive in the default object assigns the name `cgi` to any request whose URL starts with `http://server-name/cgi/`:

```
<Object name="default">
NameTrans fn="pfx2dir" from="/cgi" dir="
    <install-root>/
    <instance-directory>/mycgi" name="cgi"
...
</Object>
```

When that NameTrans directive is executed, the server starts processing directives in the object named `cgi`:

```
<Object name="cgi">
    more directives...</Object>
```

Objects that Use the ppath Attribute

When the server finishes processing the NameTrans directives in the default object, the logical URL of the request will have been converted to a physical path name. If this physical path name matches the ppath attribute of another object in `obj . conf`, the server switches to processing the directives in that object before processing the remaining ones in the default object.

For example, the following NameTrans directive translates the `http://server_name/` part of the requested URL to `install-root/instance-directory/mydir`

The URL `http://server_name/internalplan1.html` would be translated to `<install-root>/<instance-directory>/mydir/internalplan1.html`. However, suppose that `obj.conf` contains the following additional object:

```
<Object ppath="*internal*">
    more directives...</Object>
```

In this case, the partial path `*internal*` matches the path `install-root/instance-directory/mydir/internalplan1.html`. The server then starts processing the directives in this object before processing the remaining directives in the default object.

Client Tag

The `<Client>` tag is used to limit execution of a set of directives to requests received from specific clients. Directives listed between the `<Client>` and `</Client>` tags are executed only when information in the client request matches the parameter values specified.

Client Tag Parameters

The following table lists the `<Client>` tag parameters.

TABLE 4-1 Client Tag Parameters

Parameter	Description
<code>browser</code>	User-agent string sent by a browser to the Web Server
<code>chunked</code>	Boolean value set by a client requesting chunked encoding
<code>code</code>	HTTP response code
<code>dns</code>	DNS name of the client
<code>internal</code>	Boolean value indicating internally generated request
<code>ip</code>	IP address of the client
<code>keep-alive</code>	Boolean value indicating the client has requested a keep-alive connection
<code>keysize</code>	Key size used in an SSL transaction
<code>match</code>	Match mode for the <code><Client></code> tag; valid values are <code>all</code> , <code>any</code> , and <code>none</code>
<code>method</code>	HTTP method used by the browser
<code>name</code>	Name of an object as specified in a previous <code>NameTrans</code> statement

TABLE 4-1 Client Tag Parameters (Continued)

Parameter	Description
odds	Sets a random value for evaluating the enclosed directive; specified as either a percentage or a ratio, for example, 20% or 1/5
path	Physical path to the requested resource
ppath	Physical path of the requested resource
query	Query string sent in the request
reason	Text version of the HTTP response code
restarted	Boolean value indicating a request has been restarted
secret-keysize	Secret key size used in an SSL transaction
security	Indicates an encrypted request
type	Type of document requested (such as text/html or image/gif)
uri	URI section of the request from the browser
urlhost	DNS name of the virtual server requested by the client, provided in the Host header of the client request

The <Client> tag parameters provide greater control over when and if directives are executed. In the following example, use of the odds parameter gives a request a 25% chance of being redirected.

```
<Client odds="25%">NameTrans fn="redirect" from="/Pogues"
url-prefix="http://pogues.example.com"</Client>
```

One or more wildcard patterns can be used to specify Client tag parameter values.

Wildcards can also be used to exclude clients that match the parameter value specified in the <Client tag>. In the following example, the <Client> tag and the AddLog directive are combined to direct the Web Server to log access requests from all clients *except* those from the specified subnet.

```
<Client ip="~192.85.250.*">AddLog fn="flex-log" name="access"</Client>
```

Using the ~ wildcard negates the expression, which causes the Web Server to exclude clients from the specified subnet.

You can also create a negative match by setting the match parameter of the Client tag to none. In the following example, access requests from the specified subnet are excluded, as are all requests to the server www.mycompany.com

```
<Client match="none" ip="192.85.250.*" urlhost="www.mycompany.com">AddLog
fn="flex-log" name="access"</Client>
```

Variables Defined in server.xml

You can define variables in the server . xml file and reference them in an obj . conf file. For example, the following server . xml code defines and uses a variable called docroot:

```
<!DOCTYPE SERVER SYSTEM "server.dtd" [
<!ELEMENT LS (DESCRIPTION?,SSLPARAMS?)>
<!ATTLIST LS
    id ID #REQUIRED
    ip CDATA "any"
    port CDATA #REQUIRED
    security %boolean; "false"
    acceptorthreads CDATA "1"
    family CDATA #IMPLIED
    blocking %boolean; "false"
    servername CDATA #REQUIRED
>
```

You can reference the variable in obj . conf as follows:

```
NameTrans fn=document-root root="$docroot"
```

Using this docroot variable saves you from having to define document roots for virtual server classes in the obj . conf files. This variable also enables you to define different document roots for different virtual servers within the same virtual server class.

Note – Variable substitution is allowed only in an obj . conf file, not in any other Sun Java System Web Proxy Server configuration files. Any variable referenced in an obj . conf file must be defined in the server . xml file.

Flow of Control in the obj . conf File

Before the server can process a request, it must direct the request to the correct server.

After the server is determined, the server executes the obj . conf file for the server. This section discusses how the server decides which directives to execute in obj . conf.

Init Directive

Loads and initializes server modules and plug-ins, and initialize log files.

AuthTrans Directive

When the server receives a request, it executes the AuthTrans directives in the default object to check that the client is authorized to access the server.

If the object includes more than one AuthTrans directive, the server executes them all unless one of them results in an error. If an error occurs, the server skips all other directives except for Error directives.

NameTrans Directive

After authorization, the server executes a NameTrans directive in the default object to map the logical URL of the requested resource to a physical path name on the server's file system. The server looks at each NameTrans directive in the default object in turn, until the server finds one that can be applied.

If the default object contains more than one NameTrans directive, the server considers each directive until one succeeds.

The NameTrans section in the default object must contain exactly one directive that invokes the map function. For example:

```
NameTrans fn="map" from="<http://myserver> to http://yourserver
```

The pfx2dir (prefix to directory) function is used to set up additional mappings between URLs and directories. For example, the following directive translates the URL

```
http://server-name/cgi/ into the directory path name  
install-root/instance-directory/docs/mycgi:
```

```
NameTrans fn="pfx2dir" from="/cgi" dir="install-root/instance-directory/docs  
/mycgi"
```

If this directive appears *after* the one that calls document - root, it will never be executed and will result in the directory path name <install-root>/<instance-directory>/docs/cgi/ (not mycgi). This example illustrates why the directive that invokes document - root must be the last one in the NameTrans section.

How and When the Server Processes Other Objects

As a result of executing a NameTrans directive, the server might start processing directives in another object. This process happens if the NameTrans directive that was successfully executed specifies a name or generates a partial path that matches the name or ppath attribute of another object.

If the successful NameTrans directive assigns a name by specifying a name argument, the server starts processing directives in the named object, which is defined with the OBJECT tag before processing directives in the default object for the rest of the request-handling process.

For example, the following NameTrans directive in the default object assigns the name cgi to any request whose URL starts with http://server_name/cgi/.

```
<Object name="default">
...
NameTrans fn="pfx2dir" from="/cgi" dir="
    <install-root>/<
        instance-directory>/mycgi" name="cgi"
...
</Object>
```

When that NameTrans directive is executed, the server starts processing directives in the object named cgi

```
<Object name="cgi">

    more directives...</Object>
```

When a NameTrans directive has been successfully executed, a physical path name will be associated with the requested resource. If the resultant path name matches the ppath (partial path) attribute of another object, the server starts processing directives in the other object before processing directives in the default object for the rest of the request-handling process.

For example, suppose obj . conf contains an object as follows:

```
<Object ppath="*internal*">

    more directives...</Object>
```

Now suppose the successful NameTrans directive translates the requested URL to the path name <install-root>/<instance-directory>/mydir/internalplan1.html. In this case, the partial path *internal* matches the path <install-root>/<instance-directory>/mydir/internalplan1.html. The server would then start processing the directives in this object before processing the remaining directives in the default object.

PathCheck Directive

After converting the logical URL of the requested resource to a physical path name in the NameTrans step, the server executes PathCheck directives to verify that the client is allowed to access the requested resource.

If the object contains more than one `PathCheck` directive, the server executes all of the directives in the order in which they appear, unless one of the directives denies access. If access is denied, the server switches to executing directives in the `Error` section.

If the `NameTrans` directive assigned a name or generated a physical path name that matches the name or `ppath` attribute of another object, the server first applies the `PathCheck` directives in the matching object before applying the directives in the default object.

ObjectType Directive

Assuming that the `PathCheck` directives all approve access, the server next executes the `ObjectType` directives to determine the MIME type of the request. The MIME type has three attributes: `type`, `encoding`, and `language`. When the server sends the response to the client, the `type`, `language`, and `encoding` values are transmitted in the headers of the response. The `type` also frequently helps the server to determine which `Service` directive to execute to generate the response to the client.

If the object contains more than one `ObjectType` directive, the server applies all of the directives in the order in which they appear. However, once a directive sets an attribute of the MIME type, further attempts to set the same attribute are ignored. All `ObjectType` directives are applied because one directive may set one attribute, for example `type`, while another directive sets a different attribute, such as `language`.

As with the `PathCheck` directives, if another object has been matched to the request as a result of the `NameTrans` step, the server executes the `ObjectType` directives in the matching object before executing the `ObjectType` directives in the default object.

Setting the Type by File Extension

Usually, the default way the server determines the MIME type is by calling the `type-by-extension` function. This function instructs the server to look up the MIME type according to the requested resource's file extension in the MIME types table. This table is created during virtual server initialization by the MIME types file, which is usually called `mime.types`.

For example, the entry in the MIME types table for the extensions `.html` and `.htm` is usually:

```
type=text/html exts=htm,html
```

This table indicates that all files with the extension `.htm` or `.html` are text files formatted as HTML, and the type is `text/html`.

If you make changes to the MIME types file, you must reconfigure the server before those changes can take effect.

Forcing the Type

If no previous `ObjectType` directive has set the type and the server does not find a matching file extension in the MIME types table, the type still has no value even after `type-by-expression` has been executed. If the server does not recognize the file extension, force the type to be `text/plain`, so that the content of the resource is treated as plain text. Another situation in which you can set the type regardless of the file extension is forcing all resources in the designated CGI directory to have the MIME type `magnus-internal/cgi`.

The function that forces the type is `force-type`.

For example, the following directives first instruct the server to look in the MIME types table for the MIME type. Then, if the `type` attribute has not been set (that is, the file extension was not found in the MIME types table), set the `type` attribute to `text/plain`.

```
ObjectType fn="type-by-extension"
ObjectType fn="force-type" type="text/plain"
```

If the server receives a request for a file `abc.dogs`, it looks in the MIME types table. When it does not find a mapping for the extension `.dogs`, it consequently does not set the `type` attribute. Because the `type` attribute has not already been set, the second directive is successful, forcing the `type` attribute to `text/plain`.

The following example illustrates another use of `force-type`. In this example, the type is forced to `magnus-internal/cgi` before the server gets a chance to look in the MIME types table. In this case, all requests for resources in `http://server_name/cgi/` are translated into requests for resources in the directory `<install-root>/<instance-directory>/mycgi/`. Since a name is assigned to the request, the server processes `ObjectType` directives in the object named `cgi` before processing the ones in the default object. This object has one `ObjectType` directive, which forces the type to be `magnus-internal/cgi`.

```
NameTrans fn="pfx2dir" from="/cgi" dir="<
    install-root>/<
    instance-directory>/mycgi" name="cgi"
<Object name="cgi">
ObjectType fn="force-type" type="magnus-internal/cgi"
Service fn="send-cgi"
</Object>
```

The server continues processing all `ObjectType` directives including those in the default object. However, because the `type` attribute has already been set, no other directive can set it to another value.

Input Directive

The Input directive selects filters that will process incoming request data read by the `Service` step. This directive enables you to invoke the `insert-filter` SAF in order to install filters that process incoming data.

The Input directives are executed at most once per request.

You can define the appropriate position of a specific filter within the filter stack. For example, filters that translate content from XML to HTML are placed higher in the filter stack than filters that compress data for transmission. You can use the `filter_create` function to define the filter's position in the filter stack, and `init-filter-order` to override the defined position.

When two or more filters are defined to occupy the same position in the filter stack, filters that were inserted later will appear higher than filters that were inserted earlier. The order of Input `fn="insert-filter"` and Output `fn="insert-filter"` directives in `obj.conf` is important.

Output Directive

The Output directive selects filters that will process outgoing response data generated by the `Service` step. The Output directive enables you to invoke the `insert-filter` SAF to install filters that process outgoing data. All Output directives are executed when the server or a plugin first attempts to write entity body data from the client.

The Output directives are executed at most once per request.

You can define the appropriate position of a specific filter within the filter stack. For example, filters that translate content from XML to HTML are placed higher in the filter stack than filters that compress data for transmission. You can use the `filter_create` function to define the filter's position in the filter stack, `init-filter-order` to override the defined position.

When two or more filters are defined to occupy the same position in the filter stack, filters that were inserted later will appear higher than filters that were inserted earlier. The order of Input `fn="insert-filter"` and Output `fn="insert-filter"` directives in `obj.conf` is important.

Service Directive

Next, the server executes a `Service` directive to generate the response to send to the client. The server looks at each `Service` directive in turn, to find the first one that matches the type, method, and query string. If a `Service` directive does not specify type, method, or query string, then the unspecified attribute matches anything.

If the object contains more than one `Service` directive, the server applies the first one that matches the conditions of the request, and ignores all remaining `Service` directives.

As with the `PathCheck` and `ObjectType` directives, if another object has been matched to the request as a result of the `NameTrans` step, the server considers the `Service` directives in the matching object before considering the ones in the default object. If the server successfully executes a `Service` directive in the matching object, it will not execute the `Service` directives in the default object, because it only executes one `Service` directive.

Service Examples

- Assume that the `PathCheck` directives all succeed.
- The following `ObjectType` directive tells the server to look up the resource's MIME type in the MIME types table:

```
ObjectType fn="type-by-extension"
```

- The server finds the following entry in the MIME types table, which sets the `type` attribute to `text/html`:

```
type=text/html exts=htm,html
```

- The server invokes the following `Service` directive. The value of the `type` parameter matches anything that does *not* begin with `magnus-internal/`. This directive sends the requested file, `jos.html`, to the client.

```
Service method="(GET|HEAD|POST)" fn="send-file"
```

The following example uses another object:

- The `NameTrans` directive assigns the name `personnel` to the request.

```
NameTrans fn=assign-name name=personnel from=/personnel
```

- As a result of the name assignment, the server switches to processing the directives in the object named `personnel`. This object is defined as:

```
<Object name="personnel">
  Service fn="index-simple"
</Object>
```

- The `personnel` object has no `PathCheck` or `ObjectType` directives, so the server processes the `PathCheck` and `ObjectType` directives in the default object. Assume that all `PathCheck` and `ObjectType` directives succeed.

- When processing `Service` directives, the server starts by considering the `Service` directive in the `personnel` object, which is:

```
Service fn="index-simple"
```

- The server executes this `Service` directive, which calls the `index-simple` function. Since a `Service` directive has now been executed, the server does not process any other `Service` directives. However, if the matching object had not had a `Service` directive that was executed, the server would continue looking at `Service` directives in the default object.

Default Service Directive

A `Service` directive usually performs the default task, sending a file if no other `Service` directive matches a request sent by a browser. This default directive must come last in the list of `Service` directives in the default object to ensure it only gets called if no other `Service` directives have succeeded. The default `Service` directive is usually:

```
Service method="(GET|HEAD|POST)" fn="send-file"
```

This directive matches requests whose method is `GET`, `HEAD`, or `POST`, which covers nearly virtually all requests sent by browsers.

If the server has not already executed a `Service` directive when it reaches this directive, it executes the directive so long as the request method is `GET`, `HEAD` or `POST`. The invoked function is `send-file`, which simply sends the contents of the requested file to the client.

AddLog Directive

After the server generate the response and sends it to the client, the server executes `AddLog` directives to add entries to the log files.

All `AddLog` directives are executed. The server can add entries to multiple log files.

Depending on which log files are used and which format they use, the `Init` section in `magnus.conf` might need to have directives that initialize the logs. For example, if one of the `AddLog` directives calls `flex-log`, which uses the extended log format, the `Init` section must contain a directive that invokes `flex-init` to initialize the flexible logging system.

For more information about initializing logs, see the discussion of the functions [“flex-init” on page 98](#) and [“init-clf” on page 105](#) in [Chapter 5, “Predefined SAFs in the obj.conf File.”](#)

Error Directive

If an error occurs during the request-handling process, such as if a `PathCheck` or `AuthTrans` directive denies access to the requested resource, or the requested resource does not exist, the server immediately stops executing all other directives and immediately starts executing the Error directives.

Connect Directive

The `Connect` directive calls the connect function you specify.

Only the first applicable `Connect` function is called, starting from the most restrictive object. Occasionally you might want to call multiple functions until a connection is established. The function returns `REQ_NOACTION` if the next function should be called. If it fails to connect, the return value is `REQ_ABORT`. If the function connects successfully, the connected socket descriptor will be returned.

DNS Directive

The `DNS` directive calls either the `dns-config` built-in function or a DNS function that you specify.

Filter Directive

The `Filter` directive runs an external command and then sends the data through the external command before processing that data in the proxy. This process is accomplished using the `pre-filter` function.

Route Directive

The `Route` directive specifies information about where the proxy server should route requests.

Changes in Function Flow

Sometimes the function flow changes from the normal request-handling process. This change happens during internal redirects, restarts, and URI translation functions.

Internal Redirects

An example of an internal redirect is a servlet include or forward. Because there is no exposed NSAPI function to handle an internal redirect, when an internal redirect occurs, the request structure is copied into `rq->orig_rq`.

Restarts

A restart occurs when a `REQ_RESTART` is returned from a `PathCheck` or `Service` function, for example, when a CGI is redirected using a relative path.

On a restart, much of the request is cleared. Some elements of the HTTP request (`rq->reqpb`), the server's "working" variables (`rq->vars`), and response headers (`rq->rvhdrs`) are cleared. The method, protocol, and `clf-request` variables from `rq->reqpb` are saved. The saved variables are put back into the data structure. The new URI is inserted (if the new URI contains a query string, that too is inserted) into `rq->reqpb`. The parameter `rq->rq_attr.req_restarted` is set to 1.

URI Translation

At times you might need to find the physical path for a URI without actually running a request. The function `request_translate_uri` creates a new request structure puts the structure through the `AuthTrans` and `NameTrans` stages to get the physical path. Thereafter, the new request is freed.

Syntax Rules for Editing obj.conf

Several rules are important in the `obj.conf` file. Be very careful when editing this file. Simple mistakes can make the server fail to start or operate correctly.

Caution – Do not remove any directives from any `obj.conf` files that are present in the `obj.conf` file that exists when you first install Sun Java System Web Proxy Server. The server might not function properly.

Order of Directives

The order of directives is important because the server executes them in the order they appear in `obj.conf`. The outcome of some directives affect the execution of other directives.

For `PathCheck` directives, the order within the `PathCheck` section is not so important, since the server executes all `PathCheck` directives. However, the order within the `ObjectType` section is very important because if an `ObjectType` directive sets an attribute value, no other `ObjectType`

directive can change that value. For example, if the default `ObjectType` directives were listed in the following reverse order every request would have its `type` value set to `text/plain`, and the server would never have a chance to set the `type` according to the extension of the requested resource.

```
ObjectType fn="force-type" type="text/plain"  
ObjectType fn="type-by-extension"
```

Similarly, the order of directives in the `Service` section is very important. The server executes the first `Service` directive that matches the current request and does not execute any others.

Parameters

The number and names of parameters depend on the function. The order of parameters on the line is not important.

Case Sensitivity

Items in the `obj.conf` file are case sensitive, including function names, parameter names, many parameter values, and path names.

Separators

Function names can be composed only of letters, digits, and underscores. You may use the hyphen (-) character in the configuration file in place of underscore (_) for your C code function names. This rule is only true for function names.

Quotation Marks

Quotation Marks (") are required around value strings only when a space is included in the string. Otherwise quotation marks are optional. Each open-quote mark must be matched by a close-quote mark.

Spaces

- Spaces are not allowed at the beginning of a line except when continuing the previous line.
- Spaces are not allowed before or after the equal (=) sign that separates the name and value.
- Spaces are not allowed at the end of a line or on a blank line.

Line Continuation

A long line may be continued on the next line by beginning the next line with a space or tab.

Path Names

Always use forward slashes (/) rather than backslashes (\\) in path names under Windows. The backslash character escapes the next character.

Comments

Comments begin with a pound (#) sign. If you manually add comments to obj.conf and then use the Server Manager interface to make changes to your server, the Server Manager will wipe out your comments when it updates obj.conf.

About obj.conf Directive Examples

Every line in the obj.conf file begins with one of the following keywords:

```
Init
AuthTrans
  NameTrans
  PathCheck
  ObjectType
  InputOutputService
AddLog
Error
Connect
DNS
Filter
Route
<Object>
</Object>
```

If any line of any example begins with a different word in this manual, the line is wraps in a different way that in the actual file. In some cases, this wrapping is due to line-length limitations imposed by the PDF and HTML formats of the manuals.

For example, the following directive is contained on one line in the actual obj.conf file:

```
Init fn="flex-init" access="$accesslog" format.access="%Ses->client.ip%
  - %Req->vars.auth-user% [%SYSDATE%] '%Req->reqpb.clf-request%'
  %Req->srvhdrs.clf-status% %Req->srvhdrs.content-length%"
```

Predefined SAFs in the obj . conf File

This chapter describes the standard directives and predefined Server Application Functions (SAFs) that are used in the obj . conf file to give instructions to the server.

This chapter describes functions that are part of the core functionality of the Sun Java System Web Proxy Server. It does not include functions that are available only if additional components, such as server-parsed HTML, are enabled.

This chapter covers the following stages:

- “Init Functions” on page 96
- “AuthTrans” on page 134
- “NameTrans” on page 146
- “PathCheck” on page 159
- “ObjectType” on page 177
- “Input” on page 196
- “Output” on page 199
- “Service” on page 202
- “AddLog” on page 228
- “Error” on page 232
- “Connect” on page 236
- “DNS” on page 237
- “Filter” on page 240
- “Route” on page 242

Each SAF has its own arguments, which are passed to it by a directive in obj . conf. Every SAF is also passed additional arguments that contain information about the request (such as what resource was requested and what kind of client requested it), and any other server variables created or modified by SAFs called by previously invoked directives. Each SAF may examine, modify, or create server variables. Each SAF returns a result code that tells the server whether it succeeded, did nothing, or failed.

For an alphabetical list of predefined SAFs, see [Appendix D, “List of Predefined SAFs.”](#)

Server Application Functions (SAFs)

The following table lists the SAFs that can be used with each directive.

TABLE 5-1 Available Server Application Functions (SAFs) per Directive

Directive	Server Application Functions
“Init Functions” on page 96	“define-perf-bucket” on page 97
	“flex-init” on page 98
	“flex-rotate-init” on page 102
	“host-dns-cache-init” on page 103

Bucket Parameter

The following performance buckets are predefined in the Sun Java System Web Proxy Server:

- The default-bucket records statistics for the functions not associated with any user-defined or built-in bucket.

- The `all-requests` bucket records `.perf` statistics for all NSAPI SAFs, including SAFs in the `default-bucket`.

You can define additional performance buckets in the `magnus.conf` file. For more information, see the descriptions of the `perf-init` and `define-perf-bucket` functions.

You can measure the performance of any SAF in `obj.conf` by adding a `bucket=`*bucket-name* parameter to the function, for example, `bucket=cache-bucket`.

To list the performance statistics, use the “[service-dump](#)” on [page 223](#) Service function.

As an alternative, you can use the “[stats-xml](#)” on [page 226](#) Service function to generate performance statistics. Use of buckets is optional.

For more information about performance buckets, see *Sun Java System Web Proxy Server 4.0.8 Administration Guide*.

Init Functions

The Init functions load and initialize server modules and plug-ins, and initialize log files.

Syntax

```
Init fn=function-name [parm1=value1]...[parmN=valueN]
```

`function-name` identifies the server initialization function to call. These functions shouldn't be called more than once.

`parm=value` pairs are values for function-specific parameters. The number of parameters depends on the function you use. The order of the parameters doesn't matter. The functions of the **Init** directive listed here are described in detail in the following sections that follow.

- “[define-perf-bucket](#)” on [page 97](#) - Creates a performance bucket.
- “[flex-init](#)” on [page 98](#) - Initializes the flex-log flexible access logging feature
- “[flex-rotate-init](#)” on [page 102](#) - Enables rotation for flexible logs.
- “[host-dns-cache-init](#)” on [page 103](#) - Caches host names of the origin servers.
- “[icp-init](#)” on [page 104](#) - Initializes the ICP feature.
- “[init-clf](#)” on [page 105](#) - Initializes the Common Log File subsystem.
- “[init-filter-order](#)” on [page 106](#) - Controls the position of specific filters within filter stacks.
- “[init-j2ee](#)” on [page 107](#) - Initializes the Java subsystem. This function is applicable only to the Administration Server.
- “[init-proxy](#)” on [page 107](#) - Initializes the networking code used by the proxy.

- “[init-uhome](#)” on page 108 - Loads user home directory information.
- “[init-url-filter](#)” on page 109 - Specifies one or more filter files of URLs. A filter file is a file that contains a list of URLs.
- “[ip-dns-cache-init](#)” on page 109 - Configures DNS caching.
- “[load-modules](#)” on page 110 - Instructs the server to load functions from a shared object file.
- “[load-types](#)” on page 111 - Maps file extensions to MIME types.
- “[nt-console-init](#)” on page 112 - Enables the Windows console, which is the command-line shell that displays standard output and error streams.
- “[pa-init-parent-array](#)” on page 112 - Initializes a parent array member and specifies information about the PAT file for the parent array of which it is a member.
- “[pa-init-proxy-array](#)” on page 114 - Initializes a proxy array member and specifies information about the PAT file for the array of which it is a member.
- “[perf-init](#)” on page 116 - Enables system performance measurement through performance buckets.
- “[pool-init](#)” on page 116 - Configures pooled memory allocation.
- “[register-http-method](#)” on page 117 - Enables you to extend the HTTP protocol by registering new HTTP methods.
- “[stats-init](#)” on page 118 - Enables reporting of performance statistics in XML format.
- “[suppress-request-headers](#)” on page 118 - Configures the proxy server to remove outgoing headers from the request.
- “[thread-pool-init](#)” on page 119 - Configures an additional thread pool.
- “[tune-cache](#)” on page 120 - Enables you to tune the performance of your proxy server’s cache.
- “[tune-proxy](#)” on page 121 - Enables you to tune the performance of your proxy server. You should not change the default settings.
- “[um-define-junction](#)” on page 121 - Defines a URL Mapping that will be enforced by the “URL Mapping” layer.
- “[um-init](#)” on page 124 - Initializes the URL Mapping module.
- “[um-load-parser-config](#)” on page 125 - Loads a parser configuration into memory.

define-perf-bucket

Applicable in `Init`-class directives.

The `define-perf-bucket` function creates a performance bucket that you can use to measure the performance of SAFs in `obj.conf`.

Parameters

The following table describes parameters for the `define-perf-bucket` function.

TABLE 5-2 `define-perf-bucket` Parameters

Parameter	Description
<code>name</code>	Name for the bucket (for example, <code>cgi-bucket</code>)
<code>description</code>	Description of what the bucket measures (for example, CGI Stats)

Example

```
Init fn="define-perf-bucket" name="cgi-bucket" description="CGI Stats"
```

See Also

[“perf-init” on page 116](#)

flex-init

Applicable in `Init-class` directives.

The `flex-init` function opens the named log file to be used for flexible logging and establishes a record format for it. The log format is recorded in the first line of the log file. You cannot change the log format while the log file is in use by the server.

The `flex-log` function, which is applicable in `AddLog-class` directives, writes entries into the log file during the `AddLog` stage of the request-handling process.

The log file stays open until the server is shut down or restarted, at which time all logs are closed and reopened.

Note – If the server has `AddLog`-stage directives that call `flex-log`, the flexible log file must be initialized by `flex-init` during server initialization.

You may specify multiple log file names in the same `flex-init` function call. Use multiple `AddLog` directives with the `flex-log` function to log transactions to each log file.

The `flex-init` function may be called more than once. Each new log file name and format is added to the list of log files.

If you move, remove, or change the currently active log file without shutting down or restarting the server, client accesses might not be recorded. To save or backup the currently active log file, rename the file and then restart the server. The server first looks for the log file by name, and if it doesn't find that name, it creates a new file. The renamed original log file is left for you to use.

For information on rotating log files, see “[flex-rotate-init](#)” on page 102.

The `flex-init` function has three parameters: one that names the log file, one that specifies the format of each record in that file, and one that specifies the logging mode.

Parameters

The following table describes parameters for the `flex-init` function.

TABLE 5-3 flex-init Parameters

Parameter	Description
<code>logFileName</code>	<p>The name of the parameter is the name of the log file. The value of the parameter specifies either the full path to the log file or a file name relative to the server's logs directory. For example:</p> <pre>access="/usr/netscape/server4/https-servername /logs/access"mylogfile = "log1"</pre> <p>The log file name is a parameter to the <code>flex-log</code> function, which is applicable in <code>AddLog</code>-class directives.</p>
<code>buffer-size</code>	Specifies the size of the global log buffer. The default is 8192.
<code>buffers-per-file</code>	<p>Specifies the number of buffers for a given log file. The default value is determined by the server.</p> <p>Access log entries can be logged in strict chronological order by using a single buffer per log file. Add <code>buffers-per-file="1"</code> to the <code>Init fn="flex-log-init"</code> line in <code>magnus.conf</code>. This setting ensures that requests are logged in chronological order. This approach results in decreased performance when the server is under heavy load.</p>
<code>format.logFileName</code>	<p>Specifies the format of each log entry in the log file.</p> <p>For information about the format, see the “More on Log Format” section below.</p>
<code>no-format-str.access</code>	<p>Specifies whether to include the format string in the log file. You can choose <code>yes</code> or <code>no</code>.</p> <p>If you are using the Proxy Server's log analyzer, you should include a format string. If you are using a third-party analyzer, you may not want to include a format string in your log file.</p>

Log Format

The `flex-init` function recognizes anything contained between percent signs (%) as the name portion of a name-value pair stored in a parameter block in the server. (The one exception to this rule is the `%SYSDATE%` component, which delivers the current system date.) `%SYSDATE%` is formatted using the time format `%d/%b/%Y:%H:%M:%S` plus the offset from GMT.

Any additional text is treated as literal text, so you can add to the line to make it more readable. Typical components of the formatting parameter are listed in the following “flex-init” on page 98. Components that contain spaces should be bounded by escaped quotation marks (\”).

If no format parameter is specified for a log file, the common log format is used:

```
"%Ses->client.ip% - %Req->vars.auth-user% [%SYSDATE%]
\\"%Req->reqpb.clf-request%" %Req->srvhdrs.clf-status%
%Req->srvhdrs.content-length"
```

You can now log cookies by logging the Req->headers.cookie.name component.

In the following table, the components that are enclosed in escaped double quotation marks (\”) are the ones that could potentially resolve to values that contains spaces.

TABLE 5-4 Typical Components of flex-init Formatting

Flex-log Option	Component
Client host name (unless iponly is specified in flex-log or DNS name is not available) or IP address	%Ses->client.ip%
Client DNS name	%Ses->client.dns%
System date	%SYSDATE%
Status	%Req->srvhdrs.clf-status%
Response content length	%Req->srvhdrs.content-length%
Response content type	%Req->srvhdrs.content-type%
Referer header	\\"%Req->headers.referer%"
User-agent header	\\"%Req->headers.user-agent%"
HTTP method	%Req->reqpb.method%
HTTP URI	%Req->reqpb.uri%
HTTP query string	%Req->reqpb.query%
HTTP protocol version	%Req->reqpb.protocol%
DNS Time	%Req->vars.xfer-time-dns%
	Time required for Proxy to complete a DNS lookup and to attempt to connect to the server.

TABLE 5-4 Typical Components of flex-init Formatting (Continued)

Flex-log Option	Component
Connect Wait Time	%Req->vars.xfer-time-cwait% Time required for Proxy to establish a TCP/IP connection to the server and send a request.
Full Wait Time	%Req->vars.xfer-time-fwait% Time that elapses between the moment the proxy establishes a connection to a server and the moment that it receives its last packet of response.
Initial Wait Time	%Req->vars.xfer-time-iwait% Time for Proxy to receive the first packet of response from the server after the proxy sends its request.
Accept header	%Req->headers.accept%
Date header	%Req->headers.date%
If-Modified-Since header	%Req->headers.if-modified-since%
Authorization header	%Req->headers.authorization%
Any header value	%Req->headers.headername%
Name of authorized user	%Req->vars.auth-user%
Value of a cookie	%Req->headers.cookie.name%
Value of any variable in Req->vars	%Req->vars.varname%
Duration	%duration% Time in microseconds that the server spent handling the request. Statistics must be enabled for the server instance before %duration% can be used. For information about enabling statistics, see the Sun Java System Web Proxy Server 4.0.8 Administration Guide .

Examples

The first example below initializes flexible logging into the file `<install-root><instance-directory>/logs/access`.

This example shows the default format, which corresponds to the Common Log Format (CLF).

The first six elements of any log should always be in this format, because a number of log analyzers expect matching output.

```
Init fn="flex-init" access="$accesslog" format.access="%Ses->client.ip%
- %Req->vars.auth-user% [%SYSDATE%] '%Req->reqpb.clf-request%'
%Req->srvhdrs.clf-status% %Req->srvhdrs.content-length%"
```

This example will record the following items:

- IP or host name, followed by the three characters “ - ”
- User name, followed by the two characters “ [”
- System date, followed by the two characters “] ”
- Full HTTP request in quotes, followed by a single space
- HTTP result status in quotes, followed by a single space
- Content length

The second example initializes flexible logging into the file `<install-root><instance-directory>/logs/extended`.

```
Init fn=flex-init extended="<install-root><instance-directory>
/logs/extended" format.extended="%Ses->client.ip% - %Req->vars.auth-user
% [%SYSDATE%]   \\"%Req->reqpb.clf-request%\\" %Req->srvhdrs.clf-status%
%Req->srvhdrs.content-length% %Req->headers.referrer%
\\"%Req->headers.user-agent%\\" %Req->reqpb.method%
%Req->reqpb.uri% %Req->reqpb.query% %Req->reqpb.protocol%"
```

The third example shows how logging can be tuned to prevent request handling threads from making blocking calls when writing to log files. Instead you can delegate these calls to the log flush thread.

Doubling the default size of the `buffer-size` and `num-buffers` parameters and lowering the value of the `LogFlushInterval` directive in `magnus.conf` to 4 seconds frees the request-handling threads to quickly write the log data.

```
Init fn=flex-init buffer-size=16384 num-buffers=2000 access="
/<install-root><instance-directory>/logs/access"
format.access="%Ses->client.ip% - %Req->vars.auth-user% [%SYSDATE%]
\\"%Req->reqpb.clf-request%\\" %Req->srvhdrs.clf-status%
%Req->srvhdrs.content-length%"
```

[“flex-rotate-init” on page 102](#)

flex-rotate-init

Applicable in `Init`-class directives.

The `flex-rotate-init` function configures log rotation for all log files on the server, including error logs and the `common-log`, `flex-log`, and `record-useragent` `AddLog` SAFs. Call this function in the `Init` section of `magnus.conf` before calling [“flex-init” on page 98](#). The `flex-rotate-init` function enables you to specify a time interval for rotating log files. At the specified time interval, the server moves the log file to a file whose name indicates the time of the

move. The log functions in the `AddLog` stage in `obj.conf` then start logging entries in a new log file. The server does not need to be shut down while the log files are being rotated.

Note – The server keeps all rotated log files so clean them up as necessary to free disk space.

By default, log rotation is disabled.

Parameters

The following table describes parameters for the `flex-rotate-init` function.

TABLE 5-5 `flex-rotate-init` Parameters

Parameter	Description
<code>rotate-start</code>	Indicates the time to start rotation. This value is a four-digit string indicating the time in 24-hour format. For example, 0900 indicates 9 a.m., while 1800 indicates 9 p.m.
<code>rotate-interval</code>	Indicates the number of minutes to elapse between each log rotation.
<code>rotate-access</code>	(Optional) Determines whether <code>common-log</code> , <code>flex-log</code> , and <code>record-useragent</code> logs are rotated (AddLog SAFs). Values are <code>yes</code> (the default), and <code>no</code> .
<code>rotate-error</code>	(Optional) Determines whether error logs are rotated. Values are <code>yes</code> (the default), and <code>no</code> .
<code>rotate-callback</code>	(Optional) Specifies the file name of a user-supplied program to execute following log file rotation. The program is passed the post-rotation name of the rotated log file as its parameter.

Example

This example enables log rotation, starting at midnight and occurring every hour.

```
Init fn=flex-rotate-init rotate-start=2400 rotate-interval=60
```

See Also

[“flex-init” on page 98](#)

host-dns-cache-init

Applicable in `Init`-class directives.

The `host-dns-cache-init` function is used to cache host names of the origin servers. If DNS lookup are caches, then when the server gets a request from the client servers, it caches the server's host name information.

Parameters

The following table describes parameters for the `dns-cache-init` function.

TABLE 5-6 host-dns-cache-init parameters

Parameter	Description
<code>cache-size</code>	(Optional) Specifies how many entries are contained in the cache. Acceptable values are 32 to 32768. The default value is 1024.
<code>expire</code>	(Optional) Specifies how long in seconds before a cache entry should expire. Acceptable values are 1 to 31536000 (1 year). The default value is 1200 seconds (20 minutes).
<code>negative-dns-cache</code>	Enables or disables the caching of invalid host names. The default value is <code>yes</code> .

Example

```
Init fn="host-dns-cache-init" cache-size="2140" expire="600"
```

icp-init

Applicable in `Init-class` directives.

The `icp-init` function enables and initializes ICP. ICP (Internet Cache Protocol) is an object location protocol that enables caches to communicate with one another. Caches can use ICP to send queries and replies about the existence of cached URLs and about the best locations from which to retrieve those URLs.

Syntax

```
Init fn=icp-init
    config_file=file name    status=on|off
```

Parameters

The following table describes parameters for the `icp-init` function.

TABLE 5-7 icp-init parameters

Parameter	Description
<code>config_file</code>	The name of the ICP configuration file.
<code>status</code>	Specifies whether ICP is enabled or disabled. Possible values are: <ul style="list-style-type: none"> ■ <code>on</code> means that ICP is enabled. ■ <code>off</code> means that ICP is disabled.

Example

```
Init fn=icp-init
    config_file=icp.conf
    status=on
```

init-clf

Applicable in `Init-class` directives.

The `init-clf` function opens the named log files to be used for common logging. The `common-log` function writes entries into the log files during the `AddLog` stage of the request-handling process. The log files stay open until the server is shut down, at which time the log files are closed or the server is restarted. If the server is restarted the log files are closed and reopened.

Note – If the server has an `AddLog-stage` directive that calls `common-log`, common log files must be initialized by `init-clf` during initialization.

Note – If this function is called more than once, the new call will replace log file names from all previous calls.

If you move, remove, or change the log file without shutting down or restarting the server, client accesses might not be recorded. To save or backup a log file, rename the file and for UNIX, send the `-HUP` signal. Then restart the server. The server first looks for the log file by name. If the server does not find the file, it creates a new one (the renamed original log file is left for you to use).

For information on rotating log files, see [“flex-rotate-init” on page 102](#).

Parameters

The following table describes the parameters for the `init-clf` function.

TABLE 5-8 `init-clf` Parameters

Parameter	Description
<i>logFileName</i>	<p>The name of the parameter is the name of the log file. The value of the parameter specifies either the full path to the log file or a file name relative to the server's logs directory. For example:ini</p> <pre>access="/usr/netscape/server4/https-servername/logs/access"mylogfile = "log1"</pre> <p>The log file name is a parameter to the <code>common-log</code> function, which is applicable in <code>AddLog-class</code> directives.</p>

Examples

```
Init fn=init-clf access=/usr/netscape/server4/https-boots/logs/access
Init fn=init-clf templog=/tmp/mytemplog templog2=/tmp/mytemplog2
```

See Also

[“flex-rotate-init” on page 102](#)

init-filter-order

Applicable in `Init-class` directives.

The `init-filter-order` `Init SAF` can be used to control the position of specific filters within filter stacks. For example, `init-filter-order` can be used to ensure that a filter that converts outgoing XML to XHTML is inserted above a filter that converts outgoing XHTML to HTML.

Filters that appear higher in the filter stack are given an earlier opportunity to process outgoing data. Filters that appear lower in the filter stack are given an earlier opportunity to process incoming data.

Filter developers use the `filter_create` function to define the filter's position in the filter stack. For example, filters that translate content from XML to HTML are placed higher in the filter stack than filters that compress data for transmission. `init-filter-order` can be used to override the position defined by the filter developer.

When two or more filters are defined to occupy the same position in the filter stack, filters that were inserted later will appear higher than filters that were inserted earlier. The order of `Input fn="insert-filter"` and `Output fn="insert-filter"` directives in `obj.conf` becomes important. For example, consider two filters, `xhtml-to-html` and `xml-to-xhtml`, which convert XHTML to HTML and XML to XHTML, respectively. Because both filters transform data from one format to another, they may be defined to occupy the same position in the filter stack. To transform XML documents to XHTML and then to HTML before sending the data to the client, `Output fn="insert-filter"` directives in `obj.conf` would appear in the following order:

```
Output fn="insert-filter" filter="xhtml-to-html"
Output fn="insert-filter" filter="xml-to-xhtml"
```

Administrators should use the order of `Input fn="insert-filter"` and `Output fn="insert-filter"` directives in `obj.conf` to control the position of filters in the filter stack. `init-filter-order` should only be used to address specific filter interoperability problems.

The load-module SAFs that create the filters should be called before `init-filter-order` attempts to order them.

Parameters

The following table describes the parameter for the `init-filter-order` function.

TABLE 5-9 `init-filter-order` Parameters

Parameter	Description
<code>filters</code>	Comma-separated list of filters in the order they should appear within a filter stack, listed from highest to lowest.

Example

```
Init fn="init-filter-order" filters="xml-to-xhtml,xhtml-to-html,
    http-compression"
```

init-j2ee

This function is applicable only to the Administration Server in `Init-class` directives..

The `init-j2ee` function initializes the Java subsystem.

Parameters

This function requires a `LateInit=yes` parameter.

Example

```
Init fn="load-modules" shlib="install_dir/lib/libj2eeplugin.so"
    funcs="init-j2ee,ntrans-j2ee,service-j2ee,error-j2ee"
    shlib_flags="(global|now)"
Init fn="init-j2ee" LateInit=yes
```

init-proxy

Applicable in `Init-class` directives.

The `init-proxy` function initializes the Proxy Server's internal settings. This function is called during the initialization of the Proxy Server, but it should also be specified in the `obj.conf` to ensure that the values are initialized properly.

Syntax

```
Init fn=init-proxy
    timeout=<seconds>
    timeout-2=seconds
```

Parameters

The following table describes parameters for the `init-proxy` function.

TABLE 5-10 `init-proxy` Parameters

Parameter	Description
<code>timeout</code>	The number of seconds of delay allowed between consecutive network packets received from the remote server. If the delay exceeds the timeout, the connection is dropped. The default is 120 seconds (2 minutes). This value is not the maximum time allowed for an entire transaction, but the delay between the packets. For example, the entire transaction can last 15 minutes, as long as at least one packet of data is received before each timeout period.
<code>timeout-2</code> (timeout after interrupt)	The timeout after interrupt value indicates how much time the Proxy Server has to continue writing a cache file after a client has aborted the transaction. In other words, if the Proxy Server has almost finished caching a document and the client aborts the connection, the server can continue caching the document until it reaches the timeout after interrupt value. The highest recommended timeout after interrupt value is 5 minutes. The default value is 15 seconds.

Example

```
Init fn=init-proxy
    timeout=120
```

init-uhome

Applicable in `Init-class` directives.

UNIX Only. The `init-uhome` function loads information about the system's user home directories into internal hash tables. This process increases memory usage slightly, but improves performance for servers that have significant traffic to home directories.

Parameters

The following table describes the parameter for the `init-uhome` function.

TABLE 5-11 `init-uhome` parameters

Parameter	Description
<code>pwfile</code>	(Optional) Specifies the full file system path to a file other than <code>/etc/passwd</code> . If file name is not provided, the default UNIX path (<code>/etc/passwd</code>) is used.

Examples

```
Init fn=init-uhome
Init fn=init-uhome pwfile=/etc/passwd-http
```

init-url-filter

Applicable in `Init-class` directives.

The `init-url-filter` function specifies one or more filter files of URLs. A filter file is a file that contains a list of URLs.

Parameters

You can pass one or more parameters to this SAF and associate each parameter to a filter file of URLs. These parameter names may be used later in `url-filter` SAF to either allow or deny these filter files of URLs.

Example

```
PathCheck fn="init-url-filter" filt1="/path/to/filter/file1"
          filt2="/path/to/filter/file2" filt3="/path/to/filter/file3" etc...
```

ip-dns-cache-init

Applicable in `Init-class` directives.

The `ip-dns-cache-init` function specifies that DNS lookups should be cached when DNS lookups are enabled. If DNS lookups are cached, then when the server gets a client's host name information, it stores that information in the DNS cache. If the server requires information about the client in the future, the information is available in the DNS cache.

You may specify the size of the DNS cache and the time it takes before a cache entry becomes invalid. The DNS cache can contain 32 to 32768 entries. The default value is 1024 entries. Values for the time before a cache entry expires, specified in seconds can range from 1 second to 1 year. The default value is 1200 seconds (20 minutes).

Parameters

The following table describes parameters for the `ip-dns-cache-init` function.

TABLE 5-12 `ip-dns-cache-init` Parameters

Parameter	Description
<code>cache-size</code>	(Optional) Specifies how many entries are contained in the cache. Acceptable values are 32 to 32768. The default value is 1024.
<code>expire</code>	(Optional) Specifies the remaining time in seconds before a cache entry expires. Acceptable values are 1 to 31536000 (1 year); the default is 1200 seconds (20 minutes).

Example

```
Init fn="ip-dns-cache-init" cache-size="2140" expire="600"
```

load-modules

Applicable in `Init-class` directives.

The `load-modules` function loads a shared library or dynamic-link library (DLL) into the server code. Specified functions from the library can then be executed from any subsequent directives. Use this function to load new plug-ins or SAFs.

If you define your own SAFs, load them by using the `load-modules` function and specifying the shared library or DLL to load.

Parameters

The following table describes parameters for the `load-modules` function.

TABLE 5-13 `load-modules` Parameters

Parameter	Description
<code>shlib</code>	Specifies either the full path to the shared library or DLL, or a file name relative to the server configuration directory.

TABLE 5-13 load-modules Parameters (Continued)

Parameter	Description
funcs	Comma-separated list of the names of the functions in the shared library or DLL to be made available for use by other <code>Init</code> directives or by <code>Service</code> directives in <code>obj.conf</code> . The list should not contain any spaces. The dash (-) character may be used in place of the underscore (_) character in function names.
NativeThread	(Optional) Specifies which threading model to use. no causes the routines in the library to use user-level threading. yes enables kernel-level threading. The default is yes.
pool	Name of a custom thread pool, as specified in “ thread-pool-init ” on page 119 .

Examples

```
Init fn=load-modules shlib="C:/mysrvfns/corpfns.dll" funcs="moveit"
Init fn=load-modules shlib="/mysrvfns/corpfns.so"
    funcs="myinit,myservice"Init fn=myinit
```

load-types

Applicable in `Init`-class directives.

The `load-types` function scans a file that provide map filename extensions to MIME types. MIME types are essential to enable network navigation software to distinguish between file types. See [Chapter 6, “MIME Types,”](#) for more information.

Calling this function is crucial if you use Web Proxy Server Manager online forms or the FTP proxying capability.

Syntax

```
Init fn=load-types
    mime-types="mime.types"
```

This function loads the MIME type the `mime.types` file from the configuration directory, that contains the same directory `magnus.conf` and `obj.conf`. This function call is mandatory and in practice is always as shown in the syntax.

Parameters

The following table describes the parameter for the `load-types` function.

TABLE 5-14 load-types Parameters

Parameter	Description
mime-types	Specifies either the full path to the global MIME types file or a filename relative to the server configuration directory. The proxy server comes with a default file called mime.types.
local-types	Optional parameter to a file with the same format as the global MIME types file. This parameter is used to maintain types that are applicable only to your server.

Example

```
Init fn=load-types mime-types=mime.types
Init fn=load-types mime-types=/tp/mime.types \\  
    local-types=local.types
```

nt-console-init

Applicable in Init-class directives.

The `nt-console-init` function enables the Windows console, which is the command-line shell that displays standard output and error streams.

Parameters

The following table describes the parameter for the `nt-console-init` function.

TABLE 5-15 nt-console-init Parameters

Parameter	Description
stderr	Directs error messages to the Windows console. The required and only value is <code>console</code> .
stdout	Directs output to the Windows console. The required and only value is <code>console</code> .

Example

```
Init fn="nt-console-init" stdout=console stderr=console
```

pa-init-parent-array

Applicable in Init-class directives.

The `pa-init-parent-array` function initializes a parent array member and specifies information about the PAT file for the parent array of which it is a member.

Note – The `load modules` directive should come before the `pa-init-proxy-array` function in the `obj.conf` file.

Syntax

```
Init fn=pa-init-parent-array    set-status-fn=pa-set-member-status
    poll="yes|no"
    file="absolute filename"
    pollhost="host name"
    pollport="port number"
    pollhdrs="absolute filename"
    pollurl="url"
    status="on|off"
```

Parameters

The following table describes the parameter for the `pa-init-parent-array` function.

TABLE 5-16 `pa-init-parent-array` Parameters

Parameter	Description
<code>set-status-fn</code>	Specifies the function that sets the status for the member.
<code>poll</code>	Indicates whether the array member should poll for a PAT file. <ul style="list-style-type: none"> ■ <code>yes</code> means that the member should poll for the PAT file. A member should only poll for a PAT file if it is not the master proxy. The master proxy has a local copy of the PAT file, and therefore does not need to poll for it. ■ <code>no</code> means that the member should not poll for the PAT file. A member should not poll for the PAT file if it is the master proxy.
<code>file</code>	The full path name of the PAT file.
<code>pollhost</code>	The host name of the proxy to be polled for the PAT file. Specify this parameter only if the <code>poll</code> parameter is set to <code>yes</code> , meaning that the member is not the master proxy.
<code>pollport</code>	The port number on the poll host that should be contacted when polling for the PAT file. Specify this parameter only if the <code>poll</code> parameter is set to <code>yes</code> , meaning that the member is not the master proxy.

TABLE 5-16 pa-init-parent-array Parameters (Continued)

Parameter	Description
pollhdrs	The full path name of the file that contains any special headers that must be sent with the HTTP request for the PAT file. This parameter is optional and should be specified only if the poll parameter is set to yes, meaning that the member is not the master proxy.
pollurl	The URL of the PAT file to be polled for. Specify this parameter only if the poll parameter is set to yes, meaning that the member is not the master proxy.
status	Specifies whether the parent array member is on or off.

Example

The following example indicates that the member should not poll for the PAT file. This example would apply to a master proxy.

```
Init fn=pa-init-parent-array poll="no"
    file="c:/netscape/server/bin/proxy/pa1.pat"
```

The following example specifies that the member should poll for a PAT file. This member is not the master proxy.

```
Init fn=pa-init-parent-array poll="yes"
    file="c:/netscape/server/bin/proxy/pa2.pat"
    pollhost="proxy1" pollport="8080"
    pollhdrs="c:/netscape/server/proxy-name/parray/pa2.hdr"
    status="on" set-status-fn=set-member-status pollurl="/pat"
```

pa-init-proxy-array

Applicable in Init-class directives.

The pa-init-proxy-array function initializes a proxy array member and specifies information about the PAT file for the array of which it is a member.

Note – The load modules directive should come before the pa-init-proxy-array function in the obj.conf file.

Syntax

```
Init fn=pa-init-proxy-array set-status-fn=pa-set-member-status
    poll="yes|no"
    file="absolute filename"
```

```

pollhost="host name"
pollport="port number"
pollhdrs="absolute filename"
pollurl="url"
status="on|off"

```

Parameters

The following table describes the parameter for the `pa-init-proxy-array` function.

TABLE 5-17 `pa-init-proxy-array` Parameters

Parameter	Description
<code>set-status-fn</code>	Specifies the function that sets the status for the member.
<code>poll</code>	Indicates whether the array member should poll for a PAT file. <ul style="list-style-type: none"> ■ <code>yes</code> means that the member should poll for the PAT file. A member should only poll for a PAT file if it is not the master proxy. The master proxy has a local copy of the PAT file, and therefore does not need to poll for it. ■ <code>no</code> means that the member should not poll for the PAT file. A member should not poll for the PAT file if it is the master proxy.
<code>file</code>	The full path name of the PAT file.
<code>pollhost</code>	The host name of the proxy to be polled for the PAT file. Specify this parameter only if the <code>poll</code> parameter is set to <code>yes</code> , meaning that the member is not the master proxy.
<code>pollport</code>	The port number on the poll host that should be contacted when polling for the PAT file. Specify this parameter only specify if the <code>poll</code> parameter is set to <code>yes</code> , meaning that the member is not the master proxy.
<code>pollhdrs</code>	The full path name of the file that contains any special headers that must be sent with the HTTP request for the PAT file. This parameter is optional and should only be specified if the <code>poll</code> parameter is set to <code>yes</code> , meaning that the member is not the master proxy.
<code>pollurl</code>	The URL of the PAT file to be polled for. Specify this parameter only if the <code>poll</code> parameter is set to <code>yes</code> , meaning that the member is not the master proxy.
<code>status</code>	Specifies whether the parent array member is <code>on</code> or <code>off</code> .

Example

The following example tells the member not to poll for the PAT file. This example would apply to a master proxy.

```
Init fn=pa-init-proxy-array poll="no"
    file="c:/netscape/server/bin/proxy/pa1.pat"
```

The following example specifies that the member should poll for a PAT file. This member is not the master proxy.

```
Init fn=pa-init-proxy-array poll="yes"
    file="c:/netscape/server/bin/proxy/pa2.pat"
    pollhost="proxy1" pollport="8080"
    pollhdrs="c:/netscape/server/proxy-name/parray/pa2.hdr"
    status="on" set-status-fn=set-member-status pollurl="/pat"
```

perf-init

Applicable in Init-class directives.

The `perf-init` function enables system performance measurement through performance buckets.

Parameters

The following table describes the parameter for the `perf-init` function.

TABLE 5-18 `perf-init` parameters

Parameter	Description
<code>disable</code>	Flag to disable the use of system performance measurement via performance buckets. Should have a value of <code>true</code> or <code>false</code> . Default value is <code>true</code> .

Example

```
Init fn=perf-init disable=false
```

See Also

[“define-perf-bucket” on page 97](#)

pool-init

Applicable in Init-class directives.

The `pool-init` function changes the default values of pooled memory settings. The size of the free block list may be changed or pooled memory may be entirely disabled.

Memory allocation pools enable the server to run significantly faster. If you are programming with the NSAPI, note that `MALLOC`, `REALLOC`, `CALLOC`, `STRDUP`, and `FREE` work slightly differently if pooled memory is disabled. If pooling is enabled, the server automatically cleans up all memory allocated by these routines when each request completes. In most cases, this process will improve performance and prevent memory leaks. If pooling is disabled, all memory is global and no clean-up is required.

For persistent memory allocation, add the prefix `PERM_` to the name of each routine (`PERM_MALLOC`, `PERM_REALLOC`, `PERM_CALLOC`, `PERM_STRDUP`, and `PERM_FREE`).

Note – Any memory you allocate from `Init`-class functions will be allocated as persistent memory even if you use `MALLOC`. The server cleans up only the memory that is allocated while processing a request. Because `Init`-class functions are run before processing any requests, their memory is allocated globally.

Parameters

The following table describes the parameter for the `pool-init` function.

TABLE 5-19 `pool-init` Parameters

Parameter	Description
<code>free-size</code>	(Optional) Maximum size in bytes of free block list. Can not be greater than 1048576.
<code>disable</code>	(Optional) Flag to disable the use of pooled memory. Must have a value of <code>true</code> or <code>false</code> . Default value is <code>false</code> .

Example

```
Init fn=pool-init disable=true
```

register-http-method

Applicable in `Init`-class directives.

This function enables you to extend the HTTP protocol by registering new HTTP methods. You do not need to register the default HTTP methods.

Upon accepting a connection, the server checks whether the method it received is registered. If the server does not recognize the method, it returns a “501 Method Not Implemented” error message.

Parameters

The following table describes the parameter for the `register-http-method` function.

TABLE 5-20 register-http-method Parameters

Parameter	Description
methods	Comma-separated list of the names of the methods you are registering.

Example

The following example shows the use of `register-http-method` and a `Service` function for one of the methods.

```
Init fn="register-http-method" methods="MY_METHOD1,MY_METHOD2"
    Service fn="MyHandler" method="MY_METHOD1"
```

stats-init

Applicable in `Init-class` directives.

The `stats-init` function enables reporting of performance statistics in XML format. The report is generated by the `stats-xml` function in `obj.conf`.

Parameters

The following table describes parameters for the `stats-init` function.

TABLE 5-21 stats-init parameters

Parameter	Description
update-interval	Period in seconds between statistics updates within the server. Set higher for better performance, or lower for more frequent updates. The minimum value is 1. The default value is 5.
profiling	Enables NSAPI performance profiling using buckets if set to <code>yes</code> . This profiling can also be enabled through the “perf-init” on page 116 <code>Init</code> SAF. The default is <code>no</code> , which results in slightly better server performance.

Example

```
Init fn="stats-init" update-interval="5" virtual-servers="2000"
    profiling="yes"
```

suppress-request-headers

Applicable in `Init-class` and `ObjectType-class` directives.

If you specify this function at the `Init` stage, it applies to the entire proxy for all the requests.

If you specify this function at the `ObjectType` stage, you can control suppressing outgoing headers functionality for different objects in the `obj.conf` file.

The `suppress-request-headers` function configures the proxy server to remove outgoing headers from the request. This function accepts one or more `hdr` parameters through which you can specify multiple headers that you want to suppress.

For example, you might want to prevent the `from` and `Cookie` headers from being sent because the information reveals the user's credentials.

Parameters

The following table describes the parameter for the `suppress-request-headers` function.

TABLE 5-22 `suppress-request-headers` Parameters

Parameter	Description
<code>hdr</code>	Name of the HTTP request header to be suppressed.

Example

```
Init fn="suppress-request-headers" hdr="from" hdr="Cookie"
```

thread-pool-init

Applicable in `Init-class` directives.

The `thread-pool-init` function creates a new pool of user threads. A pool must be declared before it is used. To specify that a plug-in should use the new pool, specify the `pool` parameter when loading the plug-in with the `Init-class` function “[load-modules](#)” on page 110.

You can create a custom thread pool if a plug-in is not thread-aware. You can set the maximum number of threads in the pool to 1.

The older parameter `NativeThread=yes` always engages one default native pool, called `NativePool`.

The native pool on UNIX is normally not engaged, because all threads are OS-level threads. Using native pools on UNIX might introduce a small performance overhead because the pools require an additional context switch. However, the pool can be used to localize the `jvm.stickyAttach` effect or for other purposes, such as resource control and management, or to emulate single-threaded behavior for plug-ins.

On Windows, the default native pool is always being used. The Sun Java System Web Proxy Server uses fibers (user-scheduled threads) for initial request processing. Using custom additional pools on Windows introduces no additional overhead.

In addition, native thread pool parameters can be added to the `magnus.conf` file for convenience.

Parameters

The following table describes the Parameters for the `thread-pool-init` function.

TABLE 5-23 `thread-pool-init` Parameters

Parameter	Description
<code>name</code>	Name of the thread pool.
<code>maxthreads</code>	Maximum number of threads in the pool.
<code>minthreads</code>	Minimum number of threads in the pool.
<code>queueSize</code>	Size of the queue for the pool. If all threads in the pool are busy, further request-handling threads that require a thread from the pool wait in the pool queue. The number of request-handling threads that can wait in the queue is limited by the queue size. If the queue is full, the next request-handling thread that tries to access/denied the queue is therefore, the request is turned down, and the request-handling thread remains free to handle another request instead of becoming locked up in the queue.
<code>stackSize</code>	Stack size of each thread in the native (kernel) thread pool.

Example

```
Init fn=thread-pool-init name="my-custom-pool" maxthreads=5 minthreads=1
    queuesize=200Init fn=load-modules shlib="C:/mydir/myplugin.dll"
    funcs="tracker" pool="my-custom-pool"
```

See Also

[“load-modules” on page 110](#)

tune-cache

Applicable in `Init-class` directives.

The `tune-cache` function enables you to tune the performance of your proxy server’s cache. Do not change the default settings unless directed to do so by Sun Technical Support.

Syntax

```
Init fn=tune-cache
    byte-ranges
```

Parameters

The following table describes the parameter for the `tune-cache` function.

TABLE 5-24 `tune-cache` Parameters

Parameter	Description
<code>byte-ranges</code>	Determines whether the proxy is allowed to generate byte-range responses from the cache. By default, this feature is disabled.

Example

```
Init fn=tune-cache
    byte-ranges=off
```

tune-proxy

Applicable in `Init-class` directives.

The `tune-proxy` function enables you to tune the performance of your proxy server. You should not change the default settings.

Syntax

```
Init fn=tune-proxy
    ftp-listing-width=number
```

Parameters

The following table describes the parameter for the `tune-proxy` function.

TABLE 5-25 `tune-cache` parameters

Parameter	Description
<code>ftp-listing-width</code>	Increasing the width of FTP listings allows longer file names and thus reduces file name truncation. The default width is 80 characters.

Example

```
Init fn=tune-proxy
    ftp-listing-width=80
```

um-define-junction

Applicable in `Init-class` directive.

The `um-define-junction` function defines a URL Mapping or junction which will be enforced by the URL Mapping layer.

Junction definitions take two forms: junction definitions and junction mappings. A junction definition defines the overall settings for a junction. A junction mapping defines additional URL mappings that also apply to a given junction definition. They inherit all settings of the parent junction's definition, but they allow other URL mappings that are appropriate to a given junction to be associated with it. This becomes important for cookie management, as cookies from one junction will not be passed to another one.

Syntax

```
Init fn="um-define-junction"
```

Parameters

The following table describe parameters for the `um-define-junction` function.

The following parameters apply to both junction definitions and junction mappings.

TABLE 5-26 `um-define-junction` parameters

Parameter	Description
<code>junction-name</code>	The name of the junction. In the case of junction definitions, this name must be unique. In the case of junction mappings, this must be the name of an existing junction.
<code>fe-uri-prefix</code>	The front-end URI prefix that is to be associated with this junction definition or mapping. It must begin and end with a '/' character.
<code>be-url-prefix</code>	The back-end URL prefix that is to be associated with this junction definition or mapping. This is the back-end URL that will connect to the back-end application server. It must be of the form <code>http[s]://*/*</code> .

The following parameters apply only to junction mappings.

TABLE 5-27 Junction mapping parameters

Parameter	Description
<code>junction-mapping</code>	If this is set to yes, then this definition is taken to be a junction mapping.

The following parameters apply only to junction definitions.

TABLE 5-28 Junction definition parameters

Parameter	Description
<code>parser-config</code>	Specifies the parser configuration used for this junction. If not specified, the default parser configuration (the first parser configuration listed in <code>obj.conf</code>) is used.
<code>passthru-cookies</code>	Specifies a comma-separated list of cookie names is passed through to the junction without translation. This parameter is a junction-specific version of the <code>global-passthru-cookies</code> parameter of the <code>load-modules</code> function.
<code>has-javascript</code>	If set to <code>yes</code> , then JavaScript rewriting is enabled for all JavaScript content. Otherwise, JavaScript is passed without rewriting.
<code>onload-handler</code>	If set to <code>yes</code> , then a special bit of code is inserted into each request to this junction, which will set a cookie specifying the name of the junction. This cookie's name is defined in the <code>jct-cookie-name</code> of the <code>load-modules</code> function. By default, the cookie's name is <code>um_jct</code> .
<code>base-tag-handler</code>	If set to <code>yes</code> , then <code><base></code> tags receives special handling. Use care when combining this parameter with <code>has-javascript</code> , as the parser may mistake a static string value for a relative URL. Default value is <code>no</code> .
<code>rewrite-events</code>	If set to <code>no</code> , then event attributes within HTML tags are not rewritten. Default value is <code>yes</code> . This parameter operates independently of <code>has-javascript</code> , but is only relevant if <code>has-javascript</code> is set to <code>no</code> .
<code>redirect-without-trailing-slash</code>	If set to <code>yes</code> , then requests that match <code>fe-uri-prefix</code> without the trailing slash is immediately redirected to <code>fe-uri-prefix</code> with the trailing slash.
<code>add-headers</code>	Specifies a static list of headers to be added to all requests within this junction.
<code>lookup-equiv-hosts</code>	Equivalent host are strings that appear in the host part of a URL, which also represent the back-end server. By default, a new junction adds the back-end server's IP addresses to this list. Setting this option to <code>'no'</code> prevents this behavior.
<code>add-equiv-hosts</code>	Specifies a comma-delimited list of additional host names (and/or IP addresses) that are considered to be equivalent to this junction's host name. The host part of <code>be-url-prefix</code> is implicit, and does not need to be added.
<code>output-buffer-size</code>	Enables (or disables) output buffering. The proxy server employs HTTP chunking to send data to the client when it does not know the size of the content to be sent. Because the URL Mapping layer can send data in many small chunks, this can create a lot of CPU overhead on the proxy server machine. To alleviate this, URL Mapping offers its own output buffering so that data is sent to the client in fewer, larger chunks. To enable this, set <code>output-buffer-size</code> to a nonzero value.

TABLE 5-28 Junction definition parameters (Continued)

Parameter	Description
references-other-jcts	If set to yes, the other junctions are searched when trying to rewrite URLs for this junction. Use care when employing this option, as searching other junctions can be time-consuming in a configuration that contains many junctions.
use-template	If set to yes, and name is not set, then requests that match this junction is also assigned an object name that matches the junction's name. This allows additional directives to be executed only for this junction.
name	If set, then this overrides the object name for this junction. It implies use-template=yes.

Example

Junction definition:

```
Init fn="um-define-junction" jct-name="myJunction" fe-uri-prefix="/myj/"
  be-url-prefix="http://appserver.company.com/someApplication/"
```

Junction mapping:

```
Init fn="um-define-junction" jct-name="myJunction"
  fe-uri-prefix="/someApplication/cgi-bin/"
  be-url-prefix="http://appserver.company.com/someApplication/cgi-bin/"
  junction-mapping="yes"
```

um-init

Applicable in `Init-class` directives.

This parameter is mandatory. It must appear only once in the `obj.conf` file and before other URL Mapping-related directives.

Parameters

The following describes parameters for the `um-init` function:

TABLE 5-29 um-init parameters

Parameter	Description
<code>global-passthru-cookies</code>	Specifies a comma-delimited list of cookies that is always passed through to the back-end applications. If a cookie's name is followed by a ' ' character, then the cookie's name is changed to the name following the ' ' character.
<code>jct-cookie-name</code>	Sets the name of the cookie that stores the last-used back-end URL's name. By default, this parameter is set to <code>um_jct</code> .
<code>jct-cookie-prefix</code>	When cookies are set by applications within defined URL mappings, their names are prefixed by this string, followed by the name of the URL Mapping, followed by a '_' character. This setting tells the URL Mapping which cookies to pass to the back-end server on a given request.
<code>jct-cookie-domain</code>	If specified, the URL Mapping cookie (specified in <code>jct-cookie-name</code>) is set in this domain. Otherwise, the domain for the cookie is not set. You do not have to use this parameter.
<code>default-output-buffer-size</code>	Sets the default output buffer size for URL Mappings that does not explicitly set <code>output-buffer-size</code> (See <code>output-buffer-size</code> in Table 5-28). If not specified, then output buffering is disabled by default.

Example

```
Init fn=um-init
```

um-load-parser-config

Applicable in `Init-class` directive.

Parser configurations are text files that contain the names of tag attributes and tag events whose URLs are to be rewritten. It also contains strings that are considered to be illegal in URLs.

Each line of the parser configuration starts with either a tag name, or the string `**illegal`.

If the line starts with a tag name, the rest of the line is a space-separated list of attribute names that will be searched for URLs.

If the tag name is prefixed with a '*' character, then the rest of the line is a space-separated list of the event names that will be searched for URLs.

If an attribute or event name is prefixed with a '*' character, then the URL Mapping feature always attempts to rewrite URLs within that attribute or event as absolute URLs. Otherwise, the URLs are rewritten in the same form that they were specified (relative, server-relative, or absolute).

If the first word of the line is the string `**illegal`, then the rest of the line contains a space-separated list of strings that, if they are contained within a URL, are considered to be illegal. If a URL containing any of these strings is encountered, then the URL is replaced with the string `**ILLEGAL_URL**`.

All strings in this file are case-insensitive. Any lines that begin with a '#' character are considered to be comments, and are ignored. Blank lines are ignored.

Syntax

```
Init fn="um-load-parser-config"
```

Parameters

The following table describes parameters in the `um-load-parser-config` function.

TABLE 5-30 `um-load-parser-config` parameters

Parameter	Description
<code>file</code>	Specifies the location of the parser configuration file.
<code>config-name</code>	Specifies the name that is associated with this parser configuration. This setting is only necessary if you have multiple parser configurations in your <code>obj.conf</code> . If not specified, the configuration is assigned a name equal to the value of the file.

Example

```
Init fn="um-load-parser-config" file="/opt/SUNWproxy/proxy-server1/conf/proxy.cfg"
```

Summary of Init Functions

The following table lists the Init functions available in the `obj.conf` file:

TABLE 5-31 Init Functions

Function/Parameter	Allowed Values	Default Value	Description
<code>define-perf-bucket</code>			Creates a performance bucket. You can use this parameter to measure the performance of SAFs in <code>obj.conf</code> . This function only works if the <code>perf-init</code> function is enabled.

TABLE 5-31 Init Functions (Continued)

Function/Parameter	Allowed Values	Default Value	Description
<code>name</code>			A name for the bucket, for example, <code>cgi -bucket</code> .
<code>description</code>			A description of what the bucket measures, for example, <code>CGI Stats</code> .
<code>dns-cache-init</code>			Configures DNS caching.
<code>cache-size</code>	32 to 32768 (32K)	1024	(optional) Specifies how many entries are contained in the cache.
<code>expire</code>	1 to 31536000 seconds (1 year)	1200 seconds (20 minutes)	(optional) Specifies how long in seconds before a cache entry expires.
<code>flex-init</code>			Initializes the flexible logging system.
<code>logFileName</code>	A path or file name		The full path to the log file or a file name relative to the server's <code>logs</code> directory. In this example, the log file name is <code>access</code> and the path is <code>/logdir/access</code> : <code>access="/logdir/access"</code>
<code>format.logFileName</code>			Specifies the format of each log entry in the log file.
<code>relaxed.logFileName</code>	<code>true</code> , <code>on</code> , <code>yes</code> , or <code>1</code> ; <code>false</code> , <code>off</code> , <code>no</code> , or <code>0</code>		Turns on relaxed logging, which skips logging components that normally block static page acceleration if static page acceleration is enabled.
<code>buffer-size</code>	Number of bytes	8192	Specifies the size of the global log buffer.

TABLE 5-31 Init Functions (Continued)

Function/Parameter	Allowed Values	Default Value	Description
buffers-per-file	The lower bound is 1. Files must contain at least one buffer. The upper bound is dictated by the number of buffers that exist. The upper bound on the number of buffers that exist can be defined by the num-buffers parameter.	Determined by the server	Specifies the number of buffers for a given log file.
num-buffers		1000	Specifies the maximum number of logging buffers to use.
thread-buffer-size	Number of bytes	8192 (8 KB)	Specifies the size of the per thread log buffer.
flex-rotate-init			Enables rotation for logs.
rotate-start	A 4-digit string indicating the time in 24-hour format		Indicates the time to start rotation. For example, 0900 indicates 9 a.m. while 1800 indicates 9 p.m.
rotate-interval	Number of minutes		Indicates the number of minutes to elapse between each log rotation.
rotate-access	yes, no	yes	(optional) Determines whether common-log, flex-log, and record-useragent logs are rotated. For more information, see the Sun Java System Web Proxy Server 4.0.8 NSAPI Developer's Guide .
rotate-error	yes, no	yes	(optional) Determines whether error logs are rotated.

TABLE 5-31 Init Functions (Continued)

Function/Parameter	Allowed Values	Default Value	Description
rotate-callback	A path		(optional) Specifies the file name of a user-supplied program to execute after following log file rotation. The program passes the post-rotation name of the rotated log file as its parameter.
init-cgi			Changes the default settings for CGI programs.
timeout	Number of seconds	300	(optional) specifies how many seconds the server waits for CGI output before terminating the script.
cgistub-path			(optional) Specifies the path to the CGI stub binary. If not specified, iPlanet Web Server looks in the following directories, in the following order, relative to the server instance's config directory: <code>../private/Cgistub</code> , then <code>../bin/https/bin/Cgistub</code> . For information about installing an suid Cgistub, see the Sun Java System Web Proxy Server 4.0.8 NSAPI Developer's Guide .
<i>env-variable</i>			(optional) Specifies the name and value for an environment variable that the server places into the environment for the CGI.
init-clf			Initializes the Common Log subsystem.
<i>logFileName</i>	A path or file name		Specifies either the full path to the log file or a file name relative to the server's logs directory.
init-uhome			Loads user home directory information.
pwfile			(optional) Specifies the full file system path to a file other than <code>/etc/passwd</code> . If not provided, the default UNIX path (<code>/etc/passwd</code>) is used.

TABLE 5-31 Init Functions (Continued)

Function/Parameter	Allowed Values	Default Value	Description
load-modules			Loads shared libraries into the server.
shlib			Specifies either the full path to the shared library or dynamic link library, or specifies a file name relative to the server configuration directory.
funcs	A comma separated list with no spaces		A list of the names of the functions in the shared library or dynamic link library to be made available for use by other Init or Service directives. The dash (-) character can be used in place of the underscore (_) character in function names.
NativeThread	yes, no	yes	(optional) Specifies which threading model to use. no causes the routines in the library to use user-level threading. yes enables kernel-level threading.
pool			The name of a custom thread pool, as specified in thread-pool-init.
nt-console-init			Enables the NT console, which is the command-line shell that displays standard output and error streams.
stderr	console		Directs error messages to the NT console.
stdout	console		Directs output to the NT console.
perf-init			Enables system performance measurement via performance buckets.
disable	true, false	true	Disables the function when true.
pool-init			Configures pooled memory allocation.
free-size	1048576 bytes or less		(optional) Maximum size in bytes of free block list.

TABLE 5-31 Init Functions (Continued)

Function/Parameter	Allowed Values	Default Value	Description
<code>disable</code>	<code>true, false</code>	<code>false</code>	(optional) Flag to disable the use of pooled memory if <code>true</code> .
<code>register-http-method</code>			Enables you to extend the HTTP protocol by registering new HTTP methods.
<code>methods</code>	A comma-separated list		Names of the methods you are registering.
<code>stats-init</code>			Enables reporting of performance statistics in XML format.
<code>profiling</code>	<code>yes, no</code>	<code>no</code>	Enables NSAPI performance profiling using buckets. This setting can also be enabled through <code>perf-init</code> .
<code>update-interval</code>	1 or greater	5	The period in seconds between statistics updates within the server.
<code>virtual-servers</code>	1 or greater	1000	The maximum number of virtual servers for which statistics are tracked. This number should be set higher than the number of virtual servers configured.
<code>thread-pool-init</code>			Configures an additional thread pool.
<code>name</code>			Name of the thread pool.
<code>maxthreads</code>			Maximum number of threads in the pool.
<code>minthreads</code>			Minimum number of threads in the pool.
<code>queueSize</code>	Number of bytes		Size of the queue for the pool.
<code>stackSize</code>	Number of bytes		Stack size of each thread in the native (kernel) thread pool.
<code>tune-cache</code>			Enables you to tune the performance of your proxy server's cache.

TABLE 5-31 Init Functions (Continued)

Function/Parameter	Allowed Values	Default Value	Description
byte-ranges			Determines whether the proxy can generate byte-range responses from the cache.
tune-proxy			Enables you to tune the performance of your proxy server. Do not change the default settings.
ftp-listing-width		80 characters	Increasing the width of FTP listings allows longer file names and thus reduces file name truncation.
um-define-junction			Defines a URL Mapping that will be enforced by the "URL Mapping" layer.
jct-name			The name of the junction.
fe-uri-prefix			The front-end URI prefix that is associated with this junction definition or mapping.
be-url-prefix			The back-end URL prefix that is associated with this junction definition or mapping.
junction-mapping		yes	A junction mapping.
parser-config			Specifies the parser configuration that is used for this junction.
passthru-cookies			Specifies a comma-separated list of cookie names that is passed through to the junction without translation.
has-javascript		yes	Enables JavaScript rewriting for all JavaScript content.
onload-handler		um_jct	Inserts special bit of code into each request to this junction.
base-tag-handler		no	<base> tags receive special handling
rewrite-events		yes	Rewrite event attributes within HTML tags

TABLE 5-31 Init Functions (Continued)

Function/Parameter	Allowed Values	Default Value	Description
redirect-without-trailing-slash			Requests that match <code>fe-uri-prefix</code> without the trailing slash are immediately redirected to <code>fe-uri-prefix</code> with the trailing slash.
add-headers			Specifies a static list of headers to be added to all requests within this junction.
lookup-equiv-hosts		no	Prevent a new junction from adding the back-end server's IP addresses to this list.
add-equiv-hosts			Specifies a comma-delimited list of additional host names (and/or IP addresses) that are considered to be equivalent to this junction's host name.
output-buffer-size			Enables (or disables) output buffering. To enable this, set <code>output-buffer-size</code> to a nonzero value.
references-other-jcts			Searches other junctions while trying to rewrite URLs for this junction.
use-template			Assigns an object name (which matches the junction's name) to requests that match this junction.
name			Overrides the object name for this junction.
um-init			Initializes the URL Mapping module.
global-passthru-cookies			Specifies a comma-delimited list of cookies that are always passed through to the back-end applications.
jct-cookie-name		um_jct	Sets the name of the cookie that stores the last-used back-end URL's name.

TABLE 5-31 Init Functions (Continued)

Function/Parameter	Allowed Values	Default Value	Description
<code>jct-cookie-prefix</code>			Informs the URL Mapping layer which cookies to pass to the back-end server on a given request.
<code>jct-cookie-domain</code>			Sets the URL Mapping cookie in specified domain.
<code>default-output-buffer-size</code>			Sets the default output buffer size for URL Mappings that do not explicitly set <code>output-buffer-size</code> .
<code>um-load-parser-config</code>			Loads a parser configuration into memory.
<code>file</code>			Specifies the location of the parser configuration file.
<code>config-name</code>			Specifies the name associated with this parser configuration.

AuthTrans

AuthTrans stands for Authorization Translation. AuthTrans directives give the server instructions for checking authorization before allowing a client to access resources. AuthTrans directives work in conjunction with PathCheck directives. The AuthTrans function checks whether the user name and password associated with the request are acceptable. However, this function does not allow or deny access to the request. Access is handled by the PathCheck function.

The server handles the authorization of client users in two steps:

- “AuthTrans” on page 134 validates authorization information sent by the client in the Authorization header.
- “PathCheck” on page 159 checks that the authorized user is allowed access to the requested resource.

The authorization process is split into two steps so that multiple authorization schemes can be easily incorporated. This scheme also provides the flexibility to have resources that record authorization information but do not require it.

AuthTrans functions get the user name and password from the headers associated with the request. When a client initially makes a request, the user name and password are unknown so the AuthTrans functions and PathCheck functions work together to reject the request, because they cannot validate the user name and password. When the client receives the rejection, its

usual response is to present a dialog box asking for the user name and password to enter the appropriate realm. The client submits the request again, this time including the user name and password in the headers.

If more than one AuthTrans directive is present in `obj.conf`, each function is executed in order until one succeeds in authorizing the user.

The following AuthTrans-class functions are described in detail in this section:

- “[basic-auth](#)” on page 135 calls a custom function to verify user name and password. Optionally determines the user’s group.
- “[basic-ncsa](#)” on page 137 verifies user name and password against an NCSA-style or system DBM database. Optionally determines the user’s group.
- “[get-sslid](#)” on page 138 retrieves a string that is unique to the current SSL session and stores it as the `ssl-id` variable in the `Session->client` parameter block.
- “[match-browser](#)” on page 138 matches specific strings in the User-Agent string supplied by the browser, and then modifies the behavior of the Sun Java System Web Proxy Server based upon the results by setting values for specified variables.
- “[proxy-auth](#)” on page 141 translates authorization information provided through the basic proxy authorization scheme.
- “[set-variable](#)” on page 143 enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands.

basic-auth

Applicable in AuthTrans-class directives.

The `basic-auth` function calls a custom function to verify authorization information sent by the client. The `Authorization` header is sent as part of the basic server authorization scheme.

This function is usually used in conjunction with the PathCheck-class function “[require-auth](#)” on page 172.

Parameters

The following table describes the parameter for the `basic-auth` function.

TABLE 5-32 `basic-auth` parameters

Parameter	Description
<code>auth-type</code>	Specifies the type of authorization to be used. Set this value to <code>basic</code> .

TABLE 5-32 basic-auth parameters (Continued)

Parameter	Description
userdb	(Optional) Specifies the full path and file name of the user database to be used for user verification. This parameter is passed to the user function.
userfn	Name of the user custom function to verify authorization. This function must have been previously loaded with <code>load-modules</code> . It has the same interface as all of the SAFs, but it is called with the user name (<code>user</code>), password (<code>pw</code>), user database (<code>userdb</code>), and group database (<code>groupdb</code>) if supplied, in the <code>pb</code> parameter. The user function checks the name and password using the database and return <code>REQ_NOACTION</code> if they are not valid. The user function returns <code>REQ_PROCEED</code> if the name and password are valid. The <code>basic-auth</code> function then adds <code>auth-type</code> , <code>auth-user</code> (<code>user</code>), <code>auth-db</code> (<code>userdb</code>), and <code>auth-password</code> (<code>pw</code> , Windows only) to the <code>rq->vars</code> <code>pb</code> block.
groupdb	(Optional) Specifies the full path and file name of the user database. This parameter is passed to the group function.
groupfn	(Optional) Name of the group custom function that must have been previously loaded with <code>load-modules</code> . It has the same interface as all of the SAFs, but it is called with the user name (<code>user</code>), password (<code>pw</code>), user database (<code>userdb</code>), and group database (<code>groupdb</code>) in the <code>pb</code> parameter. It also has access to the <code>auth-type</code> , <code>auth-user</code> (<code>user</code>), <code>auth-db</code> (<code>userdb</code>), and <code>auth-password</code> (<code>pw</code> , Windows only) parameters in the <code>rq->vars</code> <code>pb</code> block. The group function determines the user's group using the group database, add it to <code>rq->vars</code> as <code>auth-group</code> , and return <code>REQ_PROCEED</code> if found. It returns <code>REQ_NOACTION</code> if the user's group is not found.
bucket	(Optional) Common to all <code>obj.conf</code> functions.

Examples

In `magnus.conf`:

```
Init fn=load-modules shlib=/path/to/mycustomauth.so funcs=hardcoded_auth
```

In `obj.conf`:

```
AuthTrans fn=basic-auth auth-type=basic userfn=hardcoded_authPathCheck
          fn=require-auth auth-type=basic realm="Marketing Plans"
```

See Also

[“require-auth” on page 172](#)

basic-nrsa

Applicable in AuthTrans-class directives.

The `basic-nrsa` function verifies authorization information sent by the client against a database. The Authorization header is sent as part of the basic server authorization scheme.

This function is usually used in conjunction with the PathCheck-class function “[require-auth](#)” on page 172.

Parameters

The following table describes the parameter for the `basic-nrsa` function.

TABLE 5-33 basic-nrsa Parameters

Parameter	Description
<code>auth-type</code>	Specifies the type of authorization to be used. Set this value to <code>basic</code> .
<code>dbm</code>	(Optional) Specifies the full path and base file name of the user database in the server’s native format. The native format is a system DBM file, which is a hashed file format that provides instantaneous access to large number of users. If you use this parameter, don’t use the <code>userfile</code> parameter as well.
<code>userfile</code>	(Optional) Specifies the full path name of the user database in the NCSA-style HTTPD user file format. This format consists of lines using the format <code>name:password</code> , where <code>password</code> is encrypted. If you use this parameter, don’t use <code>dbm</code> .
<code>grpfile</code>	(Optional) Specifies the NCSA-style HTTPD group file to be used. Each line of a group file consists of <code>group:user1 user2. userN</code> where each user is separated by spaces.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Examples

```
AuthTrans fn=basic-nrsa auth-type=basic dbm=/sun/server61/userdb/rsPathCheck
fn=require-auth auth-type=basic realm="Marketing Plans"AuthTrans
fn=basic-nrsa auth-type=basic userfile=/sun/server61/.htpasswd
grpfile=/sun/server61/.grpfilePathCheck fn=require-auth auth-type=basic
realm="Marketing Plans"
```

See Also

“[require-auth](#)” on page 172

get-sslid

Applicable in AuthTrans-class directives.

Note – This function is provided for backward compatibility only. The functionality of `get-sslid` has been incorporated into the standard processing of an SSL connection.

The `get-sslid` function retrieves a string that is unique to the current SSL session, and stores it as the `ssl-id` variable in the `Session->client` parameter block.

If the variable `ssl-id` is present when a CGI is invoked, it is passed to the CGI as the `HTTPS_SESSIONID` environment variable.

The `get-sslid` function has no parameters and always returns `REQ_NOACTION`. It has no effect if SSL is not enabled.

Parameters

The following table describes the parameter for the `get-sslid` function.

TABLE 5-34 `get-sslid` Parameters

Parameter	Description
bucket	(Optional) Common to all <code>obj.conf</code> functions.

match-browser

Applicable in all stage directives.

The `match-browser` SAF matches specific strings in the `User-Agent` string supplied by the browser `match-browser` then modifies the behavior of the Sun Java System Web Proxy Server based upon the results by setting values for specified variables.

Syntax

```
stage fn="match-browser" browser="string" name="value" [name="value" ...]
```

Parameters

The following table describes the parameter values for the `match-browser` function.

TABLE 5-35 match-browser Parameter Values

Value	Description
<i>stage</i>	Stage directive used in <code>obj.conf</code> processing (NameTrans, PathCheck, and so on). The <code>match-browser</code> function is applicable in all stage directives.
<i>string</i>	Wildcard pattern to compare against the User-Agent header, for example, <code>*Mozilla*</code> .
<i>name</i>	Variable to be changed. The <code>match-browser</code> SAF indirectly invokes the “set-variable” on page 143 SAF. For a list of valid variables, see “set-variable” on page 143 .
<i>value</i>	New value for the specified variable.

Example

The following AuthTrans directive instructs the Sun Java System Web Proxy Server to when the browser’s User-Agent header contains the string `Broken` or `broken`:

- Not send the SSL3 and TLS `close_notify` packet (see [“set-variable” on page 143](#)).
- Not honor requests for HTTP Keep-Alive (see [“set-variable” on page 143](#)).
- Use the HTTP/1.0 protocol rather than HTTP/1.1 (see [“set-variable” on page 143](#)).

```
AuthTrans fn="match-browser" browser="*[Bb]roken*" ssl-unclean-shutdown="true"
keep-alive="disabled" http-downgrade="1.0"
```

The following table describes the variables used in the example.

TABLE 5-36 Description of variables

Variable	Description
ssl-unclean-shutdown	<p>Microsoft Internet Explorer (MSIE) handling of SSL version 3 (SSLv3) and Transport Layer Security (TLS) keep-alive connections causes interoperability problems with non-Microsoft web servers such as iPlanet Web Server. When accessing a web server over SSL (https://) connections, Internet Explorer may display error messages or blank pages. iPlanet Web Server 6.0 SP2 introduces new functionality to work around this problem.</p> <p>Add the following line immediately below the <object name="default"> line in the server's obj.conf files:</p> <pre>AuthTrans fn="match-browser" browser="*MSIE*" ssl-unclean-shutdown="true"</pre> <p>This line instructs the server not send a close_notify alert when it closes SSLv3 connections from MSIE browsers. The close_notify packet is a required component of the SSLv3 and TLS specifications, but it is misinterpreted by MSIE.</p> <p>Note – Instructing iPlanet Web Server not send the close_notify packet may make MSIE vulnerable to a truncation attack.</p>
keep-alive	<p>Microsoft Internet Explorer (MSIE) handling of SSL version 3 (SSLv3) and Transport Layer Security (TLS) keep-alive connections causes interoperability problems with non-Microsoft web servers such as iPlanet Web Server. When accessing a web server over SSL (https://) connections, Internet Explorer may display error messages or blank pages. iPlanet Web Server 6.0 SP2 introduces new functionality to work around this problem.</p> <p>Add the following line immediately below the <object name="default"> line in the server's obj.conf files:</p> <pre>AuthTrans fn="match-browser" browser="*MSIE*" keep-alive="disabled"</pre> <p>This line instructs the server to disable keep-alive connections for Internet Explorer browsers.</p> <p>Note – Disabling keep-alive connections may decrease your server's performance.</p>

TABLE 5-36 Description of variables (Continued)

Variable	Description
http-downgrade	<p>Use the following methods to downgrade the HTTP version to 1.0:</p> <ul style="list-style-type: none"> ■ To downgrade requests for Microsoft Internet Explorer to HTTP/1.0 version, add the following to the obj.conf file: <pre>AuthTrans fn="match-browser" browser="*MSIE*" http-downgrade="1.0"</pre> ■ To downgrade all requests to HTTP/1.0 version, add the following to the magnus.conf file: <pre>HttpVersion 1.0</pre>

[“set-variable” on page 143](#)

proxy-auth

Applicable in AuthTrans-class directives.

The proxy-auth function of the AuthTrans directive translates authorization information provided through the basic proxy authorization scheme. This scheme is similar to the HTTP authorization scheme but doesn't interfere with it, so using proxy authorization doesn't block the ability to authenticate to the remote server.

This function is usually used with the PathCheck fn=require-proxy-auth function.

Syntax

```
AuthTrans fn=proxy-auth auth-type=basic dbm=full path name
AuthTrans fn=proxy-auth auth-type=basic userfile=full path name
          grpfile=full path name
```

Parameters

The following table describes the parameter values for the proxy-auth function.

TABLE 5-37 proxy-auth Parameter Values

Value	Description
auth-type	Specifies the type of authorization to be used. Set the type to “basic” unless you are running a UNIX proxy and are going to use your own function to perform authentication.

TABLE 5-37 proxy-auth Parameter Values (Continued)

Value	Description
dbm	Specifies the full path and base file name of the user database in the server's native format. The native format is a system DBM file, which is a hashed file format allowing instantaneous access to large number of users. If you use this parameter, don't use the userfile parameter.
userfile	Specifies the full path name of the user database in the NCSA-style httpd user file format. This format consists of name:password lines where password is encrypted. If you use this parameter, do not use dbm.
grpfile	(optional) Specifies the NCSA-style httpd group file to be used. Each line of a group file consists of group:user1 user2...userN, where each user is separated by spaces.

Example

A UNIX example:

```
AuthTrans fn=proxy-auth auth-type=basic
        dbm=/usr/ns-home/proxy-EXAMPLE/userdb/rs
```

A Windows NT example:

```
AuthTrans fn=proxy-auth auth-type=basic userfile=\\netscape\\server
        \\proxy-EXAMPLE\\.htpasswd grpfile=\\netscape\\server
        \\proxy-EXAMPLE\\.grpfile
```

You can have a user-provided function perform authentication by passing the user-fn parameter to the proxy-auth function.

Syntax

```
AuthTrans fn=proxy-auth auth-type=basic user-fn=your function userdb=full path name
```

Parameters

The following table describes the parameter values for the user provided proxy-auth function.

TABLE 5-38 user provided proxy-auth parameter values

Value	Description
user-fn	Specifies the name of the user-provided function that to be used to perform authentication in place of the built-in authentication. If authentication succeeds, the function returns REQ-PROCEED and if authentication fails, it returns REQ-NOACTION.

TABLE 5-38 user provided proxy-auth parameter values (Continued)

Value	Description
userdb	Specifies the full path and base file name of the user database in the server's native format. The native format is a system DBM file, which is a hashed file format allowing instantaneous access to large numbers of users.

set-variable

Applicable in all stage directives.

The `set-variable` function enables you to change server settings based upon conditional information in a request. It can also be used to manipulate variables in parameter blocks with the following commands:

- `insert-pblock="name=value"`
Adds a new value to the specified *pblock*.
- `set-pblock="name=value"`
Sets a new value in the specified *pblock*, replacing any existing values with the same name.
- `remove-pblock="name"`
Removes all values with the given name from the specified *pblock*.

Note – For more information about parameter blocks, see [Sun Java System Web Proxy Server 4.0.8 NSAPI Developer's Guide](#).

Syntax

```
stage fn="set-variable" [{insert|set|remove}-pblock="name=value"
...][name="value" ...]
```

Parameters

The following table describes parameter values for the `set-variable` function.

TABLE 5-39 set - variable parameter values

Value	Description
<i>pblock</i>	<p>One of the following Session/Request parameter block names:</p> <ul style="list-style-type: none"> ■ <i>client</i>: Contains the IP address of the client machine and the DNS name of the remote machine. For more information, see the description of the <code>Session->client</code> function in the “Data Structure Reference” chapter of the <i>Sun Java System Web Proxy Server 4.0.8 NSAPI Developer’s Guide</i>. ■ <i>vars</i>: Contains the server’s working variables, which includes anything not specifically found in the <code>reqpb</code>, <code>headers</code>, or <code>srvhdrs</code> pblocks. The contents of this pblock differ depending upon the specific request and the type of SAF. ■ <code>reqpb</code>: Contains elements of the HTTP request, which includes the HTTP method (GET, POST, and so on), the URI, the protocol (generally HTTP/1.0), and the query string. This pblock does not change during the request-response process. ■ <code>headers</code>: Contains all the request headers (such as <code>User-Agent</code>, <code>if-Modified-Since</code>, and so on) received from the client in the HTTP request. This pblock does not change during the request-response process. ■ <code>srvhdrs</code>: Contains the response headers (such as <code>Server</code>, <code>Date</code>, <code>Content-type</code>, <code>Content-length</code>, and so on) that are to be sent to the client in the HTTP response. <p>Note: For more information about parameter blocks, see <i>Sun Java System Web Proxy Server 4.0.8 NSAPI Developer’s Guide</i>.</p>
<i>name</i>	The variable to set.
<i>value</i>	The string assigned to the variable specified by <i>name</i> .

Variables

The following table lists variables supported by the `set - variable` SAF.

TABLE 5-40 Supported set - variable Variables

Parameter	Description
<code>abort</code>	A value of <code>true</code> indicates the result code should be set to <code>REQ_ABORTED</code> . Setting the result code to <code>REQ_ABORTED</code> will abort the current request and send an error to the browser.

TABLE 5-40 Supported set-variable Variables (Continued)

Parameter	Description
error	Sets the error code to be returned in the event of an aborted browser request.
escape	A Boolean value signifying whether a URL should be escaped using <code>util_uri_escape</code> . For information about <code>util_uri_escape</code> , see the “NSAPI Function Reference” chapter of <i>Sun Java System Web Proxy Server 4.0.8 NSAPI Developer’s Guide</i> .
find-pathinfo-forward	Path information after the file name in a URI. See “find-pathinfo” on page 166.
http-downgrade	HTTP version number (for example, 1.0).
http-upgrade	HTTP version number (for example, 1.0).
keep-alive	A Boolean value that establishes whether a keep-alive request from a browser will be honored.
name	Specifies an additional named object in the <code>obj.conf</code> file whose directives will be applied to this request. See also “assign-name” on page 147.
noaction	A value of <code>true</code> indicates the result code should be set to <code>REQ_NOACTION</code> . For <code>AuthTrans</code> , <code>NameTrans</code> , <code>Service</code> , and <code>Error</code> stage SAFs, setting the result code to <code>REQ_NOACTION</code> indicates that subsequent SAFs in that stage should be allowed to execute.
nostat	Causes the server <i>not</i> to perform the <code>stat()</code> function for a URL when possible. See also “assign-name” on page 147.
senthdrs	A Boolean value that indicates whether HTTP response headers have been sent to the client.
ssl-unclean-shutdown	A Boolean value that can be used to alter the way SSL3 connections are closed. As this behavior violates the SSL3 RFCs, only use this value with great caution if you know that you are experiencing problems with SSL3 shutdowns.
stop	A value of <code>true</code> indicates the result code should be set to <code>REQ_PROCEED</code> . For <code>AuthTrans</code> , <code>NameTrans</code> , <code>Service</code> , and <code>Error</code> stage SAFs, setting the result code to <code>REQ_PROCEED</code> indicates that no further SAFs in that stage should be allowed to execute.
url	Redirect requests to a specified URL.

Examples

- To deny HTTP keep-alive requests for a specific server class while still honoring keep-alive requests for the other classes, add this `AuthTrans` directive to the `obj.conf` for the server class, and set the variable `keep-alive` to `disabled`:

```
AuthTrans fn="set-variable" keep-alive="disabled"
```

To cause that same server class to use HTTP/1.0 while the rest of the server classes use HTTP/1.1, the AuthTrans directive would be:

```
AuthTrans fn="set-variable" keep-alive="disabled" http-downgrade="true"
```

- To insert an HTTP header into each response, add a NameTrans directive to `obj.conf`, using the `insert-pblock` command and specifying `srvhdrs` as your Session/Request parameter block.

For example, to insert the HTTP header P3P, you would add the following line to each request:

```
NameTrans fn="set-variable" insert-srvhdrs="P3P"
```

- To terminate processing a request based upon certain URIs, use a `<Client>` tag to specify the URIs and an AuthTrans directive that sets the variable `abort` to `true` when a match is found. Your `<Client>` tag would be comparable to the following:

```
<Client uri="*(system32|root.exe)*">AuthTrans fn="set-variable"  
abort="true"</Client>
```

See Also

[“match-browser” on page 138](#)

NameTrans

NameTrans stands for Name Translation. NameTrans directives translate virtual URLs to physical directories on your server. For example, the URL

```
http://www.test.com/some/file.html
```

could be translated to the full file system path

```
/usr/Sun/WebServer61/server1/docs/some/file.html
```

NameTrans directives should appear in the default object. If an object contains more than one NameTrans directive, the server executes each directive in order until one succeeds.

The following NameTrans-class functions are described in detail in this section

- [“assign-name” on page 147](#) tells the server to process directives in a named object.
- [“document-root” on page 149](#) translates a URL into a file system path by replacing the `http://server-name/` part of the requested resource with the document root directory.
- [“home-page” on page 149](#) translates a request for the server’s root home page (`/`) to a specific file.
- [“map” on page 150](#) looks for a certain URL prefix in the URL that the client is requesting.

- “[match-browser](#)” on page 151 matches specific strings in the User-Agent string supplied by the browser, and then modifies the behavior of the Sun Java System Web Proxy Server based upon the results by setting values for specified variables.
- “[ntrans-j2ee](#)” on page 151 determines whether a request maps to a -based web application context. Based on Java technology this function is applicable only to the Administration Server.
- “[pac-map](#)” on page 152 maps proxy-relative URLs to local files that are delivered to clients who request configuration.
- “[pat-map](#)” on page 153 maps proxy-relative URLs to local files that are delivered to proxies that request configuration.
- “[pfx2dir](#)” on page 153 translates any URL beginning with a given prefix to a file system directory and optionally enables directives in an additional named object.
- “[redirect](#)” on page 155 redirects the client to a different URL.
- “[regexp-map](#)” on page 156 allows a regular expression map.
- “[reverse-map](#)” on page 156 rewrites HTTP response headers when the proxy server is functioning as a reverse proxy.
- “[set-variable](#)” on page 157 enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands.
- “[strip-params](#)” on page 157 removes embedded semicolon-delimited parameters from the path.
- “[um-ntrans](#)” on page 158 identifies an inbound request as being related to a junction (or not).
- “[unix-home](#)” on page 158 translates a URL to a specified directory within a user’s home directory.

assign-name

Applicable in NameTrans-class directives.

The `assign-name` function specifies the name of an object in `obj.conf` that matches the current request. The server then processes the directives in the named object in preference to the ones in the default object.

For example, consider the following directive in the default object:

```
NameTrans fn=assign-name name=personnel from=/personnel
```

Suppose the server receives a request for `http://server-name/personnel`. After processing this NameTrans directive, the server looks for an object named `personnel` in `obj.conf`, and continues by processing the directives in the `personnel` object.

The `assign-name` function always returns `REQ_NOACTION`.

Parameters

The following table describes the parameters for the `assign-name` function.

TABLE 5-41 `assign-name` parameters

Parameter	Description
<code>from</code>	Wildcard pattern that specifies the path to be affected.
<code>name</code>	Specifies an additional named object in <code>obj.conf</code> whose directives are applied to this request.
<code>find-pathinfo-forward</code>	<p>(Optional) Makes the server look for the <code>PATHINFO</code> forward in the path after the <code>nttrans-base</code> instead of backward from the end of path as the server function <code>assign-name</code> does by default.</p> <p>The value you assign to this parameter is ignored. If you do not want to use this parameter, do not include it.</p> <p>The <code>find-pathinfo-forward</code> parameter is ignored if the <code>nttrans-base</code> parameter is not set in <code>rq->vars</code>. By default, <code>nttrans-base</code> is set.</p> <p>This feature can improve performance for certain URLs by reducing the number of stats performed.</p>
<code>nostat</code>	<p>(Optional) Prevents the server from performing a stat on a specified URL whenever possible.</p> <p>The effect of <code>nostat="virtual-path"</code> in the <code>NameTrans</code> function <code>assign-name</code> is that the server assumes that a stat on the specified <i>virtual-path</i> will fail. Therefore, use <code>nostat</code> only when the path of the <i>virtual-path</i> does not exist on the system, for example, for NSAPI plug-in URLs, to improve performance by avoiding unnecessary stats on those URLs.</p> <p>When the default <code>PathCheck</code> server functions are used, the server does not stat for the paths <code>/nttrans-base/virtual-path</code> and <code>/nttrans-base/virtual-path/*</code> if <code>nttrans-base</code> is set (the default condition); it does not stat for the URLs <code>/virtual-path</code> and <code>/virtual-path/*</code> if <code>nttrans-base</code> is not set.</p>
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
# This NameTrans directive is in the default object.
NameTrans fn=assign-name name=personnel from=/a/b/c/pers...
  <Object name=personnel>...additional directives...</Object>
NameTrans fn="assign-name" from="/perf" find-pathinfo-forward="" name="perf"
NameTrans fn="assign-name" from="/nsfc" nostat="/nsfc" name="nsfc"
```

document-root

Applicable in NameTrans-class directives.

The document - root function specifies the root document directory for the server. If the physical path has not been set by a previous NameTrans function, the `http://server-name/` part of the path is replaced by the physical path name for the document root.

When the server receives a request for `http://server-name/somepath/somefile`, the document - root function replaces `http://server-name/` with the value of its root parameter. For example, if the document root directory is `/usr/sun/webserver61/server1/docs`, then when the server receives a request for `http://server-name/a/b/file.html`, the document - root function translates the path name for the requested resource to `/usr/sun/webserver61/server1/docs/a/b/file.html`.

This function always returns REQ_PROCEED. NameTrans directives listed after this response are never called, so be sure that the directive that invokes document - root is the last NameTrans directive.

You can declare only one root document directory. To specify additional document directories, use the “[pfx2dir](#)” on page 153 function to set up additional path name translations.

Parameters

The following table describes parameters for the document - root function.

TABLE 5-42 document-root parameters

Parameter	Description
root	File system path to the server’s root document directory
bucket	(Optional) Common to all obj.conf functions

Examples

```
NameTrans fn=document-root root=/usr/sun/webserver61/server1/docsNameTrans
fn=document-root root=$docroot
```

See Also

“[pfx2dir](#)” on page 153

home-page

Applicable in NameTrans-class directives.

The home - page function specifies the home page for your server. This page is displayed whenever a client requests the server's home page (/).

Parameters

The following table describes parameters for the home - page function.

TABLE 5-43 home - page parameters

Parameter	Description
path	Path and name of the home page file. A path that starts with a slash (/) and is assumed to be a full path to a file. This function sets the server's path variable and returns REQ_PROCEED. Relative paths are appended to the URI and the function returns REQ_NOACTION and then continues on to the other NameTrans directives.
bucket	(Optional) Common to all obj . conf functions.

Examples

```
NameTrans fn="home-page" path="/path/to/file.html"  
NameTrans fn="home-page" path="/path/to/$id/file.html"
```

map

Applicable in NameTrans - class directives.

The map function looks for a certain URL prefix in the URL that the client is requesting. If map finds the prefix, it replaces the prefix with the mirror site prefix. Note that the trailing slashes in URL cause "Not Found" errors.

Syntax

```
NameTrans fn=map from="source site prefix" to="destination site prefix"  
name="named object"
```

Parameters

The following table describes parameters for the map function.

TABLE 5-44 map Parameters

Parameter	Description
from	The prefix to be mapped to the mirror site.
to	The mirror site prefix.
name	(optional) the object from which to derive the configuration for this mirror site.
rewrite-host	(optional) Indicates whether the Host HTTP request header is rewritten to match the host specified by the to parameter. In a reverse proxy configuration where the proxy server and origin server service the same set of virtual servers, you may want to specify rewrite-host="false". The default is true, meaning that the Host HTTP request header is rewritten.

Example

```
# Map site http://home.netscape.com/ to mirror site http://mirror.com
NameTrans fn=map from="http://home.netscape.com" to="http://mirror.com"
```

match-browser

See “[match-browser](#)” on page 138.

ntrans-j2ee

This function is applicable only to the Administration Server. It is applicable in NameTrans-class directives.

The ntrans-j2ee function determines whether a request maps to a Java web application context.

Parameters

The following table describes parameters for the ntrans-j2ee function.

TABLE 5-45 ntrans-j2ee parameters

Parameter	Description
name	Named object in obj . conf whose directives are applied to requests made to Java web applications
bucket	(Optional) Common to all obj . conf functions

Example

```
NameTrans fn="ntrans-j2ee" name="j2ee"
```

See Also

[“service-j2ee” on page 224](#), [“error-j2ee” on page 232](#)

pac-map

Applicable in NameTrans-class directives.

The pac-map function maps proxy-relative URLs to local files that are delivered to clients who request configuration.

Syntax

```
NameTrans fn=pac-map from=URL to=prefix name=named object
```

Parameters

The following table describes parameters for the pac-map function.

TABLE 5-46 pac-map parameters

Parameter	Description
from	The proxy URL to be mapped.
to	The local file to be mapped to.
name	(optional) The object (template) from which to derive configuration.

Example

```
NameTrans fn=pac-map from=http://proxy.mysite.com/pac
to=<install-root><instance-directory>pac/proxy.pac name=file
```

pat-map

Applicable in NameTrans-class directives.

The `pat-map` function maps proxy-relative URLs to local files that are delivered to proxies who request configuration.

Syntax

```
NameTrans fn=pat-map    from=URL    to=prefix    name=named object
```

Parameters

The following table describes parameters for the `pat-map` function.

TABLE 5-47 `pat-map` parameters

Parameter	Description
<code>from</code>	The proxy URL to be mapped.
<code>to</code>	The local file to be mapped to.
<code>name</code>	(optional) The object (template) from which to derive configuration.

Example

```
NameTrans fn=pat-map from=http://proxy.mysite.com/pac
          to=<install-root><instance-directory>pac/proxy.pac name=file
```

pfx2dir

Applicable in NameTrans-class directives.

The `pfx2dir` function replaces a directory prefix in the requested URL with a real directory name. It also optionally enables you to specify the name of an object that matches the current request. See the discussion of “[assign-name](#)” on [page 147](#) for details of using named objects.

Parameters

The following table describes parameters for the `pfx2dir` function.

TABLE 5-48 pfx2dir parameters

Parameter	Description
from	URI prefix to convert. Do not insert a trailing slash (/).
dir	Local file system directory path that the prefix is converted to. Do not insert a trailing slash (/).
name	(Optional) Specifies an additional named object in obj . conf whose directives will be applied to this request.
find-pathinfo-forward	<p>(Optional) Makes the server look for the PATHINFO forward in the path after the nt rans -base instead of backward from the end of path as the server function find -pathinfo does by default.</p> <p>The value you assign to this parameter is ignored. If you do not want to use this parameter, do not include it.</p> <p>The find -pathinfo -forward parameter is ignored if the nt rans -base parameter is not set in rq ->vars when the server function find -pathinfo is called. By default, nt rans -base is set.</p> <p>This feature can improve performance for certain URLs by reducing the number of stats performed in the server function find -pathinfo.</p> <p>On Windows, this feature can also be used to prevent the PATHINFO from the server URL normalization process (changing '\\ to '/') when the PathCheck server function find -pathinfo is used. Some double-byte characters have hexadecimal values that may be parsed as URL separator characters such as \\ or ~. Using the find -pathinfo -forward parameter can sometimes prevent incorrect parsing of URLs containing double-byte characters.</p>
bucket	(Optional) Common to all obj . conf functions.

Examples

In the first example, the URL `http://server-name/cgi-bin/resource` (such as `http://x.y.z/cgi-bin/test.cgi`) is translated to the physical path name `/httpd/cgi-local/resource` (such as `/httpd/cgi-local/test.cgi`), and the server also starts processing the directives in the object named `cgi`.

```
NameTrans fn=pfx2dir from=/cgi-bin dir=/httpd/cgi-local name=cgi
```

In the second example, the URL `http://server-name/icons/resource` (such as `http://x.y.z/icons/happy/smiley.gif`) is translated to the physical path name `/users/nikki/images/resource` (such as `/users/nikki/images/smiley.gif`).

```
NameTrans fn=pfx2dir from=/icons/happy dir=/users/nikki/images
```

The third example shows the use of the `find-pathinfo-forward` parameter. The URL `http://server-name/cgi-bin/resource` is translated to the physical path name `/export/home/cgi-bin/resource`.

```
NameTrans fn="pfx2dir" find-pathinfo-forward="" from="/cgi-bin"
          dir="/export/home/cgi-bin" name="cgi"
```

redirect

Applicable in NameTrans-class directives.

The `redirect` function enables you to change URLs and send the updated URL to the client. When a client accesses your server with an old path, the server treats the request as a request for the new URL.

Parameters

The following table describes parameters for the `redirect` function.

TABLE 5-49 redirect parameters

Parameter	Description
<code>from</code>	Specifies the prefix of the requested URI to match.
<code>url/url-prefix</code>	<code>url</code> specifies a complete URL to return to the client. <code>url-prefix</code> specifies the new URL prefix to return to the client. The <code>from</code> prefix is simply replaced by this URL prefix. You cannot use these parameters together.
<code>escape</code>	(Optional) Flag that tells the server to <code>util_uri_escape</code> the URL before sending it. It should be <code>yes</code> or <code>no</code> . The default is <code>yes</code> . For more information about <code>util_uri_escape</code> , see <i>Sun Java System Web Proxy Server 4.0.8 NSAPI Developer's Guide</i> .
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Examples

In the first example, any request for `http://server-name/string` is translated to a request for `http://tmpserver/string`.

```
NameTrans fn=redirect from=/ url-prefix=http://tmpserver
```

In the second example, any request for `http://server-name/toopopular/string` is translated to a request for `http://bigger/better/stronger/morepopular/string`.

```
NameTrans fn=redirect from=/toopopular
          url=http://bigger/better/stronger/morepopular
```

regexp-map

Applicable in NameTrans-class directives.

The `regexp-map` is similar to the `map` function. While the `map` function looks for an exact match of a URL prefix, `regexp-map` allows a regular expression match.

Parameters

The following table describes parameters for the `regexp-map` function.

TABLE 5-50 `regexp-map` parameters

Parameter	Description
<code>from</code>	A regular expression for the prefix to be mapped to the mirror site.
<code>to</code>	The mirror site prefix.
<code>name</code>	(Optional) A named object from which to derive the configuration for the mirror site.
<code>rewrite-host</code>	(Optional) Indicates whether the Host HTTP request header is rewritten to match the host specified by the parameter. In a reverse proxy configuration where the proxy server and origin server service the same set of virtual servers, you may wish to specify <code>rewrite-host="false"</code> . The default is <code>"true"</code> , meaning that the Host HTTP request header is rewritten.

reverse-map

Applicable in NameTrans-class directives.

The `reverse-map` function is used to rewrite HTTP response headers when the proxy server is functioning as a reverse proxy. `reverse-map` looks for the URL prefix specified by the `from` parameter in certain response headers. If the `from` prefix matches the beginning of the response header value, `reverse-map` replaces the matching portion with the `to` prefix.

Parameters

The following table describes parameters for the `reverse-map` function.

TABLE 5-51 reverse-map parameters

Parameter	Description
from	URL prefix to be rewritten.
to	URL prefix that will be substituted in place of the from prefix.
rewrite-location	(Optional) Boolean that indicates whether the Location HTTP response header should be rewritten. The default is <code>true</code> , meaning the Location header is rewritten.
rewrite-content-location	(Optional) Boolean that indicates whether the <code>content-location</code> HTTP response header should be rewritten. The default is <code>true</code> , meaning the Content-location header is rewritten.
rewrite-headername	(Optional) Boolean that indicates whether the <code>headername</code> HTTP response header should be rewritten, where <code>headername</code> is a user-defined header name. With the exception of the Location and Content-location headers, the default is <code>false</code> , meaning the <code>headername</code> header is not rewritten.
rewrite-set-cookie	Takes a boolean value and is set to <code>true</code> by default. Enables or disables cookie rewriting, which involves rewriting the <code>domain</code> and <code>path</code> parameters of the <code>set-cookie</code> headers.
cookiepath-from	Specifies the target value of the <code>path</code> parameter.
cookiepath-to	If the value of the <code>path</code> parameter matches the value of <code>cookiepath-from</code> , it will be rewritten to the value of <code>cookiepath-to</code> .

set-variable

See “[set-variable](#)” on page 143.

strip-params

Applicable in NameTrans-class directives.

The `strip-params` function removes embedded semicolon-delimited parameters from the path. For example, a URI of `/dir1;param1/dir2` would become a path of `/dir1/dir2`. When used, the `strip-params` function should be the first NameTrans directive listed.

Parameters

The following table describes the parameter for the `strip-params` function.

TABLE 5-52 strip-params Parameters

Parameter	Description
bucket	(Optional) Common to all obj.conf functions

Example

```
NameTrans fn=strip-params
```

um-ntrans

Applicable in NameTrans-class directives.

The `um-ntrans` function determines if an inbound request is related to a junction or not. It also rewrites inbound cookies, adds headers, and does any rewriting when necessary, before the request is sent to the back-end server.

If a request cannot be mapped to a junction, it is passed through without modification.

This directive must appear exactly once in `obj.conf`, typically inside the default object.

Example

```
nametrans fn="um-ntrans"
```

unix-home

Applicable in NameTrans-class directives.

UNIX Only. The `unix-home` function translates user names typically of the form `~username` into the user's home directory on the server's UNIX machine. You specify a URL prefix that signals user directories. Any request that begins with the prefix is translated to the user's home directory.

You specify the list of users with either the `/etc/passwd` file or a file with a similar structure. Each line in the file should have this structure. Elements in the `passwd` file that are not needed are indicated with `*`:

```
username:*:*:groupid:*:homedir:*
```

If you want the server to scan the password file only once at startup, use the `init`-class function `init-uhome` in `magnus.conf`.

Parameters

The following table describes the parameters for the `unix-home` function.

TABLE 5-53 unix-home Parameters

Parameter	Description
subdir	Subdirectory within the home directory that contains the user's web documents.
pwfile	(Optional) Full path and file name of the password file if it is different from /etc/passwd.
name	(Optional) Specifies an additional named object whose directives will be applied to this request.
bucket	(Optional) Common to all obj.conf functions.

Examples

```
NameTrans fn=unix-home from=~ subdir=public_html
```

```
NameTrans fn=unix-home from/~ pwfile=/mydir/passwd subdir=public_html
```

[“find-links” on page 165](#)

PathCheck

PathCheck directives check the local file system path that is returned after the NameTrans step. The path is checked for things such as CGI path information and for dangerous elements such as /./and /../and //, and then any access restriction is applied.

If object contains more than one PathCheck directive, each of the functions is executed in order.

The following PathCheck-class functions are described in detail in this section:

- [“block-multipart-posts” on page 160](#) - Blocks all multipart form file uploads when configured without any parameters.
- [“check-acl” on page 161](#) - Checks an access control list for authorization.
- [“deny-existence” on page 162](#) - Indicates that a resource was not found.
- [“deny-service” on page 162](#) - Sends a “Proxy Denies Access” error when a client tries to access a specific path.
- [“find-index” on page 164](#) - Locates a default file when a directory is requested.
- [“find-links” on page 165](#) - Denies access to directories with certain file system links.
- [“find-pathinfo” on page 166](#) - Locates extra path info beyond the file name for the PATH_INFO CGI environment variable.
- [“get-client-cert” on page 167](#) - Gets the authenticated client certificate from the SSL3 session.

- “load-config” on page 168 - Finds and loads extra configuration information from a file in the requested path.
- “match-browser” on page 170 - Matches specific strings in the User-Agent string supplied by the browser, and then modifies the behavior of the Sun Java System Web Proxy Server based upon the results by setting values for specified variables.
- “nt-uri-clean” on page 170 - Denies access to requests with unsafe path names by sending not found error.
- “ntcgicheck” on page 171 - Checks for a CGI file with a specified extension.
- “require-auth” on page 172 - Denies access to unauthorized users or groups.
- “require-proxy-auth” on page 173 - Makes sure that users are authenticated and triggers a password pop-up window.
- “set-variable” on page 173 - Enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands.
- “set-virtual-index” on page 173 - Specifies a virtual index for a directory.
- “ssl-check” on page 174 - Checks the secret keysize.
- “ssl-logout” on page 175 - Invalidates the current SSL session in the server’s SSL session cache.
- “unix-uri-clean” on page 175 - Denies access to requests with unsafe path names by sending not found error.
- “url-check” on page 176 - Checks the validity of URL syntax.
- “url-filter” on page 176 - Allows or denies URL patterns.
- “user-agent-check” on page 177 - Restricts access to the proxy server based on the type and version of the client’s web browser.

block-multipart-posts

Applicable in PathCheck-class directives.

The `block-multipart-posts` function blocks all multipart form file uploads when configured without any parameters. This can also be used to block requests based on specific content type, user-agent, or HTTP method using content-type, user-agent and method parameters.

Parameters

The following table describes parameters for the `block-multipart-posts` function.

TABLE 5-54 block-multipart-posts Parameters

Parameter	Description
content-type	(Optional) Regular expression of the content type to be blocked
user-agent	(Optional) Regular expression of the user agent to be blocked
method	(Optional) Regular expression matching the HTTP request method to be blocked

Example

```
PathCheck fn="block-multipart-posts" user-agent="Mozilla/*"
        method="(POST|PUT)"
```

check-acl

Applicable in PathCheck-class directives.

The check-acl function specifies an access control list (ACL) to use to check whether the client is allowed to access the requested resource. An access control list contains information about who is allowed to access a resource, and under what conditions access is allowed.

Regardless of the order of PathCheck directives in the object, check-acl functions are executed first. These functions cause user authentication to be performed, if required by the specified ACL, and will also update the access control state.

Parameters

The following table describes parameters for the check-acl function.

TABLE 5-55 check-acl Parameters

Parameter	Description
acl	Name of an access control list
path	(Optional) Wildcard pattern that specifies the path to which to apply the ACL.
bucket	(Optional) Common to all obj.conf functions

Example

```
PathCheck fn=check-acl acl="*HRonly*"
```

deny-existence

Applicable in PathCheck-class directives.

The deny-existence function sends a “not found” message when a client tries to access a specified path. The server sends “not found” instead of “forbidden,” so the user cannot tell if the path exists.

Parameters

The following table describes the parameters for the deny-existence function.

TABLE 5-56 deny-existence Parameters

Parameter	Description
path	(Optional) Wildcard pattern of the file system path to hide. If the path does not match, the function does nothing and returns REQ_NOACTION. If the path is not provided, it is assumed to match.
bong-file	(Optional) A full file system path that specifies a file to send rather than responding with the “not found” message.
bucket	(Optional) Common to all obj.conf functions.

Examples

```
PathCheck fn=deny-existence path=/usr/sun/server61/docs/private
PathCheck fn=deny-existence bong-file=/svr/msg/go-away.html
```

deny-service

Applicable in PathCheck-class directives and Service-class directives.

The deny-service function sends a “Proxy Denies Access” error when a client tries to access a specific path. If this directive appears in a client region, the directive performs access control on the specified clients.

The proxy specifically denies clients instead of specifically allowing them access to documents. The default object is used when a client doesn’t match any client region in objects. Because the default object uses the deny-service function, no one is allowed access by default.

Syntax

```
PathCheck fn=deny-service path=.*someexpression.*
```

Parameters

The following table describes the parameter for the deny-service function.

TABLE 5-57 deny-service parameters

Parameter	Description
path	A regular expression representing the path to check. Not specifying this parameter is equivalent to specifying *. URLs matching the expression are denied access to the proxy server.

Example

```
<Object ppath="http://sun/*">
# Deny servicing proxy requests for fun GIFs
PathCheck fn=deny-service path=.*fun*.gif
# Make sure nobody except Sun employees can use the object
# inside which this is placed.
<Client dns=*~*.sun.com>
PathCheck fn=deny-service
</Client>
</Object>
```

find-compressed

Applicable in PathCheck-class directives.

The `find-compressed` function checks if a compressed version of the requested file is available. If the following conditions are met, `find-compressed` changes the path to point to the compressed file:

- A compressed version is available
- The compressed version is at least as recent as the noncompressed version
- The client supports compression

Not all clients support compression. The `find-compressed` function enables you to use a single URL for both the compressed and noncompressed versions of a file. The version of the file that is selected is based on the individual client's capabilities.

A compressed version of a file must have the same file name as the noncompressed version but with a `.gz` suffix. For example, the compressed version of a file named `/httpd/docs/index.html` would be named `/httpd/docs/index.html.gz`. To compress files, you can use the freely available `gzip` program.

Because compressed files are sent as is to the client, you should not compress files such as SHTML pages, CGI programs, or pages created with Java Server Pages™ (JSP™) technology that need to be interpreted by the server. To compress the dynamic content generated by these types of files, use the `http-compression` filter.

The `find-compressed` function does nothing if the HTTP method is not GET or HEAD.

Parameters

The following table describes parameters for the `find-compressed` function.

TABLE 5-58 `find-compressed` parameters

Parameter	Description
<code>check-age</code>	<p>Specifies whether to check if the compressed version is older than the noncompressed version. Possible values are <code>yes</code> and <code>no</code>.</p> <ul style="list-style-type: none"> ▪ If set to <code>yes</code>, the compressed version will not be selected if it is older than the noncompressed version. ▪ If set to <code>no</code>, the compressed version will always be selected, even if it is older than the noncompressed version. <p>By default, the value is set to <code>yes</code>.</p>
<code>vary</code>	<p>Specifies whether to insert a <code>Vary: Accept-Encoding</code> header. Possible values are <code>yes</code> or <code>no</code>.</p> <ul style="list-style-type: none"> ▪ If set to <code>yes</code>, a <code>Vary: Accept-Encoding</code> header is always inserted when a compressed version of a file is selected. ▪ If set to <code>no</code>, a <code>Vary: Accept-Encoding</code> header is never inserted. <p>By default, the value is set to <code>yes</code>.</p>
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
<Object name="default">NameTrans fn="assign-name" from="*.html"
  name="find-compressed" . . </Object><Object name="find-compressed">
  PathCheck fn="find-compressed"</Object>
```

See Also

`http-compression`

find-index

Applicable in `PathCheck`-class directives.

The `find-index` function investigates whether the requested path is a directory. If the path is directory, the function searches for an index file in the directory, and then changes the path to point to the index file. If no index file is found, the server generates a directory listing.

If the `obj.conf` file contains a `NameTrans` directive that calls “[home-page](#)” on page 149 and the requested directory is the root directory, then the home page rather than the index page is returned to the client.

The `find-index` function does nothing if there is a query string, if the HTTP method is not GET, or if the path is that of a valid file.

Parameters

The following table describes parameters for the `find-index` function.

TABLE 5-59 `find-index` parameters

Parameter	Description
<code>index-names</code>	Comma-separated list of index file names to look for. Use spaces only if they are part of a file name. Do not include spaces before or after the commas. This list is casesensitive if the file system is casesensitive.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
PathCheck fn=find-index index-names=index.html,home.html
```

find-links

Applicable in PathCheck-class directives.

UNIX Only. The `find-links` function searches the current path for symbolic or hard links to other directories or file systems. If any are found, an error is returned. This function is normally used for directories that are not trusted such as user home directories. The function prevents someone from pointing to information that should not be made public.

Parameters

The following table describes parameters for the `find-links` function.

TABLE 5-60 `find-links` Parameters

Parameter	Description
<code>disable</code>	Character string of links to disable: <ul style="list-style-type: none"> ▪ <code>h</code> is hard links ▪ <code>s</code> is soft links ▪ <code>o</code> allows symbolic links from user home directories only if the user owns the target of the link

TABLE 5-60 find-links Parameters (Continued)

Parameter	Description
dir	Directory to begin checking. If you specify an absolute path, any request to that path and its subdirectories is checked for symbolic links. If you specify a partial path, any request containing that partial path is checked for symbolic links. For example, if you use /user/ and a request comes in for some/user/directory, then that directory is checked for symbolic links.
checkFileExistence	Checks linked file for existence and aborts request with 403 (forbidden) if this check fails.
bucket	(Optional) Common to all obj.conf functions.

Examples

```
PathCheck fn=find-links disable=sh dir=/foreign-dir
```

```
PathCheck fn=find-links disable=so dir=public_html
```

See Also

[“unix-home” on page 158](#)

find-pathinfo

Applicable in PathCheck-class directives.

The find-pathinfo function finds any extra path information after the file name in the URL and stores it for use in the CGI environment variable PATH_INFO.

Parameters

The following table describes parameters for the find-pathinfo function.

TABLE 5-61 find-pathinfo parameters

Parameter	Description
bucket	(Optional) Common to all obj.conf functions

Examples

```
PathCheck fn=find-pathinfo
```

```
PathCheck fn=find-pathinfo find-pathinfo-forward=""
```

get-client-cert

Applicable in PathCheck-class directives.

The `get-client-cert` function gets the authenticated client certificate from the SSL3 session. The function can apply to all HTTP methods, or only to those that match a specified pattern. The function only works when SSL is enabled on the server.

If the certificate is present or obtained from the SSL3 session, the function returns `REQ_NOACTION`, allowing the request to proceed. Otherwise, the function returns `REQ_ABORTED` and sets the protocol status to `403 FORBIDDEN`, causing the request to fail and the client to be given the `FORBIDDEN` status.

Parameters

The following table describes parameters for the `get-client-cert` function.

TABLE 5-62 `get-client-cert` Parameters

Parameter	Description
<code>dorequest</code>	<p>Controls whether to try to get the certificate or just test for its presence. If <code>dorequest</code> is absent, the default value is <code>0</code>.</p> <ul style="list-style-type: none"> ■ <code>1</code> tells the function to redo the SSL3 handshake to get a client certificate, if the server does not already have the client certificate. This action typically causes the client to present a dialog box to the user to select a client certificate. The server might already have the client certificate if it was requested on the initial handshake, or if a cached SSL session has been resumed. ■ <code>0</code> tells the function not to redo the SSL3 handshake if the server does not already have the client certificate. <p>If a certificate is obtained from the client and verified successfully by the server, the ASCII base64 encoding of the DER-encoded X.509 certificate is placed in the parameter <code>auth-cert</code> in the <code>Request->vars</code> pblock, and the function returns <code>REQ_PROCEED</code>, allowing the request to proceed.</p>
<code>require</code>	<p>Controls whether failure to get a client certificate will abort the HTTP request. If <code>require</code> is absent, the default value is <code>1</code>.</p> <ul style="list-style-type: none"> ■ <code>1</code> tells the function to abort the HTTP request if the client certificate is not present after <code>dorequest</code> is handled. In this case, the HTTP status is set to <code>PROTOCOL_FORBIDDEN</code>, and the function returns <code>REQ_ABORTED</code>. ■ <code>0</code> tells the function to return <code>REQ_NOACTION</code> if the client certificate is not present after <code>dorequest</code> is handled.

TABLE 5-62 get-client-cert Parameters (Continued)

Parameter	Description
method	(Optional) Specifies a wildcard pattern for the HTTP methods for which the function will be applied. If method is absent, the function is applied to all requests.
bucket	(Optional) Common to all obj.conf functions.

Example

```
# Get the client certificate from the session.
   If a certificate is not already associated with the session, request one.
   The request fails if the client does not present a valid certificate.
PathCheck fn="get-client-cert" dorequest="1"
```

load-config

Applicable in PathCheck-class directives.

The `load-config` function searches for configuration files in document directories and adds the file's contents to the server's existing configuration. These configuration files, also known as dynamic configuration files, specify additional access control information for the requested resource. Depending on the rules in the dynamic configuration files, the server determines whether to allow the client to access the requested resource.

Each directive that invokes `load-config` is associated with a base directory, which is either stated explicitly through the `basedir` parameter or derived from the root directory for the requested resource. The base directory determines two things:

- The topmost directory for which requests will invoke this call to the `load-config` function. For example, if the base directory is `D:/sun/server1/docs/nikki/`, then only requests for resources in this directory or its subdirectories and their subdirectories trigger the search for dynamic configuration files. A request for the resource `D:/sun/server1/docs/somefile.html` does not trigger the search in this case because the requested resource is in a parent directory of the base directory.
- The topmost directory in which the server looks for dynamic configuration files to apply to the requested resource. If the base directory is `D:/sun/server1/docs/nikki/`, the server starts its search for dynamic configuration files in this directory. It may or may not also search subdirectories (but never parent directories), depending on other factors.

When you enable dynamic configuration files through the Server Manager interface, the system writes additional objects with `ppath` parameters into the `obj.conf` file. If you manually add directives that invoke `load-config` to the default object rather than putting them in separate objects, the Server Manager interface might not reflect your changes.

If you manually add PathCheck directives that invoke `load-config` to the file `obj.conf`, put them in additional objects created with the `<OBJECT>` tag rather than putting them in the default object. Use the `ppath` attribute of the `OBJECT` tag to specify the partial path name for the resources to be affected by the access rules in the dynamic configuration file. The partial path name can be any path name that matches a pattern, which can include wildcard characters.

For example, the following `<OBJECT>` tag specifies that requests for resources in the directory `D:/sun/proxy4/docs` are subject to the access rules in the file `my.nsconfig`.

```
<Object ppath="D:/sun/server1/docs/*">PathCheck fn="load-config"
    file="my.nsconfig" descend=1 basedir="D:/sun/server1/docs" </Object>
```

Note – If the `ppath` resolves to a resource or directory that is higher in the directory tree or is in a different branch of the tree than the base directory, the `load-config` function is not invoked. The base directory specifies the highest-level directory for which requests will invoke the `load-config` function.

The `load-config` function returns `REQ_PROCEED` if configuration files were loaded, `REQ_ABORTED` on error, or `REQ_NOACTION` when no files are loaded.

Parameters

The following table describes parameters for the `load-config` function.

TABLE 5-63 `load-config` parameters

Parameter	Description
<code>file</code>	(Optional) Name of the dynamic configuration file containing the access rules to be applied to the requested resource. If not provided, the file name is assumed to be <code>.nsconfig</code> .
<code>disable-types</code>	(Optional) Specifies a wildcard pattern of types to disable for the base directory, such as <code>magnus-internal/cgi</code> . Requests for resources matching these types are aborted.
<code>descend</code>	(Optional) If present, specifies that the server should search in subdirectories of this directory for dynamic configuration files. For example, <code>descend=1</code> specifies that the server should search subdirectories. No <code>descend</code> parameter specifies that the function should search only the base directory.

TABLE 5-63 load-config parameters (Continued)

Parameter	Description
basedir	(Optional) Specifies base directory. This directory is the highest-level directory for which requests will invoke the load-config function. It is also the directory where the server starts searching for configuration files. If basedir is not specified, the base directory is assumed to be the root directory that results from translating the requested resource's URL to a physical path name. For example, if the request is for <code>http://server-name/a/b/file.html</code> , the physical file name would be <code>/document-root/a/b/file.html</code> .
bucket	(Optional) Common to all obj.conf functions.

Examples

In this example, whenever the server receives a request for any resource containing the substring `secret` that resides in `D:/Sun/WebServer61/server1/docs/nikki/` or a subdirectory it searches for a configuration file called `checkaccess.nsconfig`.

The server starts the search in the directory `D:/Sun/WebServer61/server1/docs/nikki`, and searches subdirectories too. It loads each instance of `checkaccess.nsconfig` and applies the access control rules contained in each instance to determine whether the client is allowed to access the requested resource.

```
<Object ppath="*secret*"> PathCheck fn="load-config"
  file="checkaccess.nsconfig" basedir="D:/Sun/WebServer61/server1/docs/nikki"
  descend="1" </Object>
```

match-browser

See [“match-browser” on page 138](#).

nt-uri-clean

Applicable in PathCheck-class directives.

Windows Only. The `nt-uri-clean` function denies access to any resource whose physical path contains `\\.\\. , \\ . . \\` or `\\\\` (these are potential security problems).

Parameters

The following table describes parameters for the `nt-uri-clean` function.

TABLE 5-64 nt-uri-clean Parameters

Parameter	Description
tildeok	If present, allows tilde (~) characters in URIs. This setting is a potential security risk on the Windows platform, where <code>longfi~1.htm</code> might reference <code>longfilename.htm</code> but does not go through the proper ACL checking. If present, “//” sequences are allowed.
dotdirok	If present, “//” sequences are allowed.
bucket	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
PathCheck fn=nt-uri-clean
```

See Also

[“unix-uri-clean” on page 175](#)

ntcgicheck

Applicable in PathCheck-class directives.

Windows Only. The `ntcgicheck` function specifies the file name extension to be added to any file name that does not have an extension, or to be substituted for any file name that has the extension `.cgi`.

Parameters

The following table describes parameters for the `ntcgicheck` function.

TABLE 5-65 ntcgicheck Parameters

Parameter	Description
extension	The replacement file extension
bucket	(Optional) Common to all <code>obj.conf</code> functions

Example

```
PathCheck fn=ntcgicheck extension=pl
```

See Also

[“send-wincgi” on page 222](#), [“send-shellcgi” on page 221](#)

require-auth

Applicable in PathCheck-class directives.

The `require-auth` function allows access to resources only if the user or group is authorized. Before this function is called, an authorization function such as `basic-auth` must be called in an `AuthTrans` directive.

If a user was authorized in an `AuthTrans` directive and the `auth-user` parameter is provided, then the user's name must match the `auth-user` wildcard value. Also, if the `auth-group` parameter is provided, the authorized user must belong to an authorized group, which must match the `auth-user` wildcard value.

Parameters

The following table describes parameters for the `require-auth` function.

TABLE 5-66 `require-auth` Parameters

Parameter	Description
<code>path</code>	(Optional) Wildcard local file system path on which this function should operate. If no path is provided, the function applies to all paths.
<code>auth-type</code>	Type of HTTP authorization used. This value must match the <code>auth-type</code> from the previous authorization function in <code>AuthTrans</code> . Currently, <code>basic</code> is the only authorization type defined.
<code>realm</code>	String sent to the browser indicating the secure area or realm for which a user name and password are requested.
<code>auth-user</code>	(Optional) Specifies a wildcard list of users who are allowed access. If this parameter is not provided, any user authorized by the authorization function is allowed access.
<code>auth-group</code>	(Optional) Specifies a wildcard list of groups that are allowed access.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
PathCheck fn=require-auth auth-type=basic realm="Marketing Plans"
      auth-group=mktg auth-user=(jdoe|johnd|janed)
```

See Also

[“basic-auth” on page 135](#), [“basic-nca” on page 137](#)

require-proxy-auth

Applicable in PathCheck-class directives.

The `require-proxy-auth` function is a PathCheck function that makes sure that users are authenticated and triggers a password pop-up window.

Syntax

```
PathCheck fn=require-proxy-auth auth-type=basic realm=name
auth-group=group auth-users=name
```

Parameters

The following table describes parameters for the `require-proxy-auth` function.

TABLE 5-67 `require-proxy-auth` Parameters

Parameter	Description
<code>auth-type</code>	Specifies the type of authorization to be used. Set the type to <code>basic</code> unless you are running a UNIX proxy and are going to use your own function to perform authentication.
<code>realm</code>	A string (enclosed in double-quotation marks) sent to the client application so users can see the objects for which they need authorization for.
<code>auth-user</code>	(optional) Specifies a list of users who get access. The list is enclosed in parentheses with each user name separated by the pipe <code> </code> symbol.
<code>auth-group</code>	(optional) Specifies a list of groups that get access. Groups are listed in the password-type file.

Example

```
PathCheck fn=require-auth auth-type=basic realm="Marketing Plans"
auth-group=mktg auth-users=(jdoe|johnd|janed)
```

set-variable

See “[set-variable](#)” on page 143.

set-virtual-index

Applicable in PathCheck-class directives.

The `set-virtual-index` function specifies a virtual index for a directory, which determines the URL forwarding. The index can refer to a LiveWire application, a servlet in its own namespace, a Sun ONE Application Server applogic, and so on.

`REQ_NOACTION` is returned if none of the URIs listed in the `from` parameter match the current URI. `REQ_ABORTED` is returned if the file specified by the `virtual-index` parameter is missing, or if the current URI cannot be found. `REQ_RESTART` is returned if the current URI matches any one of the URIs mentioned in the `from` parameter, or if no `from` parameter is specified.

Parameters

The following table describes parameters for the `set-virtual-index` function.

TABLE 5-68 `set-virtual-index` Parameters

Parameter	Description
<code>virtual-index</code>	URI of the content generator that acts as an index for the URI the user enters.
<code>from</code>	(Optional) Comma-separated list of URIs for which this <code>virtual-index</code> is applicable. If <code>from</code> is not specified, the <code>virtual-index</code> always applies.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
# MyLWApp is a LiveWire application
PathCheck fn=set-virtual-index
    virtual-index=MyLWApp
```

ssl-check

Applicable in `PathCheck`-class directives.

If a restriction is selected that is not consistent with the current cipher settings under Security Preferences, this function displays a warning that ciphers with larger secret key sizes need to be enabled. This function is designed to be used together with a `Client` tag to limit access of certain directories to nonexportable browsers.

The function returns `REQ_NOACTION` if SSL is not enabled, or if the `secret-keysize` parameter is not specified. If the secret key size for the current session is less than the specified `secret-keysize` and the `bong-file` parameter is not specified, the function returns `REQ_ABORTED` with a status of `PROTOCOL_FORBIDDEN`. If the `bong-file` is specified, the function returns `REQ_PROCEED`, and the path variable is set to the `bong` file name. Also, when a key size restriction is not met, the SSL session cache entry for the current session is invalidated so that a full SSL handshake will occur the next time the same client connects to the server.

Requests that use `ssl-check` are not cacheable in the accelerator file cache if `ssl-check` returns a value other than `REQ_NOACTION`.

Parameters

The following table describes parameters for the `ssl-check` function.

TABLE 5-69 `ssl-check` parameters

Parameter	Description
<code>secret-keysize</code>	(Optional) Minimum number of bits required in the secret key
<code>bong-file</code>	(Optional) Name of a file (not a URI) to be served if the restriction is not met
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions

ssl-logout

Applicable in PathCheck-class directives.

The `ssl-logout` function invalidates the current SSL session in the server's SSL session cache. This function does not affect the current request, but the next time the client connects, a new SSL session will be created. If SSL is enabled, this function returns `REQ_PROCEED` after invalidating the session cache entry. If SSL is not enabled, the function returns `REQ_NOACTION`.

Parameters

The following table describes the parameter for the `ssl-logout` function.

TABLE 5-70 `ssl-logout` parameters

Parameter	Description
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions

unix-uri-clean

Applicable in PathCheck-class directives.

UNIX Only. The `unix-uri-clean` function denies access to any resource whose physical path contains `./`, `../` or `//`, which are potential security problems.

Parameters

The following table describes the parameter for the `unix-uri-clean` function.

TABLE 5-71 unix-uri-clean parameters

Parameter	Description
dotdirok	If present, “//” sequences are allowed
bucket	(Optional) Common to all obj.conf functions

Example

```
PathCheck fn=unix-uri-clean
```

See Also

[“nt-uri-clean” on page 170](#)

url-check

Applicable in PathCheck-class directives.

The url-check function checks the validity of URL syntax.

url-filter

Applicable in PathCheck-class directives.

The url-filter can be used to allow or deny URL patterns. You can use either regular expressions of URL patterns or names of filter files of URLs as values for allow and deny parameters. The value names here refers to parameter names that were associated with filter files of URLs through init-url-filter SAE.

Parameters

The following table describes the parameter for the url-filter function.

TABLE 5-72 url-filter Parameters

Parameter	Description
allow	Regular expression matching a URL pattern or name of a filter of URLs
deny	Regular expression matching a URL pattern or name of a filter of URLs
bong-file	Absolute path the custom error file (text or HTML) to be returned to the client

Example

```
PathCheck fn="url-filter" allow="filt1" deny=".*://.*.iplanet.com/.*"
```

user-agent-check

Applicable in PathCheck-class directives.

The user-agent-check can be used to restrict access to the proxy server based on the type and version of the client's web browser. A regular expression to match the user-agent header sent from the client is passed as a parameter to this function.

Parameters

The following table describes the parameter for the user-agent-check function.

TABLE 5-73 user-agent-check parameters

Parameter	Description
ua	Regular expression matching the user-agent header sent from the client to the proxy server

Example

```
PathCheck fn = "user-agent-check" ua="Mozilla/*"
```

ObjectType

ObjectType directives determine the MIME type of the file to send to the client in response to a request. MIME attributes currently sent are type, encoding, and language. The MIME type is sent to the client as the value of the Content-Type header.

ObjectType directives also set the type parameter, which is used by Service directives to determine how to process the request according to what kind of content is being requested.

If an object contains more than one ObjectType directive, all of the directives are applied in the order they appear. If a directive sets an attribute and later directives try to set that attribute to another value, the first setting is used and the subsequent settings are ignored.

The obj.conf file has an ObjectType directive that calls the [“type-by-extension” on page 195](#) function. This function instructs the server to look in the MIME types file to deduce the content type from the extension of the requested resource.

The following ObjectType-class functions are described in detail in this section:

- [“block-auth-cert” on page 179](#) instructs the proxy server not to forward the client's SSL/TLS certificate to remote servers.
- [“block-cache-info” on page 180](#) instructs the proxy server not to forward information about local cache hits to remote servers.

- “[block-cipher](#)” on page 180 instructs the proxy server to forward the name of the client’s SSL/TLS cipher suite to remote servers.
- “[block-ip](#)” on page 180 instructs the proxy server not to forward the client’s IP address to remote servers.
- “[block-issuer-dn](#)” on page 180 instructs the proxy server not to forward the distinguished name of the issuer of the client’s SSL/TLS certificate to remote servers.
- “[block-keysize](#)” on page 181 instructs the proxy server not to forward the size of the client’s SSL/TLS key to remote servers.
- “[block-proxy-auth](#)” on page 181 instructs the proxy server not to forward the client’s proxy authentication credentials.
- “[block-secret-keysize](#)” on page 181 instructs the proxy server not to forward the size of the client’s SSL/TLS secret key to remote servers.
- “[block-ssl-id](#)” on page 181 instructs the proxy server not to forward the client’s SSL/TLS session ID to remote servers.
- “[block-user-dn](#)” on page 182 instructs the proxy server not to forward the distinguished name of the subject of the client’s SSL/TLS certificate to remote servers.
- “[cache-disable](#)” on page 182 disables cache.
- “[cache-enable](#)” on page 182 tells the proxy that an object is cacheable, based on specific criteria.
- “[cache-setting](#)” on page 184 sets parameters used for cache control.
- “[force-type](#)” on page 185 sets the Content - Type header for the response to a specific type.
- “[forward-auth-cert](#)” on page 186 instructs the proxy server to forward the client’s SSL/TLS certificate to remote servers.
- “[forward-cache-info](#)” on page 187 instructs the proxy server to forward information about local cache hits to remote servers.
- “[forward-cipher](#)” on page 187 instructs the proxy server to forward the name of the client’s SSL/TLS cipher suite to remote servers.
- “[forward-ip](#)” on page 187 instructs the proxy server to forward the client’s IP address to remote servers.
- “[forward-issuer-dn](#)” on page 188 instructs the proxy server to forward the distinguished name of the issuer of the client’s SSL/TLS certificate to remote servers.
- “[forward-keysize](#)” on page 188 instructs the proxy server to forward the size of the client’s SSL/TLS key to remote servers.
- “[forward-proxy-auth](#)” on page 189 instructs the proxy server to forward the client’s proxy authentication credentials
- “[forward-secret-keysize](#)” on page 189 instructs the proxy server to forward the size of the client’s SSL/TLS secret key to remote servers.

- “[forward-ssl-id](#)” on page 189 instructs the proxy server to forward the client’s SSL/TLS session ID to remote servers.
- “[forward-user-dn](#)” on page 190 instructs the proxy server to forward the distinguished name of the subject of the client’s SSL/TLS certificate to remote servers.
- “[http-client-config](#)” on page 190 configures the proxy server’s HTTP client.
- “[java-ip-check](#)” on page 191 allows clients to query the proxy server for the IP address used to reroute a resource.
- “[match-browser](#)” on page 138 matches specific strings in the User - Agent string supplied by the browser, and then modifies the behavior of Sun Java System Web Proxy Server based upon the results by setting values for specified variables.
- “[set-basic-auth](#)” on page 192 sets the HTTP basic authentication credentials used by the proxy server when it sends an HTTP request.
- “[set-default-type](#)” on page 192 enables you to define a default charset, content - encoding, and content - language for the response being sent back to the client.
- “[set-variable](#)” on page 193 enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands.
- “[shtml-hacktype](#)” on page 193 requests that .htm and .html files are parsed for server-parsed HTML commands.
- “[ssl-client-config](#)” on page 194 configures options used when the proxy server connects to a remote server using SSL/TLS.
- “[suppress-request-headers](#)” on page 194 configures the proxy server to remove outgoing headers from the request.
- “[type-by-exp](#)” on page 194 sets the Content - Type header for the response based on the requested path.
- “[type-by-extension](#)” on page 195 sets the Content - Type header for the response based on the file’s extension and the MIME types database.

block-auth-cert

Applicable in `ObjectType`-class directives.

The `block-auth-cert` function instructs the proxy server not to forward the client’s SSL/TLS certificate to remote servers.

Parameters

None.

block-cache-info

Applicable in `ObjectType`-class directives.

The `block-cache-info` function instructs the proxy server not to forward information about local cache hits to remote servers.

Parameters

None.

block-cipher

Applicable in `ObjectType`-class directives.

The `block-cipher` function instructs the proxy server to forward the name of the client's SSL/TLS cipher suite to remote servers.

Parameters

None.

block-ip

Applicable in `ObjectType`-class directives.

The `block-ip` function instructs the proxy server not to forward the client's IP address to remote servers.

Parameters

None.

block-issuer-dn

Applicable in `ObjectType`-class directives.

The `block-issuer-dn` function instructs the proxy server not to forward the distinguished name of the issuer of the client's SSL/TLS certificate to remote servers.

Parameter

None.

block-keysize

Applicable in `ObjectType`-class directives.

The `block-keysize` function instructs the proxy server not to forward the size of the client's SSL/TLS key to remote servers.

Parameters

None.

block-proxy-auth

Applicable in `ObjectType`-class directives.

The `block-proxy-auth` function instructs the proxy server not to forward the client's proxy authentication credentials, that is, the client's Proxy-authorization HTTP request header, to remote servers.

Parameter

None.

block-secret-keysize

Applicable in `ObjectType`-class directives.

The `block-secret-keysize` function instructs the proxy server not to forward the size of the client's SSL/TLS secret key to remote servers.

Parameters

None.

block-ssl-id

Applicable in `ObjectType`-class directives.

The `block-ssl-id` function instructs the proxy server not to forward the client's SSL/TLS session ID to remote servers.

Parameters

None.

block-user-dn

Applicable in `ObjectType`-class directives.

The `block-user-dn` function instructs the proxy server not to forward the distinguished name of the subject of the client's SSL/TLS certificate to remote servers.

Parameters

None.

cache-disable

Applicable in `ObjectType`-class directives.

The `cache-disable` function disables cache. It replaces the `cache-enable` function when cache is disabled through the administration interface.

Syntax

```
ObjectType fn=cache-disable
```

Parameters

None.

cache-enable

Applicable in `ObjectType`-class directives.

The `cache_enable` function tells the proxy that an object is cacheable, based on specific criteria. As an example, if the function appears in the object `<Object ppath="http://.*">`, then all the HTTP documents are considered cacheable, as long as other conditions for an object to be cacheable are met.

Syntax

```
ObjectType fn=cache-enable
  cache-auth=0|1
  query-maxlen=number
  min-size=number
  max-size=number    log-report=feature
  cache-local=0|1
```

Parameters

The following table describes the parameter for the `cache-enable` function.

TABLE 5-74 cache-enable Parameters

Parameter	Description
cache-enable	Tells the proxy that an object is cacheable. As an example, if it appears in the object <Object ppath="http://.*">, then all HTTP documents are considered cacheable as long as other conditions for an object to be cacheable are met.
cache-auth	Specifies whether to cache items that require authentication. If set to 1, pages that require authentication can be cached also. If not specified, defaults to 0.
query-maxlen	Specifies the number of characters in the query string the “?string” part at the end of the URL that are still cacheable. The same queries are rarely repeated exactly in the same form by more than one user, and so caching them is often not desirable. That’s why the default is 0.
min-size	The minimum size, in kilobytes, of any document to be cached. The benefits of caching are greatest with the largest documents. For this reason, some people prefer to cache only larger documents.
max-size	The maximum size in kilobytes of any document to be cached. This setting allows users to limit the maximum size of cached documents, so no single document can take up too much space.
log-report	Used to control the feature that reports local cache accesses back to the origin server so that content providers get their true access logs.
cache-local	Used to enable local host caching, that is, URLs without fully qualified domain names, in the proxy. If set to 1, local hosts are cached. If not specified, it defaults to 0, and local hosts are not cached.

Example

The following example of `cache-enable` allows you to enable caching of objects matching the current resource. This function applies to normal, non-query, non-authenticated documents of any size. The proxy requires that the document carries either `last-modified` or `expires` headers or both, and that the `content-type` reported by the origin server is accurate.

```
ObjectType fn=cache-enable
```

The example below is like the first example, but it also caches documents that require user authentication, and it caches queries up to five characters long. The `cache-auth=1` indicates that an up-to-date check is always required for documents that need user authentication. This function forces authentication again.

```
ObjectType fn=cache-enable
  cache-auth=1
  query-maxlen=5
```

The example below is also like the first example, except that it limits the size of cache files to a range of 2 Kbytes to 1 Mbytes.

```
ObjectType fn=cache-enable
    min-size=2
    max-size=1000
```

cache-setting

Applicable in `ObjectType`-class directives.

`cache-setting` is an `ObjectType` function that sets parameters used for cache control.

This function is used to explicitly cache or not cache a resource, create an object for that resource, and set the caching parameters for the object.

Syntax

```
ObjectType fn=cache-setting
    max-uncheck=seconds
    lm-factor=factor    connect-mode=always|fast-demo|never
    cover-errors=number
```

Parameters

The following table describes the parameter for the `cache-setting` function.

TABLE 5-75 `cache-setting` Parameters

Parameter	Description
<code>max-uncheck</code>	(Optional) is the maximum time in seconds allowed between consecutive up-to-date checks. If set to 0 (default), a check is made every time the document is accessed, and the <code>lm-factor</code> has no effect.
<code>lm-factor</code>	(optional) A floating-point number representing the factor used in estimating expiration time, which is how long a document might be up to date based on the time it was last modified. The time elapsed since the last modification is multiplied by this factor. The result gives the estimated time the document is likely to remain unchanged. Specifying a value of 0 turns off this function. The caching system then uses only explicit expiration information which is rarely available. Only explicit Expires HTTP headers are used. This value has no effect if <code>max-uncheck</code> is set to 0.

TABLE 5-75 cache-setting Parameters (Continued)

Parameter	Description
connect-mode	Specifies network connectivity and can be set to these values: <ul style="list-style-type: none"> ■ always (default) connects to remote servers when necessary. ■ fast-demo connects only if the item isn't found in the cache. ■ never no connection to a remote server is ever made; returns an error if the document is not found in the cache.
cover-errors	If present and greater than 0, returns a document from the cache if the remote server is down and an up-to-date check cannot be made. The value specified is the maximum number of seconds since the last up-to-date check; if more time has elapsed, an error is returned. Using this feature involves the risk of getting stale data from the cache while the remote server is down. Setting this value to 0, or not specifying it (default) causes an error to be returned if the remote server is unavailable.
term-percent	Indicates that the server should keep retrieving data if more than the specified percentage of the document has already been retrieved.

Example

```
<Object ppath="http://.*">
ObjectType fn=cache-enable
ObjectType fn=cache-setting max-uncheck="7200"
ObjectType fn=cache-setting lm-factor="0.020"
ObjectType fn=cache-setting connect-mode="fast-demo"
ObjectType fn=cache-setting cover-errors="3600"
Service fn=proxy-retrieve
</Object>

# Force check every time
ObjectType fn=cache-setting max-uncheck=0
# Check every 30 minutes, or sooner if changed less than
# 6 hours ago (factor 0.1; last change 1 hour ago would
# give 6-minute maximum check interval).
ObjectType fn=cache-setting max-uncheck=1800 lm-factor=0.1
```

force-type

Applicable in ObjectType-class directives.

The force-type function assigns a type to requests that do not already have a MIME type. This function is used to specify a default object type.

Make sure that the directive that calls this function comes last in the list of ObjectType directives, so that all other ObjectType directives have a chance to set the MIME type first. If an

object contains more than one `ObjectType` directive all of the directives are applied in the order they appear. If a directive sets an attribute and later directives try to set that attribute to a different value, the first setting is used and the subsequent settings are ignored.

Parameters

The following table describes the parameter for the `force-type` function.

TABLE 5-76 `force-type` parameters

Parameter	Description
<code>type</code>	(Optional) Type assigned to a matching request (the <code>Content-Type</code> header).
<code>enc</code>	(Optional) Encoding assigned to a matching request (the <code>Content-Encoding</code> header).
<code>lang</code>	(Optional) Language assigned to a matching request (the <code>Content-Language</code> header).
<code>charset</code>	(Optional) Character set for the <code>magnus-charset</code> parameter in <code>rq->svhdrs</code> . If the browser sent the <code>Accept-Charset</code> header or its <code>User-Agent</code> is Mozilla™/1.1 or newer, then append “; <code>charset=charset</code> ” to <code>content-type</code> , where <code>charset</code> is the value of the <code>magnus-charset</code> parameter in <code>rq->svhdrs</code> .
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
ObjectType fn=force-type type=text/plain
ObjectType fn=force-type lang=en_US
```

See Also

[“type-by-extension” on page 195](#), [“type-by-exp” on page 194](#)

forward-auth-cert

Applicable in `ObjectType-class` directives.

The `forward-auth-cert` function instructs the proxy server to forward the client’s SSL/TLS certificate to remote servers.

Parameters

The following table describes the parameter for the `forward-auth-cert` function.

TABLE 5-77 forward-auth-cert Parameters

Parameter	Description
hdr	(Optional) Name of the HTTP request header used to communicate the client's DER-encoded SSL/TLS certificate in Base64 encoding. The default is Proxy-auth-cert.

forward-cache-info

Applicable in ObjectType-class directives.

The forward-cache-info function instructs the proxy server to forward information about local cache hits to remote servers.

Parameter

The following table describes the parameter for the forward-cache-info function.

TABLE 5-78 forward-cache-info Parameters

Parameter	Description
hdr	(Optional) Name of the HTTP request header used to communicate information about local cache hits. The default is Cache-info.

forward-cipher

Applicable in ObjectType-class directives.

The forward-cipher function instructs the proxy server to forward the name of the client's SSL/TLS cipher suite to remote servers.

Parameters

The following table describes the parameter for the forward-cipher function.

TABLE 5-79 forward-cipher Parameters

Parameter	Description
hdr	(Optional) Name of the HTTP request header used to communicate the name of the client's SSL/TLS cipher suite. The default is Proxy-cipher.

forward-ip

Applicable in ObjectType-class directives.

The `forward-ip` function instructs the proxy server to forward the client's IP address to remote servers.

Parameters

The following table describes the parameter for the `forward-ip` function.

TABLE 5-80 `forward-ip` Parameters

Parameter	Description
<code>hdr</code>	(Optional) Name of the HTTP request header used to communicate the client's IP address. The default is <code>Client-ip</code> .

`forward-issuer-dn`

Applicable in `ObjectType`-class directives.

The `forward-issuer-dn` function instructs the proxy server to forward the distinguished name of the issuer of the client's SSL/TLS certificate to remote servers.

Parameters

The following table describes the parameter for the `forward-issuer-dn` function.

TABLE 5-81 `forward-issuer-dn`

Parameter	Description
<code>hdr</code>	(Optional) Name of the HTTP request header used to communicate the distinguished name of the issuer of the client's SSL/TLS certificate. The default is <code>Proxy-issuer-dn</code> .

`forward-keysize`

Applicable in `ObjectType`-class directives.

The `forward-keysize` function instructs the proxy server to forward the size of the client's SSL/TLS key to remote servers.

Parameters

The following table describes the parameter for the `forward-keysize` function.

TABLE 5-82 forward-keysize

Parameter	Description
hdr	(Optional) Name of the HTTP request header used to communicate the size of the client's SSL/TLS key. The default is Proxy-keysize.

forward-proxy-auth

Applicable in ObjectType-class directives.

The forward-proxy-auth instructs the proxy server to forward the client's proxy authentication credentials, that is, the client's Proxy-authorization HTTP request header, to remote servers.

Parameters

None.

forward-secret-keysize

Applicable in ObjectType-class directives.

The forward-secret-keysize function instructs the proxy server to forward the size of the client's SSL/TLS secret key to remote servers.

Parameters

The following table describes the parameter for the forward-secret-keysize function.

TABLE 5-83 forward-secret-keysize Parameters

Parameter	Description
hdr	(Optional) Name of the HTTP request header used to communicate the size of the client's SSL/TLS secret key. The default is Proxy-secret-keysize.

forward-ssl-id

Applicable in ObjectType-class directives.

The forward-ssl-id function instructs the proxy server to forward the client's SSL/TLS session ID to remote servers.

Parameter

The following table describes the parameter for the forward-ssl-id function.

TABLE 5-84 forward-ssl-id Parameters

Parameter	Description
hdr	(Optional) Name of the HTTP request header used to communicate the client's SSL/TLS session ID. The default is Proxy-ssl-id.

forward-user-dn

Applicable in ObjectType-class directives.

The forward-user-dn function instructs the proxy server to forward the distinguished name of the subject of the client's SSL/TLS certificate to remote servers.

Parameters

The following table describes the parameter for the forward-user-dn function.

TABLE 5-85 forward-user-dn Parameters

Parameter	Description
hdr	(Optional) Name of the HTTP request header used to communicate the distinguished name of the subject of the client's SSL/TLS certificate. The default is Proxy-user-dn.

http-client-config

Applicable in ObjectType-class directives.

The http-client-config function configures the proxy server's HTTP client.

Parameters

The following table describes the parameter for the http-client-config function.

TABLE 5-86 http-client-config Parameters

Parameter	Description
keep-alive	(Optional) Boolean that indicates whether the HTTP client should attempt to use persistent connections. The default is true.
keep-alive-timeout	(Optional) The maximum number of seconds to keep a persistent connection open. The default is 29.

TABLE 5-86 http-client-config Parameters (Continued)

Parameter	Description
always-use-keep-alive	(Optional) Boolean that indicates whether the HTTP client can reuse existing persistent connections for all types of requests. The default is <code>false</code> , meaning persistent connections will not be reused for non-GET requests nor for requests with a body.
protocol	(Optional) HTTP protocol version string. By default, the HTTP client uses either "HTTP/1.0" or "HTTP/1.1" based on the contents of the HTTP request. Do not use the protocol parameter unless you encounter specific protocol interoperability problems.
proxy-agent	(Optional) Value of the Proxy-agent HTTP request header. The default is a string that contains the proxy server product name and version.

java-ip-check

Applicable in `ObjectType`-class directives.

The `java-ip-check` function enables clients to query the proxy server for the IP address used to reroute a resource. Because DNS spoofing often occurs with Java applets, this feature enables clients to see the true IP address of the origin server. When this feature is enabled, the proxy server attaches a header containing the IP address that was used for connecting to the destination origin server.

Syntax

```
ObjectType fn=java-ip-check
      status=on|off
```

Parameters

The following table describes the parameter for the `java-ip-check` function.

TABLE 5-87 java-ip-check Parameters

Parameter	Description
status	Specifies whether Java IP address checking is enabled. Possible values are: <ul style="list-style-type: none"> ■ <code>on</code> means that Java IP address checking is enabled and that IP addresses will be forwarded to the client in the form of a document header. <code>on</code> is the default setting. ■ <code>off</code> means that Java IP address checking is disabled.

match-browser

See [“match-browser” on page 138](#).

set-basic-auth

Applicable in `ObjectType`-class directives.

The `set-basic-auth` function sets the HTTP basic authentication credentials used by the proxy server when it sends an HTTP request. `set-basic-auth` can be used to authenticate to a remote origin server or proxy server.

Parameters

The following table describes the parameter for the `set-basic-auth` function.

TABLE 5-88 `set-basic-auth` Parameters

Parameter	Description
<code>user</code>	To authenticate user
<code>password</code>	The user's password
<code>hdr</code>	(Optional) Name of the HTTP request header used to communicate the credentials

set-default-type

Applicable in `ObjectType`-class directives.

The `set-default-type` function enables you to define a default `charset`, `content-encoding`, and `content-language` for the response being sent back to the client.

If the `charset`, `content-encoding`, and `content-language` have not been set for a response, then just before the headers are sent the defaults defined by `set-default-type` are used. By placing this function in different objects in `obj.conf`, you can define different defaults for different parts of the document tree.

Parameters

The following table describes the parameter for the `set-default-type` function.

TABLE 5-89 set-default-type Parameters

Parameter	Description
enc	(Optional) Encoding assigned to a matching request (the Content-Encoding header).
lang	(Optional) Language assigned to a matching request (the Content-Language header).
charset	(Optional) Character set for the magnus-charset parameter in <code>rq->srvhdrs</code> . If the browser sent the Accept-Charset header or its User-agent is Mozilla/1.1 or newer, then append “; charset= <i>charset</i> ” to <code>content-type</code> , where <i>charset</i> is the value of the magnus-charset parameter in <code>rq->srvhdrs</code> .
bucket	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
ObjectType fn="set-default-type" charset="iso_8859-1"
```

set-variable

See [“set-variable” on page 143](#).

shtml-hacktype

Applicable in `ObjectType`-class directives.

The `shtml-hacktype` function changes the Content-Type of any `.htm` or `.html` file to `magnus-internal/parsed-html` and returns `REQ_PROCEED`. This function provides backward compatibility with server-side includes for files with `.htm` or `.html` extensions. The function can also check the execute bit for the file on UNIX systems. The use of this function is not recommended.

Parameters

The following table describes the parameter for the `shtml-hacktype` function.

TABLE 5-90 shtml-hacktype Parameters

Parameter	Description
exec-hack	(UNIX only, optional) Indicates that the function should change the content-type only if the execute bit is enabled. The value of the parameter is not important; it need only be provided. You may use <code>exec-hack=true</code> .
bucket	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
ObjectType fn=shtml-hacktype exec-hack=true
```

ssl-client-config

Applicable in `ObjectType-class` directives.

The `ssl-client-config` function configures options used when the proxy server connects to a remote server using SSL/TLS.

Parameter

The following table describes the parameter for the `ssl-client-config` function.

TABLE 5-91 ssl-client-config Parameters

Parameter	Description
client-cert-nickname	(Optional) Nickname of the client certificate to present to the remote server. The default is not to present a client certificate.
validate-server-cert	(Optional) Boolean that indicates whether the proxy server validates the certificate presented by the remote server. The default is <code>false</code> , meaning the proxy server will accept any certificate.

suppress-request-headers

See “[suppress-request-headers](#)” on page 118.

type-by-exp

Applicable in `ObjectType-class` directives.

The `type-by-exp` function matches the current path with a wildcard expression. If the two match, the type parameter information is applied to the file. This function is the same as [“type-by-extension” on page 195](#) except that you use wildcard patterns for the files or directories specified in the URLs.

Parameters

The following table describes the parameter for the `type-by-exp` function.

TABLE 5-92 `type-by-exp` Parameters

Parameter	Description
<code>exp</code>	Wildcard pattern of paths for which this function is applied.
<code>type</code>	(Optional) Type assigned to a matching request (the <code>Content-Type</code> header).
<code>enc</code>	(Optional) Encoding assigned to a matching request (the <code>Content-Encoding</code> header).
<code>lang</code>	(Optional) Language assigned to a matching request (the <code>Content-Language</code> header).
<code>charset</code>	(Optional) The character set for the <code>magnus-charset</code> parameter in <code>rq->srvhdrs</code> . If the browser sent the <code>Accept-Charset</code> header or its <code>User-Agent</code> is <code>Mozilla/1.1</code> or newer, then append <code>“; charset=charset”</code> to <code>content-type</code> , where <code>charset</code> is the value of the <code>magnus-charset</code> parameter in <code>rq->srvhdrs</code> .
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
ObjectType fn=type-by-exp exp=*.test type=application/html
```

See Also

[“type-by-extension” on page 195](#), [“force-type” on page 185](#)

type-by-extension

Applicable in `ObjectType`-class directives.

The `type-by-extension` function instructs the server to look in a table of MIME type mappings to find the MIME type of the requested resource according to the extension of the requested resource. The MIME type is added to the `Content-Type` header sent back to the client.

The table of MIME type mappings is created by a `MIME` element in the `server.xml` file, which loads a MIME types file or list and creates the mappings. For more information about `server.xml`, see [Chapter 2, “Server Configuration Elements in the `server.xml` file.”](#)

For example, the following two lines are part of a MIME types file:

```
type=text/html    exts=htm,html type=text/plain    exts=.txt
```

If the extension of the requested resource is `htm` or `html`, the `type-by-extension` file sets the type to `text/html`. If the extension is `.txt`, the function sets the type to `text/plain`.

Parameters

The following table describes the parameter for the `type-by-extension` function.

TABLE 5-93 `type-by-extension` Parameters

Parameter	Description
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
ObjectType fn=type-by-extension
```

See Also

[“type-by-exp” on page 194](#), [“force-type” on page 185](#)

Input

All Input directives are executed when the server or a plug-in first attempts to read entity body data from the client.

The Input stage enables you to select filters that will process incoming request data read by the Service step.

NSAPI filters in Sun Java System Web Proxy Server 4 enable a function to intercept (and potentially modify) the content presented to or generated by another function.

You can add NSAPI filters that process incoming data by invoking the `insert-filter` SAF in the Input stage of the request-handling process. The Input directives are executed at most once per request.

You can also define the appropriate position of a specific filter within the filter stack. For example, filters that translate content from XML to HTML are placed higher in the filter stack

than filters that compress data for transmission. You can use the `filter_create` function to define the filter's position in the filter stack, and the `init-filter-order` to override the defined position.

When two or more filters are defined to occupy the same position in the filter stack, filters that were inserted later will appear higher than filters that were inserted earlier. The order of `Input fn="insert-filter"` and `Output fn="insert-filter"` directives in `obj.conf` is important.

The following Input-class functions are described in detail in this section:

- [“insert-filter” on page 197](#) adds a filter to the filter stack to process incoming data.
- [“match-browser” on page 198](#) matches specific strings in the User-Agent string supplied by the browser, and then modifies the behavior of the Sun Java System Web Proxy Server based upon the results by setting values for specified variables.
- [“remove-filter” on page 198](#) removes a filter from the filter stack.
- [“set-variable” on page 199](#) enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands.

insert-filter

Applicable in Input-class directives.

The `insert-filter` SAF is used to add a filter to the filter stack to process incoming (client-to-server) data.

The order of `Input fn="insert-filter"` and `Output fn="insert-filter"` directives can be important.

Returns

Returns `REQ_PROCEED` if the specified filter was inserted successfully or `REQ_NOACTION` if the specified filter was not inserted because it was not required. Any other return value indicates an error.

Parameters

The following table describes the parameter for the `insert-filter` function.

TABLE 5-94 `insert-filter` Parameters

Parameter	Description
<code>filter</code>	Specifies the name of the filter to insert.

TABLE 5-94 insert-filter Parameters (Continued)

Parameter	Description
bucket	(Optional) Common to all obj.conf functions.

Example

Input `fn="insert-filter" filter="http-decompression"`

match-browser

See [“match-browser” on page 138](#).

remove-filter

Applicable in Input-, Output-, Service-, and Error-class directives.

The `remove-filter` SAF is used to remove a filter from the filter stack. If the filter has been inserted multiple times, only the topmost instance is removed. You do not have to remove filters with `remove-filter` because they will be removed automatically at the end of the request.

Returns

Returns `REQ_PROCEED` if the specified filter was removed successfully, or `REQ_NOACTION` if the specified filter was not part of the filter stack. Any other return value indicates an error.

Parameters

The following table describes the parameter for the `remove-filter` function.

TABLE 5-95 remove-filter Parameters

Parameter	Description
filter	Specifies the name of the filter to remove.
bucket	(Optional) Common to all obj.conf functions.

Example

Input `fn="remove-filter" filter="http-compression"`

set-variable

Applicable in all stage directives. The `set-variable` SAF enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands. See “[set-variable](#)” on page 143.

Output

All Output directives are executed when the server or a plug-in first attempts to write entity body data from the client.

The Output stage enables you to select filters that will process outgoing data.

You can add NSAPI filters that process outgoing data by invoking the `insert-filter` SAF in the Output stage of the request-handling process. The Output directives are executed at most once per request.

You can define the appropriate position of a specific filter within the filter stack. For example, filters that translate content from XML to HTML are placed higher in the filter stack than filters that compress data for transmission. You can use the `filter_create` function to define the filter’s position in the filter stack, and the `init-filter-order` to override the defined position.

When two or more filters are defined to occupy the same position in the filter stack, filters that were inserted later will appear higher than filters that were inserted earlier.

The following Output-class functions are described in detail in this section:

- “[content-rewrite](#)” on page 199 rewrites the string in the document that is being sent to the client.
- “[insert-filter](#)” on page 200 adds a filter to the filter stack to process outgoing data.
- “[match-browser](#)” on page 201 matches specific strings in the User-Agent string supplied by the browser, and then modifies the behavior of the Sun Java System Web Proxy Server based upon the results by setting values for specified variables.
- “[remove-filter](#)” on page 201 removes a filter from the filter stack.
- “[set-variable](#)” on page 202 enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands.

content-rewrite

The `content-rewrite` function rewrites the string in the document that is being sent to the client.

When a document is sent by the proxy server, the `content-rewrite` function is invoked if it has been configured and would replace the `from string/url` to `destination string/url` before sending the response to the client.

The patterns are strings that would be replaced in the outgoing document. The pattern can be either a URL with absolute or relative links, or any text string such as the server name and the like.

Syntax

```
Output fn="insert-filter" filter="content-rewrite" type="text/html"
      from="<sourcepattern>" to="<destpattern>"
```

Parameters

The following table describes the parameter for the `content-rewrite` function.

TABLE 5-96 `content-rewrite` Parameters

Parameter	Description
<code>filter</code>	Specifies the name of the filter to be executed.
<code>type</code>	Indicates the content-type on which this filter is applied, for example, text, html, and so on.

Example

```
Output fn="insert-filter" type="text/*" filter="content-rewrite"
      from="iPlanet" to="Sun ONE (now called) Sun Java System Web Server"
```

insert-filter

Applicable in `Output-class` directives.

The `insert-filter` SAF is used to add the content rewriting engine to the filter stack to process outgoing server-to-client data.

This directive should appear in the `http://.*` and `https://.*` objects inside of the `obj.conf` file.

The `insert-filter` SAF will result in rewriting if the request had been associated with a filter by `um-ntrans` (See [“um-ntrans” on page 158](#)).

The order of `Input fn="insert-filter"` and `Output fn="insert-filter"` directives can be important.

Returns

Returns `REQ_PROCEED` if the specified filter was inserted successfully, or `REQ_NOACTION` if the specified filter was not inserted because it was not required. Any other return value indicates an error.

Parameters

The following table describes the parameter for the `insert-filter` function.

TABLE 5-97 `insert-filter` parameters

Parameter	Description
<code>filter</code>	Specifies the name of the filter to insert. Must be set to "um-output".
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.
<code>type</code>	Specifies the MIME types to which the filter will be applied. It can be omitted, as the filter makes its own choices about what types of content to filter. If it is provided, it should be set to "*".

Example

```
Output fn="insert-filter" filter="um-output"
```

match-browser

See [“match-browser” on page 138](#).

remove-filter

Applicable in `Input-`, `Output-`, `Service-`, and `Error-class` directives.

The `remove-filter` SAF is used to remove a filter from the filter stack. If the filter has been inserted multiple times, only the topmost instance is removed. You do not have to remove filters with `remove-filter`, as they will be removed automatically at the end of the request.

Returns

Returns `REQ_PROCEED` if the specified filter was removed successfully, or `REQ_NOACTION` if the specified filter was not part of the filter stack. Any other return value indicates an error.

Parameters

The following table describes the parameter for the `remove-filter` function.

TABLE 5-98 remove-filter Parameters

Parameter	Description
filter	Specifies the name of the filter to remove.
bucket	(Optional) Common to all obj.conf functions.

Example

```
Output fn="remove-filter" filter="http-compression"
```

set-variable

Applicable in all stage directives. The `set-variable` SAF enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands. See [“set-variable” on page 143](#).

Service

The `Service`-class of functions sends the response data to the client.

Every `Service` directive has the following optional parameters to determine whether the function is executed. All optional parameters must match the current request for the function to be executed.

- `method`
(Optional) Specifies a wildcard pattern of HTTP methods for which this function will be executed. Common HTTP methods are GET, HEAD, and POST.
- `query`
(Optional) Specifies a wildcard pattern of query strings for which this function will be executed.
- `UseOutputStreamSize`
(Optional) Determines the default output stream buffer size, in bytes, for data sent to the client. If this parameter is not specified, the default is 8192 bytes.

Note – The `UseOutputStreamSize` parameter can be set to zero (0) in the `obj.conf` file to disable output stream buffering. For the `magnus.conf` file, setting `UseOutputStreamSize` to zero (0) has no effect.

- `flushTimer`

(Optional) Determines the maximum number of milliseconds between write operations in which buffering is enabled. If the interval between subsequent write operations is greater than the `flushTimer` value for an application, further buffering is disabled. This parameter is necessary for status-monitoring CGI applications that run continuously and generate periodic status update reports. If this parameter is not specified, the default is `3000` milliseconds.

- `ChunkedRequestBufferSize`

(Optional) Determines the default buffer size, in bytes, for “un-chunking” request data. If this parameter is not specified, the default is `8192` bytes.

- `ChunkedRequestTimeout`

(Optional) Determines the default timeout, in seconds, for “un-chunking” request data. If this parameter is not specified, the default is `60` seconds.

- `timeout`

(Optional) Used by the FTP and connect proxy to determine the value of connection timeout.

If an object contains more than one `Service`-class function, the first one matching the optional wildcard parameters (`method`, and `query`) is executed.

By default, the server sends the requested file to the client by calling the “[send-file](#)” on page 220 function.

```
Service method="(GET|HEAD)" fn="send-file"
```

This directive usually comes last in the set of `Service`-class directives to give all other `Service` directives a chance to be invoked. This directive is invoked if the method of the request is `GET`, `HEAD`, or `POST`. For a list of characters that can be used in patterns, see the [Sun Java System Web Proxy Server 4.0.8 NSAPI Developer’s Guide](#).

The following `Service`-class functions are described in detail in this section:

- “[add-footer](#)” on page 204 appends a footer specified by a file name or URL to an HTML file.
- “[add-header](#)” on page 206 prepends a header specified by a file name or URL to an HTML file.
- “[append-trailer](#)” on page 207 appends text to the end of an HTML file.
- “[deny-service](#)” on page 208 prevents access to the requested resource.
- “[imagemap](#)” on page 208 handles server-side image maps.
- “[index-common](#)” on page 208 generates a formatted list of the files and directories in a requested directory.
- “[index-simple](#)” on page 210 generates a simple list of files and directories in a requested directory.
- “[key-toosmall](#)” on page 211 indicates to the client that the provided certificate key size is too small to accept.

- “list-dir” on page 212 lists the contents of a directory.
- “make-dir” on page 213 creates a directory.
- “match-browser” on page 214 matches specific strings in the User-Agent string supplied by the browser, and then modifies the behavior of the Sun Java System Web Proxy Server based upon the results by setting values for specified variables.
- “proxy-retrieve” on page 214 retrieves a document from a remote server and returns it to the client. If this function manages caching if it is enabled.
- “query-handler” on page 215 handles the HTML ISINDEX tag.
- “remove-dir” on page 216 deletes an empty directory.
- “remove-file” on page 216 deletes a file.
- “remove-filter” on page 217 removes a refilter from the filter stack.
- “rename-file” on page 218 renames a file.
- “send-error” on page 219 sends an HTML file to the client in place of a specific HTTP response status.
- “send-file” on page 220 sends a local file to the client.
- “send-range” on page 221 sends a range of bytes of a file to the client.
- “send-shellcgi” on page 221 sets up environment variables, launches a shell CGI program, and sends the response to the client.
- “send-wincgi” on page 222 sets up environment variables, launches a WinCGI program, and sends the response to the client.
- “service-dump” on page 223 creates a performance report based on collected performance bucket data.
- “service-j2ee” on page 224 services requests made to Java web applications. This function is applicable only to the Administration Server.
- “service-trace” on page 225 services TRACE requests.
- “set-variable” on page 225 enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands.
- “shtml_send” on page 225 parses an HTML file for server-parsed HTML commands.
- “stats-xml” on page 226 creates a performance report in XML format.
- “upload-file” on page 228 uploads and saves a file.

add-footer

Applicable in Service-class directives.

This function appends a footer to an HTML file that is sent to the client. The footer is specified either as a file name or a URI. The footer therefore, can be dynamically generated. To specify static text as a footer, use the [“append-trailer” on page 207](#) function.

Parameters

The following table describes parameters for the add - footer function.

TABLE 5-99 add - footer Parameters

Parameter	Description
file	(Optional) Path name to the file containing the footer. Specify either <code>file</code> or <code>uri</code> . By default, the path name is relative. If the path name is absolute, pass the <code>NSIntAbsFilePath</code> parameter as <code>yes</code> .
uri	(Optional) URI pointing to the resource containing the footer. Specify either <code>file</code> or <code>uri</code> .
NSIntAbsFilePath	(Optional) If the file parameter is specified, the <code>NSIntAbsFilePath</code> parameter determines whether the file name is absolute or relative. The default is relative. Set the value to <code>yes</code> to indicate an absolute file path.
method	(Optional) Common to all <code>Service</code> -class functions.
query	(Optional) Common to all <code>Service</code> -class functions.
UseOutputStreamSize	(Optional) Common to all <code>Service</code> -class functions.
flushTimer	(Optional) Common to all <code>Service</code> -class functions.
ChunkedRequestBufferSize	(Optional) Common to all <code>Service</code> -class functions.
ChunkedRequestTimeout	(Optional) Common to all <code>Service</code> -class functions.
bucket	(Optional) Common to all <code>obj.conf</code> functions.

Examples

```
Service method=GET fn=add-footer file=
    "footers/footer1.html"
Service method=GET fn=add-footer
    file="D:/Sun/Server1/server1/footers/footer1.html"
    NSIntAbsFilePath="yes"
```

See Also

[“append-trailer” on page 207](#), [“add-header” on page 206](#)

add-header

Applicable in Service-class directives.

This function prepends a header to an HTML file that is sent to the client. The header is specified either as a file name or a URI, thus the header can be dynamically generated.

Parameters

The following table describes parameters for the add - header function.

TABLE 5-100 add-header parameters

Parameter	Description
file	(Optional) Path name to the file containing the header. Specify either <code>file</code> or <code>uri</code> . By default, the path name is relative. If the path name is absolute, pass the <code>NSIntAbsFilePath</code> parameter as <code>yes</code> .
uri	(Optional) URI pointing to the resource containing the header. Specify either <code>file</code> or <code>uri</code> .
NSIntAbsFilePath	(Optional) If the file parameter is specified, the <code>NSIntAbsFilePath</code> parameter determines whether the file name is absolute or relative. The default is relative. Set the value to <code>yes</code> to indicate an absolute file path.
method	(Optional) Common to all Service-class functions.
query	(Optional) Common to all Service-class functions.
UseOutputStreamSize	(Optional) Common to all Service-class functions.
flushTimer	(Optional) Common to all Service-class functions.
ChunkedRequestBufferSize	(Optional) Common to all Service-class functions.
ChunkedRequestTimeout	(Optional) Common to all Service-class functions.
bucket	(Optional) Common to all <code>obj.conf</code> functions.

Examples

```
Service method=GET fn=add-header file="headers/header1.html"
Service method=GET fn=add-footer
    file="D:/Sun/Server61/server1/headers/header1.html" NSIntAbsFilePath="yes"
```

See Also

[“add-footer” on page 204](#), [“append-trailer” on page 207](#)

append-trailer

Applicable in Service-class directives.

The `append-trailer` function sends an HTML file and appends text to the end. It only appends text to HTML files. This function is typically used for author information and copyright text. The date the file was last modified can be inserted.

Returns `REQ_ABORTED` if a required parameter is missing, if extra path information appears after the file name in the URL, or if the file cannot be opened for read-only access.

Parameters

The following table describes the parameters specific to the `append-trailer` function.

TABLE 5-101 `append-trailer` Parameters

Parameter	Description
<code>trailer</code>	Text to append to HTML documents. The string is unescaped with <code>util_uri_unescape</code> before being sent. The text can contain HTML tags, and can be up to 512 characters long after unescaping and inserting the date. If you use the string <code>:LASTMOD:</code> , which is replaced by the date the file was last modified, you must also specify a time format with <code>timefmt</code> .
<code>timefmt</code>	(Optional) Time format string for <code>:LASTMOD:</code> . If <code>timefmt</code> is not provided, <code>:LASTMOD:</code> will not be replaced with the time.
<code>method</code>	(Optional) Common to all Service-class functions.
<code>query</code>	(Optional) Common to all Service-class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all Service-class functions.
<code>flushTimer</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all Service-class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Examples

```
Service method=GET fn=append-trailer
    trailer="<hr><img src=/logo.gif> Copyright 1999"
# Add a trailer with the date in the format: MM/DD/YY
Service method=GET fn=append-trailer timefmt="%D"
    trailer="<HR>File last updated on: :LASTMOD:"
```

See Also

[“add-footer” on page 204](#), [“add-header” on page 206](#)

deny-service

See [“deny-service” on page 162](#).

imagemap

Applicable in Service-class directives.

The `imagemap` function responds to requests for imagemaps. Imagemaps are images that are divided into multiple areas that each have an associated URL. The information about the URL associated with each area is stored in a mapping file.

Parameters

The `imagemap` function has no specific parameters.

TABLE 5-102 `imagemap` Parameters

Parameter	Description
<code>method</code>	(Optional) Common to all Service-class functions.
<code>query</code>	(Optional) Common to all Service-class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all Service-class functions.
<code>flushTimer</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all Service-class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
Service method=(GET|HEAD) fn=imagemap
```

index-common

Applicable in Service-class directives.

The `index-common` function generates a formatted list of files in the requested directory. The list is sorted alphabetically. Files beginning with a period (.) are not displayed. Each item appears as an HTML link. This function displays more information than “[index-simple](#)” on page 210, including the size, date last modified, and an icon for each file. The listing might also include a header or readme file.

The `Init-class` function `cindex-init` in `magnus.conf` specifies the format for the index list, including where to look for the images.

If `obj.conf` contains a call to `index-common` in the `Service` stage, `magnus.conf` must initialize indexing by invoking `cindex-init` during the `Init` stage.

Indexing occurs when the requested resource is a directory that does not contain an index file or a home page, or no index file or home page has been specified by the functions “[find-index](#)” on page 164 or “[home-page](#)” on page 149.

The icons displayed are `.gif` files dependent on the `content-type` of the file, as listed in the following table

TABLE 5-103 content-type icons

Content-type	Icon
"text/*"	text.gif
"image/*"	image.gif
"audio/*"	sound.gif
"video/*"	movie.gif
"application/octet-stream"	binary.gif
directory	menu.gif
all others	unknown.gif

Parameters

The following table describes the parameters specific to the `index-common` function.

TABLE 5-104 index-common parameters

Parameter	Description
header	(Optional) Path relative to the directory being indexed and name of an HTML or plain file text that is included at the beginning of the directory listing to introduce the contents of the directory. The file is first tried with <code>.html</code> added to the end. If that name is found, the file is incorporated near the top of the directory list as HTML. If the file name is not found, it is tried without the <code>.html</code> and incorporated as preformatted plain text bracketed by <code><PRE></code> and <code></PRE></code> tags.
readme	(Optional) Path relative to the directory being indexed and name of an HTML or plain text file to append to the directory listing. This file might give more information about the contents of the directory, or indicate copyrights, authors, or other information. The file is first tried with <code>.html</code> added to the end. If that name is found, the file is incorporated at the bottom of the directory list as HTML. If the file name is not found, it is tried without the <code>.html</code> and incorporated as preformatted plain text bracketed by <code><PRE></code> and <code></PRE></code> tags.
method	(Optional) Common to all <code>Service</code> -class functions.
query	(Optional) Common to all <code>Service</code> -class functions.
UseOutputStreamSize	(Optional) Common to all <code>Service</code> -class functions.
flushTimer	(Optional) Common to all <code>Service</code> -class functions.
ChunkedRequestBufferSize	(Optional) Common to all <code>Service</code> -class functions.
ChunkedRequestTimeout	(Optional) Common to all <code>Service</code> -class functions.
bucket	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
Service fn=index-common method=(GET|HEAD)
    header=hdr readme=rdme.txt
```

See Also

[“index-simple” on page 210](#), [“find-index” on page 164](#), [“home-page” on page 149](#)

index-simple

Applicable in `Service`-class directives.

The `index-simple` function generates a simple index of the files in the requested directory. It scans a directory and returns an HTML page to the browser displaying a bulleted list of the files

and directories in the directory. The list is sorted alphabetically. Files beginning with a period (.) are not displayed. Each item appears as an HTML link.

Indexing occurs when the requested resource is a directory that does not contain either an index file or a home page, or no index file or home page has been specified by the functions [“find-index” on page 164](#) or [“home-page” on page 149](#).

Parameters

The `index-simple` function has no specific parameters.

TABLE 5-105 `index-simple` Parameters

Parameter	Description
<code>method</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>query</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>flushTimer</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
Service fn=index-simple
```

See Also

[“index-common” on page 208](#)

key-toosmall

Applicable in `Service`-class directives.

Note – This function is replaced by the `PathCheck`-class SAF [“ssl-check” on page 174](#).

The `key-toosmall` function returns a message to the client specifying that the secret key size for SSL communications is too small. This function is designed to be used together with a `Client` tag to limit access of certain directories to nonexportable browsers.

Parameters

The `key-toosmall` function has no specific parameters.

TABLE 5-106 `key-toosmall` Parameters

Parameter	Description
<code>method</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>query</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>flushTimer</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
<Object ppath=/mydocs/secret/*>Service fn=key-toosmall</Object>
```

list-dir

Applicable in `Service`-class directives.

The `list-dir` function returns a sequence of text lines to the client in response to a request whose method is `INDEX`. The format of the returned lines is:

```
name size mtime
```

The *name* field is the name of the file or directory. It is relative to the directory being indexed. It is URL-encoded, so any character might be represented by `%xx`, where `xx` is the hexadecimal representation of the character's ASCII number.

The *size* field is the size of the file, in bytes.

The *mtime* field is the numerical representation of the date of last modification of the file. The number is the number of seconds since the epoch (Jan 1, 1970 00:00 UTC) since the last modification of the file.

When remote file manipulation is enabled in the server, the `obj.conf` file contains a `Service`-class function that calls `list-dir` for requests whose method is `INDEX`.

Parameters

The `list-dir` function has no specific parameters.

TABLE 5-107 list-dir Parameters

Parameter	Description
method	(Optional) Common to all Service-class functions.
query	(Optional) Common to all Service-class functions.
UseOutputStreamSize	(Optional) Common to all Service-class functions.
flushTimer	(Optional) Common to all Service-class functions.
ChunkedRequestBufferSize	(Optional) Common to all Service-class functions.
ChunkedRequestTimeout	(Optional) Common to all Service-class functions.
bucket	(Optional) Common to all obj.conf functions.

Example

```
Service fn=list-dir method="INDEX"
```

make-dir

Applicable in Service-class directives.

The `make-dir` function creates a directory when the client sends a request whose method is MKDIR. The function can fail if the server can't write to that directory.

When remote file manipulation is enabled in the server, the `obj.conf` file contains a Service-class function that invokes `make-dir` when the request method is MKDIR.

Parameters

The `fmake-dir` function has no specific parameters.

TABLE 5-108 make-dir Parameters

Parameter	Description
method	(Optional) Common to all Service-class functions.
query	(Optional) Common to all Service-class functions.
UseOutputStreamSize	(Optional) Common to all Service-class functions.
flushTimer	(Optional) Common to all Service-class functions.
ChunkedRequestBufferSize	(Optional) Common to all Service-class functions.

TABLE 5-108 `make-dir` Parameters (Continued)

Parameter	Description
<code>ChunkedRequestTimeout</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
Service fn="make-dir" method="MKDIR"
```

match-browser

See “[match-browser](#)” on page 138.

proxy-retrieve

The `proxy-retrieve` function retrieves a document from a remote server and returns it to the client. It manages caching if it is enabled. The `proxy-retrieve` function also enables to you configure the proxy to allow or block arbitrary methods.

Syntax

```
Service fn=proxy-retrieve
    method=GET|HEAD|POST|INDEX|CONNECT...
    allow|block=<List-of-comma-separated-methods>
```

Parameters

`method` lets you specify a retrieval method.

`allow` configures the proxy to allow specified arbitrary methods.

`block` configures the proxy to block specified arbitrary methods.

Note – `allow` takes precedence over `block`.

Examples

```
# Normal proxy retrieve
Service fn=proxy-retrieve
# Proxy retrieve with POST method disabled
Service fn=proxy-retrieve
    method=(POST)
```

```
# Proxy retrieve allows methods FOO and BAR to pass through
Service fn=proxy-retrieve
    allow="FOO,BAR"
# Proxy retrieve blocks methods MKCOL,DELETE,LOCK,UNLOCK
Service fn=proxy-retrieve
    block="MKCOL,DELETE,LOCK,UNLOCK"
```

query-handler

Applicable in Service- and Error- class directives.

Note – This function is provided for backward compatibility only and is used mainly to support the obsolete ISINDEX tag. If possible, use an HTML form instead.

The query-handler function runs a CGI program instead of referencing the path requested.

Parameters

The following table describes the path parameter which is specific to the query-handler function.

TABLE 5-109 query-handler parameters

Parameter	Description
path	Full path and file name of the CGI program to run.
method	(Optional) Common to all Service-class functions.
query	(Optional) Common to all Service-class functions.
UseOutputStreamSize	(Optional) Common to all Service-class functions.
flushTimer	(Optional) Common to all Service-class functions.
ChunkedRequestBufferSize	(Optional) Common to all Service-class functions.
ChunkedRequestTimeout	(Optional) Common to all Service-class functions.
bucket	(Optional) Common to all obj.conf functions.

Examples

```
Service query=* fn=query-handler path=/http/cgi/do-grep
Service query=* fn=query-handler path=/http/cgi/proc-info
```

remove-dir

Applicable in Service-class directives.

The `remove-dir` function removes a directory when the client sends a request whose method is RMDIR. The directory must not have any files in it. The function will fail if the directory is not empty or if the server doesn't have the privileges to remove the directory.

When remote file manipulation is enabled in the server, the `obj.conf` file contains a Service-class function that invokes `remove-dir` when the request method is RMDIR.

Parameters

The `remove-dir` function has no specification parameter.

TABLE 5-110 `remove-dir` Parameters

Parameter	Description
<code>method</code>	(Optional) Common to all Service-class functions.
<code>query</code>	(Optional) Common to all Service-class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all Service-class functions.
<code>flushTimer</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all Service-class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
Service fn="remove-dir" method="RMDIR"
```

remove-file

Applicable in Service-class directives.

The `remove-file` function deletes a file when the client sends a request whose method is DELETE. It deletes the file indicated by the URL if the user is authorized and the server has the needed file system privileges.

When remote file manipulation is enabled in the server, the `obj.conf` file contains a Service-class function that invokes `remove-file` when the request method is DELETE.

Parameters

The `remove-file` function has no specification parameter.

TABLE 5-111 `remove-file` Parameters

Parameter	Description
<code>method</code>	(Optional) Common to all <code>Service-class</code> functions.
<code>query</code>	(Optional) Common to all <code>Service-class</code> functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all <code>Service-class</code> functions.
<code>flushTimer</code>	(Optional) Common to all <code>Service-class</code> functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all <code>Service-class</code> functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all <code>Service-class</code> functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
Service fn="remove-file" method="DELETE"
```

remove-filter

Applicable in `Input-`, `Output-`, `Service-`, and `Error-class` directives.

The `remove-filter` SAF is used to remove a filter from the filter stack. If the filter has been inserted multiple times, only the topmost instance is removed. In general, you do not have to remove filters with `remove-filter`, as they will be removed automatically at the end of the request.

Returns

Returns `REQ_PROCEED` if the specified filter was removed successfully, or `REQ_NOACTION` if the specified filter was not part of the filter stack. Any other return value indicates an error.

Parameters

The following table describes the filter parameters which is specific to the `remove-filter` function.

TABLE 5-112 remove-filter Parameters

Parameter	Description
filter	Specifies the name of the filter to remove.
method	(Optional) Common to all Service-class functions.
query	(Optional) Common to all Service-class functions.
UseOutputStreamSize	(Optional) Common to all Service-class functions.
flushTimer	(Optional) Common to all Service-class functions.
ChunkedRequestBufferSize	(Optional) Common to all Service-class functions.
ChunkedRequestTimeout	(Optional) Common to all Service-class functions.
bucket	(Optional) Common to all obj.conf functions.

Example

```
Service fn="remove-filter" filter="http-compression"
```

rename-file

Applicable in Service-class directives.

The rename-file function renames a file when the client sends a request with a New-URL header whose method is MOVE. The function renames the file indicated by the URL to New-URL within the same directory if the user is authorized and the server has the needed file system privileges.

When remote file manipulation is enabled in the server, the obj.conf file contains a Service-class function that invokes rename-file when the request method is MOVE.

Parameters

The rename-file function has no specification parameter.

TABLE 5-113 rename-file Parameters

Parameter	Description
method	(Optional) Common to all Service-class functions.
query	(Optional) Common to all Service-class functions.
UseOutputStreamSize	(Optional) Common to all Service-class functions.
flushTimer	(Optional) Common to all Service-class functions.

TABLE 5-113 rename-file Parameters (Continued)

Parameter	Description
ChunkedRequestBufferSize	(Optional) Common to all Service-class functions.
ChunkedRequestTimeout	(Optional) Common to all Service-class functions.
bucket	(Optional) Common to all obj.conf functions.

Example

```
Service fn="rename-file" method="MOVE"
```

send-error

Applicable in Service-class directives.

The send-error function sends an HTML file to the client in place of a specific HTTP response status. The server can therefore present an explanatory message describing the problem. The HTML page may contain images and links to the server's home page or other pages.

Parameters

The following table describes the path parameter, which is specific to the send-error function.

TABLE 5-114 send-error Parameters

Parameter	Description
path	Specifies the full file system path of an HTML file to send to the client. The file is sent as text/html regardless of its name or actual type. If the file does not exist, the server sends a simple default error page.
method	(Optional) Common to all Service-class functions.
query	(Optional) Common to all Service-class functions.
UseOutputStreamSize	(Optional) Common to all Service-class functions.
flushTimer	(Optional) Common to all Service-class functions.
ChunkedRequestBufferSize	(Optional) Common to all Service-class functions.
ChunkedRequestTimeout	(Optional) Common to all Service-class functions.
bucket	(Optional) Common to all obj.conf functions.

Example

```
Error fn=send-error code=401 path=/sun/server61/docs/errors/401.html
```

send-file

Applicable in Service-class directives.

The `send-file` function sends the contents of the requested file to the client. This function provides the `Content-Type`, `Content-Length`, and `Last-Modified` headers.

Most requests are handled by this function using the following directive, which usually comes last in the list of Service-class directives in the default object, so that it acts as a default:

```
Service method="(GET|HEAD|POST)" fn="send-file"
```

This directive is invoked if the method of the request is `GET`, `HEAD`, or `POST`.

Parameters

The following table describes the `nocache` parameter, which is specific to the `send-file` function.

TABLE 5-115 send-file parameters

Parameter	Description
<code>nocache</code>	(Optional) Prevents the server from caching responses to static file requests. For example, you can specify that files in a particular directory are not to be cached, which is useful for directories where the files change frequently. The value you assign to this parameter is ignored. If you do not want to use this parameter, do not include it.
<code>method</code>	(Optional) Common to all Service-class functions.
<code>query</code>	(Optional) Common to all Service-class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all Service-class functions.
<code>flushTimer</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all Service-class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
Service method="(GET|HEAD)" fn="send-file"
```

In the following example, the server does not cache static files from `/export/somedir/` when requested by the URL prefix `/myurl`.

```
<Object name=default>...NameTrans fn="pfx2dir" from="/myurl"
  dir="/export/mydir", name="myname"...Service method=(GET|HEAD|POST)
  fn=send-file...</Object><Object name="myname">
  Service method=(GET|HEAD) fn=send-file
  nocache=""</Object>
```

send-range

Applicable in Service-class directives.

When the client requests a portion of a document by specifying HTTP byte ranges, the send-range function returns that portion.

Parameters

The following table describes parameters for the send-range function.

TABLE 5-116 send-range parameters

Parameter	Description
method	(Optional) Common to all Service-class functions.
query	(Optional) Common to all Service-class functions.
UseOutputStreamSize	(Optional) Common to all Service-class functions.
flushTimer	(Optional) Common to all Service-class functions.
ChunkedRequestBufferSize	(Optional) Common to all Service-class functions.
ChunkedRequestTimeout	(Optional) Common to all Service-class functions.
bucket	(Optional) Common to all obj.conf functions.

Example

```
Service fn=send-range
```

send-shellcgi

Applicable in Service-class directives.

Windows Only. The send-shellcgi function runs a file as a shell CGI program and sends the results to the client. Shell CGI is a server configuration that enables you to run CGI applications using the file associations set in Windows. For information about shell CGI programs, see [Sun Java System Web Proxy Server 4.0.8 NSAPI Developer's Guide](#).

Parameters

The `send-shellcgi` function has no specification parameter.

TABLE 5-117 `send-shellcgi` Parameters

Parameter	Description
<code>method</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>query</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>flushTimer</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions

Examples

```
Service fn=send-shellcgi
```

send-wincgi

Applicable in `Service`-class directives.

Windows Only. The `send-wincgi` function runs a file as a Windows CGI program and sends the results to the client. For information about Windows CGI programs, see [Sun Java System Web Proxy Server 4.0.8 NSAPI Developer's Guide](#).

Parameters

The `send-wincgi` function has no specification parameter.

TABLE 5-118 `send-wincgi` Parameters

Parameter	Description
<code>method</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>query</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>flushTimer</code>	(Optional) Common to all <code>Service</code> -class functions.

TABLE 5-118 send-wincgi Parameters (Continued)

Parameter	Description
ChunkedRequestBufferSize	(Optional) Common to all Service-class functions.
ChunkedRequestTimeout	(Optional) Common to all Service-class functions.
bucket	(Optional) Common to all obj.conf functions.

Examples

Service fn=send-wincgi

service-dump

Applicable in Service-class directives.

The `service-dump` function creates a performance report based on collected performance bucket data. For more information, see [“Bucket Parameter” on page 95](#).

The report is at the following URL:

`http://server_id:port/.perf`

Parameters

The following table describes the parameter, which is specific to the `service-dump` function.

TABLE 5-119 service-dump Parameters

Parameter	Description
method	(Optional) Common to all Service-class functions.
query	(Optional) Common to all Service-class functions.
UseOutputStreamSize	(Optional) Common to all Service-class functions.
flushTimer	(Optional) Common to all Service-class functions.
ChunkedRequestBufferSize	(Optional) Common to all Service-class functions.
ChunkedRequestTimeout	(Optional) Common to all Service-class functions.
bucket	(Optional) Common to all obj.conf functions.

Examples

```
<Object name=default>NameTrans fn="assign-name" from="/.perf"
  name="perf"...</Object><Object name=perf>Service fn="service-dump"</Object>
```

See Also

[“stats-xml” on page 226](#)

service-j2ee

This function is applicable only to the Administration Server.

Applicable in `Service`-class directives.

The `service-j2ee` function services requests made to Java web applications.

Parameters

The `service-j2ee` function has no specification parameter.

TABLE 5-120 `service-j2ee` Parameters

Parameter	Description
<code>method</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>query</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>flushTimer</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Examples

```
<Object name=default>
NameTrans fn="ntrans-j2ee" name="j2ee"
...
</Object>
```

```
<Object name=j2ee>
Service fn="service-j2ee"
</Object>
```

See Also

[“ntrans-j2ee” on page 151](#), [“error-j2ee” on page 232](#)

service-trace

Applicable in Service-class directives.

The `service-trace` function services TRACE requests. TRACE requests are typically used to diagnose problems with web proxy servers located between a web client and web server.

Parameters

The `service_trace` function has no specification parameter.

TABLE 5-121 `service-trace` Parameters

Parameter	Description
<code>method</code>	(Optional) Common to all Service-class functions.
<code>query</code>	(Optional) Common to all Service-class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all Service-class functions.
<code>flushTimer</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all Service-class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
<Object name="default">
...
Service method="TRACE" fn="service-trace"
...
</Object>
```

set-variable

Applicable in all stage directives. The `set-variable` SAF enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands. See [“set-variable” on page 143](#).

shtml_send

Applicable in Service-class directives.

The `shtml_send` function scans an HTML document, for embedded commands. These commands might provide information from the server, include the contents of other files, or execute a CGI program. The `shtml_send` function is only available when the Shtml plug-in (`LibShtml.so` on UNIX or `libShtml.dll` on Windows) is loaded.

Parameters

The following table describes the parameters specifies to the `shtml_send` function.

TABLE 5-122 `shtml_send` Parameters

Parameter	Description
<code>ShtmlMaxDepth</code>	Maximum depth of include nesting allowed. The default value is 10.
<code>addCgiInitVars</code>	(UNIX only) If present and equal to <code>yes</code> (the default is <code>no</code>), adds the environment variables defined in the <code>init-cgi</code> SAF to the environment of any command executed through the SHTML <code>exec</code> tag.
<code>method</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>flushTimer</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>query</code>	(Optional) Common to all <code>Service</code> -class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
Service method=(GET|HEAD) fn=shtml_send
```

stats-xml

Applicable in `Service`-class directives.

The `stats-xml` function creates a performance report in XML format. If performance buckets have been defined, this performance report includes them.

However, you do need to initialize this function using the `stats-init` function in `magnus.conf`, then use a `NameTrans` function to direct requests to the `stats-xml` function. See the examples below.

The report is generated at the URL:

```
http://server_id:port/stats-xml/iwsstats.xml
```

The associated DTD file is located at the URL:

`http://server_id:port/stats-xml/iwsstats.dtd`

Parameters

The `stats-xml` function.

TABLE 5-123 `stats-xml` Parameters

Parameter	Description
<code>method</code>	(Optional) Common to all Service-class functions.
<code>query</code>	(Optional) Common to all Service-class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all Service-class functions.
<code>flushTimer</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all Service-class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Examples

In `magnus.conf`:

```
Init fn="stats-init" update-interval="5" virtual-servers="2000"
    profiling="yes"
```

In `obj.conf`:

```
<Object name="default">
...
NameTrans fn="assign-name" from="/stats-xml/*" name="stats-xml"
...
</Object>
...
<Object name="stats-xml">
Service fn="stats-xml"
</Object>
```

See Also

[“service-dump” on page 223](#)

upload-file

Applicable in Service-class directives.

The `upload-file` function uploads and saves a new file when the client sends a request whose method is PUT if the user is authorized and the server has the needed file system privileges.

When remote file manipulation is enabled in the server, the `obj.conf` file contains a Service-class function that invokes `upload-file` when the request method is PUT.

Parameters

The `upload-file` function.

TABLE 5-124 `upload-file` Parameters

Parameter	Description
<code>method</code>	(Optional) Common to all Service-class functions.
<code>query</code>	(Optional) Common to all Service-class functions.
<code>UseOutputStreamSize</code>	(Optional) Common to all Service-class functions.
<code>flushTimer</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestBufferSize</code>	(Optional) Common to all Service-class functions.
<code>ChunkedRequestTimeout</code>	(Optional) Common to all Service-class functions.
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
Service fn=upload-file
```

AddLog

After the server has responded to the request, the AddLog directives are executed to record information about the transaction.

If an object contains more than one AddLog directive, all are executed.

The following AddLog-class functions are described in detail in this section:

- [“common-log” on page 229](#) records information about the request in the common log format.
- [“flex-log” on page 230](#) records information about the request in a flexible, configurable format.

- “[match-browser](#)” on page 231 matches specific strings in the User-Agent string supplied by the browser, and then modifies the behavior of the Sun Java System Web Proxy Server based upon the results by setting values for specified variables.
- “[record-useragent](#)” on page 231 records the client’s IP address and User-Agent header.
- “[set-variable](#)” on page 232 enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands.

common-log

Applicable in AddLog-class directives.

The `common-log` function records request-specific data in the common log format used by most HTTP servers. A log analyzer is located in the `/extras/log_anly` directory for Proxy Server.

The common log must have been initialized previously by the `init-clf` function. For information about rotating logs, see `flex-rotate-init` in the *Sun Java System Web Proxy Server 4.0.8 NSAPI Developer’s Guide*.

There are also a number of free statistics generators for the common log format.

Parameters

The following table describes parameters for the `common-log` function.

TABLE 5–125 `common-log` Parameters

Parameter	Description
<code>name</code>	(Optional) Provides the name of a log file which must have been given as a parameter to the <code>init-clf</code> function in <code>magnus.conf</code> . If no name is given, the entry is recorded in the global log file.
<code>iponly</code>	(Optional) Instructs the server to log the IP address of the remote client rather than looking up and logging the DNS name. This function improves performance if DNS is off in the <code>magnus.conf</code> file. The value of <code>iponly</code> has no significance, and merely must be present, for example, <code>iponly=1</code> .
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Examples

```
# Log all accesses to the global log file
AddLog fn=common-log
# Log accesses from outside our subnet (198.93.5.*) to
  nonlocallog <Client ip="*~198.93.5.*">
AddLog fn=common-log name=nonlocallog</Client>
```

See Also

“record-useragent” on page 231, “flex-log” on page 230

flex-log

Applicable in AddLog-class directives.

The flex-log function records request-specific data in a flexible log format. This function may also record requests in the common log format. A log analyzer is located in the `/extras/flexanlg` directory for the Sun Java System Web Proxy Server.

There are also a number of free statistics generators for the common log format.

The log format is specified by the flex-init function call. For information about rotating logs, see flex-rotate-init in the *Sun Java System Web Proxy Server 4.0.8 NSAPI Developer's Guide*.

Parameters

The following table describes parameters for the flex-log function.

TABLE 5-126 flex-log Parameters

Parameter	Description
name	(Optional) Provides the name of a log file, which must have been given as a parameter to the flex-init function in magnus.conf. If no name is given, the entry is recorded in the global log file.
iponly	(Optional) Instructs the server to log the IP address of the remote client rather than looking up and logging the DNS name. This function improves performance if DNS is off in the magnus.conf file. The value of iponly has no significance, and merely must be present, for example, iponly=1.
bucket	(Optional) Common to all obj.conf functions.
buffers-per-file	Specifies the number of buffers for a given log file. The default value is determined by the server. Access log entries can be logged in chronological order by using a single buffer per log file. Add buffers-per-file=1 to the Initfn=flex-init line in magnus.conf. This setting ensures that requests are logged in chronological order. This approach results in decreased performance when the server is under heavy load.

Examples

```
# Log all accesses to the global log file
AddLog fn=flex-log
# Log accesses from outside our subnet (198.93.5.*) to
  nonlocallog <Client ip="*~198.93.5.*">
AddLog fn=flex-log name=nonlocallog</Client>
```

See Also

[“common-log” on page 229](#), [“record-useragent” on page 231](#)

match-browser

See [“match-browser” on page 138](#).

record-useragent

Applicable in AddLog-class directives.

The record-useragent function records the IP address of the client, followed by its User-Agent HTTP header. This value indicates what version of the client was used for this transaction.

Parameters

The following table describes parameters for the record-useragent function.

TABLE 5-127 record-useragent Parameters

Parameter	Description
name	(Optional) Provides the name of a log file, which must have been given as a parameter to the <code>init-clf</code> function in <code>magnus.conf</code> . If no name is given, the entry is recorded in the global log file.
bucket	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
# Record the client ip address and user-agent to browserlogAddLog
  fn=record-useragent name=browserlog
```

See Also

[“common-log” on page 229](#), [“flex-log” on page 230](#)

set-variable

Applicable in all stage directives. The `set-variable` SAF enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands. See [“set-variable” on page 143](#).

Error

If a Server Application Function results in an error, it sets the HTTP response status code and returns the value `REQ_ABORTED`. The server then stops processing the request. Instead, the server searches for an Error directive matching the HTTP response status code or its associated reason phrase, and executes the directive's function. If the server does not find a matching Error directive, it returns the response status code to the client.

The following Error-class functions are described in detail in this section:

- [“error-j2ee” on page 232](#) handles errors that occur during execution of the Java 2 Platform Enterprise Edition (J2EE™ platform) applications and modules deployed to the Sun Java System Web Proxy Server. This function is applicable only to the Administration Server.
- [“match-browser” on page 233](#) matches specific strings in the User-Agent string supplied by the browser, and then modifies the behavior of the Sun Java System Web Proxy Server based upon the results by setting values for specified variables.
- [“query-handler” on page 233](#) runs a CGI program instead of referencing the path requested.
- [“remove-filter” on page 234](#) removes a filter from the filter stack.
- [“send-error” on page 235](#) sends an HTML file to the client in place of a specific HTTP response status.
- [“set-variable” on page 235](#) enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands.

error-j2ee

This function is applicable only to the Administration Server.

Applicable in Error-class directives.

The `error-j2ee` function handles errors that occur during execution of web applications deployed to the Sun Java System Web Proxy Server individually or as part of full J2EE applications.

Parameters

The following table describes the parameter for the `error-j2ee` function.

TABLE 5-128 error-j2ee Parameters

Parameter	Description
bucket	(Optional) Common to all obj.conf functions.

See Also

“ntrans-j2ee” on page 151, “service-j2ee” on page 224

match-browser

See “match-browser” on page 138.

query-handler

Applicable in Service- and Error- class directives.

Note – This function is provided for backward compatibility only and is used mainly to support the obsolete ISINDEX tag. If possible, use an HTML form instead.

The query-handler function runs a CGI program instead of referencing the path requested.

Parameters

The following table describes parameters for the query-handler function.

TABLE 5-129 query-handler Parameters

Parameter	Description
path	Full path and file name of the CGI program to run.
reason	(Optional) Text of one of the reason strings such as “Unauthorized” or “Forbidden”. The string is not case sensitive.

TABLE 5-129 query-handler Parameters (Continued)

Parameter	Description
code	<p>(Optional) Three-digit number representing the HTTP response status code, such as 401 or 403.</p> <p>This number can be any HTTP response status code or reason phrase according to the HTTP specification.</p> <p>The common HTTP response status codes and reason strings are:</p> <ul style="list-style-type: none"> ■ 401 Unauthorized ■ 403 Forbidden
bucket	(Optional) Common to all obj.conf functions.

Examples

```
Error query=* fn=query-handler path=/http/cgi/do-grep
Error query=* fn=query-handler path=/http/cgi/proc-info
```

remove-filter

Applicable in Input-, Output-, Service-, and Error-class directives.

The `remove-filter` SAF is used to remove a filter from the filter stack. If the filter has been inserted multiple times, only the topmost instance is removed. In general, it is not necessary to remove filters with `remove-filter`, as they will be removed automatically at the end of the request.

Returns

Returns `REQ_PROCEED` if the specified filter was removed successfully, or `REQ_NOACTION` if the specified filter was not part of the filter stack. Any other return value indicates an error.

Parameters

The following table describes parameters for the `remove-filter` function.

TABLE 5-130 remove-filter Parameters

Parameter	Description
filter	Specifies the name of the filter to remove.
bucket	(Optional) Common to all obj.conf functions.

Example

```
Error fn="remove-filter" filter="http-compression"
```

send-error

Applicable in Error-class directives.

The `send-error` function sends an HTML file to the client in place of a specific HTTP response status. The server can therefore present an explanatory message describing the problem. The HTML page may contain images and links to the server's home page or other pages.

Note – The `send-error` function can be used to configure messages from the proxy server only and does not work for configuring messages in place of HTTP responses from web server.

Parameters

The following table describes parameters for the `send-error` function.

TABLE 5-131 `send-error` Parameters

Parameter	Description
<code>path</code>	Specifies the full file system path of an HTML file to send to the client. The file is sent as <code>text/html</code> regardless of its name or actual type. If the file does not exist, the server sends a simple default error page.
<code>reason</code>	(Optional) Text of one of the reason strings such as “Unauthorized” or “Forbidden”. The string is not case sensitive.
<code>code</code>	(Optional) Three-digit number representing the HTTP response status code, such as <code>401</code> or <code>403</code> . This number can be any HTTP response status code or reason phrase according to the HTTP specification. The common HTTP response status codes and reason strings are: <ul style="list-style-type: none"> ▪ <code>401</code> Unauthorized ▪ <code>403</code> Forbidden
<code>bucket</code>	(Optional) Common to all <code>obj.conf</code> functions.

Example

```
Error fn=send-error code=401 path=/sun/server61/docs/errors/401.html
```

set-variable

Applicable in all stage directives. The `set-variable` SAF enables you to change server settings based upon conditional information in a request, and to manipulate variables in parameter blocks by using specific commands. See [“set-variable” on page 143](#).

Connect

The Connect directive calls the connect function you specify.

Connect directive

Syntax

```
Connect fn=your-connect-function
```

Only the first applicable Connect function is called, starting from the most restrictive object. Occasionally you might want to call multiple functions until a connection is established. The function returns REQ_NOACTION if the next function should be called. If the function fails to connect, the return value is REQ_ABORT. If the function connects successfully, the connected socket descriptor will be returned.

The Connect function must have this prototype:

```
int your_connect_function(pblock *pb, Session *sn, Request *rq);
```

Connect receives its destination host name and port number from:

```
pblock_findval ("connect-host", rq->vars)
atoi (pblock_findval ("connect-port", rq->vars))
```

The host can be in a numeric IP address format.

To use the NSAPI custom DNS class functions to resolve the host name, make a call to this function:

```
struct hostent *servact_gethostbyname(char *host name, Session *sn,
    Request *rq);
```

Example

This example uses the native connect mechanism to establish the connection:

```
#include "base/session.h"
#include "frame/req.h"
#include <ctype.h>
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <netdb.h>
int my_connect_func(pblock *pb, Session *sn, Request *rq)
```

```

{
    struct sockaddr_in sa;
    int sd;
    memset(&sa, 0, sizeof(sa));
    sa.sin_family = AF_INET;
    sa.sin_port = htons(atoi (pblock_findval ("connect-port", rq->vars)));
    /* host name resolution */
    if (isdigit(*pblock_findval ("connect-host", rq->vars)))
        sa.sin_addr.s_addr = inet_addr(rq->host);
    else
    {
        struct hostent *hp = servact_gethostbyname(pblock_findval
            ("connect-host", rq->vars), sn, rq);
        if (!hp)
            return REQ_ABORTED; /* can't resolv */
        memcpy(&sa.sin_addr, hp->h_addr, hp->h_lenght);
    }
    /* create the socket and connect */
    sd = socket(AF_INET, SOCK_STREAM, IPPROTO_TCP);
    if (sd == -1)
        return REQ_ABORTED; /* can't create socket */
    if (connect(sd, (struct sockaddr *)&sa, sizeof(sa)) == -1) {
        close(sd);
        return REQ_ABORTED; /* can't connect */
    }
    return sd; /* ok */
}

```

DNS

The DNS directive calls either the `dns-config` built-in function or a DNS function that you specify.

dns-config

Syntax

```
DNS fn=dns-config local-domain-levels=<n>
```

`local-domain-levels` specifies the number of levels of subdomains that the local network has. The default is 1.

The Web Proxy Server optimizes DNS lookups by reducing the time spent resolving hosts that are fully qualified domain names but which DNS would by default still try to resolve relative to the local domain.

For example, from the `net.scape.com` domain, suppose you try to access the host `www.xyzy.com`. At first, DNS will try to resolve:

```
www.xyzy.com.net.scape.com
```

and only after that the real fully qualified domain name:

```
www.xyzy.com
```

If the local domain has subdomains, such as `corp.net.scape.com`, DNS would try two additional lookups:

```
www.xyzy.com.corp.net.scape.com    www.xyzy.com.net.scape.com
```

To avoid these extra DNS lookups, you can instruct the proxy to treat host names that are not local as remote. The proxy should instruct DNS not to resolve the name relative to the current domain.

If the local network has no subdomains, set the value to 0. Only if the host name has no domain (no dots in the host name) the name will be resolved relative to the local domain. Otherwise, DNS should always resolve the name as an absolute, fully qualified domain name.

If the local network has one level of subdomains, set the value to 1. Host names that include two or more dots will be treated as fully qualified domain names.

An example of one level of subdomains would be the `net.scape.com` domain, with subdomains:

```
corp.net.scape.com    engr.net.scape.com    mktg.net.scape.com
```

Hosts without a dot, such as the `step` host are resolved with respect to the current domain, for example, `engr.net.scape.com`. In this situation, the `dns-config` function will try this name:

```
step.engr.net.scape.com
```

If you are on `corp.net.scape.com` domain but the destination host `step` is on the `engr` subdomain, you can type

```
step.engr
```

instead of having to specify the fully qualified domain name:

```
step.engr.net.scape.com
```

your-dns-function

You define this DNS-class function.

Syntax

DNS *fn=your-dns-function*

Only the first applicable DNS function is called, starting from the most restrictive object. In the rare case that you need to call multiple DNS functions, the function can return REQ_NOACTION.

The DNS function must have this prototype:

```
int your_dns_function(pblock *pb, Session *sn, Request *rq);
```

To get the host name use:

```
pblock_findval("dns-host", rq->vars)
```

and set the host entry using the new NSAPI function

```
dns_set_hostent
```

The struct `hostent *` will not be freed by the caller but will be treated as a pointer to a static area, as with the `gethostbyname` call. Keep a pointer in a static variable in the custom DNS function and on the next call either use the same struct `hostent` or free it before allocating a new one.

The DNS function returns REQ_PROCEED if it is successful, and REQ_NOACTION if the next DNS function (or `gethostbyname`, if no other applicable DNS class functions exist) should be called instead. Any other return value is treated as failure to resolve the host name.

Example

This example uses the normal `gethostbyname` call to resolve the host name:

```
#include <nsapi.h>
int my_dns_func(pblock *pb, Session *sn, Request *rq)
{
    char *host = pblock_findval("dns-host", rq->vars);
    struct hostent *hostent;
    hostent = gethostbyname(host); // replace with custom DNS implementation
    dns_set_hostent(hostent, sn, rq);
    return REQ_PROCEED;
}
```

Filter

The `Filter` directive runs an external command and then pipes the data through the external command before processing that data in the proxy by using the `pre-filter` function.

Syntax

```
Filter fn="pre-filter" path="/your/filter/prog"
```

The `Filter` directive performs these tasks:

1. Runs the program `/your/filter/prog` as a separate process.
2. Establishes pipes between the proxy and the external program.
3. Writes the response data from the remote server to the stdin of the external program.
4. Reads the stdout of the program as if it were the response generated by the server.

This process is equivalent to this command:

```
Filter fn="pre-filter" path="/your/filter/prog" headers="stdin"
```

The following `Filter` functions are described in detail in this section:

- [“filter-ct” on page 240](#)
- [“filter-html” on page 241](#)
- [“pre-filter” on page 241](#)

filter-ct

Applicable in `Filter`-class directives.

`filter-ct` can be used to block response content that matches a certain MIME type.

Parameters

The following table describes the parameter for the `filter-ct` function.

TABLE 5-132 `filter-ct` Parameters

Parameter	Description
<code>regexp</code>	Regular expression of the mime type to be filtered.

Example

```
Filter fn="filter-ct" regexp="(application/octet-stream)"
```

filter-html

Applicable in `Filter`-class directives.

`filter-html` can be used to filter out HTML tags from the response content before sending it to the client.

Parameters

The following table describes parameters for the `filter-html` function.

TABLE 5-133 `filter-html` Parameters

Parameter	Description
<code>start</code>	HTML start tag
<code>end</code>	HTML end tag

Example

```
Filter fn="filter-html" start="APPLET" end="APPLET"
```

pre-filter

Applicable in `Filter`-class directives.

`pre-filter` is used to run external filter programs before returning response content to the client.

Parameters

The following table describes the parameter for the `pre-filter` function.

TABLE 5-134 `pre-filter` Parameters

Parameter	Description
<code>path</code>	absolute path to external filter program.

Example

```
Filter fn="pre-filter" path="/your/filter/prog"
```

Route

The Route directive specifies information about where the proxy server should route requests.

icp-route

Applicable in Route-class directives.

The `icp-route` function tells the proxy server to use ICP to determine the best source for a requested object whenever the local proxy does not have the object.

Syntax

```
Route fn=icp-route
      redirect=yes|no
```

Parameters

The following table describes the parameter for the `icp-route` function.

TABLE 5-135 `icp-route` Parameters

Parameter	Description
<code>redirect</code>	<p>Specifies whether the proxy server will send a redirect message back to the client telling it where to get the object.</p> <ul style="list-style-type: none"> ▪ <code>yes</code> means the proxy will send a redirect message back to the client to tell it where to retrieve the requested object. ▪ <code>no</code> means the proxy will not send a redirect message to the client. Instead it will use the information from ICP to get the object.

pa-enforce-internal-routing

Applicable in Route-class directives.

The `pa-enforce-internal-routing` function enables internal routing through a proxy array. Internal routing occurs when a non PAC-enabled client routes requests through a proxy array.

Syntax

```
Route fn="pa_enforce_internal_routing"    redirect="yes|no"
```

Parameters

The following table describes the parameter for the `pa-enforce-internal-routing` function.

TABLE 5-136 pa-enforce-internal-routing parameters

Parameter	Description
redirect	Specifies whether clients requests will be redirected. Redirecting means that if a member of a proxy array receives a request that it should not service, it tells the client which proxy to contact for that request.

pa-set-parent-route

Applicable in Route-class directives.

The pa-set-parent-route function sets a route to a parent array.

Syntax

Route fn="pa_set_parent_route"

set-proxy-server

Applicable in Route-class directives.

The set-proxy-server function directs the proxy server to connect to another proxy for retrieving the current resource. It also sets the address and port number of the proxy server to be used.

Syntax

Route fn=set-proxy-server
 server=*URL of other proxy server* host name=*otherhost name*
 port=*number*

Parameters

The following table describes parameters for the set-proxy-server function.

TABLE 5-137 set-proxy-server Parameters

Parameter	Description
server	URL of the other proxy server. If multiple server parameters are given, the proxy server will distribute load among the specified proxy servers. For compatibility with earlier releases, hostname and port may be specified instead of server.

TABLE 5-137 set-proxy-server Parameters (Continued)

Parameter	Description
host name	The name of the host on which the other proxy server is running.
port	The port number of the remote proxy server.

Example

```
Route fn=set-proxy-server
    host name=proxy.netscape.com
    port=8080
```

set-origin-server

Applicable in Route-class directives.

The set-origin-server function enables you to distributed load across a set of homogeneous HTTP origin servers by controlling which origin server the proxy server sends a request to.

Parameters

The following table describes parameters for the set-origin-server function.

TABLE 5-138 set-origin-server Parameters

Parameter	Description
server	URL of an origin server. If multiple server parameters are given, the proxy server will distribute load among the specified origin servers.
sticky-cookie	(Optional) Name of a cookie that, when present in a response, will cause subsequent requests to "stick" to that origin server. The default is JSESSIONID.
sticky-param	(Optional) Name of a URI parameter to inspect for route information. When the URI parameter is present in a request URI and its value contains a colon, ':', followed by a route ID, the request will "stick" to the origin server identified by that route ID. The default is jsessionid.
route-hdr	(Optional) Name of the HTTP request header used to communicate route IDs to origin servers. set-origin-server associates each origin server named by a server parameter with a unique route ID. Origin servers may encode this route ID in the URI parameter named by the sticky-param parameter to cause subsequent requests to "stick" to them. The default is Proxy-j route.

TABLE 5-138 set-origin-server Parameters (Continued)

Parameter	Description
route-cookie	(Optional) Name of the cookie generated by the proxy server when it encounters a sticky-cookie cookie in a response. The route-cookie cookie stores a route ID that enables the proxy server to direct subsequent requests back to the same origin server. The default is <code>JROUTE</code> .
rewrite-host	(Optional) Boolean that indicates whether the Host HTTP request header is rewritten to match the host specified by the server parameter. The default is <code>false</code> , meaning the Host header is not rewritten.
rewrite-location	(Optional) Boolean that indicates whether Location HTTP response headers that match the server parameter should be rewritten. The default is <code>true</code> , meaning matching Location headers are rewritten.
rewrite-content-location	(Optional) Boolean that indicates whether Content-location HTTP response headers that match the server parameter should be rewritten. The default is <code>true</code> , meaning matching Content-location headers are rewritten.
rewrite-headername	(Optional) Boolean that indicates whether headername HTTP response headers that match the server parameter should be rewritten, where headername is a user-defined header name. With the exception of the Location and Content-location headers, the default is <code>false</code> , meaning the headername header is not rewritten.

set-socks-server

Applicable in Route-class directives.

The `set-socks-server` directs the proxy server to connect to a SOCKS server for retrieving the current resource. It also sets the address and port number of the SOCKS server to be used.

Syntax

```
Route fn=set-socks-server
      host name=sockshost name
      port=number
```

Parameters

The following table describes parameters for the `set-socks-server` function.

TABLE 5-139 set-socks-server Parameters

Parameter	Description
host name	The name of the host on which the SOCKS server runs.

TABLE 5-139 set-socks-server Parameters (Continued)

Parameter	Description
port	The port on which the SOCKS server listens.

Example

```
ObjectType fn=set-socks-server
  host name=socks.netscape.com
  port=1080
```

unset-proxy-server

Applicable in Route-class directives.

The `unset-proxy-server` function tells the proxy server not to connect to another proxy server to retrieve the current resource. This function nullifies the settings of any less specific `set-proxy-server` functions.

Syntax

```
Route fn=unset-proxy-server
```

unset-socks-server

Applicable in Route-class directives.

The `unset-socks-server` function tells the proxy server not to connect to a SOCKS server to retrieve the current resource. This function nullifies the settings of any less specific `set-socks-server` functions.

Syntax

```
Route fn=unset-socks-server
```

MIME Types

This chapter discusses the MIME types file. The chapter contains the following section:

- “Introduction” on page 247
- “Determining the MIME Type” on page 248
- “How the Type Affects the Response” on page 248
- “Client Handling of MIME Types” on page 249
- “Syntax of the MIME Types File” on page 249
- “Sample MIME Types File” on page 249

Introduction

The MIME types file in the `config` directory contains mappings between MIME (Multipurpose Internet Mail Extensions) types and file extensions. For example, the MIME types file maps the extensions `.html` and `.htm` to the type `text/html` as follows:

```
type=text/html exts=htm,html
```

When the Sun Java System Web Proxy Server receives a request for a resource from a client, it uses the MIME type mappings to determine what kind of resource is being requested.

MIME types are defined by three attributes: `language` (`lang`), `encoding` (`enc`), and `content-type` (`type`). At least one of these attributes must be present for each type. The most commonly used attribute is `type`. The server frequently considers the `type` when deciding how to generate the response to the client. The `enc` and `lang` attributes are rarely used.

The default MIME types file is named `mime.types`.

Determining the MIME Type

During the `ObjectType` step in the request handling process, the server determines the MIME type attributes of the resource requested by the client. Several different server application functions (SAFs) can be used to determine the MIME type, but the most commonly used is `type-by-extension`. This function tells the server to look up the MIME type according to the requested resource's file extension in the MIME types table.

The directive in `obj.conf` that tells the server to look up the MIME type according to the extension is:

```
ObjectType fn=type-by-extension
```

If the server uses a different SAF, such as `force-type`, to determine the type, then the MIME types table is not used for that particular request.

For more details of the `ObjectType` step, see the [Sun Java System Web Proxy Server 4.0.8 NSAPI Developer's Guide](#).

How the Type Affects the Response

The server considers the value of the type attribute when deciding which Service directive in `obj.conf` to use to generate the response to the client.

By default, if the type does not start with `magnus-internal/`, the server sends the requested file to the client. The directive in `obj.conf` that contains this instruction is:

```
Service method=(GET|HEAD|POST) type=~magnus-internal/* fn=send-file
```

By convention, all values of type that require the server to take an action other than sending the requested resource to the client start with `magnus-internal/`.

For example, if the requested resource's file extension is `.map`, the type is mapped to `magnus-internal/imagemap`. If the extension is `.cgi`, `.exe`, or `.bat`, the type is set to `magnus-internal/cgi`:

```
type=magnus-internal/imagemap      exts=map
type=magnus-internal/cgi           exts=cgi,exe,bat
```

If the type starts with `magnus-internal/`, the server executes the Service directive in `obj.conf` that matches the specified type. For example, if the type is `magnus-internal/imagemap`, the server uses the `imagemap` function to generate the response to the client, as indicated by the following directive:

```
Service method=(GET|HEAD) type=magnus-internal/imagemap fn=imagemap
```

Client Handling of MIME Types

The Service function generates the data and sends it to the client that made the request. When the server sends the data to the client, it also sends headers. These headers include the MIME type attributes that are known, which is usually type.

When the client receives the data, it uses the MIME type to decide how to handle the data. For browser clients, the usual action is to display the data in the browser window.

If the requested resource cannot be displayed in a browser but needs to be handled by another application, its type starts with `application/`, for example, `application/octet-stream` for `.bin` file extensions or `application/x-maker` for `.fm` file extensions. The client has its own set of user-editable mappings that determines which application to use to handle which types of data.

For example, if the type is `application/x-maker`, the client usually handles it by opening Adobe® FrameMaker to display the file.

Syntax of the MIME Types File

The first line in the MIME types file identifies the file format and must read:

```
#--Sun Microsystems MIME Information
```

Other non-comment lines have the following format:

```
type=type/subtype exts=[file extensions]
```

- `type/subtype` is the type and subtype.
- `exts` are the file extensions associated with this type.

Sample MIME Types File

The following example illustrates a MIME types file:

```
#--Sun Microsystems MIME Information
# Do not delete the above line. It is used to identify the file type.
type=application/octet-stream      exts=bin,exe
type=application/oda               exts=oda
type=application/pdf               exts=pdf
type=application/postscript        exts=ai,eps,ps
type=application/rtf               exts=rtf
type=application/x-mif              exts=mif,fm
type=application/x-gtar             exts=gtar
```

type=application/x-shar	exts=shar
type=application/x-tar	exts=tar
type=application/mac-binhex40	exts=hqx
type=audio/basic	exts=au,snd
type=audio/x-aiff	exts=aif,aiff,aifc
type=audio/x-wav	exts=wav
type=image/gif	exts=gif
type=image/ief	exts=ief
type=image/jpeg	exts=jpeg,jpg,jpe
type=image/tiff	exts=tiff,tif
type=image/x-rgb	exts=rgb
type=image/x-xbitmap	exts=xbm
type=image/x-xpixmap	exts=xpm
type=image/x-xwindowdump	exts=xwd
type=text/html	exts=htm,html
type=text/plain	exts=txt
type=text/richtext	exts=rtx
type=text/tab-separated-values	exts=tsv
type=text/x-setext	exts=etx
type=video/mpeg	exts=mpeg,mpg,mpe
type=video/quicktime	exts=qt,mov
type=video/x-msvideo	exts=avi
enc=x-gzip	exts=gz
enc=x-compress	exts=z
enc=x-uuencode	exts=uu,uue
type=magnus-internal/imagemap	exts=map
type=magnus-internal/parsed-html	exts=shtml
type=magnus-internal/cgi	exts=cgi,exe,bat
type=magnus-internal/jsp	exts=jsp

Other Server Configuration Files

This chapter summarizes the important configuration files not discussed in other chapters. Configuration files that should never be modified are not listed in this module.

The following configuration files are described in alphabetical order:

- “certmap.conf” on page 251
- “dbswitch.conf” on page 253
- “Deployment Descriptors” on page 255
- “generated.instance.acl” on page 255
- “password.conf” on page 255
- “*.clfilter” on page 256
- “bu.conf” on page 256
- “icp.conf” on page 259
- “socks5.conf” on page 262
- “parray.pat” on page 272
- “parent.pat” on page 273

certmap.conf

The certmap.conf file configures how a certificate, designated by *name*, is mapped to an LDAP entry, designated by *issuerDN*.

Location

```
<install-root>/bin/https/install/misc  
<install-root>/userdb
```

Syntax

```
certmap name issuerDNname:property1 [value1]  
name:property2 [value2]  
...
```

The default certificate is named `default`, and the default `issuerDN` is also named `default`. Therefore, the first `certmap` defined in the file must be as follows:

```
certmap default default
```

Use `#` at the beginning of a line to indicate a comment.

The following table describes properties in the `certmap.conf` file. The left column lists the property names. The second column from the left lists allowed values. The third column from the left lists default values. The right column lists property descriptions.

TABLE 7-1 `certmap.conf` Properties

Attribute	Allowed Values	Default Value	Description
DNCmps	See Description	Commented out	Used to form the base DN for performing an LDAP search while mapping the certificate to a user entry. Values are as follows: <ul style="list-style-type: none"> Commented out: takes the user's DN from the certificate as is. Empty: searches the entire LDAP tree (DN == suffix). Comma-separated attributes: forms the DN.
FilterCmps	See Description	Commented out	Used to form the filter for performing an LDAP search while mapping the certificate to a user entry. Values are as follows: <ul style="list-style-type: none"> Commented out or empty: sets the filter to "objectclass=*". Comma-separated attributes: forms the filter.
verifycert	on or off	off (commented out)	Specifies whether certificates are verified.
CmapLdapAttr	LDAP attribute name	certSubjectDN (commented out)	Specifies the name of the attribute in the LDAP database that contains the DN of the certificate.
library	Path to shared lib or dll	None	Specifies the library path for custom certificate mapping code.
InitFn	Name of initialization function	None	Specifies the initialization function in the certificate mapping code referenced by <code>library</code> .

dbswitch.conf

Purpose

Specifies the LDAP directory that the Sun Java System Web Proxy Server uses.

Location

`<install-root>/userdb`

Syntax

```
directory name LDAP_URLname:property1 [value1]
name:property2 [value2]
...
```

The default contents of this file are as follows:

```
directory default null:///none
```

Edit the file as follows for anonymous binding over SSL:

```
directory default ldaps://directory.sun.com:636:/dc%3Dcom
```

Edit the file as follows for anonymous binding *not* over SSL:

```
directory default ldap://directory.sun.com:389:/dc%3Dcom
```

The following table describes properties in the `dbswitch.conf` file.

TABLE 7-2 dbswitch.conf Properties

Property	Allowed Values	Default Value	Description
<code>nsessions</code>	A positive integer	8	The number of LDAP connections for the database.
<code>dyngroups</code>	<code>off</code> , <code>on</code> , <code>recursive</code>	<code>on</code>	Determines how dynamic groups are handled. If <code>off</code> , dynamic groups are not supported. If <code>on</code> , dynamic groups are supported. If <code>recursive</code> , dynamic groups can contain other groups.
<code>binddn</code>	A valid DN		The DN used for connecting to the database. If both <code>binddn</code> and <code>bindpw</code> are not present, binding is anonymous.
<code>bindpw</code>			The password used for connecting to the database. If both <code>binddn</code> and <code>bindpw</code> are not present, binding is anonymous.

TABLE 7-2 dbswitch.conf Properties (Continued)

Property	Allowed Values	Default Value	Description
dcsuffix	A valid DN (relative to the LDAP URL)	none	<p>If present, the default value of the base DN for the request's virtual server is determined by a dc tree search of the connection group's servername attribute, starting at the dcsuffix DN.</p> <p>If not present, the default value of the base DN is the base DN value in the LDAP URL.</p> <p>The basedn attribute of a USERDB element in the server.xml file overrides this value.</p>
digestauth	off, on	off	Specifies whether the database can perform digest authentication. If set on, a special Directory Server plug-in is required. For information about how to install this plug-in, see the <i>Sun Java System Web Proxy Server 4.0.8 Administration Guide</i> .
syntax	keyfile, digest, htaccess	keyfile	Specifies what type of file auth-db will be used
keyfile			Specifies the path to the key file. Required, if syntax is set to keyfile.
digestfile			Specifies the path to the digest file. Required, if syntax is set to digestfile.
groupfile			Path to the AuthGroupFile. If the group file is the same as the user file, this file contains both user and group data. Otherwise, it contains only group data. Required if syntax is set to htaccess. For more information about the syntax of the AuthGroupFile, see the <i>Sun Java System Web Proxy Server 4.0.8 Administration Guide</i> .
userfile			Path to the AuthUserFile. If the user file is the same as the group file, this file contains both user and group data. Otherwise it contains only user data. Required if syntax is set to htaccess. For more information about the syntax of the AuthUserFile, see the <i>Sun Java System Web Proxy Server 4.0.8 Administration Guide</i> .

Deployment Descriptors

These files configure features specific to the Sun Java System Web Proxy Server for deployed web applications.

Location

The META-INF or WEB-INF directory of a module or application.

generated.instance.acl

Sets permissions for access to the server instance. This file is the default ACL file. You can create and use other ACL file.

Location

install-root/httpacl

See Also

[Sun Java System Web Proxy Server 4.0.8 Administration Guide](#)

password.conf

By default, the Sun Java System Web Proxy Server prompts the administrator for the SSL key database password before starting. If you want the Web server to be able to restart unattended, you need to save the password in a `password.conf` file. Be sure that your system is adequately protected so that this file and the key databases are not compromised.

Location

<instance-directory>/config

This file is not present by default. You must create it if you need it.

Syntax

PKCS#11_module_name:password

If you are using the internal PKCS#11 software encryption module that comes with the server, type the following:

internal:password

If you are using a different PKCS#11 module, for example for hardware encryption or hardware accelerators, specify the name of the PKCS#11 module, followed by the password.

Sun Java System Web Proxy Server 4.0.8 Administration Guide

*.clfilter

Purpose

The files `obj.conf.clfilter`, `magnus.conf.clfilter`, and `server.xml.clfilter` contain filter specifications for cluster management operations.

Location

instance-directory/config

bu.conf

The optional `bu.conf` file contains batch update directives. You can use these directives to update many documents at once. You can time these updates to occur during off-peak hours to minimize the effect on the efficiency of the server. The format of this file is described in this section.

Accept

A valid URL Accept filter consists of any POSIX regular expression. It is used as a filter to test URLs for retrieval in the case of internal updates, and determines whether branching occurs for external updates.

This directive may occur any number of times, as separate Accept lines or as comma-delimited or space-delimited entries on a single Accept line. These entries are applied sequentially. Default behavior is `*`, letting all URLs pass.

Syntax

Accept *regular expression*

Connections

For the `Connections` directive, *n* is the number of simultaneous connections to be used while retrieving. This method limits the load on your machine and, more importantly, the remote servers being contacted.

This directive can occur multiple times in a valid configuration, but only the smallest value is used.

Syntax

Connections *n*

Count

The argument *n* of the Count directive specifies the total maximum number of URLs to be updated through this process. This safeguard limits the process and defaults to a value of 300. This directive can occur multiple times in a valid configuration, but only the smallest value is used.

Syntax

Count *n*

Depth

The Depth directive enables you to ensure that, while enumerating, all collected objects are no more than a specified number of links away from the initial URL. The default is 1.

Syntax

Depth *depth*

Object boundaries

The Object wrapper signifies the boundaries between individual configurations in the `bupdate.conf` file. It can occur any number of times, though each occurrence requires a unique name.

All other directives are only valid when inside Object boundaries.

Syntax

```
<Object name=name>  
...  
</Object>
```

Reject

A valid URL Reject filter consists of any POSIX regular expression. It is used as a filter to test URLs for retrieval in the case of internal updates, and determines whether branching occurs for external updates.

This directive may occur any number of times, as separate Reject lines or as comma-delimited or space-delimited entries on a single Reject line. Entries are applied sequentially. Default behavior is no rejection for internal updates and .* (no branching, get single URL) for recursive updates.

Syntax

Reject *regular expression*

Source

In the Source directive. The argument keyword `internal` specifies batch updates are done only on objects currently in the cache. A directive of Depth 1 is assumed. For recursive enumeration, specify the name of a URL.

This directive can occur only once in a valid configuration.

Syntax

Source `internal`
Source *URL*

Type

The Type function lets you control the updating of mime types that the proxy caches. This directive can occur any number of times, in any order.

Syntax

Type `ignore`
Type `inline`
Type *mime_type*

Parameters

`ignore` means that updates will act on all MIME types that the proxy currently caches. This default behavior supersedes all other Type directives if specified.

`inline` means that in line data is updated as a special type, regardless of any later MIME type exclusions. These updates are meaningful only when doing recursive updates.

`mime-type` is assumed to be a valid entry from the system `mime-types` file, and is included in the list of MIME types to be updated. If the proxy doesn't currently cache the given MIME type, the object may be retrieved but is not cached.

icp.conf

This file is used to configure the Internet Cache Protocol (ICP) feature of the server. The three functions in the `icp.conf` file are `add_parent`, `add_sibling`, and `server`. Each function can be called as many times as necessary. Each should be on a separate line.

add_parent

The `add_parent` function identifies and configures a parent server in an ICP neighborhood.

Syntax

```
add_parent name=name icp_port=port number proxy_port=port number  
mcast_address=IP address ttl=number round=1|2
```

Note – The above text should be on one line in the `icp.conf` file.

Parameters

`name` specifies the name of the parent server. This value can be a DNS name or an IP address.

`icp_port` specifies the port on which the parent listens for ICP messages.

`proxy_port` specifies the port for the proxy on the parent.

`mcast_address` specifies the multicast address the parent listens to. A multicast address is an IP address to which multiple servers can listen. Using a multicast address enables a proxy to send one query to the network that all neighbors listening to that multicast address can receive. This process eliminates the need to send a query to each neighbor separately.

`ttl` specifies the time to live for a message sent to the multicast address. `ttl` controls the number of subnets a multicast message will be forwarded to. If the `ttl` is set to 1, the multicast message will only be forwarded to the local subnet. If the `ttl` is set to 2, the message will go to all subnets that are one hop away.

`round` specifies in which polling round the parent will be queried. A polling round is an ICP query cycle. Possible values are:

- 1 - The parent will be queried in the first query cycle with all other round one neighbors.

- 2 - The parent will only be queried if none of the neighbors in polling round one return a HIT.

Example

```
add_parent name=proxy1 icp_port=5151 proxy_port=3333
    mcast_address=189.98.3.33 ttl=3 round=2
```

add_sibling

The `add_sibling` function identifies and configures a sibling server in an ICP neighborhood.

Syntax

```
add_sibling name=name icp_port=port number proxy_port=port number
    mcast_address=IP address ttl=number round=1|2
```

Note – The above text will all be on one line in the `icp.conf` file.

Parameters

`name` specifies the name of the sibling server, which can be a DNS name or an IP address.

`icp_port` specifies the port on which the sibling listens for ICP messages.

`proxy_port` specifies the port for the proxy on the sibling.

`mcast_address` specifies the multicast address the sibling listens to. A multicast address is an IP address to which multiple servers can listen. Using a multicast address enables a proxy to send one query to the network that all neighbors listening to that multicast address can receive. This process eliminates the need to send a query to each neighbor separately.

`ttl` specifies the time to live for a message sent to the multicast address. `ttl` controls the number of subnets a multicast message will be forwarded to. If the `ttl` is set to 1, the multicast message will only be forwarded to the local subnet. If the `ttl` is set to 2, the message will go to all subnets that are one hop away.

`round` specifies in which polling round the sibling will be queried. A polling round is an ICP query cycle. Possible values are:

- 1 - The sibling will be queried in the first query cycle with all other round one neighbors. This is the default polling round value.
- 2 - The sibling will only be queried if none of the neighbors in polling round one return a HIT.

Example

```
add_sibling name=proxy2 icp_port=5151 proxy_port=3333
    mcast_address=190.99.2.11 ttl=2 round=1
```

Note – The above text will all be on one line in the `icp.conf` file.

server

The server function identifies and configures the local proxy in an ICP neighborhood.

Syntax

```
server bind_address=IP-address mcast=IP-address num_servers=number
    icp_port=port-number default_route=name
default_route_port=port number
no_hit_behavior=fastest_parent|default timeout=seconds
```

Note – The above text should be on one line in the `icp.conf` file.

Parameters

`bind_address` specifies the IP address to which the server will bind. For machines with more than one IP address, this parameter can be used to determine which address the ICP server will bind to.

`mcast` the multicast address to which the neighbor listens. A multicast address is an IP address to which multiple servers can listen. Using a multicast address enables a proxy to send one query to the network that all neighbors who are listening to that multicast address can see. The process eliminates the need to send a query to each neighbor separately.

If both a multicast address and bind address are specified for the neighbor, the neighbor uses the bind address to communicate with other neighbors. If neither a bind address nor a multicast address is specified, the communication subsystem will decide which address to use to send the data.

`num_servers` specifies the number of processes that will service ICP requests.

`icp_port` specifies the port number to which the server will listen.

`default_route` tells the proxy server where to route a request when none of the neighboring caches respond. If `default_route` and `default_route_port` are set to `origin`, the proxy server will route defaulted requests to the origin server. The meaning of `default_route` is different depending on the value of `no_hit_behavior`. If `no_hit_behavior` is set to `default`, the `default_route` is used when none of the proxy array members return a hit. If

`no_hit_behavior` is set to `fastest_parent`, the `default_route` value is used only if no parent responds.

`default_route_port` specifies the port number of the machine specified as the `default_route`. If `default_route` and `default_route_port` are set to `origin`, the proxy server will route defaulted requests to the origin server.

`timeout` specifies the maximum number of milliseconds the proxy will wait for an ICP response.

`no_hit_behavior` specifies the proxy's behavior whenever none of the neighbors returns a hit for the requested document. Possible values are:

- `fastest_parent` - The request is routed through the first parent that returned a miss.
- `default` - The request is routed to the machine specified as the default route.

Example

```
server bind_address=198.4.66.78 mcast=no num_servers=5 icp_port=5151
      default_route=proxy1 default_route_port=8080 no_hit_behavior=fastest_parent
      timeout=2000
```

Note – The above text should be on one line in the `icp.conf` file.

socks5.conf

The proxy uses the `<install-root>/<instance-directory>/config/socks5.conf` file to control access to the SOCKS proxy server SOCKD and its services. Each line defines the behavior of the proxy when it gets a request that matches the line.

When SOCKD receives a request, it checks the request against the instructions in `<install-root>/<instance-directory>/config/socks5.conf`. When it finds an instruction that matches the request, the request is permitted or denied based on the first word in the instruction (permit or deny). Once it finds a matching instruction, the daemon ignores the remaining lines in the file. If no matching instructions are found, the request is denied. You can also specify actions to take if the client's identd or user ID is incorrect by using `#NO_IDENTD`: or `#BAD_ID` as the first word of the instruction. Each line can be up to 1023 characters long.

The sections in the `socks5.conf` file do not have to appear in the following order. However, because the daemon uses only the first line that matches a request, the order of the lines within each section is extremely important. The five sections of the `socks5.conf` file are:

- **Ban host/authentication** — Identifies the hosts from which the SOCKS daemon should not accept connections and which types of authentication the SOCKS daemon should use to authenticate these hosts
- **Routing** — Identifies which interface the SOCKS daemon should use for particular IP addresses

- Variables and flags — Identifies which logging and informational messages the SOCKS daemon should use
- Proxies — Identifies the IP addresses that are accessible through another SOCKS server and whether that SOCKS server connects directly to the host
- Access control — Specifies whether the SOCKS daemon should permit or deny a request

When the SOCKS daemon receives a request, it sequentially reads the lines in each of these five sections to check for a match to the request. When it finds a line that matches the request, it reads the line to determine whether to permit or deny the request. If there are no matching lines, the request is denied.

Authentication/Ban Host Entries

There are two lines in authentication/ban host entries. The first line is the authentication line. The second line is the ban host line.

Syntax

```
auth source-hostmask source-portrange auth-methods
```

Parameters

source-hostmask identifies which hosts the SOCKS server will authenticate.

source-portrange identifies which ports the SOCKS server will authenticate.

auth-methods are the methods to be used for authentication. You can list multiple authentication methods in order of your preference. In other words, if the client does not support the first authentication method listed, the second method will be used instead. If the client does not support any of the authentication methods listed, the SOCKS server will disconnect without accepting a request. Separate multiple authentication methods by commas with no spaces in between. Possible authentication methods are:

- n — No authentication required
- u — User name and password required
- - — Any type of authentication

The second line in the authentication/ban host entry is the ban host line.

Syntax

```
ban source-hostmask source-portrange
```

Parameters

source-hostmask identifies which hosts are banned from the SOCKS server.

source-portrange identifies the ports from which the SOCKS server will not accept requests.

Example

```
auth 127.27.27.127 1024 u, -ban 127.27.27.127 1024
```

Routing Entries

Syntax

```
route dest-hostmask dest-portrange interface/address
```

Parameters

dest-hostmask indicates the hosts for which incoming and outgoing connections must go through the specified interface.

dest-portrange indicates the ports for which incoming and outgoing connections must go through the specified interface.

interface/address indicates the IP address or name of the interface through which incoming and outgoing connections must pass. IP addresses are preferred.

Example

```
route 127.27.27.127 1024 le0
```

Variables and Flags

Syntax

```
set variable value
```

Parameters

variable indicates the name of the variable to be initialized.

value is the value to set the variable to.

Example

```
set SOCKS5_BINDPORT 1080
```

Available Settings

The following settings are those that can be inserted into the variables and flags section of the `socks5.conf` file. These settings will be taken from the administration forms, but they can be added, changed, or removed manually as well.

SOCKS5_BINDPORT

The SOCKS5_BINDPORT setting sets the port at which the SOCKS server will listen. This setting cannot be changed during rehash.

Syntax

```
set SOCKS5_BINDPORT port-number
```

Parameters

port-number is the port at which the SOCKS server will listen.

Example

```
set SOCKS5_BINDPORT 1080
```

SOCKS5_PWDFILE

The SOCKS5_PWDFILE setting is used to look up user name/password pairs for user name/password authentication.

Syntax

```
set SOCKS5_PWDFILE full-pathname
```

Parameters

full-pathname is the location and name of the user name/password file.

Example

```
set SOCKS5_PWDFILE /etc/socks5.passwd
```

SOCKS5_LOGFILE

The SOCKS5_LOGFILE setting is used to determine where to write log entries.

Syntax

```
set SOCKS5_LOGFILE full-pathname
```

Parameters

full-pathname is the location and name of the SOCKS logfile.

Example

```
set SOCKS-5_LOGFILE /var/log/socks5.log
```

SOCKS5_NOIDENT

The SOCKS5_NOIDENT setting disables Ident so that SOCKS does not try to determine the user name of clients. Most servers should use this setting unless they will be acting mostly as a SOCKS4 server. SOCKS4 uses ident as authentication.

Syntax

```
set SOCKS5_NOIDENT
```

Parameters

None.

SOCKS5_DEMAND_IDENT

The SOCKS5_DEMAND_IDENT setting sets the Ident level to “require an ident response for every request.” Using Ident in this way dramatically affects the performance of your SOCKS server. If neither SOCKS5_NOIDENT or SOCKS5_DEMAND_IDENT is set, then the SOCKS server will make an Ident check for each request. The server will fulfill requests regardless of whether an Ident response is received.

Syntax

```
set SOCKS5_DEMAND_IDENT
```

Parameters

None.

SOCKS5_DEBUG

The SOCKS5_DEBUG setting causes the SOCKS server to log debug messages. You can specify the type of logging your SOCKS server will use.

If it's not a debug build of the SOCKS server, only the value 1 is valid.

Syntax

```
set SOCKS5_DEBUG number
```

Parameters

number determines the number of the type of logging your server will use. Possible values are:

- 1 — Log normal debugging messages. (the default)
- 2 — Log extensive debugging, especially related to configuration file settings.
- 3 — Log all network traffic

Example

```
set SOCKS5_DEBUG 2
```

SOCKS5_USER

The `SOCKS5_USER` setting specifies the user name to use when authenticating to another SOCKS server. This is used when the SOCKS server is routed through another downstream SOCKS server which requires authentication.

Syntax

```
set SOCKS5_USER user-name
```

Parameters

user-name is the user name the SOCKS server will use when authenticating to another SOCKS server.

Example

```
set SOCKS5_USER mozilla
```

SOCKS5_PASSWD

The `SOCKS5_PASSWD` setting sets the password to use when authenticating to another SOCKS server. Sometimes a SOCKS server passes through another SOCKS server on its way to the Internet. If you define `SOCKS5_USER`, `sockd` will authenticate to other SOCKS servers with a user name and password.

Syntax

```
set SOCKS5_PASSWD password
```

Parameters

password is the password the SOCKS server will use when authenticating to another SOCKS server.

Example

```
set SOCKS5_PASSWD m!2@
```

SOCKS5_NOREVERSEMAP

The `SOCKS5_NOREVERSEMAP` setting instructs `sockd` not to use reverse DNS. Reverse DNS translates IP addresses into host names. Using this setting can increase the speed of the SOCKS server.

If you use domain masks in the configuration file, the SOCKS server will have to use reverse DNS, so this setting will have no effect.

Syntax

```
set SOCKS5_NOREVERSEMAP
```

Parameters

None.

SOCKS5_HONORBINDPORT

The SOCKS5_HONORBINDPORT setting allows the client to specify the port in a BIND request. If this setting is not specified, the SOCKS server ignores the client's requested port and assigns a random port.

Syntax

```
set SOCKS5_HONORBINDPORT
```

Parameters

None.

SOCKS5_ALLOWBLANKETBIND

The SOCKS5_ALLOWBLANKETBIND setting allows the client to specify an IP address of all zeros (0.0.0.0) in a BIND request. If this setting is not specified, the client must specify the IP address that will be connecting to the bind port. An IP of all zeros is interpreted to mean that any IP address can connect.

Syntax

```
set SOCKS5_ALLOWBLANKETBIND
```

Parameters

None.

SOCKS5_WORKERS

The SOCKS5_WORKERS setting tunes the performance of the SOCKS server by adjusting the number of worker threads. Worker threads perform authentication and access control for new SOCKS connections. If the SOCKS server is too slow, you should increase the number of worker threads. If the server is unstable, decrease the number of worker threads.

The default number of worker threads is 40. The typical number of worker threads falls between 10 and 150.

Syntax

```
set SOCKS5_WORKERS number
```

Parameters

number is the number of worker threads the SOCKS server will use.

Example

```
set SOCKS5_WORKERS 40
```

SOCKS5_ACCEPTS

The SOCKS5_ACCEPTS setting tunes the performance of the SOCKS server by adjusting the number of accept threads. Accept threads sit on the SOCKS port listening for new SOCKS requests. If the SOCKS server is dropping connections, increase the number of accept threads. If it is unstable, decrease the number of accept threads.

The default number of accept threads is 1. The typical number of accept threads falls between 1 and 10.

Example

```
set SOCKS5_ACCEPTS number
```

Parameters

number is the number of accepts threads the SOCKS server will use.

Example

```
set SOCKS5_ACCEPTS 1
```

LDAP_URL

The LDAP-URL setting sets the URL for the LDAP server.

Syntax

```
set LDAP-URL URL
```

Parameters

URL is the URL for the LDAP server used by SOCKS.

Example

```
set LDAP-URL ldap://name:8180/0=Netscape,c=US
```

LDAP_USER

The LDAP-USER setting sets the user name that the SOCKS server will use when accessing the LDAP server.

Syntax

```
set LDAP-USER user-name
```

Parameters

user-name is the user name SOCKS will use when accessing the LDAP server.

Example

```
set LDAP-USER uid=admin
```

LDAP_PASSWD

The LDAP-PASSWD setting sets the password that the SOCKS server will use when accessing the LDAP server.

Syntax

```
set LDAP-PASSWD password
```

Parameters

password is the password SOCKS will use when accessing the LDAP server.

Example

```
set LDAP-PASSWD T$09
```

SOCKS5_TIMEOUT

The SOCKS5-TIMEOUT setting specifies the idle period that the SOCKS server will keep a connection alive between a client and a remote server before dropping the connection.

Syntax

```
set SOCKS5_TIMEOUT time
```

Parameters

time is the time, in minutes, that SOCKS will wait before timing out. The default value is 10. The value can range from 10 to 360, including both these values.

Example

```
set SOCKS5_TIMEOUT 30
```

Proxy Entries

Syntax

```
proxy-type dest-hostmask dest-portrange proxy-host proxy-port
```

Parameters

proxy-type indicates the type of proxy server. This value can be:

- socks5 — SOCKS version 5
- socks4 — SOCKS version 4
- noproxy — a direct connection

dest-hostmask indicates the hosts for which the proxy entry applies.

dest-portrange indicates the ports for which the proxy entry applies.

proxy-host indicates the names or IP of the proxy servers to use.

proxy-port indicates the ports of the proxy servers to use

Example

```
socks5 127.27.27.127 1080 proxy1
```

Access Control Entries

Syntax

```
permit|deny auth-type connection-type source-hostmask dest-hostmask source-portrange dest-portrange  
[LDAP-group]
```

Parameters

auth-type indicates the authentication method for which this access control line applies.

connection-type indicates the type of command the line matches. Possible command types are:

- c — Connect
- b — Bind; open a listen socket
- u — UDP relay
- - — any command

source-hostmask indicates the hosts for which the access control entry applies.

dest-hostmask indicates the hosts for which the access control entry applies.

source-portrange indicates the ports for which the access control entry applies.

dest-portrange is the port number of the destination.

LDAP-group is the group to deny or permit access to. This value is optional. If no LDAP group is identified, the access control entry applies to everyone.

Example

```
permit u c - - - [0-1023] group1
```

Specifying Ports

You will need to specify ports for many entries in your `socks5.conf` file. Ports can be identified by a name, number, or range. Ranges that are inclusive should be surrounded by square brackets (`[]`). Ranges that are not inclusive should be in parentheses.

parray.pat

The `parray.pat` (PAT) file describes each member in the proxy array of which the proxy you are administering is a member. The PAT file is an ASCII file used in proxy to proxy routing. It contains proxy array members' machine names, IP addresses, ports, load factors, cache sizes, and so on.

Syntax

Proxy Array Information/1.0

ArrayEnabled: *number* ConfigID: *ID number* ArrayName: *name* ListTTL: *minutes*
name IPaddress proxyport URLforPAT infostring state time status loadfactor cachesize

Parameters

Proxy Array Information is version information.

ArrayEnabled specifies whether the proxy array is enabled or disabled. Possible values are:

- 0 — The array is disabled.
- 1 — The array is enabled.

ConfigID is the identification number for the current version of the PAT file. The proxy server uses this number to determine whether the PAT file has changed.

ArrayName is the name of the proxy array.

ListTTL specifies how often the proxy should check the PAT file to see if it has changed. This value is specified in minutes.

`name` is the name of a specific member of the proxy array.

`IPaddress` is the IP address of the member.

`proxyport` is the port at which the master proxy accepts HTTP requests.

`URLforPAT` is the URL of the PAT file that the member will poll the master proxy for.

`infostring` is version information.

`statetime` is the amount of time the member has been in its current state.

`status` specifies whether the member is enabled or disabled.

- `on` means that the member is on.
- `off` means that the member is off. If the member is off, its requests will be routed through another member of the array.

`loadfactor` is an integer that reflects the number of requests that should be routed through the member.

`cachesize` is the size of the member's cache.

Example

```
Proxy Array Information/1.0
ArrayEnabled: 1
ConfigID: 1
ArrayName: parray
ListTTL: 10
```

```
proxy1 200.29.186.77 8080 http://pat SunJavaSystemWebProxy/4 0 on 100 512
proxy2 187.21.165.22 8080 http://pat SunJavaSystemWebProxy/4 0 on 100 512
```

parent.pat

The `parent.pat` file is the Proxy Array Table file that contains information about an upstream proxy array. This file has the same syntax as the `parray.pat` file.

Configuration Changes Between iPlanet Web Proxy Server 3.6 and Sun Java System Web Proxy Server 4

This chapter points you to the configuration changes between iPlanet Web proxy Server 3.6 and Sun Java System Web Proxy Server 4.

Configuration changes

See *Sun Java System Web Proxy Server 4.0.8 Installation and Migration Guide*.

Time Formats

This appendix describes the format strings used for dates and times in the server log. These formats are used by the NSAPI function `util_strftime`, by some built-in SAFs such as `append-trailer`, and by server-parsed HTML (`parse-html`).

The formats are similar to those used by the `strftime` C library routine, but not identical.

Format strings for dates and times

The following table describes the format strings for dates and times.

TABLE B-1 Format Strings

Attribute	Allowed Values
%a	Abbreviated weekday name (3 chars)
%d	Day of month as decimal number (01-31)
%S	Second as decimal number (00-59)
%M	Minute as decimal number (00-59)
%H	Hour in 24-hour format (00-23)
%Y	Year with century, as a decimal number, up to 2099
%b	Abbreviated month name (3 characters)
%h	Abbreviated month name (3 characters)
%T	Time "HH:MM:SS"
%X	Time "HH:MM:SS"

TABLE B-1 Format Strings (Continued)

Attribute	Allowed Values
%A	Full weekday name
%B	Full month name
%C	"%a %b %e %H:%M:%S %Y"
%c	Date & time "%m/%d/%y %H:%M:%S"
%D	Date "%m/%d/%y"
%e	Day of month as a decimal number (1-31) without leading zeros
%I	Hour in 12-hour format (01-12)
%j	Day of year as a decimal number (001-366)
%k	Hour in 24-hour format (0-23) without leading zeros
%l	Hour in 12-hour format (1-12) without leading zeros
%m	Month as decimal number (01-12)
%n	Line feed
%p	a.m./p.m. indicator for 12-hour clock
%R	Time "%H:%M"
%r	Time "%I:%M:%S %p"
%t	Tab
%U	Week of year as a decimal number, with Sunday as first day of week (00-51)
%w	Weekday as a decimal number (0-6; Sunday is 0)
%W	Week of year as a decimal number, with Monday as the first day of the week (00-51)
%x	Date "%m/%d/%y"
%y	Year without the century, as a decimal number (00-99)
%%	Percent sign

Server Configuration Elements

The following list provides an alphabetical list of server configuration elements.
