| DESCRIPTION | <p>The <code>cbreak()</code> and <code>nocbreak()</code> routines put the terminal into and out of <code>cbreak()</code> mode, respectively. In this mode, characters typed by the user are immediately available to the program, and erase/kill character-processing is not performed. When out of this mode, the tty driver buffers the typed characters until a newline or carriage return is typed. Interrupt and flow control characters are unaffected by this mode. Initially the terminal may or may not be in <code>cbreak()</code> mode, as the mode is inherited; therefore, a program should call <code>cbreak()</code> or <code>nocbreak()</code> explicitly. Most interactive programs using curses set the <code>cbreak()</code> mode.</p> <p>Note that <code>cbreak()</code> overrides <code>raw()</code>. (See <code>curs_getch(3CURSES)</code> for a discussion of how these routines interact with <code>echo()</code> and <code>noecho()</code>.)</p> <p>The <code>echo()</code> and <code>noecho()</code> routines control whether characters typed by the user are echoed by <code>getch()</code> as they are typed. Echoing by the tty driver is always disabled, but initially <code>getch()</code> is in echo mode, so characters typed are echoed. Authors of</p> |

qiflush(3CURSES)

most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling `noecho()`. (See `curs_getch(3CURSES)` for a discussion of how these routines interact with `cbreak()` and `nocbreak()`.)

The `halfdelay()` routine is used for half-delay mode, which is similar to `cbreak()` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, `ERR` is returned if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

If the `intrflush()` option is enabled, (*bf* is `TRUE`), when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing `curses` to have the wrong idea of what is on the screen. Disabling (*bf* is `FALSE`), the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.

The `keypad()` option enables the keypad of the user's terminal. If enabled (*bf* is `TRUE`), the user can press a function key (such as an arrow key) and `wgetch()` returns a single value representing the function key, as in `KEY_LEFT`. If disabled (*bf* is `FALSE`), `curses` does not treat function keys specially and the program has to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option causes the terminal keypad to be turned on when `wgetch()` is called. The default value for keypad is false.

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the tty driver (see `termio(7I)`). To force 8 bits to be returned, invoke `meta(win, TRUE)`. To force 7 bits to be returned, invoke `meta(win, FALSE)`. The window argument, *win*, is always ignored. If the terminfo capabilities `smm` (`meta_on`) and `rmm` (`meta_off`) are defined for the terminal, `smm` is sent to the terminal when `meta(win, TRUE)` is called and `rmm` is sent when `meta(win, FALSE)` is called.

The `nodelay()` option causes `getch()` to be a non-blocking call. If no input is ready, `getch()` returns `ERR`. If disabled (*bf* is `FALSE`), `getch()` waits until a key is pressed.

While interpreting an input escape sequence, `wgetch()` sets a timer while waiting for the next character. If `notimeout(win, TRUE)` is called, then `wgetch()` does not set a timer. The purpose of the timeout is to differentiate between sequences received from a function key and those typed by a user.

With the `raw()` and `noraw()` routines, the terminal is placed into or out of raw mode. Raw mode is similar to `cbreak()` mode, in that characters typed are immediately passed through to the user program. The differences are that in raw mode, the interrupt, quit, suspend, and flow control characters are all passed through uninterpreted, instead of generating a signal. The behavior of the `BREAK` key depends on other bits in the tty driver that are not set by `curses`.

## qiflush(3CURSES)

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the INTR, QUIT and SUSP characters will not be done (see `termio(7I)`). When `qiflush()` is called, the queues will be flushed when these control characters are read.

The `timeout()` and `wtimeout()` routines set blocking or non-blocking read for a given window. If *delay* is negative, blocking read is used (that is, waits indefinitely for input). If *delay* is zero, then non-blocking read is used (that is, read returns ERR if no input is waiting). If *delay* is positive, then read blocks for *delay* milliseconds, and returns ERR if there is still no input. Hence, these routines provide the same functionality as `nodelay()`, plus the additional capability of being able to block for only *delay* milliseconds (where *delay* is positive).

`curses` does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh()` or `doupdate()` is called again. This allows faster response to commands typed in advance. Normally, the input FILE pointer passed to `newterm()`, or `stdin` in the case that `initscr()` was used, will be used to do this typeahead checking. The `typeahead()` routine specifies that the file descriptor *fildes* is to be used to check for typeahead instead. If *fildes* is `-1`, then no typeahead checking is done.

**RETURN VALUES** All routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_getch(3CURSES)`, `curs_initscr(3CURSES)`, `curses(3CURSES)`, `attributes(5)`, `termio(7I)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `echo()`, `noecho()`, `halfdelay()`, `intrflush()`, `meta()`, `nodelay()`, `notimeout()`, `noqiflush()`, `qiflush()`, `timeout()`, and `wtimeout()` may be macros.

| DESCRIPTION | <p>The <code>cbreak()</code> and <code>nocbreak()</code> routines put the terminal into and out of <code>cbreak()</code> mode, respectively. In this mode, characters typed by the user are immediately available to the program, and erase/kill character-processing is not performed. When out of this mode, the tty driver buffers the typed characters until a newline or carriage return is typed. Interrupt and flow control characters are unaffected by this mode. Initially the terminal may or may not be in <code>cbreak()</code> mode, as the mode is inherited; therefore, a program should call <code>cbreak()</code> or <code>nocbreak()</code> explicitly. Most interactive programs using curses set the <code>cbreak()</code> mode.</p> <p>Note that <code>cbreak()</code> overrides <code>raw()</code>. (See <code>curs_getch(3CURSES)</code> for a discussion of how these routines interact with <code>echo()</code> and <code>noecho()</code>.)</p> <p>The <code>echo()</code> and <code>noecho()</code> routines control whether characters typed by the user are echoed by <code>getch()</code> as they are typed. Echoing by the tty driver is always disabled, but initially <code>getch()</code> is in echo mode, so characters typed are echoed. Authors of</p> |

## raw(3CURSES)

most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling `noecho()`. (See `curs_getch(3CURSES)` for a discussion of how these routines interact with `cbreak()` and `nocbreak()`.)

The `halfdelay()` routine is used for half-delay mode, which is similar to `cbreak()` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, `ERR` is returned if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

If the `intrflush()` option is enabled, (*bf* is `TRUE`), when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing `curses` to have the wrong idea of what is on the screen. Disabling (*bf* is `FALSE`), the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.

The `keypad()` option enables the keypad of the user's terminal. If enabled (*bf* is `TRUE`), the user can press a function key (such as an arrow key) and `wgetch()` returns a single value representing the function key, as in `KEY_LEFT`. If disabled (*bf* is `FALSE`), `curses` does not treat function keys specially and the program has to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option causes the terminal keypad to be turned on when `wgetch()` is called. The default value for keypad is false.

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the tty driver (see `termio(7I)`). To force 8 bits to be returned, invoke `meta(win, TRUE)`. To force 7 bits to be returned, invoke `meta(win, FALSE)`. The window argument, *win*, is always ignored. If the terminfo capabilities `smm` (`meta_on`) and `rmm` (`meta_off`) are defined for the terminal, `smm` is sent to the terminal when `meta(win, TRUE)` is called and `rmm` is sent when `meta(win, FALSE)` is called.

The `nodelay()` option causes `getch()` to be a non-blocking call. If no input is ready, `getch()` returns `ERR`. If disabled (*bf* is `FALSE`), `getch()` waits until a key is pressed.

While interpreting an input escape sequence, `wgetch()` sets a timer while waiting for the next character. If `notimeout(win, TRUE)` is called, then `wgetch()` does not set a timer. The purpose of the timeout is to differentiate between sequences received from a function key and those typed by a user.

With the `raw()` and `noraw()` routines, the terminal is placed into or out of raw mode. Raw mode is similar to `cbreak()` mode, in that characters typed are immediately passed through to the user program. The differences are that in raw mode, the interrupt, quit, suspend, and flow control characters are all passed through uninterpreted, instead of generating a signal. The behavior of the `BREAK` key depends on other bits in the tty driver that are not set by `curses`.

raw(3CURSES)

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the INTR, QUIT and SUSP characters will not be done (see `termio(7I)`). When `qiflush()` is called, the queues will be flushed when these control characters are read.

The `timeout()` and `wtimeout()` routines set blocking or non-blocking read for a given window. If *delay* is negative, blocking read is used (that is, waits indefinitely for input). If *delay* is zero, then non-blocking read is used (that is, read returns ERR if no input is waiting). If *delay* is positive, then read blocks for *delay* milliseconds, and returns ERR if there is still no input. Hence, these routines provide the same functionality as `nodelay()`, plus the additional capability of being able to block for only *delay* milliseconds (where *delay* is positive).

`curses` does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh()` or `doupdate()` is called again. This allows faster response to commands typed in advance. Normally, the input FILE pointer passed to `newterm()`, or `stdin` in the case that `initscr()` was used, will be used to do this typeahead checking. The `typeahead()` routine specifies that the file descriptor *fildev* is to be used to check for typeahead instead. If *fildev* is `-1`, then no typeahead checking is done.

#### RETURN VALUES

All routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

#### SEE ALSO

`curs_getch(3CURSES)`, `curs_initscr(3CURSES)`, `curses(3CURSES)`, `attributes(5)`, `termio(7I)`

#### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `echo()`, `noecho()`, `halfdelay()`, `intrflush()`, `meta()`, `nodelay()`, `notimeout()`, `noqiflush()`, `qiflush()`, `timeout()`, and `wtimeout()` may be macros.

| NAME        | curs_refresh, refresh, wrefresh, wnoutrefresh, doupdate, redrawwin, wredrawln – refresh curses windows and lines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| SYNOPSIS    | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int refresh(void); int wrefresh(WINDOW *win); int wnoutrefresh(WINDOW *win); int doupdate(void); int redrawwin(WINDOW *win); int wredrawln(WINDOW *win, int beg_line, int num_lines);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DESCRIPTION | <p>The <code>refresh()</code> and <code>wrefresh()</code> routines (or <code>wnoutrefresh()</code> and <code>doupdate()</code>) must be called to get any output on the terminal, as other routines merely manipulate data structures. The routine <code>wrefresh()</code> copies the named window to the physical terminal screen, taking into account what is already there in order to do optimizations. The <code>refresh()</code> routine is the same, using <code>stdscr</code> as the default window. Unless <code>leaveok()</code> has been enabled, the physical cursor of the terminal is left at the location of the cursor for that window.</p> <p>The <code>wnoutrefresh()</code> and <code>doupdate()</code> routines allow multiple updates with more efficiency than <code>wrefresh()</code> alone. In addition to all the window structures, <code>curses</code> keeps two data structures representing the terminal screen: a physical screen, describing what is actually on the screen, and a virtual screen, describing what the programmer wants to have on the screen.</p> <p>The routine <code>wrefresh()</code> works by first calling <code>wnoutrefresh()</code>, which copies the named window to the virtual screen, and then calling <code>doupdate()</code>, which compares the virtual screen to the physical screen and does the actual update. If the programmer wishes to output several windows at once, a series of calls to <code>wrefresh()</code> results in alternating calls to <code>wnoutrefresh()</code> and <code>doupdate()</code>, causing several bursts of output to the screen. By first calling <code>wnoutrefresh()</code> for each window, it is then possible to call <code>doupdate()</code> once, resulting in only one burst of output, with fewer total characters transmitted and less CPU time used. If the <code>win</code> argument to <code>wrefresh()</code> is the global variable <code>curscr</code>, the screen is immediately cleared and repainted from scratch.</p> <p>The <code>redrawwin()</code> routine indicates to <code>curses</code> that some screen lines are corrupted and should be thrown away before anything is written over them. These routines could be used for programs such as editors, which want a command to redraw some part of the screen or the entire screen. The routine <code>wredrawln()</code> is preferred over <code>redrawwin()</code> where a noisy communication line exists and redrawing the entire window could be subject to even more communication noise. Just redrawing several lines offers the possibility that they would show up unblemished.</p> |

redrawwin(3CURSES)

**RETURN VALUES** All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_outopts(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `refresh()` and `redrawwin()` may be macros.

| <b>NAME</b>          | redrawwin, wredrawln – redraw screen or portion of screen                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |

| <b>PARAMETERS</b>    | <p><i>win</i> Is a pointer to the window in which to redraw.</p> <p><i>beg_line</i> Is the first line to redraw.</p> <p><i>num_lines</i> Is the number of lines to redraw.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>redrawwin()</code> and <code>wredrawln()</code> functions force portions of a window to be redrawn to the terminal when the next refresh operation is performed.</p> <p>The <code>redrawwin()</code> function forces the entire window <i>win</i> to be redrawn, while the <code>wredrawln()</code> function forces only <i>num_lines</i> lines starting with <i>beg_line</i> to be redrawn. Normally, refresh operations use optimization methods to reduce the actual amount of the screen to redraw based on the current screen contents. These functions tell the refresh operations not to attempt any optimization when redrawing the indicated areas.</p> <p>These functions are useful when the data that exists on the screen is believed to be corrupt and for applications such as screen editors that redraw portions of the screen.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |                     |          |          |        |
| <b>ATTRIBUTES</b>    | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |

| NAME        | <code> curs_refresh, refresh, wrefresh, wnoutrefresh, doupdate, redrawwin, wredrawln </code> – refresh curses windows and lines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| SYNOPSIS    | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int refresh(void); int wrefresh(WINDOW *win); int wnoutrefresh(WINDOW *win); int doupdate(void); int redrawwin(WINDOW *win); int wredrawln(WINDOW *win, int beg_line, int num_lines);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| DESCRIPTION | <p>The <code>refresh()</code> and <code>wrefresh()</code> routines (or <code>wnoutrefresh()</code> and <code>doupdate()</code>) must be called to get any output on the terminal, as other routines merely manipulate data structures. The routine <code>wrefresh()</code> copies the named window to the physical terminal screen, taking into account what is already there in order to do optimizations. The <code>refresh()</code> routine is the same, using <code>stdscr</code> as the default window. Unless <code>leaveok()</code> has been enabled, the physical cursor of the terminal is left at the location of the cursor for that window.</p> <p>The <code>wnoutrefresh()</code> and <code>doupdate()</code> routines allow multiple updates with more efficiency than <code>wrefresh()</code> alone. In addition to all the window structures, <code>curses</code> keeps two data structures representing the terminal screen: a physical screen, describing what is actually on the screen, and a virtual screen, describing what the programmer wants to have on the screen.</p> <p>The routine <code>wrefresh()</code> works by first calling <code>wnoutrefresh()</code>, which copies the named window to the virtual screen, and then calling <code>doupdate()</code>, which compares the virtual screen to the physical screen and does the actual update. If the programmer wishes to output several windows at once, a series of calls to <code>wrefresh()</code> results in alternating calls to <code>wnoutrefresh()</code> and <code>doupdate()</code>, causing several bursts of output to the screen. By first calling <code>wnoutrefresh()</code> for each window, it is then possible to call <code>doupdate()</code> once, resulting in only one burst of output, with fewer total characters transmitted and less CPU time used. If the <code>win</code> argument to <code>wrefresh()</code> is the global variable <code>curscr</code>, the screen is immediately cleared and repainted from scratch.</p> <p>The <code>redrawwin()</code> routine indicates to <code>curses</code> that some screen lines are corrupted and should be thrown away before anything is written over them. These routines could be used for programs such as editors, which want a command to redraw some part of the screen or the entire screen. The routine <code>redrawln()</code> is preferred over <code>redrawwin()</code> where a noisy communication line exists and redrawing the entire window could be subject to even more communication noise. Just redrawing several lines offers the possibility that they would show up unblemished.</p> |

`refresh(3CURSES)`

**RETURN VALUES** All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_outopts(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `refresh()` and `redrawwin()` may be macros.

## refresh(3XCURSES)

| NAME                | douupdate, refresh, wnoutrefresh, wrefresh – refresh windows and lines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |

| DESCRIPTION         | <p>The <code>refresh()</code> and <code>wrefresh()</code> functions copy <code>stdscr</code> and <code>win</code>, respectively, to the terminal screen. These functions call the <code>wnoutrefresh()</code> function to copy the specified window to <code>curscr</code> and the <code>douupdate()</code> function to do the actual update. The physical cursor is mapped to the same position as the logical cursor of the last window to update <code>curscr</code> unless <code>leaveok(3XCURSES)</code> is enabled (in which case, the cursor is placed in a position that X/Open Curses finds convenient).</p> <p>When outputting several windows at once, it is often more efficient to call the <code>wnoutrefresh()</code> and <code>douupdate()</code> functions directly. A call to <code>wnoutrefresh()</code> for each window, followed by only one call to <code>douupdate()</code> to update the screen, results in one burst of output, fewer characters sent, and less CPU time used.</p> <p>If the <code>win</code> parameter to <code>wrefresh()</code> is the global variable <code>curscr</code>, the screen is immediately cleared and repainted from scratch.</p> <p>For details on how the <code>wnoutrefresh()</code> function handles overlapping windows with broad glyphs, see the Overlapping Windows section of the <code>curses(3XCURSES)</code> reference manual page.</p> |                |                 |                     |          |          |        |
| PARAMETERS          | <p><i>win</i>            Is a pointer to the window in which to refresh.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The following routines give low-level access to various curses functionality. These routines typically are used inside library routines.</p> <p>The <code>def_prog_mode()</code> and <code>def_shell_mode()</code> routines save the current terminal modes as the “program” (in curses) or “shell” (not in curses) state for use by the <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines. This is done automatically by <code>initscr()</code>.</p> <p>The <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines restore the terminal to “program” (in curses) or “shell” (out of curses) state. These are done automatically by <code>endwin()</code> and, after an <code>endwin()</code>, by <code>doupdate()</code>, so they normally are not called.</p> <p>The <code>resetty()</code> and <code>savetty()</code> routines save and restore the state of the terminal modes. <code>savetty()</code> saves the current state in a buffer and <code>resetty()</code> restores the state to what it was at the last call to <code>savetty()</code>.</p> <p>With the <code>getsyx()</code> routine, the current coordinates of the virtual screen cursor are returned in <code>y</code> and <code>x</code>. If <code>leaveok()</code> is currently TRUE, then <code>-1,-1</code> is returned. If lines have been removed from the top of the screen, using <code>ripoffline()</code>, <code>y</code> and <code>x</code> include these lines; therefore, <code>y</code> and <code>x</code> should be used only as arguments for <code>setsyx()</code>.</p> <p>With the <code>setsyx()</code> routine, the virtual screen cursor is set to <code>y, x</code>. If <code>y</code> and <code>x</code> are both <code>-1</code>, then <code>leaveok()</code> is set. The two routines <code>getsyx()</code> and <code>setsyx()</code> are designed to be used by a library routine, which manipulates curses windows but does not</p> |

reset\_prog\_mode(3CURSES)

want to change the current position of the program's cursor. The library routine would call `getsyx()` at the beginning, do its manipulation of its own windows, do a `wnoutrefresh()` on its windows, call `setsyx()`, and then call `doupdate()`.

The `riporffline()` routine provides access to the same facility that `slk_init()` (see `curs_slk(3CURSES)`) uses to reduce the size of the screen. `riporffline()` must be called before `initscr()` or `newterm()` is called. If `line` is positive, a line is removed from the top of `stdscr()`; if `line` is negative, a line is removed from the bottom. When this is done inside `initscr()`, the routine `init()` (supplied by the user) is called with two arguments: a window pointer to the one-line window that has been allocated and an integer with the number of columns in the window. Inside this initialization routine, the integer variables `LINES` and `COLS` (defined in `<curses.h>`) are not guaranteed to be accurate and `wrefresh()` or `doupdate()` must not be called. It is allowable to call `wnoutrefresh()` during the initialization routine.

`riporffline()` can be called up to five times before calling `initscr()` or `newterm()`.

With the `curs_set()` routine, the cursor state is set to invisible, normal, or very visible for *visibility* equal to 0, 1, or 2 respectively. If the terminal supports the *visibility* requested, the previous *cursor* state is returned; otherwise, `ERR` is returned.

The `napms()` routine is used to sleep for *ms* milliseconds.

**RETURN VALUES** Except for `curs_set()`, these routines always return `OK`. `curs_set()` returns the previous cursor state, or `ERR` if the requested *visibility* is not supported.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_initscr(3CURSES)`, `curs_outopts(3CURSES)`, `curs_refresh(3CURSES)`, `curs_scr_dump(3CURSES)`, `curs_slk(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `getsyx()` is a macro, so an ampersand (&) is not necessary before the variables *y* and *x*.

## reset\_prog\_mode(3XCURSES)

| NAME                | def_prog_mode, def_shell_mode, reset_prog_mode, reset_shell_mode – save/restore terminal modes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |                     |          |          |        |

| DESCRIPTION         | <p>The <code>def_prog_mode()</code> and <code>def_shell_mode()</code> functions save the current terminal modes as "program" (within X/Open Curses) or "shell" (outside X/Open Curses). The modes are saved automatically by <code>initscr(3XCURSES)</code>, <code>newterm(3XCURSES)</code>, and <code>setupterm(3XCURSES)</code>.</p> <p>The <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> functions reset the current terminal modes to "program" (within X/Open Curses) or "shell" (outside X/Open Curses). The <code>endwin(3XCURSES)</code> function automatically calls the <code>reset_shell_mode()</code> function and the <code>doupdate(3XCURSES)</code> function calls the <code>reset_prog_mode()</code> function after calling <code>endwin()</code>.</p> |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The following routines give low-level access to various curses functionality. These routines typically are used inside library routines.</p> <p>The <code>def_prog_mode()</code> and <code>def_shell_mode()</code> routines save the current terminal modes as the “program” (in curses) or “shell” (not in curses) state for use by the <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines. This is done automatically by <code>initscr()</code>.</p> <p>The <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines restore the terminal to “program” (in curses) or “shell” (out of curses) state. These are done automatically by <code>endwin()</code> and, after an <code>endwin()</code>, by <code>doupdate()</code>, so they normally are not called.</p> <p>The <code>resetty()</code> and <code>savetty()</code> routines save and restore the state of the terminal modes. <code>savetty()</code> saves the current state in a buffer and <code>resetty()</code> restores the state to what it was at the last call to <code>savetty()</code>.</p> <p>With the <code>getsyx()</code> routine, the current coordinates of the virtual screen cursor are returned in <code>y</code> and <code>x</code>. If <code>leaveok()</code> is currently TRUE, then -1,-1 is returned. If lines have been removed from the top of the screen, using <code>ripoffline()</code>, <code>y</code> and <code>x</code> include these lines; therefore, <code>y</code> and <code>x</code> should be used only as arguments for <code>setsyx()</code>.</p> <p>With the <code>setsyx()</code> routine, the virtual screen cursor is set to <code>y</code>, <code>x</code>. If <code>y</code> and <code>x</code> are both -1, then <code>leaveok()</code> is set. The two routines <code>getsyx()</code> and <code>setsyx()</code> are designed to be used by a library routine, which manipulates curses windows but does not</p> |

reset\_shell\_mode(3CURSES)

want to change the current position of the program's cursor. The library routine would call `getsyx()` at the beginning, do its manipulation of its own windows, do a `wnoutrefresh()` on its windows, call `setsyx()`, and then call `doupdate()`.

The `riporffline()` routine provides access to the same facility that `slk_init()` (see `curs_slk(3CURSES)`) uses to reduce the size of the screen. `riporffline()` must be called before `initscr()` or `newterm()` is called. If `line` is positive, a line is removed from the top of `stdscr()`; if `line` is negative, a line is removed from the bottom. When this is done inside `initscr()`, the routine `init()` (supplied by the user) is called with two arguments: a window pointer to the one-line window that has been allocated and an integer with the number of columns in the window. Inside this initialization routine, the integer variables `LINES` and `COLS` (defined in `<curses.h>`) are not guaranteed to be accurate and `wrefresh()` or `doupdate()` must not be called. It is allowable to call `wnoutrefresh()` during the initialization routine.

`riporffline()` can be called up to five times before calling `initscr()` or `newterm()`.

With the `curs_set()` routine, the cursor state is set to invisible, normal, or very visible for *visibility* equal to 0, 1, or 2 respectively. If the terminal supports the *visibility* requested, the previous *cursor* state is returned; otherwise, `ERR` is returned.

The `napms()` routine is used to sleep for *ms* milliseconds.

#### RETURN VALUES

Except for `curs_set()`, these routines always return `OK`. `curs_set()` returns the previous cursor state, or `ERR` if the requested *visibility* is not supported.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

#### SEE ALSO

`curs_initscr(3CURSES)`, `curs_outopts(3CURSES)`, `curs_refresh(3CURSES)`, `curs_scr_dump(3CURSES)`, `curs_slk(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

#### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `getsyx()` is a macro, so an ampersand (&) is not necessary before the variables *y* and *x*.

reset\_shell\_mode(3XCURSES)

| NAME                | def_prog_mode, def_shell_mode, reset_prog_mode, reset_shell_mode – save/restore terminal modes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |                     |          |          |        |

| DESCRIPTION         | <p>The <code>def_prog_mode()</code> and <code>def_shell_mode()</code> functions save the current terminal modes as "program" (within X/Open Curses) or "shell" (outside X/Open Curses). The modes are saved automatically by <code>initscr(3XCURSES)</code>, <code>newterm(3XCURSES)</code>, and <code>setupterm(3XCURSES)</code>.</p> <p>The <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> functions reset the current terminal modes to "program" (within X/Open Curses) or "shell" (outside X/Open Curses). The <code>endwin(3XCURSES)</code> function automatically calls the <code>reset_shell_mode()</code> function and the <code>doupdate(3XCURSES)</code> function calls the <code>reset_prog_mode()</code> function after calling <code>endwin()</code>.</p> |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |                     |          |          |        |
| ATTRIBUTES          | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The following routines give low-level access to various curses functionality. Theses routines typically are used inside library routines.</p> <p>The <code>def_prog_mode()</code> and <code>def_shell_mode()</code> routines save the current terminal modes as the “program” (in curses) or “shell” (not in curses ) state for use by the <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines. This is done automatically by <code>initscr()</code>.</p> <p>The <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines restore the terminal to “program” (in curses) or “shell” (out of curses) state. These are done automatically by <code>endwin()</code> and, after an <code>endwin()</code>, by <code>doupdate()</code>, so they normally are not called.</p> <p>The <code>resetty()</code> and <code>savetty()</code> routines save and restore the state of the terminal modes. <code>savetty()</code> saves the current state in a buffer and <code>resetty()</code> restores the state to what it was at the last call to <code>savetty()</code>.</p> <p>With the <code>getsyx()</code> routine, the current coordinates of the virtual screen cursor are returned in <code>y</code> and <code>x</code>. If <code>leaveok()</code> is currently TRUE, then <code>-1,-1</code> is returned. If lines have been removed from the top of the screen, using <code>ripoffline()</code>, <code>y</code> and <code>x</code> include these lines; therefore, <code>y</code> and <code>x</code> should be used only as arguments for <code>setsyx()</code>.</p> <p>With the <code>setsyx()</code> routine, the virtual screen cursor is set to <code>y, x</code>. If <code>y</code> and <code>x</code> are both <code>-1</code>, then <code>leaveok()</code> is set. The two routines <code>getsyx()</code> and <code>setsyx()</code> are designed to be used by a library routine, which manipulates curses windows but does not</p> |

resetty(3CURSES)

want to change the current position of the program's cursor. The library routine would call getsyx() at the beginning, do its manipulation of its own windows, do a wnoutrefresh() on its windows, call setsyx(), and then call doupdate().

The ripoffline() routine provides access to the same facility that slk\_init() (see curs\_slk(3CURSES)) uses to reduce the size of the screen. ripoffline() must be called before initscr() or newterm() is called. If line is positive, a line is removed from the top of stdscr(); if line is negative, a line is removed from the bottom. When this is done inside initscr(), the routine init() (supplied by the user) is called with two arguments: a window pointer to the one-line window that has been allocated and an integer with the number of columns in the window. Inside this initialization routine, the integer variables LINES and COLS (defined in <curses.h>) are not guaranteed to be accurate and wrefresh() or doupdate() must not be called. It is allowable to call wnoutrefresh() during the initialization routine.

ripoffline() can be called up to five times before calling initscr() or newterm().

With the curs\_set() routine, the cursor state is set to invisible, normal, or very visible for *visibility* equal to 0, 1, or 2 respectively. If the terminal supports the *visibility* requested, the previous *cursor* state is returned; otherwise, ERR is returned.

The napms() routine is used to sleep for *ms* milliseconds.

#### RETURN VALUES

Except for curs\_set(), these routines always return OK. curs\_set() returns the previous cursor state, or ERR if the requested *visibility* is not supported.

#### ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

#### SEE ALSO

curs\_initscr(3CURSES), curs\_outopts(3CURSES), curs\_refresh(3CURSES), curs\_scr\_dump(3CURSES), curs\_slk(3CURSES), curses(3CURSES), attributes(5)

#### NOTES

The header <curses.h> automatically includes the headers <stdio.h> and <unctrl.h>.

Note that getsyx() is a macro, so an ampersand (&) is not necessary before the variables *y* and *x*.

## resetty(3XCURSES)

| NAME                | resetty, savetty – restore/save terminal modes                                                                                                                                                                                                                      |                |                 |                     |          |          |        |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| SYNOPSIS            | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int resetty(void);  int savetty(void);</pre>                              |                |                 |                     |          |          |        |
| DESCRIPTION         | The savetty() and resetty() functions save and restore the terminal state, respectively. The savetty() function saves the current state in a buffer; the resetty() function restores the state to that stored in the buffer at the time of the last savetty() call. |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
| ATTRIBUTES          | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                     |                |                 |                     |          |          |        |

| DESCRIPTION | <p>These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, curses routines are more suitable and their use is recommended.</p> <p>Initially, <code>setupterm()</code> should be called. Note that <code>setupterm()</code> is automatically called by <code>initscr()</code> and <code>newterm()</code>. This defines the set of terminal-dependent variables (listed in <code>terminfo(4)</code>). The <i>terminfo</i> variables <code>lines</code> and <code>columns</code> are initialized by <code>setupterm()</code> as follows: If <code>use_env(FALSE)</code> has been called, values for <code>lines</code> and <code>columns</code> specified in <i>terminfo</i> are used. Otherwise, if the environment variables <code>LINES</code> and <code>COLUMNS</code> exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database are used.</p> <p>The headers <code>&lt;curses.h&gt;</code> and <code>&lt;term.h&gt;</code> should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through <code>tparm()</code> to instantiate them. All <i>terminfo</i> strings (including the output</p> |

## restartterm(3CURSES)

of `tparm()` should be printed with `tputs()` or `putp()`. Call the `reset_shell_mode()` routine to restore the tty modes before exiting (see `curs_kernel(3CURSES)`). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call `reset_shell_mode` and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call `reset_prog_mode` after returning from the shell.

The `setupterm()` routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fildef* which is initialized for output. If *errret* is not null, then `setupterm()` returns OK or ERR and stores a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo* database could not be found. If *errret* is null, `setupterm()` prints an error message upon finding an error and exits. Thus, the simplest call is:

`setupterm((char *)0, 1, (int *)0);` which uses all the defaults and sends the output to `stdout`.

The `setterm()` routine is being replaced by `setupterm()`. The call:

`setupterm(term, 1, (int *)0)` provides the same functionality as `setterm(term)`. The `setterm()` routine is included here for compatibility and is supported at Level 2.

The `set_curterm()` routine sets the variable `cur_term` to *nterm*, and makes all of the *terminfo* boolean, numeric, and string variables use the values from *nterm*.

The `del_curterm()` routine frees the space pointed to by *oterm* and makes it available for further use. If *oterm* is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another `setupterm()` has been called.

The `restartterm()` routine is similar to `setupterm()` and `initscr()`, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The `tparm()` routine instantiates the string *str* with parameters *pi*. A pointer is returned to the result of *str* with the parameters applied.

The `tputs()` routine applies padding information to the string *str* and outputs it. The *str* must be a *terminfo* string variable or the return value from `tparm()`, `tgetstr()`, or `tgoto()`. *affcnt* is the number of lines affected, or 1 if not applicable. *putc* is a `putchar()`-like routine to which the characters are passed, one at a time.

restartterm(3CURSES)

The `putp()` routine calls `tputs(str, 1, putchar)`. Note that the output of `putpA()` always goes to `stdout`, not to the *fil*des specified in `setupterm()`.

The `vidputs()` routine displays the string on the terminal in the video attribute mode *attrs*, which is any combination of the attributes listed in `curses(3CURSES)`. The characters are passed to the `putchar()`-like routine `putc()`.

The `vidattr()` routine is like the `vidputs()` routine, except that it outputs through `putchar()`.

The `mvcur()` routine provides low-level cursor motion.

The `tigetflag()`, `tigetnum()` and `tigetstr()` routines return the value of the capability corresponding to the *terminfo capname* passed to them, such as `xenl`.

With the `tigetflag()` routine, the value `-1` is returned if *capname* is not a boolean capability.

With the `tigetnum()` routine, the value `-2` is returned if *capname* is not a numeric capability.

With the `tigetstr()` routine, the value `(char *)-1` is returned if *capname* is not a string capability.

The *capname* for each capability is given in the table column entitled *capname* code in the capabilities section of `terminfo(4)`.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

## RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

## SEE ALSO

`curs_initscr(3CURSES)`, `curs_kernel(3CURSES)`, `curs_termcap(3CURSES)`, `curses(3CURSES)`, `putc(3C)`, `terminfo(4)`, `attributes(5)`

restartterm(3CURSES)

**NOTES** | The header `< curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

The `setupterm()` routine should be used in place of `setterm()`.

Note that `vidattr()` and `vidputs()` may be macros.

| NAME        | del_curterm, restartterm, set_curterm, setupterm – interfaces to the terminfo database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |       |             |   |        |   |                             |    |                                      |

| DESCRIPTION | <p>Within X/Open Curses, the setupterm() function is automatically called by the initscr (3XC) and newterm (3XC) functions. This function can be also be used outside of X/Open Curses when a program has to deal directly with the terminfo database to handle certain terminal capabilities. The use of appropriate X/Open Curses functions is recommended in all other situations.</p> <p>The setupterm() function loads terminal-dependent variables for the terminfo layer of X/Open Curses. The setupterm() function initializes the terminfo variables lines and columns such that if use_env (FALSE) has been called, the terminfo values assigned in the database are used regardless of the environmental variables LINES and COLUMNS or the program's window dimensions; when use_env (TRUE) has been called, which is the default, the environment variables LINES and COLUMNS are used, if they exist. If the environment variables do not exist and the program is running in a window, the current window size is used.</p> <p>The term parameter of setupterm() specifies the terminal; if null, terminal type is taken from the TERM environment variable. All output is sent to fildes which is initialized for output. If errret is not null, OK or ERR is returned and a status value is stored in the integer pointed to by errret. The following status values may be returned:</p> <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>1</td><td>Normal</td></tr> <tr> <td>0</td><td>Terminal could not be found</td></tr> <tr> <td>-1</td><td>terminfo database could not be found</td></tr> </tbody> </table> <p>If errret is null, an error message is printed, and the setupterm() function calls the exit() function with a non-zero parameter.</p> | Value | Description | 1 | Normal | 0 | Terminal could not be found | -1 | terminfo database could not be found |
| Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |       |             |   |        |   |                             |    |                                      |
| 1           | Normal                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |       |             |   |        |   |                             |    |                                      |

restartterm(3XCURSES)

The `set_curterm()` function sets the `cur_term` variable to *nterm*. The values from *nterm* as well as other state information for the terminal are used by X/Open Curses functions such as `beep(3XCURSES)`, `flash(3XCURSES)`, `mvcur(3XCURSES)`, `tigetflag(3XCURSES)`, `tigetstr(3XCURSES)`, and `tigetnum(3XCURSES)`.

The `del_curterm()` function frees the space pointed to by *oterm*. If *oterm* and the `cur_term` variable are the same, all Boolean, numeric, or string terminfo variables will refer to invalid memory locations until you call `setupterm()` and specify a new terminal type.

The `restartterm()` function assumes that a call to `setupterm()` has already been made (probably from `initscr()` or `newterm()`). It allows you to specify a new terminal type in *term* and updates the data returned by `baudrate(3XCURSES)` based on *fildes*. Other information created by the `initscr()`, `newterm()`, and `setupterm()` functions is preserved.

#### PARAMETERS

|               |                                                                 |
|---------------|-----------------------------------------------------------------|
| <i>oterm</i>  | Is the terminal type for which to free space.                   |
| <i>term</i>   | Is the terminal type for which variables are set.               |
| <i>fildes</i> | Is a file descriptor initialized for output.                    |
| <i>errret</i> | Is a pointer to an integer in which the status value is stored. |
| <i>nterm</i>  | Is the new terminal to become the current terminal.             |

#### RETURN VALUES

On success, the `set_curterm()` function returns the previous value of `cur_term`. Otherwise, it returns a null pointer.

On success, the other functions return OK. Otherwise, they return ERR.

#### ERRORS

None.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |

| DESCRIPTION | <p> The following routines give low-level access to various curses functionality. Theses routines typically are used inside library routines. </p> <p> The <b>def_prog_mode()</b> and <b>def_shell_mode()</b> routines save the current terminal modes as the “program” (in curses) or “shell” (not in curses) state for use by the <b>reset_prog_mode()</b> and <b>reset_shell_mode()</b> routines. This is done automatically by <b>initscr()</b>. </p> <p> The <b>reset_prog_mode()</b> and <b>reset_shell_mode()</b> routines restore the terminal to “program” (in curses) or “shell” (out of curses) state. These are done automatically by <b>endwin()</b> and, after an <b>endwin()</b>, by <b>doupdate()</b>, so they normally are not called. </p> <p> The <b>resetty()</b> and <b>savetty()</b> routines save and restore the state of the terminal modes. <b>savetty()</b> saves the current state in a buffer and <b>resetty()</b> restores the state to what it was at the last call to <b>savetty()</b>. </p> <p> With the <b>getsyx()</b> routine, the current coordinates of the virtual screen cursor are returned in <i>y</i> and <i>x</i>. If <b>leaveok()</b> is currently TRUE, then -1,-1 is returned. If lines have been removed from the top of the screen, using <b>ripoffline()</b>, <i>y</i> and <i>x</i> include these lines; therefore, <i>y</i> and <i>x</i> should be used only as arguments for <b>setsyx()</b>. </p> <p> With the <b>setsyx()</b> routine, the virtual screen cursor is set to <i>y</i>, <i>x</i>. If <i>y</i> and <i>x</i> are both -1, then <b>leaveok()</b> is set. The two routines <b>getsyx()</b> and <b>setsyx()</b> are designed to be used by a library routine, which manipulates curses windows but does not </p> |

## riposffline(3CURSES)

want to change the current position of the program's cursor. The library routine would call `getsyx()` at the beginning, do its manipulation of its own windows, do a `wnoutrefresh()` on its windows, call `setsyx()`, and then call `doupdate()`.

The `riposffline()` routine provides access to the same facility that `slk_init()` (see `curs_slk(3CURSES)`) uses to reduce the size of the screen. `riposffline()` must be called before `initscr()` or `newterm()` is called. If `line` is positive, a line is removed from the top of `stdscr()`; if `line` is negative, a line is removed from the bottom. When this is done inside `initscr()`, the routine `init()` (supplied by the user) is called with two arguments: a window pointer to the one-line window that has been allocated and an integer with the number of columns in the window. Inside this initialization routine, the integer variables `LINES` and `COLS` (defined in `<curses.h>`) are not guaranteed to be accurate and `wrefresh()` or `doupdate()` must not be called. It is allowable to call `wnoutrefresh()` during the initialization routine.

`riposffline()` can be called up to five times before calling `initscr()` or `newterm()`.

With the `curs_set()` routine, the cursor state is set to invisible, normal, or very visible for *visibility* equal to 0, 1, or 2 respectively. If the terminal supports the *visibility* requested, the previous *cursor* state is returned; otherwise, `ERR` is returned.

The `napms()` routine is used to sleep for *ms* milliseconds.

### RETURN VALUES

Except for `curs_set()`, these routines always return `OK`. `curs_set()` returns the previous cursor state, or `ERR` if the requested *visibility* is not supported.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

### SEE ALSO

`curs_initscr(3CURSES)`, `curs_outopts(3CURSES)`, `curs_refresh(3CURSES)`, `curs_scr_dump(3CURSES)`, `curs_slk(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `getsyx()` is a macro, so an ampersand (&) is not necessary before the variables *y* and *x*.

| NAME                | ripoffline – reserve screen line for dedicated purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                     |  |                |                 |                     |          |          |        |

| DESCRIPTION         | <p>The ripoffline() function reserves a screen line as a one line window.</p> <p>To use this function, it must be called before you call initscr(3XCURSES) or newterm(3XCURSES). When initscr() or newterm() is called, so is the function pointed to by init. The function pointed to by init takes two arguments: a pointer to the one-line window and the number of columns in that window. This function cannot use the LINES or COLS variables and cannot call wrefresh(3XCURSES) or doupdate(3XCURSES), but may call wnoutrefresh(3XCURSES).</p> |                                                                                                                                     |  |                |                 |                     |          |          |        |
| RETURN VALUES       | The rioffline() function always returns OK.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                     |  |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The following routines give low-level access to various curses functionality. Theses routines typically are used inside library routines.</p> <p>The <code>def_prog_mode()</code> and <code>def_shell_mode()</code> routines save the current terminal modes as the “program” (in curses) or “shell” (not in curses ) state for use by the <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines. This is done automatically by <code>initscr()</code>.</p> <p>The <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines restore the terminal to “program” (in curses) or “shell” (out of curses) state. These are done automatically by <code>endwin()</code> and, after an <code>endwin()</code>, by <code>doupdate()</code>, so they normally are not called.</p> <p>The <code>resetty()</code> and <code>savetty()</code> routines save and restore the state of the terminal modes. <code>savetty()</code> saves the current state in a buffer and <code>resetty()</code> restores the state to what it was at the last call to <code>savetty()</code>.</p> <p>With the <code>getsyx()</code> routine, the current coordinates of the virtual screen cursor are returned in <code>y</code> and <code>x</code>. If <code>leaveok()</code> is currently TRUE, then <code>-1,-1</code> is returned. If lines have been removed from the top of the screen, using <code>ripoffline()</code>, <code>y</code> and <code>x</code> include these lines; therefore, <code>y</code> and <code>x</code> should be used only as arguments for <code>setsyx()</code>.</p> <p>With the <code>setsyx()</code> routine, the virtual screen cursor is set to <code>y, x</code>. If <code>y</code> and <code>x</code> are both <code>-1</code>, then <code>leaveok()</code> is set. The two routines <code>getsyx()</code> and <code>setsyx()</code> are designed to be used by a library routine, which manipulates curses windows but does not</p> |

savetty(3CURSES)

want to change the current position of the program's cursor. The library routine would call getsyx() at the beginning, do its manipulation of its own windows, do a wnoutrefresh() on its windows, call setsyx(), and then call doupdate().

The ripoffline() routine provides access to the same facility that slk\_init() (see curs\_slk(3CURSES)) uses to reduce the size of the screen. ripoffline() must be called before initscr() or newterm() is called. If line is positive, a line is removed from the top of stdscr(); if line is negative, a line is removed from the bottom. When this is done inside initscr(), the routine init() (supplied by the user) is called with two arguments: a window pointer to the one-line window that has been allocated and an integer with the number of columns in the window. Inside this initialization routine, the integer variables LINES and COLS (defined in <curses.h>) are not guaranteed to be accurate and wrefresh() or doupdate() must not be called. It is allowable to call wnoutrefresh() during the initialization routine.

ripoffline() can be called up to five times before calling initscr() or newterm().

With the curs\_set() routine, the cursor state is set to invisible, normal, or very visible for *visibility* equal to 0, 1, or 2 respectively. If the terminal supports the *visibility* requested, the previous *cursor* state is returned; otherwise, ERR is returned.

The napms() routine is used to sleep for *ms* milliseconds.

#### RETURN VALUES

Except for curs\_set(), these routines always return OK. curs\_set() returns the previous cursor state, or ERR if the requested *visibility* is not supported.

#### ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

#### SEE ALSO

curs\_initscr(3CURSES), curs\_outopts(3CURSES), curs\_refresh(3CURSES), curs\_scr\_dump(3CURSES), curs\_slk(3CURSES), curses(3CURSES), attributes(5)

#### NOTES

The header <curses.h> automatically includes the headers <stdio.h> and <unctrl.h>.

Note that getsyx() is a macro, so an ampersand (&) is not necessary before the variables *y* and *x*.

## savetty(3XCURSES)

| NAME                | resetty, savetty – restore/save terminal modes                                                                                                                                                                                                                      |                |                 |                     |          |          |        |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| SYNOPSIS            | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int resetty(void);  int savetty(void);</pre>                              |                |                 |                     |          |          |        |
| DESCRIPTION         | The savetty() and resetty() functions save and restore the terminal state, respectively. The savetty() function saves the current state in a buffer; the resetty() function restores the state to that stored in the buffer at the time of the last savetty() call. |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
| ATTRIBUTES          | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                     |                |                 |                     |          |          |        |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -lform -lcurses [ library... ] #include &lt;form.h&gt;  int set_form_win(FORM *form, WINDOW *win); WINDOW *form_win(FORM *form); int set_form_sub(FORM *form, WINDOW *sub); WINDOW *form_sub(FORM *form); int scale_form(FORM *form, int *rows, int *cols);</pre>                                                                                                                                                                                                          |                |                                     |                |               |                |                           |                 |                                       |          |                     |
| <b>DESCRIPTION</b>   | <p>set_form_win() sets the window of <i>form</i> to <i>win</i>. form_win() returns a pointer to the window associated with <i>form</i>. set_form_sub() sets the subwindow of <i>form</i> to <i>sub</i>. form_sub() returns a pointer to the subwindow associated with <i>form</i>. scale_form() returns the smallest window size necessary for the subwindow of <i>form</i>. <i>rows</i> and <i>cols</i> are pointers to the locations used to return the number of rows and columns for the form.</p> |                |                                     |                |               |                |                           |                 |                                       |          |                     |
| <b>RETURN VALUES</b> | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr> <tr> <td>E_NOT_CONNECTED</td><td>The field is not connected to a form.</td></tr> <tr> <td>E_POSTED</td><td>The form is posted.</td></tr> </table>               | E_OK           | The function returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An argument is incorrect. | E_NOT_CONNECTED | The field is not connected to a form. | E_POSTED | The form is posted. |
| E_OK                 | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                                     |                |               |                |                           |                 |                                       |          |                     |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -lmenu -lcurses [ library... ] #include &lt;menu.h&gt;  int set_menu_win(MENU *menu, WINDOW *win); WINDOW *menu_win(MENU *menu); int set_menu_sub(MENU *menu, WINDOW *sub); WINDOW *menu_sub(MENU *menu); int scale_window(MENU *menu, int *rows, int *cols);</pre>                                                                                                                                                                                                                      |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| <b>DESCRIPTION</b>   | <p>set_menu_win() sets the window of <i>menu</i> to <i>win</i>. menu_win() returns a pointer to the window of <i>menu</i>. set_menu_sub() sets the subwindow of <i>menu</i> to <i>sub</i>. menu_sub() returns a pointer to the subwindow of <i>menu</i>. scale_window() returns the minimum window size necessary for the subwindow of <i>menu</i>. <i>rows</i> and <i>cols</i> are pointers to the locations used to return the values.</p>                                                                         |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| <b>RETURN VALUES</b> | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table> <tr> <td>E_OK</td><td>The routine returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An incorrect argument was passed to the routine.</td></tr> <tr> <td>E_POSTED</td><td>The menu is already posted.</td></tr> <tr> <td>E_NOT_CONNECTED</td><td>No items are connected to the menu.</td></tr> </table> | E_OK           | The routine returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An incorrect argument was passed to the routine. | E_POSTED | The menu is already posted. | E_NOT_CONNECTED | No items are connected to the menu. |
| E_OK                 | The routine returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| E_SYSTEM_ERROR       | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| E_BAD_ARGUMENT       | An incorrect argument was passed to the routine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |

| NAME           | curs_scanw, scanw, wscanw, mvscanw, mvwscanw, vwscanw – convert formatted input from a curses widow                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int scanw(char *fmt, /* arg */ ...); int wscanw(WINDOW *win, char *fmt, /* arg */ ...); int mvscanw(int y, int x, char *fmt, /* arg */ ...); int mvwscanw(WINDOW *win, int y, int x, char *fmt, /* arg */...); int vwscanw(WINDOW *win, char *fmt, va_list varlist);</pre>                                                                                                                                                            |                |                 |          |        |
| DESCRIPTION    | <p>The scanw(), wscanw(), and mvscanw() routines correspond to scanf() (see scanf(3C)). The effect of these routines is as though wgetstr() were called on the window, and the resulting line used as input for the scan. Fields which do not map to a variable in the fmt field are lost.</p> <p>The vwscanw() routine is similar to vwprintw() in that it performs a wscanw() using a variable argument list. The third argument is a va_list, a pointer to a list of arguments, as defined in &lt;varargs.h&gt;.</p> |                |                 |          |        |
| RETURN VALUES  | <p>vwscanw() returns ERR on failure and an integer equal to the number of fields scanned on success.</p> <p>Applications may interrogate the return value from the scanw, wscanw(), mvscanw(), and mvwscanw() routines to determine the number of fields which were mapped in the call.</p>                                                                                                                                                                                                                             |                |                 |          |        |

| NOTES          | The header <curses.h> automatically includes the headers <stdio.h> and <unctrl.h>.                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |          |        |

## scanw(3XCURSES)

| <b>NAME</b>          | mvscanw, mvwscanw, scanw, wscanw – convert formatted input from a window                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int mvscanw(int y, int x, char *fmt, ...); int mvwscanw(WINDOW *win, int y, int x, char *fmt, ...); int scanw(char *fmt, ...); int wscanw(WINDOW *win, char *fmt, ...);</pre> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>y</i> Is the y (row) coordinate of the position of the character to be read.</p> <p><i>x</i> Is the x (column) coordinate of the position of the character to be read.</p> <p><i>fmt</i> Is a scanf ( ) format string.</p> <p><i>win</i> Is a pointer to the window in which the character is to be read.</p>                                                     |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | These functions are similar to scanf(3C). Their effect is as though mvwgetstr(3XCURSES) were called to get a multi-byte character string from the current or specified window at the current or specified cursor position, and then sscanf ( ) were used to interpret and convert that string.                                                                          |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>   | <p>With the <code>scr_dump()</code> routine, the current contents of the virtual screen are written to the file <i>filename</i>.</p> <p>With the <code>scr_restore()</code> routine, the virtual screen is set to the contents of <i>filename</i>, which must have been written using <code>scr_dump()</code>. The next call to <code>doupdate()</code> restores the screen to the way it looked in the dump file.</p> <p>With the <code>scr_init()</code> routine, the contents of <i>filename</i> are read in and used to initialize the curses data structures about what the terminal currently has on its screen. If the data is determined to be valid, curses bases its next update of the screen on this information rather than clearing the screen and starting from scratch. <code>scr_init()</code> is used after <code>initscr()</code> or a <code>system(3C)</code> call to share the screen with another process which has done a <code>scr_dump()</code> after its <code>endwin()</code> call. The data is declared invalid if the time-stamp of the tty is old or the terminfo capabilities <code>rmcup()</code> and <code>nrrmc()</code> exist.</p> <p>The <code>scr_set()</code> routine is a combination of <code>scr_restore()</code> and <code>scr_init()</code>. It tells the program that the information in <i>filename</i> is what is currently on the screen, and also what the program wants on the screen. This can be thought of as a screen inheritance function.</p> <p>To read (write) a window from (to) a file, use the <code>getwin()</code> and <code>putwin()</code> routines (see <code>curs_util(3CURSES)</code>).</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer ERR upon failure and OK upon success.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>scr_dump</b>(const char *filename); int <b>scr_init</b>(const char *filename); int <b>scr_restore</b>(const char *filename); int <b>scr_set</b>(const char *filename);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <i>filename</i> Is a pointer to the file in which screen contents are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>These function perform input/output functions on a screen basis.</p> <p>The <code>scr_dump()</code> function writes the contents of the virtual screen, <code>curscr</code>, to <i>filename</i>.</p> <p>The <code>scr_restore()</code> function reads the contents of <i>filename</i> from <code>curscr</code> (which must have been written with <code>scr_dump()</code>). The next refresh operation restores the screen to the way it looks in <i>filename</i>.</p> <p>The <code>scr_init()</code> function reads the contents of <i>filename</i> and uses those contents to initialize the X/Open Curses data structures to what is actually on screen. The next refresh operation bases its updates on this data, unless the terminal has been written to since <i>filename</i> was saved or the terminfo capabilities <code>rmcup</code> and <code>nrrmc</code> are defined for the current terminal.</p> <p>The <code>scr_set()</code> function combines <code>scr_restore()</code> and <code>scr_init()</code>. It informs the program that the contents of the file <i>filename</i> are what is currently on the screen and that the program wants those contents on the screen.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |

## scr\_init(3CURSES)

| NAME           | curs_scr_dump, scr_dump, scr_restore, scr_init, scr_set – read (write) a curses screen from (to) a file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |

| DESCRIPTION    | <p>With the <code>scr_dump()</code> routine, the current contents of the virtual screen are written to the file <i>filename</i>.</p> <p>With the <code>scr_restore()</code> routine, the virtual screen is set to the contents of <i>filename</i>, which must have been written using <code>scr_dump()</code>. The next call to <code>doupdate()</code> restores the screen to the way it looked in the dump file.</p> <p>With the <code>scr_init()</code> routine, the contents of <i>filename</i> are read in and used to initialize the curses data structures about what the terminal currently has on its screen. If the data is determined to be valid, curses bases its next update of the screen on this information rather than clearing the screen and starting from scratch. <code>scr_init()</code> is used after <code>initscr()</code> or a <code>system(3C)</code> call to share the screen with another process which has done a <code>scr_dump()</code> after its <code>endwin()</code> call. The data is declared invalid if the time-stamp of the tty is old or the terminfo capabilities <code>rmcup()</code> and <code>nrrmc()</code> exist.</p> <p>The <code>scr_set()</code> routine is a combination of <code>scr_restore()</code> and <code>scr_init()</code>. It tells the program that the information in <i>filename</i> is what is currently on the screen, and also what the program wants on the screen. This can be thought of as a screen inheritance function.</p> <p>To read (write) a window from (to) a file, use the <code>getwin()</code> and <code>putwin()</code> routines (see <code>curs_util(3CURSES)</code>).</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and OK upon success.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |

Note that `scr_init()`, `scr_set()`, and `scr_restore()` may be macros.

## scr\_init(3XCURSES)

| NAME                | scr_dump, scr_init, scr_restore, scr_set – write screen contents to/from a file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |

| PARAMETERS          | <i>filename</i> Is a pointer to the file in which screen contents are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |                     |          |          |        |
| DESCRIPTION         | <p>These function perform input/output functions on a screen basis.</p> <p>The <code>scr_dump()</code> function writes the contents of the virtual screen, <code>curscr</code>, to <i>filename</i>.</p> <p>The <code>scr_restore()</code> function reads the contents of <i>filename</i> from <code>curscr</code> (which must have been written with <code>scr_dump()</code>). The next refresh operation restores the screen to the way it looks in <i>filename</i>.</p> <p>The <code>scr_init()</code> function reads the contents of <i>filename</i> and uses those contents to initialize the X/Open Curses data structures to what is actually on screen. The next refresh operation bases its updates on this data, unless the terminal has been written to since <i>filename</i> was saved or the terminfo capabilities <code>rmcup</code> and <code>nrrmc</code> are defined for the current terminal.</p> <p>The <code>scr_set()</code> function combines <code>scr_restore()</code> and <code>scr_init()</code>. It informs the program that the contents of the file <i>filename</i> are what is currently on the screen and that the program wants those contents on the screen.</p> |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |

| DESCRIPTION    | <p>With the <code>scroll()</code> routine, the window is scrolled up one line. This involves moving the lines in the window data structure. As an optimization, if the scrolling region of the window is the entire screen, the physical screen is scrolled at the same time.</p> <p>With the <code>scr1()</code> and <code>wscr1()</code> routines, for positive <i>n</i> scroll the window up <i>n</i> lines (line <i>i+n</i> becomes <i>i</i>); otherwise scroll the window down <i>n</i> lines. This involves moving the lines in the window character image structure. The current cursor position is not changed.</p> <p>For these functions to work, scrolling must be enabled via <code>scrollok()</code>.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |          |        |

| <b>PARAMETERS</b>    | <p><i>n</i> number and direction of lines to scroll</p> <p><i>win</i> pointer to the window in which to scroll</p>                                                                                                                                                                                                                                                                                                                                           |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>scroll()</code> function scrolls the window <i>win</i> up one line. The current cursor position is not changed.</p> <p>The <code>srl()</code> and <code>wscr()</code> functions scroll the window <code>stdscr</code> or <i>win</i> up or down <i>n</i> lines, where <i>n</i> is a positive (scroll up) or negative (scroll down) integer.</p> <p>The <code>scrollok(3XCURSES)</code> function must be enabled for these functions to work.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>scroll</b>(WINDOW *win); int <b>scl</b>(int n); int <b>wscrl</b>(WINDOW *win, int n);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>With the <code>scroll()</code> routine, the window is scrolled up one line. This involves moving the lines in the window data structure. As an optimization, if the scrolling region of the window is the entire screen, the physical screen is scrolled at the same time.</p> <p>With the <code>scl()</code> and <code>wscrl()</code> routines, for positive <math>n</math> scroll the window up <math>n</math> lines (line <math>i+n</math> becomes <math>i</math>); otherwise scroll the window down <math>n</math> lines. This involves moving the lines in the window character image structure. The current cursor position is not changed.</p> <p>For these functions to work, scrolling must be enabled via <code>scrollok()</code>.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |

| PARAMETERS          | <p><i>n</i> number and direction of lines to scroll</p> <p><i>win</i> pointer to the window in which to scroll</p>                                                                                                                                                                                                                                                                                                                                           |                |                 |                     |          |          |        |
| DESCRIPTION         | <p>The <code>scroll()</code> function scrolls the window <i>win</i> up one line. The current cursor position is not changed.</p> <p>The <code>srl()</code> and <code>wscr()</code> functions scroll the window <code>stdscr</code> or <i>win</i> up or down <i>n</i> lines, where <i>n</i> is a positive (scroll up) or negative (scroll down) integer.</p> <p>The <code>scrollok(3XCURSES)</code> function must be enabled for these functions to work.</p> |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |

| NAME        | curs_outopts, clearok, idlok, idcok, immedok, leaveok, setscreg, wsetscreg, scrolllok, nl, nonl – curses terminal output option control routines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| SYNOPSIS    | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int clearok(WINDOW *win, bool bf); int idlok(WINDOW *win, bool bf); void idcok(WINDOW *win, bool bf); void immedok(WINDOW *win, bool bf); int leaveok(WINDOW *win, bool bf); int setscreg(int top, int bot); int wsetscreg(WINDOW *win, int top, int bot); int scrolllok(WINDOW *win, bool bf); int nl(void); int nonl(void);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| DESCRIPTION | <p>These routines set options that deal with output within curses. All options are initially FALSE, unless otherwise stated. It is not necessary to turn these options off before calling <code>endwin()</code>.</p> <p>With the <code>clearok()</code> routine, if enabled (<i>bf</i> is TRUE), the next call to <code>wrefresh()</code> with this window will clear the screen completely and redraw the entire screen from scratch. This is useful when the contents of the screen are uncertain, or in some cases for a more pleasing visual effect. If the <i>win</i> argument to <code>clearok()</code> is the global variable <code>curscr()</code>, the next call to <code>wrefresh()</code> with any window causes the screen to be cleared and repainted from scratch.</p> <p>With the <code>idlok()</code> routine, if enabled (<i>bf</i> is TRUE), curses considers using the hardware insert/delete line feature of terminals so equipped. If disabled (<i>bf</i> is FALSE), curses very seldom uses this feature. (The insert/delete character feature is always considered.) This option should be enabled only if the application needs insert/delete line, for example, for a screen editor. It is disabled by default because insert/delete line tends to be visually annoying when used in applications where it isn't really needed. If insert/delete line cannot be used, curses redraws the changed portions of all lines.</p> <p>With the <code>idcok()</code> routine, if enabled (<i>bf</i> is TRUE), curses considers using the hardware insert/delete character feature of terminals so equipped. This is enabled by default.</p> <p>With the <code>immedok()</code> routine, if enabled (<i>bf</i> is TRUE), any change in the window image, such as the ones caused by <code>waddch()</code>, <code>wclrtoeol()</code>, <code>wscrl()</code>, etc., automatically cause a call to <code>wrefresh()</code>. However, it may degrade the performance considerably, due to repeated calls to <code>wrefresh()</code>. It is disabled by default.</p> |

## scrollok(3CURSES)

Normally, the hardware cursor is left at the location of the window cursor being refreshed. The `leaveok()` option allows the cursor to be left wherever the update happens to leave it. It is useful for applications where the cursor is not used, since it reduces the need for cursor motions. If possible, the cursor is made invisible when this option is enabled.

The `setscrreg()` and `wsetscrreg()` routines allow the application programmer to set a software scrolling region in a window. *top* and *bot* are the line numbers of the top and bottom margin of the scrolling region. (Line 0 is the top line of the window.) If this option and `scrollok()` are enabled, an attempt to move off the bottom margin line causes all lines in the scrolling region to scroll up one line. Only the text of the window is scrolled. (Note that this has nothing to do with the use of a physical scrolling region capability in the terminal, like that in the VT100. If `idlok()` is enabled and the terminal has either a scrolling region or insert/delete line capability, they will probably be used by the output routines.)

The `scrollok()` option controls what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If disabled, (*bf* is FALSE), the cursor is left on the bottom line. If enabled, (*bf* is TRUE), `wrefresh()` is called on the window, and the physical terminal and window are scrolled up one line. (Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call `idlok()`.)

The `nl()` and `nonl()` routines control whether newline is translated into carriage return and linefeed on output, and whether return is translated into newline on input. Initially, the translations do occur. By disabling these translations using `nonl()`, `curses` is able to make better use of the linefeed capability, resulting in faster cursor motion.

**RETURN VALUES** `setscrreg()` and `wsetscrreg()` return OK upon success and ERR upon failure. All other routines that return an integer always return OK.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_addch(3CURSES)`, `curs_clear(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curs_scroll(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `clearok()`, `leaveok()`, `scrollok()`, `idcok()`, `nl()`, `nonl()`, and `setscrreg()` may be macros.

`scrollok(3CURSES)`

The `immedok()` routine is useful for windows that are used as terminal emulators.

## scrollok(3XCURSES)

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| DESCRIPTION | <p>These functions set options that deal with the output within Curses functions.</p> <p>The <code>clearok()</code> function assigns the value of <i>bf</i> to an internal flag in the specified window that governs clearing of the screen during a refresh. If, during a refresh operation on the specified window, the flag in <i>curscr</i> is TRUE or the flag in the specified window is TRUE, <code>clearok()</code> clears the screen, redraws it in its entirety, and sets the flag to FALSE in <i>curscr</i> and in the specified window. The initial state is unspecified</p> <p>The <code>idlok()</code> function specifies whether the implementation may use the hardware insert-line, delete-line, and scroll features of terminals so equipped. If <i>bf</i> is TRUE, use of these features is enabled. If <i>bf</i> is FALSE, use of these features is disabled and lines are instead redrawn as required. The initial state is FALSE.</p> <p>The <code>leaveok()</code> function controls the cursor position after a refresh operation. If <i>bf</i> is TRUE, refresh operations on the specified window may leave the terminal's cursor at an arbitrary position. If <i>bf</i> is FALSE, then at the end of any refresh operation, the terminal's cursor is positioned at the cursor position contained in the specified window. The initial state is FALSE.</p> <p>The <code>scrollok()</code> function controls the use of scrolling. If <i>bf</i> is TRUE, then scrolling is enabled for the specified window. If <i>bf</i> is FALSE, scrolling is disabled for the specified window. The initial state is FALSE.</p> <p>The <code>setscreg()</code> and <code>wsetscreg()</code> functions define a software scrolling region in the current or specified window. The <i>top</i> and <i>bottom</i> arguments are the line numbers of the first and last line defining the scrolling region. (Line 0 is the top line of the window.) If this option and <code>scrollok()</code> are enabled, an attempt to move off the last line of the margin causes all lines in the scrolling region to scroll one line in the</p> |

scrolllok(3XCURSES)

direction of the first line. Only characters in the window are scrolled. If a software scrolling region is set and `scrolllok()` is not enabled, an attempt to move off the last line of the margin does not reposition any lines in the scrolling region.

**PARAMETERS**

*win* Is a pointer to a window.  
*bf* Is a Boolean expression.  
*top* Is the top line of the scrolling region (top of the window is line 0).  
*bot* Is the bottom line of the scrolling region (top of the window is line 0).

**RETURN VALUES**

Upon successful completion, the `setscrreg()` and `wsetscrreg()` functions return OK. Otherwise, they return ERR.

The other functions always return OK.

**ERRORS**

No errors are defined.

**USAGE**

The only reason to enable the `idlok()` feature is to use scrolling to achieve the visual effect of motion of a partial window, such as for a screen editor. In other cases, the feature can be visually annoying.

The `leaveok()` option provides greater efficiency for applications that do not use the cursor.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

## scr\_restore(3CURSES)

| NAME           | scr_dump, scr_restore, scr_init, scr_set – read (write) a curses screen from (to) a file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |          |        |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int scr_dump(char *filename); int scr_restore(char *filename); int scr_init(char *filename); int scr_set(char *filename);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |          |        |
| DESCRIPTION    | <p>With the <code>scr_dump()</code> routine, the current contents of the virtual screen are written to the file <i>filename</i>.</p> <p>With the <code>scr_restore()</code> routine, the virtual screen is set to the contents of <i>filename</i>, which must have been written using <code>scr_dump()</code>. The next call to <code>doupdate()</code> restores the screen to the way it looked in the dump file.</p> <p>With the <code>scr_init()</code> routine, the contents of <i>filename</i> are read in and used to initialize the curses data structures about what the terminal currently has on its screen. If the data is determined to be valid, curses bases its next update of the screen on this information rather than clearing the screen and starting from scratch. <code>scr_init()</code> is used after <code>initscr()</code> or a <code>system(3C)</code> call to share the screen with another process which has done a <code>scr_dump()</code> after its <code>endwin()</code> call. The data is declared invalid if the time-stamp of the tty is old or the terminfo capabilities <code>rmcup()</code> and <code>nrrmc()</code> exist.</p> <p>The <code>scr_set()</code> routine is a combination of <code>scr_restore()</code> and <code>scr_init()</code>. It tells the program that the information in <i>filename</i> is what is currently on the screen, and also what the program wants on the screen. This can be thought of as a screen inheritance function.</p> <p>To read (write) a window from (to) a file, use the <code>getwin()</code> and <code>putwin()</code> routines (see <code>curs_util(3CURSES)</code>).</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and OK upon success.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |
| ATTRIBUTES     | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |

| SYNOPSIS            | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int scr_dump(const char *filename); int scr_init(const char *filename); int scr_restore(const char *filename); int scr_set(const char *filename);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| PARAMETERS          | <i>filename</i> Is a pointer to the file in which screen contents are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |                     |          |          |        |
| DESCRIPTION         | <p>These function perform input/output functions on a screen basis.</p> <p>The <code>scr_dump()</code> function writes the contents of the virtual screen, <code>curscr</code>, to <i>filename</i>.</p> <p>The <code>scr_restore()</code> function reads the contents of <i>filename</i> from <code>curscr</code> (which must have been written with <code>scr_dump()</code>). The next refresh operation restores the screen to the way it looks in <i>filename</i>.</p> <p>The <code>scr_init()</code> function reads the contents of <i>filename</i> and uses those contents to initialize the X/Open Curses data structures to what is actually on screen. The next refresh operation bases its updates on this data, unless the terminal has been written to since <i>filename</i> was saved or the terminfo capabilities <code>rmcup</code> and <code>nrrmc</code> are defined for the current terminal.</p> <p>The <code>scr_set()</code> function combines <code>scr_restore()</code> and <code>scr_init()</code>. It informs the program that the contents of the file <i>filename</i> are what is currently on the screen and that the program wants those contents on the screen.</p> |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>   | <p>With the <code>scr_dump()</code> routine, the current contents of the virtual screen are written to the file <i>filename</i>.</p> <p>With the <code>scr_restore()</code> routine, the virtual screen is set to the contents of <i>filename</i>, which must have been written using <code>scr_dump()</code>. The next call to <code>doupdate()</code> restores the screen to the way it looked in the dump file.</p> <p>With the <code>scr_init()</code> routine, the contents of <i>filename</i> are read in and used to initialize the curses data structures about what the terminal currently has on its screen. If the data is determined to be valid, curses bases its next update of the screen on this information rather than clearing the screen and starting from scratch. <code>scr_init()</code> is used after <code>initscr()</code> or a <code>system(3C)</code> call to share the screen with another process which has done a <code>scr_dump()</code> after its <code>endwin()</code> call. The data is declared invalid if the time-stamp of the tty is old or the terminfo capabilities <code>rmcup()</code> and <code>nrrmc()</code> exist.</p> <p>The <code>scr_set()</code> routine is a combination of <code>scr_restore()</code> and <code>scr_init()</code>. It tells the program that the information in <i>filename</i> is what is currently on the screen, and also what the program wants on the screen. This can be thought of as a screen inheritance function.</p> <p>To read (write) a window from (to) a file, use the <code>getwin()</code> and <code>putwin()</code> routines (see <code>curs_util(3CURSES)</code>).</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer ERR upon failure and OK upon success.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |

`scr_set(3CURSES)`

Note that `scr_init()`, `scr_set()`, and `scr_restore()` may be macros.

| <b>NAME</b>          | scr_dump, scr_init, scr_restore, scr_set – write screen contents to/from a file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |

| <b>PARAMETERS</b>    | <i>filename</i> Is a pointer to the file in which screen contents are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>These function perform input/output functions on a screen basis.</p> <p>The <code>scr_dump()</code> function writes the contents of the virtual screen, <code>curscr</code>, to <i>filename</i>.</p> <p>The <code>scr_restore()</code> function reads the contents of <i>filename</i> from <code>curscr</code> (which must have been written with <code>scr_dump()</code>). The next refresh operation restores the screen to the way it looks in <i>filename</i>.</p> <p>The <code>scr_init()</code> function reads the contents of <i>filename</i> and uses those contents to initialize the X/Open Curses data structures to what is actually on screen. The next refresh operation bases its updates on this data, unless the terminal has been written to since <i>filename</i> was saved or the terminfo capabilities <code>rmcup</code> and <code>nrrmc</code> are defined for the current terminal.</p> <p>The <code>scr_set()</code> function combines <code>scr_restore()</code> and <code>scr_init()</code>. It informs the program that the contents of the file <i>filename</i> are what is currently on the screen and that the program wants those contents on the screen.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>setcchar</b>(cchar_t *wcval, const wchar_t *wch, const attr_t attrs,              short color_pair, const void *opts);</pre>                                                                                                                    |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>wcval</i> Is a pointer to a location where a cchar_t character (and its rendition) can be stored.</p> <p><i>wch</i> Is a pointer to a wide character.</p> <p><i>attrs</i> Is the set of attributes to apply to <i>wch</i> in creating <i>wcval</i>.</p> <p><i>color_pair</i> Is the color pair to apply to <i>wch</i> in creating <i>wcval</i>.</p> <p><i>opts</i> Is reserved for future use. Currently, this must be a null pointer.</p> |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | The setcchar() function takes the wide character pointed to by <i>wch</i> , combines it with the attributes indicated by <i>attrs</i> and the color pair indicated by <i>color_pair</i> and stores the result in the object pointed to by <i>wcval</i> .                                                                                                                                                                                         |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, the setcchar() function returns OK. Otherwise, it returns ERR.                                                                                                                                                                                                                                                                                                                                                                       |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |

| DESCRIPTION     | <p>The current item of a menu is the item where the cursor is currently positioned. <code>set_current_item()</code> sets the current item of <i>menu</i> to <i>item</i>. <code>current_item()</code> returns a pointer to the the current item in <i>menu</i>.</p> <p><code>set_top_row()</code> sets the top row of <i>menu</i> to <i>row</i>. The left-most item on the new top row becomes the current item. <code>top_row()</code> returns the number of the menu row currently displayed at the top of <i>menu</i>.</p> <p><code>item_index()</code> returns the index to the <i>item</i> in the item pointer array. The value of this index ranges from 0 through <i>N</i>-1, where <i>N</i> is the total number of items connected to the menu.</p> |                |                                    |                |               |                |                                                  |             |                                                                        |                 |                                     |
| RETURN VALUES   | <p><code>current_item()</code> returns NULL on error.</p> <p><code>top_row()</code> and <code>index_item()</code> return -1 on error.</p> <p><code>set_current_item()</code> and <code>set_top_row()</code> return one of the following:</p> <table><tr><td>E_OK</td><td>The routine returned successfully.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error.</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An incorrect argument was passed to the routine.</td></tr><tr><td>E_BAD_STATE</td><td>The routine was called from an initialization or termination function.</td></tr><tr><td>E_NOT_CONNECTED</td><td>No items are connected to the menu.</td></tr></table>                                                                                      | E_OK           | The routine returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An incorrect argument was passed to the routine. | E_BAD_STATE | The routine was called from an initialization or termination function. | E_NOT_CONNECTED | No items are connected to the menu. |
| E_OK            | The routine returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                                    |                |               |                |                                                  |             |                                                                        |                 |                                     |

| DESCRIPTION | <p>These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, curses routines are more suitable and their use is recommended.</p> <p>Initially, <code>setupterm()</code> should be called. Note that <code>setupterm()</code> is automatically called by <code>initscr()</code> and <code>newterm()</code>. This defines the set of terminal-dependent variables (listed in <code>terminfo(4)</code>). The <i>terminfo</i> variables <code>lines</code> and <code>columns</code> are initialized by <code>setupterm()</code> as follows: If <code>use_env(FALSE)</code> has been called, values for <code>lines</code> and <code>columns</code> specified in <i>terminfo</i> are used. Otherwise, if the environment variables <code>LINES</code> and <code>COLUMNS</code> exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database are used.</p> <p>The headers <code>&lt;curses.h&gt;</code> and <code>&lt;term.h&gt;</code> should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through <code>tparm()</code> to instantiate them. All <i>terminfo</i> strings (including the output</p> |

## set\_curterm(3CURSES)

of `tparm()` should be printed with `tputs()` or `putp()`. Call the `reset_shell_mode()` routine to restore the tty modes before exiting (see `curs_kernel(3CURSES)`). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call `reset_shell_mode` and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call `reset_prog_mode` after returning from the shell.

The `setupterm()` routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fildef* which is initialized for output. If *errret* is not null, then `setupterm()` returns OK or ERR and stores a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo* database could not be found. If *errret* is null, `setupterm()` prints an error message upon finding an error and exits. Thus, the simplest call is:

`setupterm((char *)0, 1, (int *)0);` which uses all the defaults and sends the output to `stdout`.

The `setterm()` routine is being replaced by `setupterm()`. The call:

`setupterm(term, 1, (int *)0)` provides the same functionality as `setterm(term)`. The `setterm()` routine is included here for compatibility and is supported at Level 2.

The `set_curterm()` routine sets the variable `cur_term` to *nterm*, and makes all of the *terminfo* boolean, numeric, and string variables use the values from *nterm*.

The `del_curterm()` routine frees the space pointed to by *oterm* and makes it available for further use. If *oterm* is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another `setupterm()` has been called.

The `restartterm()` routine is similar to `setupterm()` and `initscr()`, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The `tparm()` routine instantiates the string *str* with parameters *pi*. A pointer is returned to the result of *str* with the parameters applied.

The `tputs()` routine applies padding information to the string *str* and outputs it. The *str* must be a *terminfo* string variable or the return value from `tparm()`, `tgetstr()`, or `tgoto()`. *affcnt* is the number of lines affected, or 1 if not applicable. *putc* is a `putchar()`-like routine to which the characters are passed, one at a time.

set\_curterm(3CURSES)

The `putp()` routine calls `tputs(str, 1, putchar)`. Note that the output of `putpA()` always goes to `stdout`, not to the *fil*des specified in `setupterm()`.

The `vidputs()` routine displays the string on the terminal in the video attribute mode *attrs*, which is any combination of the attributes listed in `curses(3CURSES)`. The characters are passed to the `putchar()`-like routine `putc()`.

The `vidattr()` routine is like the `vidputs()` routine, except that it outputs through `putchar()`.

The `mvcur()` routine provides low-level cursor motion.

The `tigetflag()`, `tigetnum()` and `tigetstr()` routines return the value of the capability corresponding to the *terminfo capname* passed to them, such as `xenl`.

With the `tigetflag()` routine, the value `-1` is returned if *capname* is not a boolean capability.

With the `tigetnum()` routine, the value `-2` is returned if *capname* is not a numeric capability.

With the `tigetstr()` routine, the value `(char *)-1` is returned if *capname* is not a string capability.

The *capname* for each capability is given in the table column entitled *capname* code in the capabilities section of `terminfo(4)`.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

## RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

## SEE ALSO

`curs_initscr(3CURSES)`, `curs_kernel(3CURSES)`, `curs_termcap(3CURSES)`, `curses(3CURSES)`, `putc(3C)`, `terminfo(4)`, `attributes(5)`

set\_curterm(3CURSES)

**NOTES** | The header `< curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

The `setupterm()` routine should be used in place of `setterm()`.

Note that `vidattr()` and `vidputs()` may be macros.

| NAME        | del_curterm, restartterm, set_curterm, setupterm – interfaces to the terminfo database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |       |             |   |        |   |                             |    |                                      |

| DESCRIPTION | <p>Within X/Open Curses, the setupterm() function is automatically called by the initscr (3XC) and newterm (3XC) functions. This function can be also be used outside of X/Open Curses when a program has to deal directly with the terminfo database to handle certain terminal capabilities. The use of appropriate X/Open Curses functions is recommended in all other situations.</p> <p>The setupterm() function loads terminal-dependent variables for the terminfo layer of X/Open Curses. The setupterm() function initializes the terminfo variables lines and columns such that if use_env (FALSE) has been called, the terminfo values assigned in the database are used regardless of the environmental variables LINES and COLUMNS or the program's window dimensions; when use_env (TRUE) has been called, which is the default, the environment variables LINES and COLUMNS are used, if they exist. If the environment variables do not exist and the program is running in a window, the current window size is used.</p> <p>The term parameter of setupterm() specifies the terminal; if null, terminal type is taken from the TERM environment variable. All output is sent to fildes which is initialized for output. If errret is not null, OK or ERR is returned and a status value is stored in the integer pointed to by errret. The following status values may be returned:</p> <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>1</td><td>Normal</td></tr> <tr> <td>0</td><td>Terminal could not be found</td></tr> <tr> <td>-1</td><td>terminfo database could not be found</td></tr> </tbody> </table> <p>If errret is null, an error message is printed, and the setupterm() function calls the exit() function with a non-zero parameter.</p> | Value | Description | 1 | Normal | 0 | Terminal could not be found | -1 | terminfo database could not be found |
| Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |       |             |   |        |   |                             |    |                                      |

## set\_curterm(3XCURSES)

The `set_curterm()` function sets the `cur_term` variable to *nterm*. The values from *nterm* as well as other state information for the terminal are used by X/Open Curses functions such as `beep(3XCURSES)`, `flash(3XCURSES)`, `mvcur(3XCURSES)`, `tigetflag(3XCURSES)`, `tigetstr(3XCURSES)`, and `tigetnum(3XCURSES)`.

The `del_curterm()` function frees the space pointed to by *oterm*. If *oterm* and the `cur_term` variable are the same, all Boolean, numeric, or string terminfo variables will refer to invalid memory locations until you call `setupterm()` and specify a new terminal type.

The `restartterm()` function assumes that a call to `setupterm()` has already been made (probably from `initscr()` or `newterm()`). It allows you to specify a new terminal type in *term* and updates the data returned by `baudrate(3XCURSES)` based on *fildes*. Other information created by the `initscr()`, `newterm()`, and `setupterm()` functions is preserved.

### PARAMETERS

|               |                                                                 |
|---------------|-----------------------------------------------------------------|
| <i>oterm</i>  | Is the terminal type for which to free space.                   |
| <i>term</i>   | Is the terminal type for which variables are set.               |
| <i>fildes</i> | Is a file descriptor initialized for output.                    |
| <i>errret</i> | Is a pointer to an integer in which the status value is stored. |
| <i>nterm</i>  | Is the new terminal to become the current terminal.             |

### RETURN VALUES

On success, the `set_curterm()` function returns the previous value of `cur_term`. Otherwise, it returns a null pointer.

On success, the other functions return OK. Otherwise, they return ERR.

### ERRORS

None.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| SYNOPSIS       | <pre>cc [ flag... ] file... -lform -lcurses [ library... ] #include &lt;form.h&gt;  int set_field_fore(FIELD *field, chtype attr); chtype field_fore(FIELD *field); int set_field_back(FIELD *field, chtype attr); chtype field_back(FIELD *field); int set_field_pad(FIELD *field, int pad); int field_pad(FIELD *field);</pre>                                                                                                                                                                                                                                                                                                                                                                     |                |                                     |                |               |                |                           |
| DESCRIPTION    | <p>set_field_fore() sets the foreground attribute of <i>field</i>. The foreground attribute is the low-level curses display attribute used to display the field contents. field_fore() returns the foreground attribute of <i>field</i>.</p> <p>set_field_back() sets the background attribute of <i>field</i>. The background attribute is the low-level curses display attribute used to display the extent of the field. field_back() returns the background attribute of <i>field</i>.</p> <p>set_field_pad() sets the pad character of <i>field</i> to <i>pad</i>. The pad character is the character used to fill within the field. field_pad() returns the pad character of <i>field</i>.</p> |                |                                     |                |               |                |                           |
| RETURN VALUES  | <p>field_fore(), field_back(), and field_pad() return default values if <i>field</i> is NULL. If <i>field</i> is not NULL and is not a valid FIELD pointer, the return value from these routines is undefined.</p> <p>set_field_fore(), set_field_back(), and set_field_pad() return one of the following:</p> <table><tr><td>E_OK</td><td>The function returned successfully.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error.</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr></table>                                                                                                                                                                             | E_OK           | The function returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An argument is incorrect. |
| E_OK           | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                                     |                |               |                |                           |
| E_SYSTEM_ERROR | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                                     |                |               |                |                           |

| <b>SYNOPSIS</b>      | <pre>cc [ <i>flag...</i> ] <i>file...</i> -lform -lcurses [ <i>library...</i> ] #include &lt;form.h&gt;  int <b>set_field_buffer</b>(FIELD *<i>field</i>, int <i>buf</i>, char *<i>value</i>); char *<b>field_buffer</b>(FIELD *<i>field</i>, int <i>buf</i>); int <b>set_field_status</b>(FIELD *<i>field</i>, int <i>status</i>); int <b>field_status</b>(FIELD *<i>field</i>); int <b>set_max_field</b>(FIELD *<i>field</i>, int <i>max</i>);</pre>                                                                                                                                                                                                            |                |                                     |                |              |                |                           |
| <b>DESCRIPTION</b>   | <p>set_field_buffer() sets buffer <i>buf</i> of <i>field</i> to <i>value</i>. Buffer 0 stores the displayed contents of the field. Buffers other than 0 are application specific and not used by the forms library routines. field_buffer() returns the value of <i>field</i> buffer <i>buf</i>.</p> <p>Every field has an associated status flag that is set whenever the contents of field buffer 0 changes. set_field_status() sets the status flag of <i>field</i> to <i>status</i>. field_status() returns the status of <i>field</i>.</p> <p>set_max_field() sets a maximum growth on a dynamic field, or if <i>max</i>=0 turns off any maximum growth.</p> |                |                                     |                |              |                |                           |
| <b>RETURN VALUES</b> | <p>field_buffer() returns NULL on error.</p> <p>field_status() returns TRUE or FALSE.</p> <p>set_field_buffer(), set_field_status(), and set_max_field() return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr> </table>                                                                                                                                                                                                                                                         | E_OK           | The function returned successfully. | E_SYSTEM_ERROR | System error | E_BAD_ARGUMENT | An argument is incorrect. |
| E_OK                 | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                                     |                |              |                |                           |

| NAME           | form_field_attributes, set_field_fore, field_fore, set_field_back, field_back, set_field_pad, field_pad – format the general display attributes of forms                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                                     |                |               |                |                           |
| SYNOPSIS       | <pre>cc [ flag... ] file... -lform -lcurses [ library... ] #include &lt;form.h&gt;  int set_field_fore(FIELD *field, chtype attr); chtype field_fore(FIELD *field); int set_field_back(FIELD *field, chtype attr); chtype field_back(FIELD *field); int set_field_pad(FIELD *field, int pad); int field_pad(FIELD *field);</pre>                                                                                                                                                                                                                                                                                                                                                                     |                |                                     |                |               |                |                           |
| DESCRIPTION    | <p>set_field_fore() sets the foreground attribute of <i>field</i>. The foreground attribute is the low-level curses display attribute used to display the field contents. field_fore() returns the foreground attribute of <i>field</i>.</p> <p>set_field_back() sets the background attribute of <i>field</i>. The background attribute is the low-level curses display attribute used to display the extent of the field. field_back() returns the background attribute of <i>field</i>.</p> <p>set_field_pad() sets the pad character of <i>field</i> to <i>pad</i>. The pad character is the character used to fill within the field. field_pad() returns the pad character of <i>field</i>.</p> |                |                                     |                |               |                |                           |
| RETURN VALUES  | <p>field_fore(), field_back(), and field_pad() return default values if <i>field</i> is NULL. If <i>field</i> is not NULL and is not a valid FIELD pointer, the return value from these routines is undefined.</p> <p>set_field_fore(), set_field_back(), and set_field_pad() return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr> </table>                                                                                                                                                                      | E_OK           | The function returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An argument is incorrect. |
| E_OK           | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                                     |                |               |                |                           |

| <b>NAME</b>          | form_hook, set_form_init, form_init, set_form_term, form_term, set_field_init, field_init, set_field_term, field_term – assign application-specific routines for invocation by forms                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |      |                                     |                |               |
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -lform -lcurses [ library... ] #include &lt;form.h&gt;  int set_form_init(FORM *form, void (*func)(FORM*)); void (*form_init)(FORM *form); int set_form_term(FORM *form, void (*func)(FORM*)); void (*form_term)(FORM *form); int set_field_init(FORM *form, void (*func)(FORM*)); void (*field_init)(FORM *form); int set_field_term(FORM *form, void (*func)(FORM*)); void (*field_term)(FORM *form);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |      |                                     |                |               |
| <b>DESCRIPTION</b>   | <p>These routines allow the programmer to assign application specific routines to be executed automatically at initialization and termination points in the forms application. The user need not specify any application-defined initialization or termination routines at all, but they may be helpful for displaying messages or page numbers and other chores.</p> <p>set_form_init() assigns an application-defined initialization function to be called when the <i>form</i> is posted and just after a page change. form_init() returns a pointer to the initialization function, if any.</p> <p>set_form_term() assigns an application-defined function to be called when the <i>form</i> is unposted and just before a page change. form_term() returns a pointer to the function, if any.</p> <p>set_field_init() assigns an application-defined function to be called when the <i>form</i> is posted and just after the current field changes. field_init() returns a pointer to the function, if any.</p> <p>set_field_term() assigns an application-defined function to be called when the <i>form</i> is unposted and just before the current field changes. field_term() returns a pointer to the function, if any.</p> |      |                                     |                |               |
| <b>RETURN VALUES</b> | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | E_OK | The function returned successfully. | E_SYSTEM_ERROR | System error. |
| E_OK                 | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |      |                                     |                |               |
| E_SYSTEM_ERROR       | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |      |                                     |                |               |

set\_field\_init(3CURSES)

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curses(3CURSES), forms(3CURSES), attributes(5)

**NOTES** The header `<form.h>` automatically includes the headers `<eti.h>` and `<curses.h>`.

set\_field\_just(3CURSES)

| NAME           | form_field_just, set_field_just, field_just – format the general appearance of forms                                                                                                                                                                                                                                                                                                             |                |                                     |                |               |                |                           |

| NAME           | form_field_attributes, set_field_fore, field_fore, set_field_back, field_back, set_field_pad, field_pad – format the general display attributes of forms                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                                     |                |               |                |                           |
| SYNOPSIS       | <pre>cc [ flag... ] file... -lform -lcurses [ library... ] #include &lt;form.h&gt;  int set_field_fore(FIELD *field, chtype attr); chtype field_fore(FIELD *field); int set_field_back(FIELD *field, chtype attr); chtype field_back(FIELD *field); int set_field_pad(FIELD *field, int pad); int field_pad(FIELD *field);</pre>                                                                                                                                                                                                                                                                                                                                                                     |                |                                     |                |               |                |                           |
| DESCRIPTION    | <p>set_field_fore() sets the foreground attribute of <i>field</i>. The foreground attribute is the low-level curses display attribute used to display the field contents. field_fore() returns the foreground attribute of <i>field</i>.</p> <p>set_field_back() sets the background attribute of <i>field</i>. The background attribute is the low-level curses display attribute used to display the extent of the field. field_back() returns the background attribute of <i>field</i>.</p> <p>set_field_pad() sets the pad character of <i>field</i> to <i>pad</i>. The pad character is the character used to fill within the field. field_pad() returns the pad character of <i>field</i>.</p> |                |                                     |                |               |                |                           |
| RETURN VALUES  | <p>field_fore(), field_back(), and field_pad() return default values if <i>field</i> is NULL. If <i>field</i> is not NULL and is not a valid FIELD pointer, the return value from these routines is undefined.</p> <p>set_field_fore(), set_field_back(), and set_field_pad() return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr> </table>                                                                                                                                                                      | E_OK           | The function returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An argument is incorrect. |
| E_OK           | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                                     |                |               |                |                           |
| E_SYSTEM_ERROR | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                                     |                |               |                |                           |
| E_BAD_ARGUMENT | An argument is incorrect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                                     |                |               |                |                           |

| <b>SYNOPSIS</b>      | <pre>cc [ <i>flag...</i> ] <i>file...</i> -lform -lcurses [ <i>library...</i> ] #include &lt;form.h&gt;  int <b>set_field_buffer</b>(FIELD *<i>field</i>, int <i>buf</i>, char *<i>value</i>); char *<b>field_buffer</b>(FIELD *<i>field</i>, int <i>buf</i>); int <b>set_field_status</b>(FIELD *<i>field</i>, int <i>status</i>); int <b>field_status</b>(FIELD *<i>field</i>); int <b>set_max_field</b>(FIELD *<i>field</i>, int <i>max</i>);</pre>                                                                                                                                                                                                            |                |                                     |                |              |                |                           |
| <b>DESCRIPTION</b>   | <p>set_field_buffer() sets buffer <i>buf</i> of <i>field</i> to <i>value</i>. Buffer 0 stores the displayed contents of the field. Buffers other than 0 are application specific and not used by the forms library routines. field_buffer() returns the value of <i>field</i> buffer <i>buf</i>.</p> <p>Every field has an associated status flag that is set whenever the contents of field buffer 0 changes. set_field_status() sets the status flag of <i>field</i> to <i>status</i>. field_status() returns the status of <i>field</i>.</p> <p>set_max_field() sets a maximum growth on a dynamic field, or if <i>max</i>=0 turns off any maximum growth.</p> |                |                                     |                |              |                |                           |
| <b>RETURN VALUES</b> | <p>field_buffer() returns NULL on error.</p> <p>field_status() returns TRUE or FALSE.</p> <p>set_field_buffer(), set_field_status(), and set_max_field() return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr> </table>                                                                                                                                                                                                                                                         | E_OK           | The function returned successfully. | E_SYSTEM_ERROR | System error | E_BAD_ARGUMENT | An argument is incorrect. |
| E_OK                 | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                                     |                |              |                |                           |

| DESCRIPTION    | <p>These routines allow the programmer to assign application specific routines to be executed automatically at initialization and termination points in the forms application. The user need not specify any application-defined initialization or termination routines at all, but they may be helpful for displaying messages or page numbers and other chores.</p> <p>set_form_init() assigns an application-defined initialization function to be called when the <i>form</i> is posted and just after a page change. form_init() returns a pointer to the initialization function, if any.</p> <p>set_form_term() assigns an application-defined function to be called when the <i>form</i> is unposted and just before a page change. form_term() returns a pointer to the function, if any.</p> <p>set_field_init() assigns an application-defined function to be called when the <i>form</i> is posted and just after the current field changes. field_init() returns a pointer to the function, if any.</p> <p>set_field_term() assigns an application-defined function to be called when the <i>form</i> is unposted and just before the current field changes. field_term() returns a pointer to the function, if any.</p> |      |                                     |                |               |
| RETURN VALUES  | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table><tr><td>E_OK</td><td>The function returned successfully.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error.</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | E_OK | The function returned successfully. | E_SYSTEM_ERROR | System error. |
| E_OK           | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |      |                                     |                |               |
| E_SYSTEM_ERROR | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |      |                                     |                |               |

| SYNOPSIS       | <pre>cc [ <i>flag...</i> ] <i>file...</i> -lform -lcurses [ <i>library...</i> ] #include &lt;form.h&gt;  int <b>set_field_type</b>(FIELD *<i>field</i>, FIELDTYPE *<i>type</i>, ...); FIELDTYPE *<b>field_type</b>(FIELD *<i>field</i>); char *<b>field_arg</b>(FIELD *<i>field</i>);</pre>                                                                                                                                                                                                                                                                                                                      |                |                                     |                |               |
| DESCRIPTION    | <p>set_field_type() associates the specified field type with <i>field</i>. Certain field types take additional arguments. TYPE_ALNUM, for instance, requires one, the minimum width specification for the field. The other predefined field types are: TYPE_ALPHA, TYPE_ENUM, TYPE_INTEGER, TYPE_NUMERIC, and TYPE_REGEX.</p> <p>field_type() returns a pointer to the field type of <i>field</i>. NULL is returned if no field type is assigned.</p> <p>field_arg() returns a pointer to the field arguments associated with the field type of <i>field</i>. NULL is returned if no field type is assigned.</p> |                |                                     |                |               |

| <b>DESCRIPTION</b>   | <p>new_fieldtype() creates a new field type. The application programmer must write the function <i>field_check</i>, which validates the field value, and the function <i>char_check</i>, which validates each character. free_fieldtype() frees the space allocated for the field type.</p> <p>By associating function pointers with a field type, set_fieldtype_arg() connects to the field type additional arguments necessary for a set_field_type() call. Function <i>mak_arg</i> allocates a structure for the field specific parameters to set_field_type() and returns a pointer to the saved data. Function <i>copy_arg</i> duplicates the structure created by <i>make_arg</i>. Function <i>free_arg</i> frees any storage allocated by <i>make_arg</i> or <i>copy_arg</i>.</p> <p>The form_driver() requests REQ_NEXT_CHOICE and REQ_PREV_CHOICE let the user request the next or previous value of a field type comprising an ordered set of values. set_fieldtype_choice() allows the application programmer to implement these requests for the given field type. It associates with the given field type those application-defined functions that return pointers to the next or previous choice for the field.</p> <p>link_fieldtype() returns a pointer to the field type built from the two given types. The constituent types may be any application-defined or pre-defined types.</p> |      |                                     |                |               |                |                           |             |                                          |
| <b>RETURN VALUES</b> | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr> <tr> <td>E_CONNECTED</td><td>Type is connected to one or more fields.</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | E_OK | The function returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An argument is incorrect. | E_CONNECTED | Type is connected to one or more fields. |
| E_OK                 | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |      |                                     |                |               |                |                           |             |                                          |
| E_SYSTEM_ERROR       | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |      |                                     |                |               |                |                           |             |                                          |

| <b>DESCRIPTION</b>   | <p>new_fieldtype() creates a new field type. The application programmer must write the function <i>field_check</i>, which validates the field value, and the function <i>char_check</i>, which validates each character. free_fieldtype() frees the space allocated for the field type.</p> <p>By associating function pointers with a field type, set_fieldtype_arg() connects to the field type additional arguments necessary for a set_field_type() call. Function <i>mak_arg</i> allocates a structure for the field specific parameters to set_field_type() and returns a pointer to the saved data. Function <i>copy_arg</i> duplicates the structure created by <i>make_arg</i>. Function <i>free_arg</i> frees any storage allocated by <i>make_arg</i> or <i>copy_arg</i>.</p> <p>The form_driver() requests REQ_NEXT_CHOICE and REQ_PREV_CHOICE let the user request the next or previous value of a field type comprising an ordered set of values. set_fieldtype_choice() allows the application programmer to implement these requests for the given field type. It associates with the given field type those application-defined functions that return pointers to the next or previous choice for the field.</p> <p>link_fieldtype() returns a pointer to the field type built from the two given types. The constituent types may be any application-defined or pre-defined types.</p> |      |                                     |                |               |                |                           |             |                                          |
| <b>RETURN VALUES</b> | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr> <tr> <td>E_CONNECTED</td><td>Type is connected to one or more fields.</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | E_OK | The function returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An argument is incorrect. | E_CONNECTED | Type is connected to one or more fields. |
| E_OK                 | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |      |                                     |                |               |                |                           |             |                                          |
| E_SYSTEM_ERROR       | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |      |                                     |                |               |                |                           |             |                                          |
| E_BAD_ARGUMENT       | An argument is incorrect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |      |                                     |                |               |                |                           |             |                                          |

## set\_field\_userptr(3CURSES)

| NAME           | form_field_userptr, set_field_userptr, field_userptr – associate application data with forms                                                                                                                                                                     |                |                 |          |        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag... ] file... -lform -lcurses [ library... ] #include &lt;form.h&gt;  int <b>set_field_userptr</b>(FIELD *field, char *ptr); char *<b>field_userptr</b>(FIELD *field);</pre>                                                                       |                |                 |          |        |
| DESCRIPTION    | Every field has an associated user pointer that can be used to store pertinent data. <code>set_field_userptr()</code> sets the user pointer of <i>field</i> . <code>field_userptr()</code> returns the user pointer of <i>field</i> .                            |                |                 |          |        |
| RETURN VALUES  | <code>field_userptr()</code> returns NULL on error. <code>set_field_userptr()</code> returns one of the following:<br><br>E_OK                                      The function returned successfully.<br>E_SYSTEM_ERROR                          System error. |                |                 |          |        |
| ATTRIBUTES     | See <code>attributes(5)</code> for descriptions of the following attributes:<br><br><table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>Unsafe</td></tr></tbody></table>                               | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| <b>DESCRIPTION</b>   | <p>These routines allow the programmer to assign application specific routines to be executed automatically at initialization and termination points in the forms application. The user need not specify any application-defined initialization or termination routines at all, but they may be helpful for displaying messages or page numbers and other chores.</p> <p>set_form_init() assigns an application-defined initialization function to be called when the <i>form</i> is posted and just after a page change. form_init() returns a pointer to the initialization function, if any.</p> <p>set_form_term() assigns an application-defined function to be called when the <i>form</i> is unposted and just before a page change. form_term() returns a pointer to the function, if any.</p> <p>set_field_init() assigns an application-defined function to be called when the <i>form</i> is posted and just after the current field changes. field_init() returns a pointer to the function, if any.</p> <p>set_field_term() assigns an application-defined function to be called when the <i>form</i> is unposted and just before the current field changes. field_term() returns a pointer to the function, if any.</p> |      |                                     |                |               |
| <b>RETURN VALUES</b> | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | E_OK | The function returned successfully. | E_SYSTEM_ERROR | System error. |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -lform -lcurses [ library... ] #include &lt;form.h&gt;  int set_form_win(FORM *form, WINDOW *win); WINDOW *form_win(FORM *form); int set_form_sub(FORM *form, WINDOW *sub); WINDOW *form_sub(FORM *form); int scale_form(FORM *form, int *rows, int *cols);</pre>                                                                                                                                                                                                          |                |                                     |                |               |                |                           |                 |                                       |          |                     |
| <b>DESCRIPTION</b>   | <p>set_form_win() sets the window of <i>form</i> to <i>win</i>. form_win() returns a pointer to the window associated with <i>form</i>. set_form_sub() sets the subwindow of <i>form</i> to <i>sub</i>. form_sub() returns a pointer to the subwindow associated with <i>form</i>. scale_form() returns the smallest window size necessary for the subwindow of <i>form</i>. <i>rows</i> and <i>cols</i> are pointers to the locations used to return the number of rows and columns for the form.</p> |                |                                     |                |               |                |                           |                 |                                       |          |                     |
| <b>RETURN VALUES</b> | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr> <tr> <td>E_NOT_CONNECTED</td><td>The field is not connected to a form.</td></tr> <tr> <td>E_POSTED</td><td>The form is posted.</td></tr> </table>               | E_OK           | The function returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An argument is incorrect. | E_NOT_CONNECTED | The field is not connected to a form. | E_POSTED | The form is posted. |
| E_OK                 | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                                     |                |               |                |                           |                 |                                       |          |                     |
| E_SYSTEM_ERROR       | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                                     |                |               |                |                           |                 |                                       |          |                     |

| <b>NAME</b>          | form_hook, set_form_init, form_init, set_form_term, form_term, set_field_init, field_init, set_field_term, field_term – assign application-specific routines for invocation by forms                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |      |                                     |                |               |
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -lform -lcurses [ library... ] #include &lt;form.h&gt;  int set_form_init(FORM *form, void (*func)(FORM*)); void (*form_init)(FORM *form); int set_form_term(FORM *form, void (*func)(FORM*)); void (*form_term)(FORM *form); int set_field_init(FORM *form, void (*func)(FORM*)); void (*field_init)(FORM *form); int set_field_term(FORM *form, void (*func)(FORM*)); void (*field_term)(FORM *form);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |      |                                     |                |               |
| <b>DESCRIPTION</b>   | <p>These routines allow the programmer to assign application specific routines to be executed automatically at initialization and termination points in the forms application. The user need not specify any application-defined initialization or termination routines at all, but they may be helpful for displaying messages or page numbers and other chores.</p> <p>set_form_init() assigns an application-defined initialization function to be called when the <i>form</i> is posted and just after a page change. form_init() returns a pointer to the initialization function, if any.</p> <p>set_form_term() assigns an application-defined function to be called when the <i>form</i> is unposted and just before a page change. form_term() returns a pointer to the function, if any.</p> <p>set_field_init() assigns an application-defined function to be called when the <i>form</i> is posted and just after the current field changes. field_init() returns a pointer to the function, if any.</p> <p>set_field_term() assigns an application-defined function to be called when the <i>form</i> is unposted and just before the current field changes. field_term() returns a pointer to the function, if any.</p> |      |                                     |                |               |
| <b>RETURN VALUES</b> | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | E_OK | The function returned successfully. | E_SYSTEM_ERROR | System error. |
| E_OK                 | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |      |                                     |                |               |
| E_SYSTEM_ERROR       | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |      |                                     |                |               |

`set_form_term(3CURSES)`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curses(3CURSES)`, `forms(3CURSES)`, `attributes(5)`

**NOTES** The header `<form.h>` automatically includes the headers `<eti.h>` and `<curses.h>`.

## set\_form\_userptr(3CURSES)

| NAME           | form_userptr, set_form_userptr – associate application data with forms                                                                                                                                                                                         |                |                 |          |        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag... ] file... -lform -lcurses [ library... ] #include &lt;form.h&gt;  int set_form_userptr(FORM *form, char *ptr); char *form_userptr(FORM *form);</pre>                                                                                         |                |                 |          |        |
| DESCRIPTION    | Every form has an associated user pointer that can be used to store pertinent data. <code>set_form_userptr()</code> sets the user pointer of <i>form</i> . <code>form_userptr()</code> returns the user pointer of <i>form</i> .                               |                |                 |          |        |
| RETURN VALUES  | <code>form_userptr()</code> returns NULL on error. <code>set_form_userptr()</code> returns one of the following:<br><br>E_OK                                      The function returned successfully.<br>E_SYSTEM_ERROR                          System error. |                |                 |          |        |
| ATTRIBUTES     | See <code>attributes(5)</code> for descriptions of the following attributes:<br><br><table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>Unsafe</td></tr></tbody></table>                             | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE                                                                                                                                                                                                                                                |                |                 |          |        |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -lform -lcurses [ library... ] #include &lt;form.h&gt;  int set_form_win(FORM *form, WINDOW *win); WINDOW *form_win(FORM *form); int set_form_sub(FORM *form, WINDOW *sub); WINDOW *form_sub(FORM *form); int scale_form(FORM *form, int *rows, int *cols);</pre>                                                                                                                                                                                                          |                |                                     |                |               |                |                           |                 |                                       |          |                     |
| <b>DESCRIPTION</b>   | <p>set_form_win() sets the window of <i>form</i> to <i>win</i>. form_win() returns a pointer to the window associated with <i>form</i>. set_form_sub() sets the subwindow of <i>form</i> to <i>sub</i>. form_sub() returns a pointer to the subwindow associated with <i>form</i>. scale_form() returns the smallest window size necessary for the subwindow of <i>form</i>. <i>rows</i> and <i>cols</i> are pointers to the locations used to return the number of rows and columns for the form.</p> |                |                                     |                |               |                |                           |                 |                                       |          |                     |
| <b>RETURN VALUES</b> | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr> <tr> <td>E_NOT_CONNECTED</td><td>The field is not connected to a form.</td></tr> <tr> <td>E_POSTED</td><td>The form is posted.</td></tr> </table>               | E_OK           | The function returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An argument is incorrect. | E_NOT_CONNECTED | The field is not connected to a form. | E_POSTED | The form is posted. |
| E_OK                 | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                                     |                |               |                |                           |                 |                                       |          |                     |
| E_SYSTEM_ERROR       | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                                     |                |               |                |                           |                 |                                       |          |                     |

| <b>NAME</b>          | menu_item_userptr, set_item_userptr, item_userptr – associate application data with menus items                                                                                                                                                                          |                |                 |          |        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -lmenu -lcurses [ library... ] #include &lt;menu.h&gt;  int <b>set_item_userptr</b>(ITEM *item, char *userptr); char *<b>item_userptr</b>(ITEM *item);</pre>                                                                                 |                |                 |          |        |
| <b>DESCRIPTION</b>   | Every item has an associated user pointer that can be used to store relevant information. <code>set_item_userptr()</code> sets the user pointer of <i>item</i> . <code>item_userptr()</code> returns the user pointer of <i>item</i> .                                   |                |                 |          |        |
| <b>RETURN VALUES</b> | <p><code>item_userptr()</code> returns NULL on error. <code>set_item_userptr()</code> returns one of the following:</p> <p>E_OK                                      The routine returned successfully.</p> <p>E_SYSTEM_ERROR                          System error.</p> |                |                 |          |        |
| <b>ATTRIBUTES</b>    | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                             |                |                 |          |        |

| <b>SYNOPSIS</b>               | <pre>cc [ flag... ] file... -lmenu -lcurses [ library... ] #include &lt;menu.h&gt;  int set_item_value (ITEM *item, int bool); int item_value (ITEM *item);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                   |                                    |                             |               |                               |                                                |
| <b>DESCRIPTION</b>            | <p>Unlike single-valued menus, multi-valued menus enable the end-user to select one or more items from a menu. <code>set_item_value()</code> sets the selected value of the <i>item</i> — TRUE (selected) or FALSE (not selected). <code>set_item_value()</code> may be used only with multi-valued menus. To make a menu multi-valued, use <code>set_menu_opts</code> or <code>menu_opts_off()</code> to turn off the option <code>O_ONEVALUE</code>. (See <code>menu_opts(3CURSES)</code>).</p> <p><code>item_value()</code> returns the select value of <i>item</i>, either TRUE (selected) or FALSE (unselected).</p> |                   |                                    |                             |               |                               |                                                |
| <b>RETURN VALUES</b>          | <p><code>set_item_value()</code> returns one of the following:</p> <table> <tr> <td><code>E_OK</code></td><td>The routine returned successfully.</td></tr> <tr> <td><code>E_SYSTEM_ERROR</code></td><td>System error.</td></tr> <tr> <td><code>E_REQUEST_DENIED</code></td><td>The menu driver could not process the request.</td></tr> </table>                                                                                                                                                                                                                                                                          | <code>E_OK</code> | The routine returned successfully. | <code>E_SYSTEM_ERROR</code> | System error. | <code>E_REQUEST_DENIED</code> | The menu driver could not process the request. |
| <code>E_OK</code>             | The routine returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                   |                                    |                             |               |                               |                                                |
| <code>E_SYSTEM_ERROR</code>   | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                   |                                    |                             |               |                               |                                                |
| <code>E_REQUEST_DENIED</code> | The menu driver could not process the request.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                   |                                    |                             |               |                               |                                                |

| DESCRIPTION    | <p>set_field_buffer() sets buffer <i>buf</i> of <i>field</i> to <i>value</i>. Buffer 0 stores the displayed contents of the field. Buffers other than 0 are application specific and not used by the forms library routines. field_buffer() returns the value of <i>field</i> buffer <i>buf</i>.</p> <p>Every field has an associated status flag that is set whenever the contents of field buffer 0 changes. set_field_status() sets the status flag of <i>field</i> to <i>status</i>. field_status() returns the status of <i>field</i>.</p> <p>set_max_field() sets a maximum growth on a dynamic field, or if <i>max</i>=0 turns off any maximum growth.</p> |                |                                     |                |              |                |                           |
| RETURN VALUES  | <p>field_buffer() returns NULL on error.</p> <p>field_status() returns TRUE or FALSE.</p> <p>set_field_buffer(), set_field_status(), and set_max_field() return one of the following:</p> <table><tr><td>E_OK</td><td>The function returned successfully.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr></table>                                                                                                                                                                                                                                                                | E_OK           | The function returned successfully. | E_SYSTEM_ERROR | System error | E_BAD_ARGUMENT | An argument is incorrect. |
| E_OK           | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                                     |                |              |                |                           |

| DESCRIPTION    | <p>set_menu_fore() sets the foreground attribute of <i>menu</i> — the display attribute for the current item (if selectable) on single-valued menus and for selected items on multi-valued menus. This display attribute is a curses library visual attribute. menu_fore() returns the foreground attribute of <i>menu</i>.</p> <p>set_menu_back() sets the background attribute of <i>menu</i> — the display attribute for unselected, yet selectable, items. This display attribute is a curses library visual attribute.</p> <p>set_menu_grey() sets the grey attribute of <i>menu</i> — the display attribute for nonselectable items in multi-valued menus. This display attribute is a curses library visual attribute. menu_grey() returns the grey attribute of <i>menu</i>.</p> <p>The pad character is the character that fills the space between the name and description of an item. set_menu_pad() sets the pad character for <i>menu</i> to <i>pad</i>. menu_pad() returns the pad character of <i>menu</i>.</p> |                |                                    |                |               |                |                                                  |

| DESCRIPTION    | <p>set_menu_fore() sets the foreground attribute of <i>menu</i> — the display attribute for the current item (if selectable) on single-valued menus and for selected items on multi-valued menus. This display attribute is a curses library visual attribute. menu_fore() returns the foreground attribute of <i>menu</i>.</p> <p>set_menu_back() sets the background attribute of <i>menu</i> — the display attribute for unselected, yet selectable, items. This display attribute is a curses library visual attribute.</p> <p>set_menu_grey() sets the grey attribute of <i>menu</i> — the display attribute for nonselectable items in multi-valued menus. This display attribute is a curses library visual attribute. menu_grey() returns the grey attribute of <i>menu</i>.</p> <p>The pad character is the character that fills the space between the name and description of an item. set_menu_pad() sets the pad character for <i>menu</i> to <i>pad</i>. menu_pad() returns the pad character of <i>menu</i>.</p> |                |                                    |                |               |                |                                                  |

| DESCRIPTION    | <p>set_menu_format() sets the maximum number of rows and columns of items that may be displayed at one time on a menu. If the menu contains more items than can be displayed at once, the menu will be scrollable.</p> <p>menu_format() returns the maximum number of rows and columns that may be displayed at one time on <i>menu</i>. <i>rows</i> and <i>cols</i> are pointers to the variables used to return these values.</p> |                |                                    |                |               |                |                                                  |          |                             |
| RETURN VALUES  | <p>set_menu_format() returns one of the following:</p> <table><tr><td>E_OK</td><td>The routine returned successfully.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error.</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An incorrect argument was passed to the routine.</td></tr><tr><td>E_POSTED</td><td>The menu is already posted.</td></tr></table>                                                                                | E_OK           | The routine returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An incorrect argument was passed to the routine. | E_POSTED | The menu is already posted. |
| E_OK           | The routine returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                  |                |                                    |                |               |                |                                                  |          |                             |

| <b>DESCRIPTION</b>   | <p>set_menu_fore() sets the foreground attribute of <i>menu</i> — the display attribute for the current item (if selectable) on single-valued menus and for selected items on multi-valued menus. This display attribute is a curses library visual attribute. menu_fore() returns the foreground attribute of <i>menu</i>.</p> <p>set_menu_back() sets the background attribute of <i>menu</i> — the display attribute for unselected, yet selectable, items. This display attribute is a curses library visual attribute.</p> <p>set_menu_grey() sets the grey attribute of <i>menu</i> — the display attribute for nonselectable items in multi-valued menus. This display attribute is a curses library visual attribute. menu_grey() returns the grey attribute of <i>menu</i>.</p> <p>The pad character is the character that fills the space between the name and description of an item. set_menu_pad() sets the pad character for <i>menu</i> to <i>pad</i>. menu_pad() returns the pad character of <i>menu</i>.</p> |      |                                    |                |               |                |                                                  |
| <b>RETURN VALUES</b> | <p>These routines return one of the following:</p> <table> <tr> <td>E_OK</td><td>The routine returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An incorrect argument was passed to the routine.</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | E_OK | The routine returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An incorrect argument was passed to the routine. |
| E_OK                 | The routine returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |      |                                    |                |               |                |                                                  |

| <b>DESCRIPTION</b>   | <p>set_item_init() assigns the application-defined function to be called when the <i>menu</i> is posted and just after the current item changes. item_init() returns a pointer to the item initialization routine, if any, called when the <i>menu</i> is posted and just after the current item changes.</p> <p>set_item_term() assigns an application-defined function to be called when the <i>menu</i> is unposted and just before the current item changes. item_term() returns a pointer to the termination function, if any, called when the <i>menu</i> is unposted and just before the current item changes.</p> <p>set_menu_init() assigns an application-defined function to be called when the <i>menu</i> is posted and just after the top row changes on a posted menu. menu_init() returns a pointer to the menu initialization routine, if any, called when the <i>menu</i> is posted and just after the top row changes on a posted menu.</p> <p>set_menu_term() assigns an application-defined function to be called when the <i>menu</i> is unposted and just before the top row changes on a posted menu. menu_term() returns a pointer to the menu termination routine, if any, called when the <i>menu</i> is unposted and just before the top row changes on a posted menu.</p> |      |                                    |                |               |
| <b>RETURN VALUES</b> | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table> <tr> <td>E_OK</td><td>The routine returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | E_OK | The routine returned successfully. | E_SYSTEM_ERROR | System error. |
| E_OK                 | The routine returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |      |                                    |                |               |

| SYNOPSIS       | <pre>cc [ flag... ] file... -lmenu -lcurses [ library... ] #include &lt;menu.h&gt;  int set_menu_mark(MENU *menu, char *mark); char *menu_mark(MENU *menu);</pre>                                                                                                                                                   |                |                                    |                |               |                |                                                  |
| DESCRIPTION    | menus displays mark strings to distinguish selected items in a menu (or the current item in a single-valued menu). set_menu_mark() sets the mark string of <i>menu</i> to <i>mark</i> . menu_mark() returns a pointer to the mark string of <i>menu</i> .                                                           |                |                                    |                |               |                |                                                  |
| RETURN VALUES  | menu_mark() returns NULL on error. set_menu_mark() returns one of the following:<br><table><tr><td>E_OK</td><td>The routine returned successfully.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error.</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An incorrect argument was passed to the routine.</td></tr></table> | E_OK           | The routine returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An incorrect argument was passed to the routine. |
| E_OK           | The routine returned successfully.                                                                                                                                                                                                                                                                                  |                |                                    |                |               |                |                                                  |
| E_SYSTEM_ERROR | System error.                                                                                                                                                                                                                                                                                                       |                |                                    |                |               |                |                                                  |
| E_BAD_ARGUMENT | An incorrect argument was passed to the routine.                                                                                                                                                                                                                                                                    |                |                                    |                |               |                |                                                  |

| DESCRIPTION    | <p>set_menu_fore() sets the foreground attribute of <i>menu</i> — the display attribute for the current item (if selectable) on single-valued menus and for selected items on multi-valued menus. This display attribute is a curses library visual attribute. menu_fore() returns the foreground attribute of <i>menu</i>.</p> <p>set_menu_back() sets the background attribute of <i>menu</i> — the display attribute for unselected, yet selectable, items. This display attribute is a curses library visual attribute.</p> <p>set_menu_grey() sets the grey attribute of <i>menu</i> — the display attribute for nonselectable items in multi-valued menus. This display attribute is a curses library visual attribute. menu_grey() returns the grey attribute of <i>menu</i>.</p> <p>The pad character is the character that fills the space between the name and description of an item. set_menu_pad() sets the pad character for <i>menu</i> to <i>pad</i>. menu_pad() returns the pad character of <i>menu</i>.</p> |                |                                    |                |               |                |                                                  |

| SYNOPSIS       | <pre>cc [ flag... ] file... -lmenu -lcurses [ library... ] #include &lt;menu.h&gt;  char *menu_pattern(MENU *menu); int set_menu_pattern(MENU *menu, char *pat);</pre>                                                                                                                                                                                                                                                     |                |                                    |                |               |                |                                                  |            |                                |
| DESCRIPTION    | <p>Every menu has a pattern buffer to match entered data with menu items. <code>set_menu_pattern()</code> sets the pattern buffer to <i>pat</i> and tries to find the first item that matches the pattern. If it does, the matching item becomes the current item. If not, the current item does not change. <code>menu_pattern()</code> returns the string in the pattern buffer of <i>menu</i>.</p>                      |                |                                    |                |               |                |                                                  |            |                                |
| RETURN VALUES  | <p><code>menu_pattern()</code> returns NULL on error. <code>set_menu_pattern()</code> returns one of the following:</p> <table><tr><td>E_OK</td><td>The routine returned successfully.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error.</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An incorrect argument was passed to the routine.</td></tr><tr><td>E_NO_MATCH</td><td>The character failed to match.</td></tr></table> | E_OK           | The routine returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An incorrect argument was passed to the routine. | E_NO_MATCH | The character failed to match. |
| E_OK           | The routine returned successfully.                                                                                                                                                                                                                                                                                                                                                                                         |                |                                    |                |               |                |                                                  |            |                                |
| E_SYSTEM_ERROR | System error.                                                                                                                                                                                                                                                                                                                                                                                                              |                |                                    |                |               |                |                                                  |            |                                |
| E_BAD_ARGUMENT | An incorrect argument was passed to the routine.                                                                                                                                                                                                                                                                                                                                                                           |                |                                    |                |               |                |                                                  |            |                                |
| E_NO_MATCH     | The character failed to match.                                                                                                                                                                                                                                                                                                                                                                                             |                |                                    |                |               |                |                                                  |            |                                |

| SYNOPSIS        | <pre>cc [ flag... ] file... -lmenu -lcurses [ library... ] #include &lt;menu.h&gt;  int set_menu_win(MENU *menu, WINDOW *win); WINDOW *menu_win(MENU *menu); int set_menu_sub(MENU *menu, WINDOW *sub); WINDOW *menu_sub(MENU *menu); int scale_window(MENU *menu, int *rows, int *cols);</pre>                                                                                                                                                                                                           |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| DESCRIPTION     | <p>set_menu_win() sets the window of <i>menu</i> to <i>win</i>. menu_win() returns a pointer to the window of <i>menu</i>. set_menu_sub() sets the subwindow of <i>menu</i> to <i>sub</i>. menu_sub() returns a pointer to the subwindow of <i>menu</i>. scale_window() returns the minimum window size necessary for the subwindow of <i>menu</i>. <i>rows</i> and <i>cols</i> are pointers to the locations used to return the values.</p>                                                              |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| RETURN VALUES   | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table><tr><td>E_OK</td><td>The routine returned successfully.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error.</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An incorrect argument was passed to the routine.</td></tr><tr><td>E_POSTED</td><td>The menu is already posted.</td></tr><tr><td>E_NOT_CONNECTED</td><td>No items are connected to the menu.</td></tr></table> | E_OK           | The routine returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An incorrect argument was passed to the routine. | E_POSTED | The menu is already posted. | E_NOT_CONNECTED | No items are connected to the menu. |
| E_OK            | The routine returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| E_SYSTEM_ERROR  | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| E_BAD_ARGUMENT  | An incorrect argument was passed to the routine.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -lmenu -lcurses [ library... ] #include &lt;menu.h&gt;  int set_menu_win(MENU *menu, WINDOW *win); WINDOW *menu_win(MENU *menu); int set_menu_sub(MENU *menu, WINDOW *sub); WINDOW *menu_sub(MENU *menu); int scale_window(MENU *menu, int *rows, int *cols);</pre>                                                                                                                                                                                                                      |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| <b>DESCRIPTION</b>   | <p>set_menu_win() sets the window of <i>menu</i> to <i>win</i>. menu_win() returns a pointer to the window of <i>menu</i>. set_menu_sub() sets the subwindow of <i>menu</i> to <i>sub</i>. menu_sub() returns a pointer to the subwindow of <i>menu</i>. scale_window() returns the minimum window size necessary for the subwindow of <i>menu</i>. <i>rows</i> and <i>cols</i> are pointers to the locations used to return the values.</p>                                                                         |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| <b>RETURN VALUES</b> | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table> <tr> <td>E_OK</td><td>The routine returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An incorrect argument was passed to the routine.</td></tr> <tr> <td>E_POSTED</td><td>The menu is already posted.</td></tr> <tr> <td>E_NOT_CONNECTED</td><td>No items are connected to the menu.</td></tr> </table> | E_OK           | The routine returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An incorrect argument was passed to the routine. | E_POSTED | The menu is already posted. | E_NOT_CONNECTED | No items are connected to the menu. |
| E_OK                 | The routine returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| E_SYSTEM_ERROR       | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| E_BAD_ARGUMENT       | An incorrect argument was passed to the routine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |
| E_POSTED             | The menu is already posted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                                    |                |               |                |                                                  |          |                             |                 |                                     |

| <b>NAME</b>          | panel_userptr, set_panel_userptr – associate application data with a panels <i>panel</i>                                                                                                                                                                        |                |                 |          |        |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lpanel -lcurses [ <i>library</i> .. ] #include &lt;panel.h&gt;  int <b>set_panel_userptr</b>(PANEL *<i>panel</i>, char *<i>ptr</i>) ; char * <b>panel_userptr</b>(PANEL *<i>panel</i>) ;</pre>                     |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>Each panel has a user pointer available for maintaining relevant information.</p> <p><code>set_panel_userptr()</code> sets the user pointer of <i>panel</i> to <i>ptr</i>.</p> <p><code>panel_userptr()</code> returns the user pointer of <i>panel</i>.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | <p><code>set_panel_userptr</code> returns OK if successful, ERR otherwise.</p> <p><code>panel_userptr</code> returns NULL if there is no user pointer assigned to <i>panel</i>.</p>                                                                             |                |                 |          |        |

| DESCRIPTION | <p>These routines set options that deal with output within <code>curses</code>. All options are initially <code>FALSE</code>, unless otherwise stated. It is not necessary to turn these options off before calling <code>endwin()</code>.</p> <p>With the <code>clearok()</code> routine, if enabled (<i>bf</i> is <code>TRUE</code>), the next call to <code>wrefresh()</code> with this window will clear the screen completely and redraw the entire screen from scratch. This is useful when the contents of the screen are uncertain, or in some cases for a more pleasing visual effect. If the <i>win</i> argument to <code>clearok()</code> is the global variable <code>curscr()</code>, the next call to <code>wrefresh()</code> with any window causes the screen to be cleared and repainted from scratch.</p> <p>With the <code>idlok()</code> routine, if enabled (<i>bf</i> is <code>TRUE</code>), <code>curses</code> considers using the hardware insert/delete line feature of terminals so equipped. If disabled (<i>bf</i> is <code>FALSE</code>), <code>curses</code> very seldom uses this feature. (The insert/delete character feature is always considered.) This option should be enabled only if the application needs insert/delete line, for example, for a screen editor. It is disabled by default because insert/delete line tends to be visually annoying when used in applications where it isn't really needed. If insert/delete line cannot be used, <code>curses</code> redraws the changed portions of all lines.</p> <p>With the <code>idcok()</code> routine, if enabled (<i>bf</i> is <code>TRUE</code>), <code>curses</code> considers using the hardware insert/delete character feature of terminals so equipped. This is enabled by default.</p> <p>With the <code>immedok()</code> routine, if enabled (<i>bf</i> is <code>TRUE</code>), any change in the window image, such as the ones caused by <code>waddch()</code>, <code>wclrtoeol()</code>, <code>wscrl()</code>, etc., automatically cause a call to <code>wrefresh()</code>. However, it may degrade the performance considerably, due to repeated calls to <code>wrefresh()</code>. It is disabled by default.</p> |

## setscrreg(3CURSES)

Normally, the hardware cursor is left at the location of the window cursor being refreshed. The `leaveok()` option allows the cursor to be left wherever the update happens to leave it. It is useful for applications where the cursor is not used, since it reduces the need for cursor motions. If possible, the cursor is made invisible when this option is enabled.

The `setscrreg()` and `wsetscrreg()` routines allow the application programmer to set a software scrolling region in a window. *top* and *bot* are the line numbers of the top and bottom margin of the scrolling region. (Line 0 is the top line of the window.) If this option and `scrollok()` are enabled, an attempt to move off the bottom margin line causes all lines in the scrolling region to scroll up one line. Only the text of the window is scrolled. (Note that this has nothing to do with the use of a physical scrolling region capability in the terminal, like that in the VT100. If `idlok()` is enabled and the terminal has either a scrolling region or insert/delete line capability, they will probably be used by the output routines.)

The `scrollok()` option controls what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If disabled, (*bf* is FALSE), the cursor is left on the bottom line. If enabled, (*bf* is TRUE), `wrefresh()` is called on the window, and the physical terminal and window are scrolled up one line. (Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call `idlok()`.)

The `nl()` and `nonl()` routines control whether newline is translated into carriage return and linefeed on output, and whether return is translated into newline on input. Initially, the translations do occur. By disabling these translations using `nonl()`, `curses` is able to make better use of the linefeed capability, resulting in faster cursor motion.

**RETURN VALUES** `setscrreg()` and `wsetscrreg()` return OK upon success and ERR upon failure. All other routines that return an integer always return OK.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_addch(3CURSES)`, `curs_clear(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curs_scroll(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `clearok()`, `leaveok()`, `scrollok()`, `idcok()`, `nl()`, `nonl()`, and `setscrreg()` may be macros.

`setscrreg(3CURSES)`

The `immedok()` routine is useful for windows that are used as terminal emulators.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| DESCRIPTION | <p>These functions set options that deal with the output within Curses functions.</p> <p>The <code>clearok()</code> function assigns the value of <i>bf</i> to an internal flag in the specified window that governs clearing of the screen during a refresh. If, during a refresh operation on the specified window, the flag in <i>curscr</i> is TRUE or the flag in the specified window is TRUE, <code>clearok()</code> clears the screen, redraws it in its entirety, and sets the flag to FALSE in <i>curscr</i> and in the specified window. The initial state is unspecified.</p> <p>The <code>idlok()</code> function specifies whether the implementation may use the hardware insert-line, delete-line, and scroll features of terminals so equipped. If <i>bf</i> is TRUE, use of these features is enabled. If <i>bf</i> is FALSE, use of these features is disabled and lines are instead redrawn as required. The initial state is FALSE.</p> <p>The <code>leaveok()</code> function controls the cursor position after a refresh operation. If <i>bf</i> is TRUE, refresh operations on the specified window may leave the terminal's cursor at an arbitrary position. If <i>bf</i> is FALSE, then at the end of any refresh operation, the terminal's cursor is positioned at the cursor position contained in the specified window. The initial state is FALSE.</p> <p>The <code>scrollok()</code> function controls the use of scrolling. If <i>bf</i> is TRUE, then scrolling is enabled for the specified window. If <i>bf</i> is FALSE, scrolling is disabled for the specified window. The initial state is FALSE.</p> <p>The <code>setscrreg()</code> and <code>wsetscrreg()</code> functions define a software scrolling region in the current or specified window. The <i>top</i> and <i>bottom</i> arguments are the line numbers of the first and last line defining the scrolling region. (Line 0 is the top line of the window.) If this option and <code>scrollok()</code> are enabled, an attempt to move off the last line of the margin causes all lines in the scrolling region to scroll one line in the</p> |

## setscrreg(3XCURSES)

|                     | direction of the first line. Only characters in the window are scrolled. If a software scrolling region is set and <code>scrollok()</code> is not enabled, an attempt to move off the last line of the margin does not reposition any lines in the scrolling region.                                                                                               |                |                           |                     |                          |            |                                                                        |            |                                                                           |

| USAGE               | <p>The only reason to enable the <code>idlok()</code> feature is to use scrolling to achieve the visual effect of motion of a partial window, such as for a screen editor. In other cases, the feature can be visually annoying.</p> <p>The <code>leaveok()</code> option provides greater efficiency for applications that do not use the cursor.</p>             |                |                           |                     |                          |            |                                                                        |            |                                                                           |

| DESCRIPTION | <p>The following routines give low-level access to various curses functionality. These routines typically are used inside library routines.</p> <p>The <code>def_prog_mode()</code> and <code>def_shell_mode()</code> routines save the current terminal modes as the “program” (in curses) or “shell” (not in curses) state for use by the <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines. This is done automatically by <code>initscr()</code>.</p> <p>The <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines restore the terminal to “program” (in curses) or “shell” (out of curses) state. These are done automatically by <code>endwin()</code> and, after an <code>endwin()</code>, by <code>doupdate()</code>, so they normally are not called.</p> <p>The <code>resetty()</code> and <code>savetty()</code> routines save and restore the state of the terminal modes. <code>savetty()</code> saves the current state in a buffer and <code>resetty()</code> restores the state to what it was at the last call to <code>savetty()</code>.</p> <p>With the <code>getsyx()</code> routine, the current coordinates of the virtual screen cursor are returned in <code>y</code> and <code>x</code>. If <code>leaveok()</code> is currently TRUE, then -1,-1 is returned. If lines have been removed from the top of the screen, using <code>ripoffline()</code>, <code>y</code> and <code>x</code> include these lines; therefore, <code>y</code> and <code>x</code> should be used only as arguments for <code>setsyx()</code>.</p> <p>With the <code>setsyx()</code> routine, the virtual screen cursor is set to <code>y</code>, <code>x</code>. If <code>y</code> and <code>x</code> are both -1, then <code>leaveok()</code> is set. The two routines <code>getsyx()</code> and <code>setsyx()</code> are designed to be used by a library routine, which manipulates curses windows but does not</p> |

## setsyx(3CURSES)

want to change the current position of the program's cursor. The library routine would call `getsyx()` at the beginning, do its manipulation of its own windows, do a `wnoutrefresh()` on its windows, call `setsyx()`, and then call `doupdate()`.

The `riporffline()` routine provides access to the same facility that `slk_init()` (see `curs_slk(3CURSES)`) uses to reduce the size of the screen. `riporffline()` must be called before `initscr()` or `newterm()` is called. If `line` is positive, a line is removed from the top of `stdscr()`; if `line` is negative, a line is removed from the bottom. When this is done inside `initscr()`, the routine `init()` (supplied by the user) is called with two arguments: a window pointer to the one-line window that has been allocated and an integer with the number of columns in the window. Inside this initialization routine, the integer variables `LINES` and `COLS` (defined in `< curses.h>`) are not guaranteed to be accurate and `wrefresh()` or `doupdate()` must not be called. It is allowable to call `wnoutrefresh()` during the initialization routine.

`riporffline()` can be called up to five times before calling `initscr()` or `newterm()`.

With the `curs_set()` routine, the cursor state is set to invisible, normal, or very visible for *visibility* equal to 0, 1, or 2 respectively. If the terminal supports the *visibility* requested, the previous *cursor* state is returned; otherwise, `ERR` is returned.

The `napms()` routine is used to sleep for *ms* milliseconds.

### RETURN VALUES

Except for `curs_set()`, these routines always return `OK`. `curs_set()` returns the previous cursor state, or `ERR` if the requested *visibility* is not supported.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

### SEE ALSO

`curs_initscr(3CURSES)`, `curs_outopts(3CURSES)`, `curs_refresh(3CURSES)`, `curs_scr_dump(3CURSES)`, `curs_slk(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `getsyx()` is a macro, so an ampersand (&) is not necessary before the variables *y* and *x*.

| DESCRIPTION | <p>initscr() is almost always the first routine that should be called (the exceptions are slk_init(), filter(), ripoffline(), use_env() and, for multiple-terminal applications, newterm().) This determines the terminal type and initializes all curses data structures. initscr() also causes the first call to refresh() to clear the screen. If errors occur, initscr() writes an appropriate error message to standard error and exits; otherwise, a pointer is returned to stdscr(). If the program needs an indication of error conditions, newterm() should be used instead of initscr(); initscr() should only be called once per application.</p> <p>A program that outputs to more than one terminal should use the newterm() routine for each terminal instead of initscr(). A program that needs an indication of error conditions, so it can continue to run in a line-oriented mode if the terminal cannot support a screen-oriented program, would also use this routine. The routine newterm() should be called once for each terminal. It returns a variable of type SCREEN * which should be saved as a reference to that terminal. The arguments are the <i>type</i> of the terminal to be used in place of \$TERM, a file pointer for output to the terminal, and another file pointer for input from the terminal (if <i>type</i> is NULL, \$TERM will be used). The program must also call endwin() for each terminal being used before exiting from curses. If newterm() is called more than once for the same terminal, the first terminal referred to must be the last one for which endwin() is called.</p> <p>A program should always call endwin() before exiting or escaping from curses mode temporarily. This routine restores tty modes, moves the cursor to the lower left-hand corner of the screen and resets the terminal into the proper non-visual mode. Calling refresh() or doupdate() after a temporary escape causes the program to resume visual mode.</p> <p>The isendwin() routine returns TRUE if endwin() has been called without any subsequent calls to wrefresh(), and FALSE otherwise.</p> |

set\_term(3CURSES)

The `set_term()` routine is used to switch between different terminals. The screen reference `new` becomes the new current terminal. The previous terminal is returned by the routine. This is the only routine which manipulates `SCREEN` pointers; all other routines affect only the current terminal.

The `delscreen()` routine frees storage associated with the `SCREEN` data structure. The `endwin()` routine does not do this, so `delscreen()` should be called after `endwin()` if a particular `SCREEN` is no longer needed.

**RETURN VALUES** `endwin()` returns the integer `ERR` upon failure and `OK` upon successful completion.

Routines that return pointers always return `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_kernel(3CURSES)`, `curs_refresh(3CURSES)`, `curs_slk(3CURSES)`, `curs_util(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `initscr()` and `newterm()` may be macros.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| DESCRIPTION | <p>These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, curses routines are more suitable and their use is recommended.</p> <p>Initially, <code>setupterm()</code> should be called. Note that <code>setupterm()</code> is automatically called by <code>initscr()</code> and <code>newterm()</code>. This defines the set of terminal-dependent variables (listed in <code>terminfo(4)</code>). The <i>terminfo</i> variables <code>lines</code> and <code>columns</code> are initialized by <code>setupterm()</code> as follows: If <code>use_env(FALSE)</code> has been called, values for <code>lines</code> and <code>columns</code> specified in <i>terminfo</i> are used. Otherwise, if the environment variables <code>LINES</code> and <code>COLUMNS</code> exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database are used.</p> <p>The headers <code>&lt;curses.h&gt;</code> and <code>&lt;term.h&gt;</code> should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through <code>tparm()</code> to instantiate them. All <i>terminfo</i> strings (including the output</p> |

## setterm(3CURSES)

of `tparm()` should be printed with `tputs()` or `putp()`. Call the `reset_shell_mode()` routine to restore the tty modes before exiting (see `curs_kernel(3CURSES)`). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call `reset_shell_mode` and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call `reset_prog_mode` after returning from the shell.

The `setupterm()` routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fildef* which is initialized for output. If *errret* is not null, then `setupterm()` returns OK or ERR and stores a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo* database could not be found. If *errret* is null, `setupterm()` prints an error message upon finding an error and exits. Thus, the simplest call is:

`setupterm((char *)0, 1, (int *)0);` which uses all the defaults and sends the output to `stdout`.

The `setterm()` routine is being replaced by `setupterm()`. The call:

`setupterm(term, 1, (int *)0)` provides the same functionality as `setterm(term)`. The `setterm()` routine is included here for compatibility and is supported at Level 2.

The `set_curterm()` routine sets the variable `cur_term` to *nterm*, and makes all of the *terminfo* boolean, numeric, and string variables use the values from *nterm*.

The `del_curterm()` routine frees the space pointed to by *oterm* and makes it available for further use. If *oterm* is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another `setupterm()` has been called.

The `restartterm()` routine is similar to `setupterm()` and `initscr()`, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The `tparm()` routine instantiates the string *str* with parameters *pi*. A pointer is returned to the result of *str* with the parameters applied.

The `tputs()` routine applies padding information to the string *str* and outputs it. The *str* must be a *terminfo* string variable or the return value from `tparm()`, `tgetstr()`, or `tgoto()`. *affcnt* is the number of lines affected, or 1 if not applicable. *putc* is a `putchar()`-like routine to which the characters are passed, one at a time.

setterm(3CURSES)

The `putp()` routine calls `tputs(str, 1, putchar)`. Note that the output of `putpA()` always goes to `stdout`, not to the *fil*des specified in `setupterm()`.

The `vidputs()` routine displays the string on the terminal in the video attribute mode *attrs*, which is any combination of the attributes listed in `curses(3CURSES)`. The characters are passed to the `putchar()`-like routine `putc()`.

The `vidattr()` routine is like the `vidputs()` routine, except that it outputs through `putchar()`.

The `mvcur()` routine provides low-level cursor motion.

The `tigetflag()`, `tigetnum()` and `tigetstr()` routines return the value of the capability corresponding to the *terminfo* *capname* passed to them, such as `xenl`.

With the `tigetflag()` routine, the value `-1` is returned if *capname* is not a boolean capability.

With the `tigetnum()` routine, the value `-2` is returned if *capname* is not a numeric capability.

With the `tigetstr()` routine, the value `(char *)-1` is returned if *capname* is not a string capability.

The *capname* for each capability is given in the table column entitled *capname* code in the capabilities section of `terminfo(4)`.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

**RETURN VALUES** All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_initscr(3CURSES)`, `curs_kernel(3CURSES)`, `curs_termcap(3CURSES)`, `curses(3CURSES)`, `putc(3C)`, `terminfo(4)`, `attributes(5)`

setterm(3CURSES)

**NOTES** | The header `< curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

The `setupterm()` routine should be used in place of `setterm()`.

Note that `vidattr()` and `vidputs()` may be macros.

|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME          | set_term – switch between terminals                                                                                                                                                                                            |
| SYNOPSIS      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  SCREEN *set_term(SCREEN *new);</pre> |
| PARAMETERS    | <i>new</i> Is the new terminal to which the set_term() function will switch.                                                                                                                                                   |
| DESCRIPTION   | The set_term() function switches to the terminal specified by <i>new</i> and returns a screen reference to the previous terminal. Calls to subsequent X/Open Curses functions affect the new terminal.                         |
| RETURN VALUES | On success, the set_term() function returns a pointer to the previous screen. Otherwise, it returns a null pointer.                                                                                                            |
| ERRORS        | None.                                                                                                                                                                                                                          |
| ATTRIBUTES    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                |

| SYNOPSIS        | <pre>cc [ flag... ] file... -lmenu -lcurses [ library... ] #include &lt;menu.h&gt;  int set_current_item(MENU *menu, ITEM *item); ITEM *current_item(MENU *menu); int set_top_row(MENU *menu, int row); int top_row(MENU *menu); int item_index(ITEM *item);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                                    |                |               |                |                                                  |             |                                                                        |                 |                                     |
| DESCRIPTION     | <p>The current item of a menu is the item where the cursor is currently positioned. <code>set_current_item()</code> sets the current item of <i>menu</i> to <i>item</i>. <code>current_item()</code> returns a pointer to the the current item in <i>menu</i>.</p> <p><code>set_top_row()</code> sets the top row of <i>menu</i> to <i>row</i>. The left-most item on the new top row becomes the current item. <code>top_row()</code> returns the number of the menu row currently displayed at the top of <i>menu</i>.</p> <p><code>item_index()</code> returns the index to the <i>item</i> in the item pointer array. The value of this index ranges from 0 through <i>N</i>-1, where <i>N</i> is the total number of items connected to the menu.</p> |                |                                    |                |               |                |                                                  |             |                                                                        |                 |                                     |
| RETURN VALUES   | <p><code>current_item()</code> returns NULL on error.</p> <p><code>top_row()</code> and <code>index_item()</code> return -1 on error.</p> <p><code>set_current_item()</code> and <code>set_top_row()</code> return one of the following:</p> <table><tr><td>E_OK</td><td>The routine returned successfully.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error.</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An incorrect argument was passed to the routine.</td></tr><tr><td>E_BAD_STATE</td><td>The routine was called from an initialization or termination function.</td></tr><tr><td>E_NOT_CONNECTED</td><td>No items are connected to the menu.</td></tr></table>                                                                                      | E_OK           | The routine returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An incorrect argument was passed to the routine. | E_BAD_STATE | The routine was called from an initialization or termination function. | E_NOT_CONNECTED | No items are connected to the menu. |
| E_OK            | The routine returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                                    |                |               |                |                                                  |             |                                                                        |                 |                                     |
| E_SYSTEM_ERROR  | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                                    |                |               |                |                                                  |             |                                                                        |                 |                                     |
| E_BAD_ARGUMENT  | An incorrect argument was passed to the routine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                                    |                |               |                |                                                  |             |                                                                        |                 |                                     |
| E_BAD_STATE     | The routine was called from an initialization or termination function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                                    |                |               |                |                                                  |             |                                                                        |                 |                                     |

| DESCRIPTION | <p>             These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, curses routines are more suitable and their use is recommended.         </p> <p>             Initially, <code>setupterm()</code> should be called. Note that <code>setupterm()</code> is automatically called by <code>initscr()</code> and <code>newterm()</code>. This defines the set of terminal-dependent variables (listed in <i>terminfo</i>(4)). The <i>terminfo</i> variables <code>lines</code> and <code>columns</code> are initialized by <code>setupterm()</code> as follows: If <code>use_env(FALSE)</code> has been called, values for <code>lines</code> and <code>columns</code> specified in <i>terminfo</i> are used. Otherwise, if the environment variables <code>LINES</code> and <code>COLUMNS</code> exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database are used.         </p> <p>             The headers <code>&lt;curses.h&gt;</code> and <code>&lt;term.h&gt;</code> should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through <code>tparm()</code> to instantiate them. All <i>terminfo</i> strings (including the output         </p> |

## setupterm(3CURSES)

of `tparm()` should be printed with `tputs()` or `putp()`. Call the `reset_shell_mode()` routine to restore the tty modes before exiting (see `curs_kernel(3CURSES)`). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call `reset_shell_mode` and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call `reset_prog_mode` after returning from the shell.

The `setupterm()` routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fildev* which is initialized for output. If *errret* is not null, then `setupterm()` returns OK or ERR and stores a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo* database could not be found. If *errret* is null, `setupterm()` prints an error message upon finding an error and exits. Thus, the simplest call is:

`setupterm((char *)0, 1, (int *)0);` which uses all the defaults and sends the output to `stdout`.

The `setterm()` routine is being replaced by `setupterm()`. The call:

`setupterm(term, 1, (int *)0)` provides the same functionality as `setterm(term)`. The `setterm()` routine is included here for compatibility and is supported at Level 2.

The `set_curterm()` routine sets the variable `cur_term` to *nterm*, and makes all of the *terminfo* boolean, numeric, and string variables use the values from *nterm*.

The `del_curterm()` routine frees the space pointed to by *oterm* and makes it available for further use. If *oterm* is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another `setupterm()` has been called.

The `restartterm()` routine is similar to `setupterm()` and `initscr()`, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The `tparm()` routine instantiates the string *str* with parameters *pi*. A pointer is returned to the result of *str* with the parameters applied.

The `tputs()` routine applies padding information to the string *str* and outputs it. The *str* must be a *terminfo* string variable or the return value from `tparm()`, `tgetstr()`, or `tgoto()`. *affcnt* is the number of lines affected, or 1 if not applicable. *putc* is a `putchar()`-like routine to which the characters are passed, one at a time.

## setupterm(3CURSES)

The `putp()` routine calls `tputs(str, 1, putchar)`. Note that the output of `putpA()` always goes to `stdout`, not to the *fildev* specified in `setupterm()`.

The `vidputs()` routine displays the string on the terminal in the video attribute mode *attrs*, which is any combination of the attributes listed in `curses(3CURSES)`. The characters are passed to the `putchar()`-like routine `putc()`.

The `vidattr()` routine is like the `vidputs()` routine, except that it outputs through `putchar()`.

The `mvcur()` routine provides low-level cursor motion.

The `tigetflag()`, `tigetnum()` and `tigetstr()` routines return the value of the capability corresponding to the *terminfo capname* passed to them, such as `xenl`.

With the `tigetflag()` routine, the value `-1` is returned if *capname* is not a boolean capability.

With the `tigetnum()` routine, the value `-2` is returned if *capname* is not a numeric capability.

With the `tigetstr()` routine, the value `(char *)-1` is returned if *capname* is not a string capability.

The *capname* for each capability is given in the table column entitled *capname* code in the capabilities section of `terminfo(4)`.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

## RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

## SEE ALSO

`curs_initscr(3CURSES)`, `curs_kernel(3CURSES)`, `curs_termcap(3CURSES)`, `curses(3CURSES)`, `putc(3C)`, `terminfo(4)`, `attributes(5)`

`setupterm(3CURSES)`

**NOTES** | The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

The `setupterm()` routine should be used in place of `setterm()`.

Note that `vidattr()` and `vidputs()` may be macros.

## setupterm(3XCURSES)

| NAME        | del_curterm, restartterm, set_curterm, setupterm – interfaces to the terminfo database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |   |        |   |                             |    |                                      |

| DESCRIPTION | <p>Within X/Open Curses, the <code>setupterm()</code> function is automatically called by the <code>initscr</code> (3XC) and <code>newterm</code> (3XC) functions. This function can be also be used outside of X/Open Curses when a program has to deal directly with the <code>terminfo</code> database to handle certain terminal capabilities. The use of appropriate X/Open Curses functions is recommended in all other situations.</p> <p>The <code>setupterm()</code> function loads terminal-dependent variables for the <code>terminfo</code> layer of X/Open Curses. The <code>setupterm()</code> function initializes the <code>terminfo</code> variables <code>lines</code> and <code>columns</code> such that if <code>use_env</code> (FALSE) has been called, the <code>terminfo</code> values assigned in the database are used regardless of the environmental variables <code>LINES</code> and <code>COLUMNS</code> or the program's window dimensions; when <code>use_env</code> (TRUE) has been called, which is the default, the environment variables <code>LINES</code> and <code>COLUMNS</code> are used, if they exist. If the environment variables do not exist and the program is running in a window, the current window size is used.</p> <p>The <code>term</code> parameter of <code>setupterm()</code> specifies the terminal; if null, terminal type is taken from the <code>TERM</code> environment variable. All output is sent to <code>fildes</code> which is initialized for output. If <code>errret</code> is not null, OK or ERR is returned and a status value is stored in the integer pointed to by <code>errret</code>. The following status values may be returned:</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>1</td><td>Normal</td></tr><tr><td>0</td><td>Terminal could not be found</td></tr><tr><td>-1</td><td>terminfo database could not be found</td></tr></tbody></table> <p>If <code>errret</code> is null, an error message is printed, and the <code>setupterm()</code> function calls the <code>exit()</code> function with a non-zero parameter.</p> | Value | Description | 1 | Normal | 0 | Terminal could not be found | -1 | terminfo database could not be found |
| Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |       |             |   |        |   |                             |    |                                      |

setupterm(3XCURSES)

The `set_curterm()` function sets the `cur_term` variable to *nterm*. The values from *nterm* as well as other state information for the terminal are used by X/Open Curses functions such as `beep(3XCURSES)`, `flash(3XCURSES)`, `mvcur(3XCURSES)`, `tigetflag(3XCURSES)`, `tigetstr(3XCURSES)`, and `tigetnum(3XCURSES)`.

The `del_curterm()` function frees the space pointed to by *oterm*. If *oterm* and the `cur_term` variable are the same, all Boolean, numeric, or string `terminfo` variables will refer to invalid memory locations until you call `setupterm()` and specify a new terminal type.

The `restartterm()` function assumes that a call to `setupterm()` has already been made (probably from `initscr()` or `newterm()`). It allows you to specify a new terminal type in *term* and updates the data returned by `baudrate(3XCURSES)` based on *fildev*. Other information created by the `initscr()`, `newterm()`, and `setupterm()` functions is preserved.

|            |               |                                                                 |
|------------|---------------|-----------------------------------------------------------------|
| PARAMETERS | <i>oterm</i>  | Is the terminal type for which to free space.                   |
|            | <i>term</i>   | Is the terminal type for which variables are set.               |
|            | <i>fildev</i> | Is a file descriptor initialized for output.                    |
|            | <i>errret</i> | Is a pointer to an integer in which the status value is stored. |
|            | <i>nterm</i>  | Is the new terminal to become the current terminal.             |

**RETURN VALUES** On success, the `set_curterm()` function returns the previous value of `cur_term`. Otherwise, it returns a null pointer.

On success, the other functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lpanel -lcurses [ library .. ] #include &lt;panel.h&gt;  int show_panel (PANEL *panel) ; int hide_panel (PANEL *panel) ; int panel_hidden (PANEL *panel) ;</pre>                                                                                                                                                                                          |                |                 |          |        |
| DESCRIPTION    | <p>show_panel () makes <i>panel</i>, previously hidden, visible and places it on top of the deck of panels.</p> <p>hide_panel () removes <i>panel</i> from the panel deck and, thus, hides it from view. The internal data structure of the panel is retained.</p> <p>panel_hidden () returns TRUE (1) or FALSE (0) indicating whether or not <i>panel</i> is in the deck of panels.</p> |                |                 |          |        |
| RETURN VALUES  | show_panel () and hide_panel () return the integer OK upon successful completion or ERR upon error.                                                                                                                                                                                                                                                                                      |                |                 |          |        |

| DESCRIPTION | <p>curses manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, <i>curses</i> takes over the bottom line of <code>stdscr</code>, reducing the size of <code>stdscr</code> and the variable <code>LINES</code>. <i>curses</i> standardizes on eight labels of up to eight characters each.</p> <p>To use soft labels, the <code>slk_init()</code> routine must be called before <code>initscr()</code> or <code>newterm()</code> is called. If <code>initscr()</code> eventually uses a line from <code>stdscr</code> to emulate the soft labels, then <code>fmt</code> determines how the labels are arranged on the screen. Setting <code>fmt</code> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement.</p> <p>With the <code>slk_set()</code> routine, <i>labnum</i> is the label number, from 1 to 8. <i>label</i> is the string to be put on the label, up to eight characters in length. A null string or a null pointer sets up a blank label. <code>fmt</code> is either 0, 1, or 2, indicating whether the label is to be left-justified, centered, or right-justified, respectively, within the label.</p> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> routines correspond to the <code>wrefresh()</code> and <code>wnoutrefresh()</code> routines.</p> <p>With the <code>slk_label()</code> routine, the current label for label number <i>labnum</i> is returned with leading and trailing blanks stripped.</p> <p>With the <code>slk_clear()</code> routine, the soft labels are cleared from the screen.</p> <p>With the <code>slk_restore()</code> routine, the soft labels are restored to the screen after a <code>slk_clear()</code> is performed.</p> |

slk\_attroff(3CURSES)

With the `slk_touch()` routine, all the soft labels are forced to be output the next time a `slk_noutrefresh()` is performed.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` routines correspond to `attron()`, `attrset()`, and `attroff()`. They have an effect only if soft labels are simulated on the bottom line of the screen.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`slk_label()` returns `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_attr(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Most applications would use `slk_noutrefresh()` because a `wrefresh()` is likely to follow soon.

slk\_attr\_off(3XCURSES)

**DESCRIPTION**

The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of *stdscr*, reducing the size of *stdscr* and the value of the `LINES` external variable. There can be up to eight labels of up to eight display columns each.

To use soft labels, `slk_init()` must be called before calling `initscr(3XCURSES)`, `newterm(3XCURSES)`, or `ripgoffline(3XCURSES)`. If `initscr()` eventually uses a line from *stdscr* to emulate the soft labels, then *fnt* determines how the labels are arranged on the screen. Setting *fnt* to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for *fnt* are unspecified.

The `slk_init()` function has the effect of calling `ripgoffline()` to reserve one screen line to accommodate the requested format.

The `slk_set()` and `slk_wset()` functions specify the text of soft label number *labnum*, within the range from 1 to and including 8. The *label* argument is the string to be put the lable. With `slk_set()` and `slk_wset()`, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The *justify* argument can have the following values to indicate how to justify *label* within the space reserved for it:

- 0           Align the start of *label* with the start of the space
- 1           Center *label* within the space
- 2           Align the end of *label* with the end of the space

The `slk_refresh()` and `slk_noutrefresh()` functions correspond to the `wrefresh(3XCURSES)` and `wnoutrefresh(3XCURSES)` functions.

The `slk_label()` function obtains soft label number *labnum*.

The `slk_clear()` function immediately clears the soft labels from the screen.

The `slk_restore()` function immediately restores the soft labels to the screen after a call to `slk_clear()`.

The `slk_touch()` function forces all the soft labels to be output the next time `slk_refresh()` or `slk_noutrefresh()` is called.

The `slk_attron()`, `slk_attrset()`, and `slk_attrtff()` functions correspond to the `attron(3XCURSES)`, `attrset(3XCURSES)`, and `attroff(3XCURSES)` functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.

The `slk_attr_on()`, `slk_attr_off()`, `slk_attr_set()` and `slk_color()` functions correspond to the `attr_on(3XCURSES)`, `attr_off(3XCURSES)`, `attr_set(3XCURSES)`, and `color_set(3XCURSES)` functions. As a result, they support color and the attribute constants with the `WA_` prefix.

`slk_attr_off(3XCURSES)`

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | <p>The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of <i>stdscr</i>, reducing the size of <i>stdscr</i> and the value of the <code>LINES</code> external variable. There can be up to eight labels of up to eight display columns each.</p> <p>To use soft labels, <code>slk_init()</code> must be called before calling <code>initscr(3XCURSES)</code>, <code>newterm(3XCURSES)</code>, or <code>ripoffline(3XCURSES)</code>. If <code>initscr()</code> eventually uses a line from <i>stdscr</i> to emulate the soft labels, then <i>fmt</i> determines how the labels are arranged on the screen. Setting <i>fmt</i> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for <i>fmt</i> are unspecified.</p> <p>The <code>slk_init()</code> function has the effect of calling <code>ripoffline()</code> to reserve one screen line to accommodate the requested format.</p> <p>The <code>slk_set()</code> and <code>slk_wset()</code> functions specify the text of soft label number <i>labnum</i>, within the range from 1 to and including 8. The <i>label</i> argument is the string to be put the lable. With <code>slk_set()</code> and <code>slk_wset()</code>, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The <i>justify</i> argument can have the following values to indicate how to justify <i>label</i> within the space reserved for it:</p> <ul style="list-style-type: none"> <li>0           Align the start of <i>label</i> with the start of the space</li> <li>1           Center <i>label</i> within the space</li> <li>2           Align the end of <i>label</i> with the end of the space</li> </ul> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> functions correspond to the <code>wrefresh(3XCURSES)</code> and <code>wnoutrefresh(3XCURSES)</code> functions.</p> <p>The <code>slk_label()</code> function obtains soft label number <i>labnum</i>.</p> <p>The <code>slk_clear()</code> function immediately clears the soft labels from the screen.</p> <p>The <code>slk_restore()</code> function immediately restores the soft labels to the screen after a call to <code>slk_clear()</code>.</p> <p>The <code>slk_touch()</code> function forces all the soft labels to be output the next time <code>slk_refresh()</code> or <code>slk_noutrefresh()</code> is called.</p> <p>The <code>slk_attron()</code>, <code>slk_attrset()</code>, and <code>slk_attroff()</code> functions correspond to the <code>attron(3XCURSES)</code>, <code>attrset(3XCURSES)</code>, and <code>attroff(3XCURSES)</code> functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.</p> <p>The <code>slk_attr_on()</code>, <code>slk_attr_off()</code>, <code>slk_attr_set()</code> and <code>slk_color()</code> functions correspond to the <code>attr_on(3XCURSES)</code>, <code>attr_off(3XCURSES)</code>, <code>attr_set(3XCURSES)</code>, and <code>color_set(3XCURSES)</code> functions. As a result, they support color and the attribute constants with the <code>WA_</code> prefix.</p> |

slk\_attroff(3XCURSES)

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

| DESCRIPTION | <p>curses manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, <i>curses</i> takes over the bottom line of <code>stdscr</code>, reducing the size of <code>stdscr</code> and the variable <code>LINES</code>. <i>curses</i> standardizes on eight labels of up to eight characters each.</p> <p>To use soft labels, the <code>slk_init()</code> routine must be called before <code>initscr()</code> or <code>newterm()</code> is called. If <code>initscr()</code> eventually uses a line from <code>stdscr</code> to emulate the soft labels, then <code>fmt</code> determines how the labels are arranged on the screen. Setting <code>fmt</code> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement.</p> <p>With the <code>slk_set()</code> routine, <i>labnum</i> is the label number, from 1 to 8. <i>label</i> is the string to be put on the label, up to eight characters in length. A null string or a null pointer sets up a blank label. <code>fmt</code> is either 0, 1, or 2, indicating whether the label is to be left-justified, centered, or right-justified, respectively, within the label.</p> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> routines correspond to the <code>wrefresh()</code> and <code>wnoutrefresh()</code> routines.</p> <p>With the <code>slk_label()</code> routine, the current label for label number <i>labnum</i> is returned with leading and trailing blanks stripped.</p> <p>With the <code>slk_clear()</code> routine, the soft labels are cleared from the screen.</p> <p>With the <code>slk_restore()</code> routine, the soft labels are restored to the screen after a <code>slk_clear()</code> is performed.</p> |

slk\_attron(3CURSES)

With the `slk_touch()` routine, all the soft labels are forced to be output the next time a `slk_noutrefresh()` is performed.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` routines correspond to `attron()`, `attrset()`, and `attroff()`. They have an effect only if soft labels are simulated on the bottom line of the screen.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`slk_label()` returns `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_attr(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Most applications would use `slk_noutrefresh()` because a `wrefresh()` is likely to follow soon.

Currently, this must be a null pointer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |              |                                                   |             |                                                                     |                          |                  |            |                                                             |               |                                  |              |                                          |                |                                                       |
| <i>color_pair_number</i> | Is a color pair.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |              |                                                   |             |                                                                     |                          |                  |            |                                                             |               |                                  |              |                                          |                |                                                       |
| <i>fmt</i>               | Is the format of how the labels are arranged on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |              |                                                   |             |                                                                     |                          |                  |            |                                                             |               |                                  |              |                                          |                |                                                       |
| <i>labnum</i>            | Is the number of the soft label.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |              |                                                   |             |                                                                     |                          |                  |            |                                                             |               |                                  |              |                                          |                |                                                       |
| <i>label</i>             | Is the name to be given to a soft label.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |              |                                                   |             |                                                                     |                          |                  |            |                                                             |               |                                  |              |                                          |                |                                                       |
| <i>justify</i>           | Is a number indicating how to justify the label name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |              |                                                   |             |                                                                     |                          |                  |            |                                                             |               |                                  |              |                                          |                |                                                       |

slk\_attr\_on(3XCURSES)

**DESCRIPTION**

The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of *stdscr*, reducing the size of *stdscr* and the value of the `LINES` external variable. There can be up to eight labels of up to eight display columns each.

To use soft labels, `slk_init()` must be called before calling `initscr(3XCURSES)`, `newterm(3XCURSES)`, or `ripoffline(3XCURSES)`. If `initscr()` eventually uses a line from *stdscr* to emulate the soft labels, then *fnt* determines how the labels are arranged on the screen. Setting *fnt* to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for *fnt* are unspecified.

The `slk_init()` function has the effect of calling `ripoffline()` to reserve one screen line to accommodate the requested format.

The `slk_set()` and `slk_wset()` functions specify the text of soft label number *labnum*, within the range from 1 to and including 8. The *label* argument is the string to be put the lable. With `slk_set()` and `slk_wset()`, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The *justify* argument can have the following values to indicate how to justify *label* within the space reserved for it:

- 0           Align the start of *label* with the start of the space
- 1           Center *label* within the space
- 2           Align the end of *label* with the end of the space

The `slk_refresh()` and `slk_noutrefresh()` functions correspond to the `wrefresh(3XCURSES)` and `wnoutrefresh(3XCURSES)` functions.

The `slk_label()` function obtains soft label number *labnum*.

The `slk_clear()` function immediately clears the soft labels from the screen.

The `slk_restore()` function immediately restores the soft labels to the screen after a call to `slk_clear()`.

The `slk_touch()` function forces all the soft labels to be output the next time `slk_refresh()` or `slk_noutrefresh()` is called.

The `slk_attron()`, `slk_attrset()`, and `slk_attrtff()` functions correspond to the `attron(3XCURSES)`, `attrset(3XCURSES)`, and `attroff(3XCURSES)` functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.

The `slk_attr_on()`, `slk_attr_off()`, `slk_attr_set()` and `slk_color()` functions correspond to the `attr_on(3XCURSES)`, `attr_off(3XCURSES)`, `attr_set(3XCURSES)`, and `color_set(3XCURSES)` functions. As a result, they support color and the attribute constants with the `WA_` prefix.

slk\_attr\_on(3XCURSES)

|                     | <p>The <i>opts</i> argument is reserved for definition in a future release. | RETURN VALUES       | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| ERRORS              | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| USAGE               | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

**DESCRIPTION**

The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of *stdscr*, reducing the size of *stdscr* and the value of the `LINES` external variable. There can be up to eight labels of up to eight display columns each.

To use soft labels, `slk_init()` must be called before calling `initscr(3XCURSES)`, `newterm(3XCURSES)`, or `ripoffline(3XCURSES)`. If `initscr()` eventually uses a line from *stdscr* to emulate the soft labels, then *fnt* determines how the labels are arranged on the screen. Setting *fnt* to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for *fnt* are unspecified.

The `slk_init()` function has the effect of calling `ripoffline()` to reserve one screen line to accommodate the requested format.

The `slk_set()` and `slk_wset()` functions specify the text of soft label number *labnum*, within the range from 1 to and including 8. The *label* argument is the string to be put the lable. With `slk_set()` and `slk_wset()`, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The *justify* argument can have the following values to indicate how to justify *label* within the space reserved for it:

- 0           Align the start of *label* with the start of the space
- 1           Center *label* within the space
- 2           Align the end of *label* with the end of the space

The `slk_refresh()` and `slk_noutrefresh()` functions correspond to the `wrefresh(3XCURSES)` and `wnoutrefresh(3XCURSES)` functions.

The `slk_label()` function obtains soft label number *labnum*.

The `slk_clear()` function immediately clears the soft labels from the screen.

The `slk_restore()` function immediately restores the soft labels to the screen after a call to `slk_clear()`.

The `slk_touch()` function forces all the soft labels to be output the next time `slk_refresh()` or `slk_noutrefresh()` is called.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` functions correspond to the `attron(3XCURSES)`, `attrset(3XCURSES)`, and `attroff(3XCURSES)` functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.

The `slk_attr_on()`, `slk_attr_off()`, `slk_attr_set()` and `slk_color()` functions correspond to the `attr_on(3XCURSES)`, `attr_off(3XCURSES)`, `attr_set(3XCURSES)`, and `color_set(3XCURSES)` functions. As a result, they support color and the attribute constants with the `WA_` prefix.

slk\_atron(3XCURSES)

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. | <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

| DESCRIPTION | <p>curses manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, <i>curses</i> takes over the bottom line of <code>stdscr</code>, reducing the size of <code>stdscr</code> and the variable <code>LINES</code>. <i>curses</i> standardizes on eight labels of up to eight characters each.</p> <p>To use soft labels, the <code>slk_init()</code> routine must be called before <code>initscr()</code> or <code>newterm()</code> is called. If <code>initscr()</code> eventually uses a line from <code>stdscr</code> to emulate the soft labels, then <code>fmt</code> determines how the labels are arranged on the screen. Setting <code>fmt</code> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement.</p> <p>With the <code>slk_set()</code> routine, <i>labnum</i> is the label number, from 1 to 8. <i>label</i> is the string to be put on the label, up to eight characters in length. A null string or a null pointer sets up a blank label. <code>fmt</code> is either 0, 1, or 2, indicating whether the label is to be left-justified, centered, or right-justified, respectively, within the label.</p> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> routines correspond to the <code>wrefresh()</code> and <code>wnoutrefresh()</code> routines.</p> <p>With the <code>slk_label()</code> routine, the current label for label number <i>labnum</i> is returned with leading and trailing blanks stripped.</p> <p>With the <code>slk_clear()</code> routine, the soft labels are cleared from the screen.</p> <p>With the <code>slk_restore()</code> routine, the soft labels are restored to the screen after a <code>slk_clear()</code> is performed.</p> |

slk\_attrset(3CURSES)

With the `slk_touch()` routine, all the soft labels are forced to be output the next time a `slk_noutrefresh()` is performed.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` routines correspond to `attron()`, `attrset()`, and `attroff()`. They have an effect only if soft labels are simulated on the bottom line of the screen.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`slk_label()` returns `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_attr(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Most applications would use `slk_noutrefresh()` because a `wrefresh()` is likely to follow soon.

slk\_attr\_set(3XCURSES)

**DESCRIPTION**

The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of *stdscr*, reducing the size of *stdscr* and the value of the *LINES* external variable. There can be up to eight labels of up to eight display columns each.

To use soft labels, *slk\_init()* must be called before calling *initscr(3XCURSES)*, *newterm(3XCURSES)*, or *ripgoffline(3XCURSES)*. If *initscr()* eventually uses a line from *stdscr* to emulate the soft labels, then *fnt* determines how the labels are arranged on the screen. Setting *fnt* to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for *fnt* are unspecified.

The *slk\_init()* function has the effect of calling *ripgoffline()* to reserve one screen line to accommodate the requested format.

The *slk\_set()* and *slk\_wset()* functions specify the text of soft label number *labnum*, within the range from 1 to and including 8. The *label* argument is the string to be put the lable. With *slk\_set()* and *slk\_wset()*, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The *justify* argument can have the following values to indicate how to justify *label* within the space reserved for it:

- 0           Align the start of *label* with the start of the space
- 1           Center *label* within the space
- 2           Align the end of *label* with the end of the space

The *slk\_refresh()* and *slk\_noutrefresh()* functions correspond to the *wrefresh(3XCURSES)* and *wnoutrefresh(3XCURSES)* functions.

The *slk\_label()* function obtains soft label number *labnum*.

The *slk\_clear()* function immediately clears the soft labels from the screen.

The *slk\_restore()* function immediately restores the soft labels to the screen after a call to *slk\_clear()*.

The *slk\_touch()* function forces all the soft labels to be output the next time *slk\_refresh()* or *slk\_noutrefresh()* is called.

The *slk\_attron()*, *slk\_attrset()*, and *slk\_attrtff()* functions correspond to the *attron(3XCURSES)*, *attrset(3XCURSES)*, and *attroff(3XCURSES)* functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.

The *slk\_attr\_on()*, *slk\_attr\_off()*, *slk\_attr\_set()* and *slk\_color()* functions correspond to the *attr\_on(3XCURSES)*, *attr\_off(3XCURSES)*, *attr\_set(3XCURSES)*, and *color\_set(3XCURSES)* functions. As a result, they support color and the attribute constants with the *WA\_* prefix.

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |

| <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

**DESCRIPTION**

The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of *stdscr*, reducing the size of *stdscr* and the value of the `LINES` external variable. There can be up to eight labels of up to eight display columns each.

To use soft labels, `slk_init()` must be called before calling `initscr(3XCURSES)`, `newterm(3XCURSES)`, or `ripoffline(3XCURSES)`. If `initscr()` eventually uses a line from *stdscr* to emulate the soft labels, then *fmt* determines how the labels are arranged on the screen. Setting *fmt* to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for *fmt* are unspecified.

The `slk_init()` function has the effect of calling `ripoffline()` to reserve one screen line to accommodate the requested format.

The `slk_set()` and `slk_wset()` functions specify the text of soft label number *labnum*, within the range from 1 to and including 8. The *label* argument is the string to be put the lable. With `slk_set()` and `slk_wset()`, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The *justify* argument can have the following values to indicate how to justify *label* within the space reserved for it:

- 0           Align the start of *label* with the start of the space
- 1           Center *label* within the space
- 2           Align the end of *label* with the end of the space

The `slk_refresh()` and `slk_noutrefresh()` functions correspond to the `wrefresh(3XCURSES)` and `wnoutrefresh(3XCURSES)` functions.

The `slk_label()` function obtains soft label number *labnum*.

The `slk_clear()` function immediately clears the soft labels from the screen.

The `slk_restore()` function immediately restores the soft labels to the screen after a call to `slk_clear()`.

The `slk_touch()` function forces all the soft labels to be output the next time `slk_refresh()` or `slk_noutrefresh()` is called.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` functions correspond to the `attron(3XCURSES)`, `attrset(3XCURSES)`, and `attroff(3XCURSES)` functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.

The `slk_attr_on()`, `slk_attr_off()`, `slk_attr_set()` and `slk_color()` functions correspond to the `attr_on(3XCURSES)`, `attr_off(3XCURSES)`, `attr_set(3XCURSES)`, and `color_set(3XCURSES)` functions. As a result, they support color and the attribute constants with the `WA_` prefix.

slk\_attrset(3XCURSES)

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |

| <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

| DESCRIPTION | <p>curses manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, <i>curses</i> takes over the bottom line of <code>stdscr</code>, reducing the size of <code>stdscr</code> and the variable <code>LINES</code>. <i>curses</i> standardizes on eight labels of up to eight characters each.</p> <p>To use soft labels, the <code>slk_init()</code> routine must be called before <code>initscr()</code> or <code>newterm()</code> is called. If <code>initscr()</code> eventually uses a line from <code>stdscr</code> to emulate the soft labels, then <code>fmt</code> determines how the labels are arranged on the screen. Setting <code>fmt</code> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement.</p> <p>With the <code>slk_set()</code> routine, <i>labnum</i> is the label number, from 1 to 8. <i>label</i> is the string to be put on the label, up to eight characters in length. A null string or a null pointer sets up a blank label. <code>fmt</code> is either 0, 1, or 2, indicating whether the label is to be left-justified, centered, or right-justified, respectively, within the label.</p> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> routines correspond to the <code>wrefresh()</code> and <code>wnoutrefresh()</code> routines.</p> <p>With the <code>slk_label()</code> routine, the current label for label number <i>labnum</i> is returned with leading and trailing blanks stripped.</p> <p>With the <code>slk_clear()</code> routine, the soft labels are cleared from the screen.</p> <p>With the <code>slk_restore()</code> routine, the soft labels are restored to the screen after a <code>slk_clear()</code> is performed.</p> |

`slk_clear(3CURSES)`

With the `slk_touch()` routine, all the soft labels are forced to be output the next time a `slk_noutrefresh()` is performed.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` routines correspond to `attron()`, `attrset()`, and `attroff()`. They have an effect only if soft labels are simulated on the bottom line of the screen.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`slk_label()` returns `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_attr(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Most applications would use `slk_noutrefresh()` because a `wrefresh()` is likely to follow soon.

slk\_clear(3XCURSES)

**DESCRIPTION**

The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of *stdscr*, reducing the size of *stdscr* and the value of the `LINES` external variable. There can be up to eight labels of up to eight display columns each.

To use soft labels, `slk_init()` must be called before calling `initscr(3XCURSES)`, `newterm(3XCURSES)`, or `ripgoffline(3XCURSES)`. If `initscr()` eventually uses a line from *stdscr* to emulate the soft labels, then *fnt* determines how the labels are arranged on the screen. Setting *fnt* to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for *fnt* are unspecified.

The `slk_init()` function has the effect of calling `ripgoffline()` to reserve one screen line to accommodate the requested format.

The `slk_set()` and `slk_wset()` functions specify the text of soft label number *labnum*, within the range from 1 to and including 8. The *label* argument is the string to be put the lable. With `slk_set()` and `slk_wset()`, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The *justify* argument can have the following values to indicate how to justify *label* within the space reserved for it:

- 0           Align the start of *label* with the start of the space
- 1           Center *label* within the space
- 2           Align the end of *label* with the end of the space

The `slk_refresh()` and `slk_noutrefresh()` functions correspond to the `wrefresh(3XCURSES)` and `wnoutrefresh(3XCURSES)` functions.

The `slk_label()` function obtains soft label number *labnum*.

The `slk_clear()` function immediately clears the soft labels from the screen.

The `slk_restore()` function immediately restores the soft labels to the screen after a call to `slk_clear()`.

The `slk_touch()` function forces all the soft labels to be output the next time `slk_refresh()` or `slk_noutrefresh()` is called.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` functions correspond to the `attron(3XCURSES)`, `attrset(3XCURSES)`, and `attroff(3XCURSES)` functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.

The `slk_attr_on()`, `slk_attr_off()`, `slk_attr_set()` and `slk_color()` functions correspond to the `attr_on(3XCURSES)`, `attr_off(3XCURSES)`, `attr_set(3XCURSES)`, and `color_set(3XCURSES)` functions. As a result, they support color and the attribute constants with the `WA_` prefix.

slk\_clear(3XCURSES)

|                     | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| RETURN VALUES       | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| ERRORS              | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| USAGE               | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | <p>The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of <i>stdscr</i>, reducing the size of <i>stdscr</i> and the value of the <code>LINES</code> external variable. There can be up to eight labels of up to eight display columns each.</p> <p>To use soft labels, <code>slk_init()</code> must be called before calling <code>initscr(3XCURSES)</code>, <code>newterm(3XCURSES)</code>, or <code>ripoffline(3XCURSES)</code>. If <code>initscr()</code> eventually uses a line from <i>stdscr</i> to emulate the soft labels, then <i>fmt</i> determines how the labels are arranged on the screen. Setting <i>fmt</i> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for <i>fmt</i> are unspecified.</p> <p>The <code>slk_init()</code> function has the effect of calling <code>ripoffline()</code> to reserve one screen line to accommodate the requested format.</p> <p>The <code>slk_set()</code> and <code>slk_wset()</code> functions specify the text of soft label number <i>labnum</i>, within the range from 1 to and including 8. The <i>label</i> argument is the string to be put the lable. With <code>slk_set()</code> and <code>slk_wset()</code>, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The <i>justify</i> argument can have the following values to indicate how to justify <i>label</i> within the space reserved for it:</p> <ul style="list-style-type: none"> <li>0           Align the start of <i>label</i> with the start of the space</li> <li>1           Center <i>label</i> within the space</li> <li>2           Align the end of <i>label</i> with the end of the space</li> </ul> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> functions correspond to the <code>wrefresh(3XCURSES)</code> and <code>wnoutrefresh(3XCURSES)</code> functions.</p> <p>The <code>slk_label()</code> function obtains soft label number <i>labnum</i>.</p> <p>The <code>slk_clear()</code> function immediately clears the soft labels from the screen.</p> <p>The <code>slk_restore()</code> function immediately restores the soft labels to the screen after a call to <code>slk_clear()</code>.</p> <p>The <code>slk_touch()</code> function forces all the soft labels to be output the next time <code>slk_refresh()</code> or <code>slk_noutrefresh()</code> is called.</p> <p>The <code>slk_attron()</code>, <code>slk_attrset()</code>, and <code>slk_attroff()</code> functions correspond to the <code>attron(3XCURSES)</code>, <code>attrset(3XCURSES)</code>, and <code>attroff(3XCURSES)</code> functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.</p> <p>The <code>slk_attr_on()</code>, <code>slk_attr_off()</code>, <code>slk_attr_set()</code> and <code>slk_color()</code> functions correspond to the <code>attr_on(3XCURSES)</code>, <code>attr_off(3XCURSES)</code>, <code>attr_set(3XCURSES)</code>, and <code>color_set(3XCURSES)</code> functions. As a result, they support color and the attribute constants with the <code>WA_</code> prefix.</p> |

slk\_color(3XCURSES)

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |

| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

| DESCRIPTION | <p>curses manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, <i>curses</i> takes over the bottom line of <code>stdscr</code>, reducing the size of <code>stdscr</code> and the variable <code>LINES</code>. <i>curses</i> standardizes on eight labels of up to eight characters each.</p> <p>To use soft labels, the <code>slk_init()</code> routine must be called before <code>initscr()</code> or <code>newterm()</code> is called. If <code>initscr()</code> eventually uses a line from <code>stdscr</code> to emulate the soft labels, then <code>fmt</code> determines how the labels are arranged on the screen. Setting <code>fmt</code> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement.</p> <p>With the <code>slk_set()</code> routine, <i>labnum</i> is the label number, from 1 to 8. <i>label</i> is the string to be put on the label, up to eight characters in length. A null string or a null pointer sets up a blank label. <code>fmt</code> is either 0, 1, or 2, indicating whether the label is to be left-justified, centered, or right-justified, respectively, within the label.</p> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> routines correspond to the <code>wrefresh()</code> and <code>wnoutrefresh()</code> routines.</p> <p>With the <code>slk_label()</code> routine, the current label for label number <i>labnum</i> is returned with leading and trailing blanks stripped.</p> <p>With the <code>slk_clear()</code> routine, the soft labels are cleared from the screen.</p> <p>With the <code>slk_restore()</code> routine, the soft labels are restored to the screen after a <code>slk_clear()</code> is performed.</p> |

slk\_init(3CURSES)

With the `slk_touch()` routine, all the soft labels are forced to be output the next time a `slk_noutrefresh()` is performed.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` routines correspond to `attron()`, `attrset()`, and `attroff()`. They have an effect only if soft labels are simulated on the bottom line of the screen.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`slk_label()` returns `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_attr(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Most applications would use `slk_noutrefresh()` because a `wrefresh()` is likely to follow soon.

## slk\_init(3XCURSES)

### DESCRIPTION

The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of *stdscr*, reducing the size of *stdscr* and the value of the `LINES` external variable. There can be up to eight labels of up to eight display columns each.

To use soft labels, `slk_init()` must be called before calling `initscr(3XCURSES)`, `newterm(3XCURSES)`, or `ripoffline(3XCURSES)`. If `initscr()` eventually uses a line from *stdscr* to emulate the soft labels, then *fnt* determines how the labels are arranged on the screen. Setting *fnt* to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for *fnt* are unspecified.

The `slk_init()` function has the effect of calling `ripoffline()` to reserve one screen line to accommodate the requested format.

The `slk_set()` and `slk_wset()` functions specify the text of soft label number *labnum*, within the range from 1 to and including 8. The *label* argument is the string to be put the lable. With `slk_set()` and `slk_wset()`, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The *justify* argument can have the following values to indicate how to justify *label* within the space reserved for it:

- 0           Align the start of *label* with the start of the space
- 1           Center *label* within the space
- 2           Align the end of *label* with the end of the space

The `slk_refresh()` and `slk_noutrefresh()` functions correspond to the `wrefresh(3XCURSES)` and `wnoutrefresh(3XCURSES)` functions.

The `slk_label()` function obtains soft label number *labnum*.

The `slk_clear()` function immediately clears the soft labels from the screen.

The `slk_restore()` function immediately restores the soft labels to the screen after a call to `slk_clear()`.

The `slk_touch()` function forces all the soft labels to be output the next time `slk_refresh()` or `slk_noutrefresh()` is called.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` functions correspond to the `attron(3XCURSES)`, `attrset(3XCURSES)`, and `attroff(3XCURSES)` functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.

The `slk_attr_on()`, `slk_attr_off()`, `slk_attr_set()` and `slk_color()` functions correspond to the `attr_on(3XCURSES)`, `attr_off(3XCURSES)`, `attr_set(3XCURSES)`, and `color_set(3XCURSES)` functions. As a result, they support color and the attribute constants with the `WA_` prefix.

slk\_init(3XCURSES)

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

| DESCRIPTION | <p>curses manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, <code>curses</code> takes over the bottom line of <code>stdscr</code>, reducing the size of <code>stdscr</code> and the variable <code>LINES</code>. <code>curses</code> standardizes on eight labels of up to eight characters each.</p> <p>To use soft labels, the <code>slk_init()</code> routine must be called before <code>initscr()</code> or <code>newterm()</code> is called. If <code>initscr()</code> eventually uses a line from <code>stdscr</code> to emulate the soft labels, then <code>fmt</code> determines how the labels are arranged on the screen. Setting <code>fmt</code> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement.</p> <p>With the <code>slk_set()</code> routine, <i>labnum</i> is the label number, from 1 to 8. <i>label</i> is the string to be put on the label, up to eight characters in length. A null string or a null pointer sets up a blank label. <code>fmt</code> is either 0, 1, or 2, indicating whether the label is to be left-justified, centered, or right-justified, respectively, within the label.</p> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> routines correspond to the <code>wrefresh()</code> and <code>wnoutrefresh()</code> routines.</p> <p>With the <code>slk_label()</code> routine, the current label for label number <i>labnum</i> is returned with leading and trailing blanks stripped.</p> <p>With the <code>slk_clear()</code> routine, the soft labels are cleared from the screen.</p> <p>With the <code>slk_restore()</code> routine, the soft labels are restored to the screen after a <code>slk_clear()</code> is performed.</p> |

slk\_label(3CURSES)

With the `slk_touch()` routine, all the soft labels are forced to be output the next time a `slk_noutrefresh()` is performed.

The `slk_attron()`, `slk_attrset()`, and `slk_attrtoss()` routines correspond to `attron()`, `attrset()`, and `attroff()`. They have an effect only if soft labels are simulated on the bottom line of the screen.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`slk_label()` returns `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_attr(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Most applications would use `slk_noutrefresh()` because a `wrefresh()` is likely to follow soon.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | <p>The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of <i>stdscr</i>, reducing the size of <i>stdscr</i> and the value of the <code>LINES</code> external variable. There can be up to eight labels of up to eight display columns each.</p> <p>To use soft labels, <code>slk_init()</code> must be called before calling <code>initscr(3XCURSES)</code>, <code>newterm(3XCURSES)</code>, or <code>ripoffline(3XCURSES)</code>. If <code>initscr()</code> eventually uses a line from <i>stdscr</i> to emulate the soft labels, then <i>fmt</i> determines how the labels are arranged on the screen. Setting <i>fmt</i> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for <i>fmt</i> are unspecified.</p> <p>The <code>slk_init()</code> function has the effect of calling <code>ripoffline()</code> to reserve one screen line to accommodate the requested format.</p> <p>The <code>slk_set()</code> and <code>slk_wset()</code> functions specify the text of soft label number <i>labnum</i>, within the range from 1 to and including 8. The <i>label</i> argument is the string to be put the lable. With <code>slk_set()</code> and <code>slk_wset()</code>, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The <i>justify</i> argument can have the following values to indicate how to justify <i>label</i> within the space reserved for it:</p> <ul style="list-style-type: none"> <li>0           Align the start of <i>label</i> with the start of the space</li> <li>1           Center <i>label</i> within the space</li> <li>2           Align the end of <i>label</i> with the end of the space</li> </ul> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> functions correspond to the <code>wrefresh(3XCURSES)</code> and <code>wnoutrefresh(3XCURSES)</code> functions.</p> <p>The <code>slk_label()</code> function obtains soft label number <i>labnum</i>.</p> <p>The <code>slk_clear()</code> function immediately clears the soft labels from the screen.</p> <p>The <code>slk_restore()</code> function immediately restores the soft labels to the screen after a call to <code>slk_clear()</code>.</p> <p>The <code>slk_touch()</code> function forces all the soft labels to be output the next time <code>slk_refresh()</code> or <code>slk_noutrefresh()</code> is called.</p> <p>The <code>slk_attron()</code>, <code>slk_attrset()</code>, and <code>slk_attroff()</code> functions correspond to the <code>attron(3XCURSES)</code>, <code>attrset(3XCURSES)</code>, and <code>attroff(3XCURSES)</code> functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.</p> <p>The <code>slk_attr_on()</code>, <code>slk_attr_off()</code>, <code>slk_attr_set()</code> and <code>slk_color()</code> functions correspond to the <code>attr_on(3XCURSES)</code>, <code>attr_off(3XCURSES)</code>, <code>attr_set(3XCURSES)</code>, and <code>color_set(3XCURSES)</code> functions. As a result, they support color and the attribute constants with the <code>WA_</code> prefix.</p> |

slk\_label(3XCURSES)

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |

| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

| DESCRIPTION | <p>curses manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, <i>curses</i> takes over the bottom line of <code>stdscr</code>, reducing the size of <code>stdscr</code> and the variable <code>LINES</code>. <i>curses</i> standardizes on eight labels of up to eight characters each.</p> <p>To use soft labels, the <code>slk_init()</code> routine must be called before <code>initscr()</code> or <code>newterm()</code> is called. If <code>initscr()</code> eventually uses a line from <code>stdscr</code> to emulate the soft labels, then <code>fmt</code> determines how the labels are arranged on the screen. Setting <code>fmt</code> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement.</p> <p>With the <code>slk_set()</code> routine, <i>labnum</i> is the label number, from 1 to 8. <i>label</i> is the string to be put on the label, up to eight characters in length. A null string or a null pointer sets up a blank label. <code>fmt</code> is either 0, 1, or 2, indicating whether the label is to be left-justified, centered, or right-justified, respectively, within the label.</p> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> routines correspond to the <code>wrefresh()</code> and <code>wnoutrefresh()</code> routines.</p> <p>With the <code>slk_label()</code> routine, the current label for label number <i>labnum</i> is returned with leading and trailing blanks stripped.</p> <p>With the <code>slk_clear()</code> routine, the soft labels are cleared from the screen.</p> <p>With the <code>slk_restore()</code> routine, the soft labels are restored to the screen after a <code>slk_clear()</code> is performed.</p> |

slk\_noutrefresh(3CURSES)

With the `slk_touch()` routine, all the soft labels are forced to be output the next time a `slk_noutrefresh()` is performed.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` routines correspond to `attron()`, `attrset()`, and `attroff()`. They have an effect only if soft labels are simulated on the bottom line of the screen.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`slk_label()` returns `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_attr(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Most applications would use `slk_noutrefresh()` because a `wrefresh()` is likely to follow soon.

slk\_noutrefresh(3XCURSES)

**DESCRIPTION**

The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of *stdscr*, reducing the size of *stdscr* and the value of the *LINES* external variable. There can be up to eight labels of up to eight display columns each.

To use soft labels, *slk\_init()* must be called before calling *initscr(3XCURSES)*, *newterm(3XCURSES)*, or *ripoffline(3XCURSES)*. If *initscr()* eventually uses a line from *stdscr* to emulate the soft labels, then *fnt* determines how the labels are arranged on the screen. Setting *fnt* to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for *fnt* are unspecified.

The *slk\_init()* function has the effect of calling *ripoffline()* to reserve one screen line to accommodate the requested format.

The *slk\_set()* and *slk\_wset()* functions specify the text of soft label number *labnum*, within the range from 1 to and including 8. The *label* argument is the string to be put the lable. With *slk\_set()* and *slk\_wset()*, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The *justify* argument can have the following values to indicate how to justify *label* within the space reserved for it:

- 0           Align the start of *label* with the start of the space
- 1           Center *label* within the space
- 2           Align the end of *label* with the end of the space

The *slk\_refresh()* and *slk\_noutrefresh()* functions correspond to the *wrefresh(3XCURSES)* and *wnoutrefresh(3XCURSES)* functions.

The *slk\_label()* function obtains soft label number *labnum*.

The *slk\_clear()* function immediately clears the soft labels from the screen.

The *slk\_restore()* function immediately restores the soft labels to the screen after a call to *slk\_clear()*.

The *slk\_touch()* function forces all the soft labels to be output the next time *slk\_refresh()* or *slk\_noutrefresh()* is called.

The *slk\_attron()*, *slk\_attrset()*, and *slk\_attroff()* functions correspond to the *attron(3XCURSES)*, *attrset(3XCURSES)*, and *attroff(3XCURSES)* functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.

The *slk\_attr\_on()*, *slk\_attr\_off()*, *slk\_attr\_set()* and *slk\_color()* functions correspond to the *attr\_on(3XCURSES)*, *attr\_off(3XCURSES)*, *attr\_set(3XCURSES)*, and *color\_set(3XCURSES)* functions. As a result, they support color and the attribute constants with the *WA\_* prefix.

slk\_noutrefresh(3XCURSES)

|                     | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| RETURN VALUES       | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| ERRORS              | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| USAGE               | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

| DESCRIPTION | <p>curses manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, <code>curses</code> takes over the bottom line of <code>stdscr</code>, reducing the size of <code>stdscr</code> and the variable <code>LINES</code>. <code>curses</code> standardizes on eight labels of up to eight characters each.</p> <p>To use soft labels, the <code>slk_init()</code> routine must be called before <code>initscr()</code> or <code>newterm()</code> is called. If <code>initscr()</code> eventually uses a line from <code>stdscr</code> to emulate the soft labels, then <code>fmt</code> determines how the labels are arranged on the screen. Setting <code>fmt</code> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement.</p> <p>With the <code>slk_set()</code> routine, <i>labnum</i> is the label number, from 1 to 8. <i>label</i> is the string to be put on the label, up to eight characters in length. A null string or a null pointer sets up a blank label. <code>fmt</code> is either 0, 1, or 2, indicating whether the label is to be left-justified, centered, or right-justified, respectively, within the label.</p> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> routines correspond to the <code>wrefresh()</code> and <code>wnoutrefresh()</code> routines.</p> <p>With the <code>slk_label()</code> routine, the current label for label number <i>labnum</i> is returned with leading and trailing blanks stripped.</p> <p>With the <code>slk_clear()</code> routine, the soft labels are cleared from the screen.</p> <p>With the <code>slk_restore()</code> routine, the soft labels are restored to the screen after a <code>slk_clear()</code> is performed.</p> |

slk\_refresh(3CURSES)

With the `slk_touch()` routine, all the soft labels are forced to be output the next time a `slk_noutrefresh()` is performed.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` routines correspond to `attron()`, `attrset()`, and `attroff()`. They have an effect only if soft labels are simulated on the bottom line of the screen.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`slk_label()` returns `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_attr(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Most applications would use `slk_noutrefresh()` because a `wrefresh()` is likely to follow soon.

**DESCRIPTION**

The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of *stdscr*, reducing the size of *stdscr* and the value of the `LINES` external variable. There can be up to eight labels of up to eight display columns each.

To use soft labels, `slk_init()` must be called before calling `initscr(3XCURSES)`, `newterm(3XCURSES)`, or `ripoffline(3XCURSES)`. If `initscr()` eventually uses a line from *stdscr* to emulate the soft labels, then *fmt* determines how the labels are arranged on the screen. Setting *fmt* to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for *fmt* are unspecified.

The `slk_init()` function has the effect of calling `ripoffline()` to reserve one screen line to accommodate the requested format.

The `slk_set()` and `slk_wset()` functions specify the text of soft label number *labnum*, within the range from 1 to and including 8. The *label* argument is the string to be put the lable. With `slk_set()` and `slk_wset()`, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The *justify* argument can have the following values to indicate how to justify *label* within the space reserved for it:

- 0           Align the start of *label* with the start of the space
- 1           Center *label* within the space
- 2           Align the end of *label* with the end of the space

The `slk_refresh()` and `slk_noutrefresh()` functions correspond to the `wrefresh(3XCURSES)` and `wnoutrefresh(3XCURSES)` functions.

The `slk_label()` function obtains soft label number *labnum*.

The `slk_clear()` function immediately clears the soft labels from the screen.

The `slk_restore()` function immediately restores the soft labels to the screen after a call to `slk_clear()`.

The `slk_touch()` function forces all the soft labels to be output the next time `slk_refresh()` or `slk_noutrefresh()` is called.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` functions correspond to the `attron(3XCURSES)`, `attrset(3XCURSES)`, and `attroff(3XCURSES)` functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.

The `slk_attr_on()`, `slk_attr_off()`, `slk_attr_set()` and `slk_color()` functions correspond to the `attr_on(3XCURSES)`, `attr_off(3XCURSES)`, `attr_set(3XCURSES)`, and `color_set(3XCURSES)` functions. As a result, they support color and the attribute constants with the `WA_` prefix.

slk\_refresh(3XCURSES)

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

| DESCRIPTION | <p>curses manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, <i>curses</i> takes over the bottom line of <code>stdscr</code>, reducing the size of <code>stdscr</code> and the variable <code>LINES</code>. <i>curses</i> standardizes on eight labels of up to eight characters each.</p> <p>To use soft labels, the <code>slk_init()</code> routine must be called before <code>initscr()</code> or <code>newterm()</code> is called. If <code>initscr()</code> eventually uses a line from <code>stdscr</code> to emulate the soft labels, then <code>fmt</code> determines how the labels are arranged on the screen. Setting <code>fmt</code> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement.</p> <p>With the <code>slk_set()</code> routine, <i>labnum</i> is the label number, from 1 to 8. <i>label</i> is the string to be put on the label, up to eight characters in length. A null string or a null pointer sets up a blank label. <code>fmt</code> is either 0, 1, or 2, indicating whether the label is to be left-justified, centered, or right-justified, respectively, within the label.</p> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> routines correspond to the <code>wrefresh()</code> and <code>wnoutrefresh()</code> routines.</p> <p>With the <code>slk_label()</code> routine, the current label for label number <i>labnum</i> is returned with leading and trailing blanks stripped.</p> <p>With the <code>slk_clear()</code> routine, the soft labels are cleared from the screen.</p> <p>With the <code>slk_restore()</code> routine, the soft labels are restored to the screen after a <code>slk_clear()</code> is performed.</p> |

slk\_restore(3CURSES)

With the `slk_touch()` routine, all the soft labels are forced to be output the next time a `slk_noutrefresh()` is performed.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` routines correspond to `attron()`, `attrset()`, and `attroff()`. They have an effect only if soft labels are simulated on the bottom line of the screen.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`slk_label()` returns `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_attr(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Most applications would use `slk_noutrefresh()` because a `wrefresh()` is likely to follow soon.

Currently, this must be a null pointer.</p> <p><i>color_pair_number</i> Is a color pair.</p> <p><i>fmt</i> Is the format of how the labels are arranged on the screen.</p> <p><i>labnum</i> Is the number of the soft label.</p> <p><i>label</i> Is the name to be given to a soft label.</p> <p><i>justify</i> Is a number indicating how to justify the label name.</p>                                                                                                                                                                                                                                                                                                                                       |  |

slk\_restore(3XCURSES)

**DESCRIPTION**

The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of *stdscr*, reducing the size of *stdscr* and the value of the `LINES` external variable. There can be up to eight labels of up to eight display columns each.

To use soft labels, `slk_init()` must be called before calling `initscr(3XCURSES)`, `newterm(3XCURSES)`, or `ripoffline(3XCURSES)`. If `initscr()` eventually uses a line from *stdscr* to emulate the soft labels, then *fnt* determines how the labels are arranged on the screen. Setting *fnt* to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for *fnt* are unspecified.

The `slk_init()` function has the effect of calling `ripoffline()` to reserve one screen line to accommodate the requested format.

The `slk_set()` and `slk_wset()` functions specify the text of soft label number *labnum*, within the range from 1 to and including 8. The *label* argument is the string to be put the lable. With `slk_set()` and `slk_wset()`, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The *justify* argument can have the following values to indicate how to justify *label* within the space reserved for it:

- 0           Align the start of *label* with the start of the space
- 1           Center *label* within the space
- 2           Align the end of *label* with the end of the space

The `slk_refresh()` and `slk_noutrefresh()` functions correspond to the `wrefresh(3XCURSES)` and `wnoutrefresh(3XCURSES)` functions.

The `slk_label()` function obtains soft label number *labnum*.

The `slk_clear()` function immediately clears the soft labels from the screen.

The `slk_restore()` function immediately restores the soft labels to the screen after a call to `slk_clear()`.

The `slk_touch()` function forces all the soft labels to be output the next time `slk_refresh()` or `slk_noutrefresh()` is called.

The `slk_attron()`, `slk_attrset()`, and `slk_attrtff()` functions correspond to the `attron(3XCURSES)`, `attrset(3XCURSES)`, and `attroff(3XCURSES)` functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.

The `slk_attr_on()`, `slk_attr_off()`, `slk_attr_set()` and `slk_color()` functions correspond to the `attr_on(3XCURSES)`, `attr_off(3XCURSES)`, `attr_set(3XCURSES)`, and `color_set(3XCURSES)` functions. As a result, they support color and the attribute constants with the `WA_` prefix.

`slk_restore(3XCURSES)`

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

| DESCRIPTION | <p>curses manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, <code>curses</code> takes over the bottom line of <code>stdscr</code>, reducing the size of <code>stdscr</code> and the variable <code>LINES</code>. <code>curses</code> standardizes on eight labels of up to eight characters each.</p> <p>To use soft labels, the <code>slk_init()</code> routine must be called before <code>initscr()</code> or <code>newterm()</code> is called. If <code>initscr()</code> eventually uses a line from <code>stdscr</code> to emulate the soft labels, then <code>fmt</code> determines how the labels are arranged on the screen. Setting <code>fmt</code> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement.</p> <p>With the <code>slk_set()</code> routine, <i>labnum</i> is the label number, from 1 to 8. <i>label</i> is the string to be put on the label, up to eight characters in length. A null string or a null pointer sets up a blank label. <code>fmt</code> is either 0, 1, or 2, indicating whether the label is to be left-justified, centered, or right-justified, respectively, within the label.</p> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> routines correspond to the <code>wrefresh()</code> and <code>wnoutrefresh()</code> routines.</p> <p>With the <code>slk_label()</code> routine, the current label for label number <i>labnum</i> is returned with leading and trailing blanks stripped.</p> <p>With the <code>slk_clear()</code> routine, the soft labels are cleared from the screen.</p> <p>With the <code>slk_restore()</code> routine, the soft labels are restored to the screen after a <code>slk_clear()</code> is performed.</p> |

slk\_set(3CURSES)

With the `slk_touch()` routine, all the soft labels are forced to be output the next time a `slk_noutrefresh()` is performed.

The `slk_attron()`, `slk_attrset()`, and `slk_attrtoss()` routines correspond to `attron()`, `attrset()`, and `attroff()`. They have an effect only if soft labels are simulated on the bottom line of the screen.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`slk_label()` returns `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_attr(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Most applications would use `slk_noutrefresh()` because a `wrefresh()` is likely to follow soon.

| <b>DESCRIPTION</b> | <p>The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of <i>stdscr</i>, reducing the size of <i>stdscr</i> and the value of the <code>LINES</code> external variable. There can be up to eight labels of up to eight display columns each.</p> <p>To use soft labels, <code>slk_init()</code> must be called before calling <code>initscr(3XCURSES)</code>, <code>newterm(3XCURSES)</code>, or <code>ripoffline(3XCURSES)</code>. If <code>initscr()</code> eventually uses a line from <i>stdscr</i> to emulate the soft labels, then <i>fnt</i> determines how the labels are arranged on the screen. Setting <i>fnt</i> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for <i>fnt</i> are unspecified.</p> <p>The <code>slk_init()</code> function has the effect of calling <code>ripoffline()</code> to reserve one screen line to accommodate the requested format.</p> <p>The <code>slk_set()</code> and <code>slk_wset()</code> functions specify the text of soft label number <i>labnum</i>, within the range from 1 to and including 8. The <i>label</i> argument is the string to be put the lable. With <code>slk_set()</code> and <code>slk_wset()</code>, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The <i>justify</i> argument can have the following values to indicate how to justify <i>label</i> within the space reserved for it:</p> <ul style="list-style-type: none"> <li>0           Align the start of <i>label</i> with the start of the space</li> <li>1           Center <i>label</i> within the space</li> <li>2           Align the end of <i>label</i> with the end of the space</li> </ul> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> functions correspond to the <code>wrefresh(3XCURSES)</code> and <code>wnoutrefresh(3XCURSES)</code> functions.</p> <p>The <code>slk_label()</code> function obtains soft label number <i>labnum</i>.</p> <p>The <code>slk_clear()</code> function immediately clears the soft labels from the screen.</p> <p>The <code>slk_restore()</code> function immediately restores the soft labels to the screen after a call to <code>slk_clear()</code>.</p> <p>The <code>slk_touch()</code> function forces all the soft labels to be output the next time <code>slk_refresh()</code> or <code>slk_noutrefresh()</code> is called.</p> <p>The <code>slk_attron()</code>, <code>slk_attrset()</code>, and <code>slk_attroff()</code> functions correspond to the <code>attron(3XCURSES)</code>, <code>attrset(3XCURSES)</code>, and <code>attroff(3XCURSES)</code> functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.</p> <p>The <code>slk_attr_on()</code>, <code>slk_attr_off()</code>, <code>slk_attr_set()</code> and <code>slk_color()</code> functions correspond to the <code>attr_on(3XCURSES)</code>, <code>attr_off(3XCURSES)</code>, <code>attr_set(3XCURSES)</code>, and <code>color_set(3XCURSES)</code> functions. As a result, they support color and the attribute constants with the <code>WA_</code> prefix.</p> |

slk\_set(3XCURSES)

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

| DESCRIPTION | <p>curses manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, <i>curses</i> takes over the bottom line of <code>stdscr</code>, reducing the size of <code>stdscr</code> and the variable <code>LINES</code>. <i>curses</i> standardizes on eight labels of up to eight characters each.</p> <p>To use soft labels, the <code>slk_init()</code> routine must be called before <code>initscr()</code> or <code>newterm()</code> is called. If <code>initscr()</code> eventually uses a line from <code>stdscr</code> to emulate the soft labels, then <code>fmt</code> determines how the labels are arranged on the screen. Setting <code>fmt</code> to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement.</p> <p>With the <code>slk_set()</code> routine, <i>labnum</i> is the label number, from 1 to 8. <i>label</i> is the string to be put on the label, up to eight characters in length. A null string or a null pointer sets up a blank label. <code>fmt</code> is either 0, 1, or 2, indicating whether the label is to be left-justified, centered, or right-justified, respectively, within the label.</p> <p>The <code>slk_refresh()</code> and <code>slk_noutrefresh()</code> routines correspond to the <code>wrefresh()</code> and <code>wnoutrefresh()</code> routines.</p> <p>With the <code>slk_label()</code> routine, the current label for label number <i>labnum</i> is returned with leading and trailing blanks stripped.</p> <p>With the <code>slk_clear()</code> routine, the soft labels are cleared from the screen.</p> <p>With the <code>slk_restore()</code> routine, the soft labels are restored to the screen after a <code>slk_clear()</code> is performed.</p> |

slk\_touch(3CURSES)

With the `slk_touch()` routine, all the soft labels are forced to be output the next time a `slk_noutrefresh()` is performed.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` routines correspond to `attron()`, `attrset()`, and `attroff()`. They have an effect only if soft labels are simulated on the bottom line of the screen.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`slk_label()` returns `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_attr(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Most applications would use `slk_noutrefresh()` because a `wrefresh()` is likely to follow soon.

Currently, this must be a null pointer.</p> <p><i>color_pair_number</i> Is a color pair.</p> <p><i>fmt</i> Is the format of how the labels are arranged on the screen.</p> <p><i>labnum</i> Is the number of the soft label.</p> <p><i>label</i> Is the name to be given to a soft label.</p> <p><i>justify</i> Is a number indicating how to justify the label name.</p>                                                                                                                                                                                                                                                                                                                                       |  |

slk\_touch(3XCURSES)

**DESCRIPTION**

The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of *stdscr*, reducing the size of *stdscr* and the value of the `LINES` external variable. There can be up to eight labels of up to eight display columns each.

To use soft labels, `slk_init()` must be called before calling `initscr(3XCURSES)`, `newterm(3XCURSES)`, or `ripoffline(3XCURSES)`. If `initscr()` eventually uses a line from *stdscr* to emulate the soft labels, then *fnt* determines how the labels are arranged on the screen. Setting *fnt* to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for *fnt* are unspecified.

The `slk_init()` function has the effect of calling `ripoffline()` to reserve one screen line to accommodate the requested format.

The `slk_set()` and `slk_wset()` functions specify the text of soft label number *labnum*, within the range from 1 to and including 8. The *label* argument is the string to be put the lable. With `slk_set()` and `slk_wset()`, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The *justify* argument can have the following values to indicate how to justify *label* within the space reserved for it:

- 0           Align the start of *label* with the start of the space
- 1           Center *label* within the space
- 2           Align the end of *label* with the end of the space

The `slk_refresh()` and `slk_noutrefresh()` functions correspond to the `wrefresh(3XCURSES)` and `wnoutrefresh(3XCURSES)` functions.

The `slk_label()` function obtains soft label number *labnum*.

The `slk_clear()` function immediately clears the soft labels from the screen.

The `slk_restore()` function immediately restores the soft labels to the screen after a call to `slk_clear()`.

The `slk_touch()` function forces all the soft labels to be output the next time `slk_refresh()` or `slk_noutrefresh()` is called.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` functions correspond to the `attron(3XCURSES)`, `attrset(3XCURSES)`, and `attroff(3XCURSES)` functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.

The `slk_attr_on()`, `slk_attr_off()`, `slk_attr_set()` and `slk_color()` functions correspond to the `attr_on(3XCURSES)`, `attr_off(3XCURSES)`, `attr_set(3XCURSES)`, and `color_set(3XCURSES)` functions. As a result, they support color and the attribute constants with the `WA_` prefix.

`slk_touch(3XCURSES)`

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

**DESCRIPTION**

The Curses interface manipulates the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, Curses takes over the bottom line of *stdscr*, reducing the size of *stdscr* and the value of the `LINES` external variable. There can be up to eight labels of up to eight display columns each.

To use soft labels, `slk_init()` must be called before calling `initscr(3XCURSES)`, `newterm(3XCURSES)`, or `ripoffline(3XCURSES)`. If `initscr()` eventually uses a line from *stdscr* to emulate the soft labels, then *fnt* determines how the labels are arranged on the screen. Setting *fnt* to 0 indicates a 3-2-3 arrangement of the labels; 1 indicates a 4-4 arrangement. Other values for *fnt* are unspecified.

The `slk_init()` function has the effect of calling `ripoffline()` to reserve one screen line to accommodate the requested format.

The `slk_set()` and `slk_wset()` functions specify the text of soft label number *labnum*, within the range from 1 to and including 8. The *label* argument is the string to be put the lable. With `slk_set()` and `slk_wset()`, the width of the label is limited to eight columns positions. A null string or a null pointer specifies a blank label. The *justify* argument can have the following values to indicate how to justify *label* within the space reserved for it:

- 0           Align the start of *label* with the start of the space
- 1           Center *label* within the space
- 2           Align the end of *label* with the end of the space

The `slk_refresh()` and `slk_noutrefresh()` functions correspond to the `wrefresh(3XCURSES)` and `wnoutrefresh(3XCURSES)` functions.

The `slk_label()` function obtains soft label number *labnum*.

The `slk_clear()` function immediately clears the soft labels from the screen.

The `slk_restore()` function immediately restores the soft labels to the screen after a call to `slk_clear()`.

The `slk_touch()` function forces all the soft labels to be output the next time `slk_refresh()` or `slk_noutrefresh()` is called.

The `slk_attron()`, `slk_attrset()`, and `slk_attroff()` functions correspond to the `attron(3XCURSES)`, `attrset(3XCURSES)`, and `attroff(3XCURSES)` functions. They have an effect only if soft labels are stimulated on the bottom line of the screen.

The `slk_attr_on()`, `slk_attr_off()`, `slk_attr_set()` and `slk_color()` functions correspond to the `attr_on(3XCURSES)`, `attr_off(3XCURSES)`, `attr_set(3XCURSES)`, and `color_set(3XCURSES)` functions. As a result, they support color and the attribute constants with the `WA_` prefix.

slk\_wset(3XCURSES)

|                      | <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the <i>opts</i> argument is a null pointer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>RETURN VALUES</b> | <p>Upon successful completion, the <code>slk_label()</code> function returns the requested label with leading and trailing blanks stripped. Otherwise, it returns a null pointer.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | <p>No errors are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>USAGE</b>         | <p>When using multi-byte character sets, applications should check the width of the string by calling <code>mbstowcs(3C)</code> and then <code>wcswidth(3C)</code> before calling <code>slk_set()</code>. When using wide characters, applications should check the width of the string by calling <code>wcswidth()</code> before calling <code>slk_set()</code>.</p> <p>Since the number of columns that a wide string will occupy is codeset-specific, call <code>wcwidth(3C)</code> and <code>wcswidth(3C)</code> to check the number of column positions in the string before calling <code>slk_wset()</code>.</p> <p>Most applications would use <code>slk_noutrefresh()</code> because a <code>wrefresh()</code> is likely to follow soon.</p> |                |                 |                     |          |          |        |

| DESCRIPTION | <p>These functions generate graphics output for a set of output devices. The format of the output is dependent upon which link editor option is used when the program is compiled and linked (see Link Editor).</p> <p>The term "current point" refers to the current setting for the <math>x</math> and <math>y</math> coordinates.</p> <p>The <code>arc()</code> function specifies a circular arc. The coordinates <math>(x0, y0)</math> specify the center of the arc. The coordinates <math>(x1, y1)</math> specify the starting point of the arc. The coordinates <math>(x2, y2)</math> specify the end point of the circular arc.</p> <p>The <code>box()</code> function specifies a rectangle with coordinates <math>(x0, y0)</math>, <math>(x0, y1)</math>, <math>(x1, y0)</math>, and <math>(x1, y1)</math>. The current point is set to <math>(x1, y1)</math>.</p> <p>The <code>circle()</code> function specifies a circle with a center at the coordinates <math>(x, y)</math> and a radius of <math>r</math>.</p> <p>The <code>closevt()</code> and <code>closepl()</code> functions flush the output.</p> <p>The <code>cont()</code> function specifies a line beginning at the current point and ending at the coordinates <math>(x, y)</math>. The current point is set to <math>(x, y)</math>.</p> |

space(3PLOT)

The `erase()` function starts another frame of output.

The `label()` function places the null terminated string `s` so that the first character falls on the current point. The string is then terminated by a NEWLINE character.

The `line()` function draws a line starting at the coordinates  $(x0, y0)$  and ending at the coordinates  $(x1, y1)$ . The current point is set to  $(x1, y1)$ .

The `linemod()` function specifies the style for drawing future lines. `s` may contain one of the following: `dotted`, `solid`, `longdashed`, `shortdashed`, or `dotdashed`.

The `move()` function sets the current point to the coordinates  $(x, y)$ .

The `openpl()` or `openvt()` function must be called to open the device before any other plot functions are called.

The `point()` function plots the point given by the coordinates  $(x, y)$ . The current point is set to  $(x, y)$ .

The `space()` function specifies the size of the plotting area. The plot will be reduced or enlarged as necessary to fit the area specified. The coordinates  $(x0, y0)$  specify the lower left hand corner of the plotting area. The coordinates  $(x1, y1)$  specify the upper right hand corner of the plotting area.

**Link Editor** Various flavors of these functions exist for different output devices. They are obtained by using the following `ld(1)` options:

|                     |                                                                                                        |

| <b>NAME</b>               | <code> curs_attr, attroff, wattroff, attron, wattron, attrset, wattrset, standend, wstandend, standout, wstandout </code> – curses character and window attribute control routines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                         |                                        |                          |             |                        |               |                      |          |                    |             |                     |                      |                           |                         |
| <b>SYNOPSIS</b>           | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int attroff(int attrs); int wattroff(WINDOW *win, int attrs); int attron(int attrs); int wattron(WINDOW *win, int attrs); int attrset(int attrs); int wattrset(WINDOW *win, int attrs); int standend(void); int wstandend(WINDOW *win); int standout(void); int wstandout(WINDOW *win);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                         |                                        |                          |             |                        |               |                      |          |                    |             |                     |                      |                           |                         |
| <b>DESCRIPTION</b>        | <p>All of these routines manipulate the current attributes of the named window. The current attributes of a window are applied to all characters that are written into the window with <code>waddch()</code>, <code>waddstr()</code>, and <code>wprintw()</code>. Attributes are a property of the character, and move with the character through any scrolling and insert/delete line/character operations. To the extent possible on the particular terminal, they are displayed as the graphic rendition of characters put on the screen.</p> <p>The routine <code>attrset()</code> sets the current attributes of the given window to <i>attrs</i>. The routine <code>attroff()</code> turns off the named attributes without turning any other attributes on or off. The routine <code>attron()</code> turns on the named attributes without affecting any others. The routine <code>standout()</code> is the same as <code>attron(A_STANDOUT)</code>. The routine <code>standend()</code> is the same as <code>attrset()</code>, that is, it turns off all attributes.</p> |                         |                                        |                          |             |                        |               |                      |          |                    |             |                     |                      |                           |                         |
| <b>Attributes</b>         | <p>The following video attributes, defined in <code>&lt;curses.h&gt;</code>, can be passed to the routines <code>attron()</code>, <code>attroff()</code>, and <code>attrset()</code>, or OR-ed with the characters passed to <code>addch()</code>.</p> <table> <tbody> <tr> <td><code>A_STANDOUT</code></td><td>Best highlighting mode of the terminal</td></tr> <tr> <td><code>A_UNDERLINE</code></td><td>Underlining</td></tr> <tr> <td><code>A_REVERSE</code></td><td>Reverse video</td></tr> <tr> <td><code>A_BLINK</code></td><td>Blinking</td></tr> <tr> <td><code>A_DIM</code></td><td>Half bright</td></tr> <tr> <td><code>A_BOLD</code></td><td>Extra bright or bold</td></tr> <tr> <td><code>A_ALTCHARSET</code></td><td>Alternate character set</td></tr> </tbody> </table>                                                                                                                                                                                                                                                                                           | <code>A_STANDOUT</code> | Best highlighting mode of the terminal | <code>A_UNDERLINE</code> | Underlining | <code>A_REVERSE</code> | Reverse video | <code>A_BLINK</code> | Blinking | <code>A_DIM</code> | Half bright | <code>A_BOLD</code> | Extra bright or bold | <code>A_ALTCHARSET</code> | Alternate character set |

standend(3CURSES)

A\_CHARTEXT Bit-mask to extract a character

COLOR\_PAIR(*n*) Color-pair number *n*

The following macro is the reverse of COLOR\_PAIR(*n*) :

PAIR\_NUMBER(*attrs*) Returns the pair number associated with the  
COLOR\_PAIR(*n*) attribute

**RETURN VALUES** These routines always return 1.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curs\_addch(3CURSES), curs\_addstr(3CURSES), curs\_printw(3CURSES),  
curses(3CURSES), attributes(5)

**NOTES** The header <curses.h> automatically includes the headers <stdio.h> and  
<unctrl.h>.

Note that attroff(), wattroff(), attron(), wattroff(), wattrset(),  
standend(), and standout() may be macros.

## standend(3XCURSES)

| NAME                | standend, standout, wstandend, wstandout – set/clear window attributes                                                                                                                                                                                                                             |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>        | <p>All of these routines manipulate the current attributes of the named window. The current attributes of a window are applied to all characters that are written into the window with <code>waddch()</code>, <code>waddstr()</code>, and <code>wprintw()</code>. Attributes are a property of the character, and move with the character through any scrolling and insert/delete line/character operations. To the extent possible on the particular terminal, they are displayed as the graphic rendition of characters put on the screen.</p> <p>The routine <code>attrset()</code> sets the current attributes of the given window to <i>attrs</i>. The routine <code>attroff()</code> turns off the named attributes without turning any other attributes on or off. The routine <code>attron()</code> turns on the named attributes without affecting any others. The routine <code>standout()</code> is the same as <code>attron(A_STANDOUT)</code>. The routine <code>standend()</code> is the same as <code>attrset()</code>, that is, it turns off all attributes.</p> |                         |                                        |                          |             |                        |               |                      |          |                    |             |                     |                      |                           |                         |

standout(3CURSES)

A\_CHARTEXT                      Bit-mask to extract a character

COLOR\_PAIR(*n*)                      Color-pair number *n*

The following macro is the reverse of COLOR\_PAIR(*n*) :

PAIR\_NUMBER(*attrs*)                      Returns the pair number associated with the  
COLOR\_PAIR(*n*) attribute

**RETURN VALUES**                      These routines always return 1.

**ATTRIBUTES**                      See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO**                      curs\_addch(3CURSES), curs\_addstr(3CURSES), curs\_printw(3CURSES),  
curses(3CURSES), attributes(5)

**NOTES**                      The header <curses.h> automatically includes the headers <stdio.h> and  
<unctrl.h>.

Note that attroff(), wattroff(), attron(), wattron(), wattrset(),  
standend(), and standout() may be macros.

| <b>NAME</b>                 | <p> <code> curs_color, start_color, init_pair, init_color, has_colors, can_change_color, color_content, pair_content</code> – curses color manipulation routines </p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>             | <pre> cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int start_color(void);  int init_pair(short pair, short fg, short bg);  int init_color(short color, short red, short green, short blue);  bool has_colors(void);  bool can_change_color(void);  int color_content(short color, short *redp, short *greenp, short *bluep);  int pair_content(short pair, short *fgp, short *bgp); </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Overview</b>             | <p> curses provides routines that manipulate color on color alphanumeric terminals. To use these routines <code>start_color()</code> must be called, usually right after <code>initscr()</code>. See <code>curs_initscr(3CURSES)</code>. Colors are always used in pairs (referred to as color-pairs). A color-pair consists of a foreground color (for characters) and a background color (for the field on which the characters are displayed). A programmer initializes a color-pair with the routine <code>init_pair</code>. After it has been initialized, <code>COLOR_PAIR(n)</code>, a macro defined in <code>&lt;curses.h&gt;</code>, can be used in the same ways other video attributes can be used. If a terminal is capable of redefining colors, the programmer can use the routine <code>init_color()</code> to change the definition of a color. The routines <code>has_colors()</code> and <code>can_change_color()</code> return <code>TRUE</code> or <code>FALSE</code>, depending on whether the terminal has color capabilities and whether the programmer can change the colors. The routine <code>color_content()</code> allows a programmer to identify the amounts of red, green, and blue components in an initialized color. The routine <code>pair_content()</code> allows a programmer to find out how a given color-pair is currently defined. </p> |
| <b>Routine Descriptions</b> | <p> The <code>start_color()</code> routine requires no arguments. It must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after <code>initscr()</code>. <code>start_color()</code> initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables, <code>COLORS</code> and <code>COLOR_PAIRS</code> (respectively defining the maximum number of colors and color-pairs the terminal can support). It also restores the colors on the terminal to the values they had when the terminal was just turned on. </p> <p> The <code>init_pair()</code> routine changes the definition of a color-pair. It takes three arguments: the number of the color-pair to be changed, the foreground color number, and the background color number. The value of the first argument must be between 1 and <code>COLOR_PAIRS-1</code>. The value of the second and third arguments must be between 0 and <code>COLORS</code>. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair is changed to the new definition. </p>                                                                                                                                              |

start\_color(3CURSES)

The `init_color()` routine changes the definition of a color. It takes four arguments: the number of the color to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of the first argument must be between 0 and `COLORS`. (See the section `COLORS` for the default color index.) Each of the last three arguments must be a value between 0 and 1000. When `init_color()` is used, all occurrences of that color on the screen immediately change to the new definition.

The `has_colors()` routine requires no arguments. It returns `TRUE` if the terminal can manipulate colors; otherwise, it returns `FALSE`. This routine facilitates writing terminal-independent programs. For example, a programmer can use it to decide whether to use color or some other video attribute.

The `can_change_color()` routine requires no arguments. It returns `TRUE` if the terminal supports colors and can change their definitions; other, it returns `FALSE`. This routine facilitates writing terminal-independent programs.

The `color_content()` routine gives users a way to find the intensity of the red, green, and blue (RGB) components in a color. It requires four arguments: the color number, and three addresses of `shorts` for storing the information about the amounts of red, green, and blue components in the given color. The value of the first argument must be between 0 and `COLORS`. The values that are stored at the addresses pointed to by the last three arguments are between 0 (no component) and 1000 (maximum amount of component).

The `pair_content()` routine allows users to find out what colors a given color-pair consists of. It requires three arguments: the color-pair number, and two addresses of `shorts` for storing the foreground and the background color numbers. The value of the first argument must be between 1 and `COLOR_PAIRS-1`. The values that are stored at the addresses pointed to by the second and third arguments are between 0 and `COLORS`.

**Colors** In `< curses.h >` the following macros are defined. These are the default colors. `curses` also assumes that `COLOR_BLACK` is the default background color for all terminals.

```
COLOR_BLACK
COLOR_RED
COLOR_GREEN
COLOR_YELLOW
COLOR_BLUE
COLOR_MAGENTA
COLOR_CYAN
COLOR_WHITE
```

**RETURN VALUES** All routines that return an integer return `ERR` upon failure and `OK` upon successful completion.

start\_color(3CURSES)

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curs\_attr(3CURSES), curs\_initscr(3CURSES), curses(3CURSES), attributes(5)

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

start\_color(3XCURSES)

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>DESCRIPTION</b>           | These functions manipulate color on terminals that support color.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Querying Capabilities</b> | The has_colors() function indicates whether the terminal is a color terminal. The can_change_color() function indicates whether the terminal is a color terminal on which colors can be redefined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Initialization</b>        | <p>The start_color() function must be called to enable use of colors and before any color manipulation function is called. The function initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white) that can be specified by the color macros (such as COLOR_BLACK) defined in &lt;curses.h&gt;. The initial appearance of these colors is unspecified.</p> <p>The function also initializes two global external variables:</p> <ul style="list-style-type: none"> <li>■ COLORS defines the number of colors that the terminal supports. See Color Identification below. If COLORS is 0, the terminal does not support redefinition of colors and can_change_color() will return FALSE.</li> <li>■ COLOR_PAIRS defines the maximum number of color-pairs that the terminal supports. See User-defined Color Pairs below.</li> </ul> |

start\_color(3XCURSES)

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |              |                                                                                            |            |                                                                       |              |                                                                         |             |                                                                        |          |                                |             |                                                                                                      |          |                                                                                                   |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|--------------------------------------------------------------------------------------------|------------|-----------------------------------------------------------------------|--------------|-------------------------------------------------------------------------|-------------|------------------------------------------------------------------------|----------|--------------------------------|-------------|------------------------------------------------------------------------------------------------------|----------|---------------------------------------------------------------------------------------------------|
|                                        | <p>The <code>start_color()</code> function also restores the colors on the terminal to terminal-specific initial values. The initial background color is assumed to be black for all terminals.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |              |                                                                                            |            |                                                                       |              |                                                                         |             |                                                                        |          |                                |             |                                                                                                      |          |                                                                                                   |
| <p><b>Color Identification</b></p>     | <p>The <code>init_color()</code> function redefines color number <i>color</i>, on terminals that support the redefinition of colors, to have the red, green, and blue intensity components specified by <i>red</i>, <i>green</i>, and <i>blue</i>, respectively. Calling <code>init_color()</code> also changes all occurrences of the specified color on the screen to the new definition.</p> <p>The <code>color_content()</code> function identifies the intensity components of color number <i>color</i>. It stores the red, green, and blue intensity components of this color in the addresses pointed to by <i>red</i>, <i>green</i>, and <i>blue</i>, respectively.</p> <p>For both functions, the <i>color</i> argument must be in the range from 0 to and including <code>COLORS-1</code>. Valid intensity value range from 0 (no intensity component) up to and including 1000 (maximum intensity in that component).</p>                                                                                                                                                                                                                                                                      |              |                                                                                            |            |                                                                       |              |                                                                         |             |                                                                        |          |                                |             |                                                                                                      |          |                                                                                                   |
| <p><b>User-defined Color Pairs</b></p> | <p>Calling <code>init_pair()</code> defines or redefines color-pair number <i>pair</i> to have foreground color <i>f</i> and background color <i>b</i>. Calling <code>init_pair()</code> changes any characters that were displayed in the color pair's old definition to the new definition and refreshes the screen.</p> <p>After defining the color pair, the macro <code>COLOR_PAIR(<i>n</i>)</code> returns the value of color pair <i>n</i>. This value is the color attribute as it would be extracted from a <code>chtype</code>. Controversy, the macro <code>COLOR_NUMBER(<i>value</i>)</code> returns the color pair number associated with the color attribute <i>value</i>.</p> <p>The <code>pair_content()</code> retrieves the component colors of a color-pair number <i>pair</i>. It stores the foreground and background color numbers in the variables pointed to by <i>f</i> and <i>b</i>, respectively.</p> <p>With <code>init_pair()</code> and <code>pair_content()</code>, the value of <i>pair</i> must be in a range from 0 to and including <code>COLOR_PAIRS-1</code>. Valid values for <i>f</i> and <i>b</i> are the range from 0 to and including <code>COLORS-1</code>.</p> |              |                                                                                            |            |                                                                       |              |                                                                         |             |                                                                        |          |                                |             |                                                                                                      |          |                                                                                                   |

| <i>pair</i>                            | Is the number of the color pair for which to provide information (1 to <code>COLOR_PAIRS-1</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |              |                                                                                            |            |                                                                       |              |                                                                         |             |                                                                        |          |                                |             |                                                                                                      |          |                                                                                                   |
| <i>f</i>                               | Is a pointer to the number of the foreground color (0 to <code>COLORS-1</code> ) in <i>pair</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |              |                                                                                            |            |                                                                       |              |                                                                         |             |                                                                        |          |                                |             |                                                                                                      |          |                                                                                                   |

start\_color(3XCURSES)

*b* Is a pointer to the number of the background color (0 to COLORS-1) in *pair*.

*value* Is a color attribute value.

**RETURN VALUES** The has\_colors() function returns TRUE if the terminal can manipulate colors. Otherwise, it returns FALSE.

The can\_change\_color() function returns TRUE if the terminal supports colors and is able to change their definitions. Otherwise, it returns FALSE.

Upon successful completion, the other functions return OK. Otherwise, they return ERR.

**ERRORS** No errors are defined.

**USAGE** To use these functions, start\_color() must be called, usually right after initscr(3XCURSES).

The can\_change\_color() and has\_colors() functions facilitate writing terminal-independent applications. For example, a programmer can use them to decide whether to use color or some other video attribute.

On color terminals, a typical value of COLORS is 8 and the macros such as COLOR\_BLACK return a value within the range from 0 to and including 7. However, applications cannot rely on this to be true.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO** attroff(3XCURSES), delscreen(3XCURSES), initscr(3XCURSES), libcurses(3XCURSES), attributes(5), standards(5)

| SYNOPSIS            | <pre>cc [ <i>flag...</i> ] <i>file...</i> -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ <i>library...</i> ]  c89 [ <i>flag...</i> ] <i>file...</i> -lcurses [ <i>library...</i> ]  #include &lt;curses.h&gt;  extern WINDOW *stdscr;</pre> |                |                 |                     |          |          |        |
| DESCRIPTION         | The external variable <code>stdscr</code> specifies the default window used by functions that to not specify a window using an argument of type <code>WINDOW *</code> . Other windows may be created using <code>newwin()</code> .                               |                |                 |                     |          |          |        |

| NAME        | curs_pad, newpad, subpad, prefresh, pnoutrefresh, pechochar, pechowchar – create and display curses pads                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| DESCRIPTION | <p>The <code>newpad()</code> routine creates and returns a pointer to a new pad data structure with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (for example, from scrolling or echoing of input) do not occur. It is not legal to call <code>wrefresh(3CURSES)</code> with a <i>pad</i> as an argument; the routines <code>prefresh()</code> or <code>pnoutrefresh()</code> should be called instead. Note that these routines require additional parameters to specify the part of the pad to be displayed and the location on the screen to be used for the display.</p> <p>The <code>subpad()</code> routine creates and returns a pointer to a subwindow within a pad with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. Unlike <code>subwin(3CURSES)</code>, which uses screen coordinates, the window is at position (<i>begin_x</i>, <i>begin_y</i>) on the pad. The window is made in the middle of the window <i>orig</i>, so that changes made to one window affect both windows. During the use of this routine, it will often be necessary to call <code>touchwin(3CURSES)</code> or <code>touchline(3CURSES)</code> on <i>orig</i> before calling <code>prefresh()</code>.</p> <p>The <code>prefresh()</code> and <code>pnoutrefresh()</code> routines are analogous to <code>wrefresh(3CURSES)</code> and <code>wnoutrefresh(3CURSES)</code> except that they relate to pads instead of windows. The additional parameters are needed to indicate what part of the pad and screen are involved. <i>pminrow</i> and <i>pmincol</i> specify the upper left-hand corner of the rectangle to be displayed in the pad. <i>sminrow</i>, <i>smincol</i>, <i>smaxrow</i>, and <i>smaxcol</i> specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of <i>pminrow</i>, <i>pmincol</i>, <i>sminrow</i>, or <i>smincol</i> are treated as if they were zero.</p> |

subpad(3CURSES)

The `pechochar()` routine is functionally equivalent to a call to `addch(3CURSES)` followed by a call to `refresh(3CURSES)`, a call to `waddch(3CURSES)` followed by a call to `wrefresh(3CURSES)`, or a call to `waddch(3CURSES)` followed by a call to `prefresh()`. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents. In the case of `pechochar()`, the last location of the pad on the screen is reused for the arguments to `prefresh()`.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

Routines that return pointers return `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `addch(3CURSES)`, `curses(3CURSES)`, `refresh(3CURSES)`, `subwin(3CURSES)`, `touchline(3CURSES)`, `touchwin(3CURSES)`, `waddch(3CURSES)`, `wnoutrefresh(3CURSES)`, `wrefresh(3CURSES)`, `attributes(5)`

**NOTES** The header file `<curses.h>` automatically includes the header files `<stdio.h>`, `<unctrl.h>` and `<wider.h>`.

Note that `pechochar()` may be a macro.

| PARAMETERS  | <p><i>nlines</i> Is the number of lines in the pad to be created.</p> <p><i>ncols</i> Is the number of columns in the pad to be created.</p> <p><i>pad</i> Is a pointer to the pad to refresh.</p> <p><i>pminrow</i> Is the row coordinate of the upper left corner of the pad rectangle to be copied</p> <p><i>pmincol</i> Is the column coordinate of the upper left corner of the pad rectangle to be copied.</p> <p><i>sminrow</i> Is the row coordinate of the upper left corner of the rectangle on the physical screen where pad is to be positioned.</p> <p><i>smincol</i> Is the column coordinate of the upper left corner of the rectangle on the physical screen where pad is to be positioned.</p> <p><i>smaxrow</i> Is the row coordinate of the lower right corner of the rectangle on the physical screen where the pad is to be positioned.</p> <p><i>smaxcol</i> Is the column coordinate of the lower right corner of the rectangle on the physical screen where the pad is to be positioned.</p> <p><i>orig</i> Is a pointer to the parent pad within which a sub-pad is created.</p> |  |
| DESCRIPTION | <p>The <code>newpad()</code> function creates a new pad with the specified number of lines and columns. A pointer to the new pad structure is returned. A pad differs from a window in that it is not restricted to the size of the physical screen. It is useful when only part of a large window will be displayed at any one time.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |

## subpad(3XCURSES)

Automatic refreshes by scrolling or echoing of input do not take place when pads are used. Pads have their own refresh commands, `prefresh()` and `pnoutrefresh()`.

The `prefresh()` function copies the specified portion of the logical pad to the terminal screen. The parameters *pmincol* and *pminrow* specify the upper left corner of the rectangular area of the pad to be displayed. The lower right coordinate of the rectangular area of the pad that is to be displayed is calculated from the screen parameters (*sminrow*, *smincol*, *smaxrow*, *smaxcol*).

This function calls the `pnoutrefresh()` function to copy the specified portion of *pad* to the terminal screen and the `doupdate(3XCURSES)` function to do the actual update. The logical cursor is copied to the same location in the physical window unless `leaveok(3XCURSES)` is enabled (in which case, the cursor is placed in a position that the program finds convenient).

When outputting several pads at once, it is often more efficient to call the `pnoutrefresh()` and `doupdate()` functions directly. A call to `pnoutrefresh()` for each pad first, followed by only one call to `doupdate()` to update the screen, results in one burst of output, fewer characters sent, and less CPU time used.

The `subpad()` function creates a sub-pad within the pad *orig* with the specified number of lines and columns. A pointer to the new pad structure is returned. The sub-pad is positioned in the middle of *orig*. Any changes made to one pad affect the other. `touchwin(3XCURSES)` or `touchline(3XCURSES)` will likely have to be called on pad *orig* to correctly update the window.

### RETURN VALUES

On success, the `newpad()` and `subpad()` functions return a pointer to the new pad data structure. Otherwise, they return a null pointer.

On success, the `pnoutrefresh()` and `prefresh()` functions return `OK`. Otherwise, they return `ERR`.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

### SEE ALSO

| DESCRIPTION | <p>The <code>newwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The upper left-hand corner of the window is at line <i>begin_y</i>, column <i>begin_x</i>. If either <i>nlines</i> or <i>ncols</i> is zero, they default to <code>LINES</code> — <i>begin_y</i> and <code>COLS</code> — <i>begin_x</i>. A new full-screen window is created by calling <code>newwin(0, 0, 0, 0)</code>.</p> <p>The <code>delwin()</code> routine deletes the named window, freeing all memory associated with it. Subwindows must be deleted before the main window can be deleted.</p> <p>The <code>mvwin()</code> routine moves the window so that the upper left-hand corner is at position (<i>x</i>, <i>y</i>). If the move would cause the window to be off the screen, it is an error and the window is not moved. Moving subwindows is allowed, but should be avoided.</p> <p>The <code>subwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The window is at position (<i>begin_y</i>, <i>begin_x</i>) on the screen. (This position is relative to the screen, and not to the window <i>orig</i>.) The window is made in the middle of the window <i>orig</i>, so that changes made to one window will affect both windows. The subwindow shares memory with the window <i>orig</i>. When using this routine, it is necessary to call <code>touchwin()</code> or <code>touchline()</code> on <i>orig</i> before calling <code>wrefresh()</code> on the subwindow.</p> <p>The <code>derwin()</code> routine is the same as <code>subwin()</code>, except that <i>begin_y</i> and <i>begin_x</i> are relative to the origin of the window <i>orig</i> rather than the screen. There is no difference between the subwindows and the derived windows.</p> |

## subwin(3CURSES)

The `mvderwin()` routine moves a derived window (or subwindow) inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

The `dupwin()` routine creates an exact duplicate of the window *win*.

Each `curses` window maintains two data structures: the character image structure and the status structure. The character image structure is shared among all windows in the window hierarchy (that is, the window with all subwindows). The status structure, which contains information about individual line changes in the window, is private to each window. The routine `wrefresh()` uses the status data structure when performing screen updating. Since status structures are not shared, changes made to one window in the hierarchy may not be properly reflected on the screen.

The routine `wsyncup()` causes the changes in the status structure of a window to be reflected in the status structures of its ancestors. If `syncok()` is called with second argument `TRUE` then `wsyncup()` is called automatically whenever there is a change in the window.

The routine `wcursyncup()` updates the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

The routine `wsyncdown()` updates the status structure of the window to reflect the changes in the status structures of its ancestors. Applications seldom call this routine because it is called automatically by `wrefresh()`.

### RETURN VALUES

Routines that return an integer return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`delwin()` returns the integer `ERR` upon failure and `OK` upon successful completion.

Routines that return pointers return `NULL` on error.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

### SEE ALSO

`curs_refresh(3CURSES)`, `curs_touch(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

If many small changes are made to the window, the `wsyncup()` option could degrade performance.

`subwin(3CURSES)`

Note that `syncok()` may be a macro.

| <b>DESCRIPTION</b> | <p>The <code>derwin()</code> function creates a subwindow within window <i>orig</i>, with the specified number of lines and columns, and upper left corner positioned at <i>begin_x</i>, <i>begin_y</i> relative to window <i>orig</i>. A pointer to the new window structure is returned.</p> <p>The <code>newwin()</code> function creates a new window with the specified number of lines and columns and upper left corner positioned at <i>begin_x</i>, <i>begin_y</i>. A pointer to the new window structure is returned. A full-screen window can be created by calling <code>newwin(0,0,0,0)</code>.</p> <p>If the number of lines specified is zero, <code>newwin()</code> uses a default value of <code>LINES</code> minus <i>begin_y</i>; if the number of columns specified is zero, <code>newwin()</code> uses the default value of <code>COLS</code> minus <i>begin_x</i>.</p> <p>The <code>subwin()</code> function creates a subwindow within window <i>orig</i>, with the specified number of lines and columns, and upper left corner positioned at <i>begin_x</i>, <i>begin_y</i> (relative to the physical screen, <i>not</i> to window <i>orig</i>). A pointer to the new window structure is returned.</p> <p>The original window and subwindow share character storage of the overlapping area (each window maintains its own pointers, cursor location, and other items). This means that characters and attributes are identical in overlapping areas regardless of which window characters are written to.</p> <p>When using subwindows, it is often necessary to call <code>touchwin(3XCURSES)</code> before <code>wrefresh(3XCURSES)</code> to maintain proper screen contents.</p> |             |                                                                    |               |                                          |              |                                            |                |                                                                                                     |

| <i>orig</i>        | Is a pointer to the parent window for the newly created subwindow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |             |                                                                    |               |                                          |              |                                            |                |                                                                                                     |
| <i>nlines</i>      | Is the number of lines in the subwindow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |             |                                                                    |               |                                          |              |                                            |                |                                                                                                     |
| <i>ncols</i>       | Is the number of columns in the subwindow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                                                                    |               |                                          |              |                                            |                |                                                                                                     |
| <i>begin_y</i>     | Is the y (row) coordinate of the upper left corner of the subwindow, relative to the parent window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |             |                                                                    |               |                                          |              |                                            |                |                                                                                                     |

subwin(3XCURSES)

*begin\_x* Is the x (column) coordinate of the upper left corner of the subwindow, relative to the parent window.

**RETURN VALUES** On success, these functions return a pointer to the newly-created window. Otherwise, they return `ERR`.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO** `doupdate(3XCURSES)`, `is_linetouched(3XCURSES)`, `libcurses(3XCURSES)`, `attributes(5)`, `standards(5)`

| DESCRIPTION | <p>The <code>newwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The upper left-hand corner of the window is at line <i>begin_y</i>, column <i>begin_x</i>. If either <i>nlines</i> or <i>ncols</i> is zero, they default to <code>LINES</code> — <i>begin_y</i> and <code>COLS</code> — <i>begin_x</i>. A new full-screen window is created by calling <code>newwin(0,0,0,0)</code>.</p> <p>The <code>delwin()</code> routine deletes the named window, freeing all memory associated with it. Subwindows must be deleted before the main window can be deleted.</p> <p>The <code>mvwin()</code> routine moves the window so that the upper left-hand corner is at position (<i>x</i>, <i>y</i>). If the move would cause the window to be off the screen, it is an error and the window is not moved. Moving subwindows is allowed, but should be avoided.</p> <p>The <code>subwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The window is at position (<i>begin_y</i>, <i>begin_x</i>) on the screen. (This position is relative to the screen, and not to the window <i>orig</i>.) The window is made in the middle of the window <i>orig</i>, so that changes made to one window will affect both windows. The subwindow shares memory with the window <i>orig</i>. When using this routine, it is necessary to call <code>touchwin()</code> or <code>touchline()</code> on <i>orig</i> before calling <code>wrefresh()</code> on the subwindow.</p> <p>The <code>derwin()</code> routine is the same as <code>subwin()</code>, except that <i>begin_y</i> and <i>begin_x</i> are relative to the origin of the window <i>orig</i> rather than the screen. There is no difference between the subwindows and the derived windows.</p> |

syncok(3CURSES)

The `mvderwin()` routine moves a derived window (or subwindow) inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

The `dupwin()` routine creates an exact duplicate of the window *win*.

Each `curses` window maintains two data structures: the character image structure and the status structure. The character image structure is shared among all windows in the window hierarchy (that is, the window with all subwindows). The status structure, which contains information about individual line changes in the window, is private to each window. The routine `wrefresh()` uses the status data structure when performing screen updating. Since status structures are not shared, changes made to one window in the hierarchy may not be properly reflected on the screen.

The routine `wsyncup()` causes the changes in the status structure of a window to be reflected in the status structures of its ancestors. If `syncok()` is called with second argument `TRUE` then `wsyncup()` is called automatically whenever there is a change in the window.

The routine `wcursyncup()` updates the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

The routine `wsyncdown()` updates the status structure of the window to reflect the changes in the status structures of its ancestors. Applications seldom call this routine because it is called automatically by `wrefresh()`.

#### RETURN VALUES

Routines that return an integer return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`delwin()` returns the integer `ERR` upon failure and `OK` upon successful completion.

Routines that return pointers return `NULL` on error.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

#### SEE ALSO

`curs_refresh(3CURSES)`, `curs_touch(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

#### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

If many small changes are made to the window, the `wsyncup()` option could degrade performance.

`syncok(3CURSES)`

Note that `syncok()` may be a macro.

| <b>NAME</b>          | syncok, wcursyncup, wsyncdown, wsyncup – synchronize window with its parents or children                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |

| <b>PARAMETERS</b>    | <p><i>win</i> Is a pointer to a window.</p> <p><i>bf</i> Is a Boolean expression.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>syncok()</code> function uses the value of <i>bf</i> to determine whether or not the window <i>win</i>'s ancestors are implicitly touched whenever there is a change to <i>win</i>. If <i>bf</i> is TRUE, this touching occurs. If <i>bf</i> is FALSE, it does not occur. The initial value for <i>bf</i> is FALSE.</p> <p>The <code>wcursyncup()</code> function moves the cursor in <i>win</i>'s ancestors to match its position in <i>win</i>.</p> <p>The <code>wsyncdown()</code> function touches <i>win</i> if any of its ancestors have been touched.</p> <p>The <code>wsyncup()</code> function touches all ancestors of <i>win</i>.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | <p>On success, the <code>syncok()</code> function returns OK. Otherwise, it returns ERR.</p> <p>The other functions do not return a value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |

| DESCRIPTION   | <p>The <code>baudrate()</code> routine returns the output speed of the terminal. The number returned is in bits per second, for example 9600, and is an integer.</p> <p>With the <code>erasechar()</code> routine, the user's current erase character is returned.</p> <p>The <code>has_ic()</code> routine is true if the terminal has insert- and delete-character capabilities.</p> <p>The <code>has_il()</code> routine is true if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This might be used to determine if it would be appropriate to turn on physical scrolling using <code>scrolllok()</code>.</p> <p>With the <code>killchar()</code> routine, the user's current line kill character is returned.</p> <p>The <code>longname()</code> routine returns a pointer to a static area containing a verbose description of the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to <code>initscr()</code> or <code>newterm()</code>. The area is overwritten by each call to <code>newterm()</code> and is not restored by <code>set_term()</code>, so the value should be saved between calls to <code>newterm()</code> if <code>longname()</code> is going to be used with multiple terminals.</p> <p>If a given terminal doesn't support a video attribute that an application program is trying to use, <code>curses</code> may substitute a different video attribute for it. The <code>termattrs()</code> function returns a logical OR of all video attributes supported by the terminal. This information is useful when a <code>curses</code> program needs complete control over the appearance of the screen.</p> <p>The <code>termname()</code> routine returns the value of the environment variable <code>TERM</code> (truncated to 14 characters).</p> |
| RETURN VALUES | <code>longname()</code> and <code>termname()</code> return <code>NULL</code> on error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

termattrs(3CURSES)

Routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO**

curl\_initscr(3CURSES), curl\_outopts(3CURSES), curses(3CURSES), attributes(5)

**NOTES**

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `termattrs()` may be a macro.

term\_attrs(3XCURSES)

| NAME                | termattrs, term_attrs – get supported terminal video attributes                                                                                                                                                                                                            |                |                 |                     |          |          |        |

| DESCRIPTION   | <p>The <code>baudrate()</code> routine returns the output speed of the terminal. The number returned is in bits per second, for example 9600, and is an integer.</p> <p>With the <code>erasechar()</code> routine, the user's current erase character is returned.</p> <p>The <code>has_ic()</code> routine is true if the terminal has insert- and delete-character capabilities.</p> <p>The <code>has_il()</code> routine is true if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This might be used to determine if it would be appropriate to turn on physical scrolling using <code>scrolllok()</code>.</p> <p>With the <code>killchar()</code> routine, the user's current line kill character is returned.</p> <p>The <code>longname()</code> routine returns a pointer to a static area containing a verbose description of the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to <code>initscr()</code> or <code>newterm()</code>. The area is overwritten by each call to <code>newterm()</code> and is not restored by <code>set_term()</code>, so the value should be saved between calls to <code>newterm()</code> if <code>longname()</code> is going to be used with multiple terminals.</p> <p>If a given terminal doesn't support a video attribute that an application program is trying to use, <code>curses</code> may substitute a different video attribute for it. The <code>termattrs()</code> function returns a logical OR of all video attributes supported by the terminal. This information is useful when a <code>curses</code> program needs complete control over the appearance of the screen.</p> <p>The <code>termname()</code> routine returns the value of the environment variable <code>TERM</code> (truncated to 14 characters).</p> |
| RETURN VALUES | <code>longname()</code> and <code>termname()</code> return <code>NULL</code> on error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

termname(3CURSES)

Routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curs\_initscr(3CURSES), curs\_outopts(3CURSES), curses(3CURSES), attributes(5)

**NOTES** The header <curses.h> automatically includes the headers <stdio.h> and <unctrl.h>.

Note that termattrs() may be a macro.

termname(3XCURSES)

| NAME                | termname – return the value of the environmental variable TERM                                                                                                                                                                                                                    |                |                 |                     |          |          |        |

| SYNOPSIS            | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  char *termname(void);</pre>                                                             |                |                 |                     |          |          |        |
| DESCRIPTION         | The <code>termname()</code> function returns a pointer to the value of the environmental variable TERM (truncated to 14 characters).                                                                                                                                              |                |                 |                     |          |          |        |
| RETURN VALUES       | The <code>termname()</code> returns a pointer to the terminal's name.                                                                                                                                                                                                             |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                             |                |                 |                     |          |          |        |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt; #include &lt;term.h&gt;  int tgetent(char *bp, char *name); int tgetflag(char id[2]); int tgetnum(char id[2]); char *tgetstr(char id[2], char **area); char *tgoto(char *cap, int col, int row); int tputs(char *str, int affcnt, int (*putc)(void));</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |
| DESCRIPTION    | <p>These routines are included as a conversion aid for programs that use the <i>termcap</i> library. Their parameters are the same and the routines are emulated using the <i>terminfo</i> database. These routines are supported at Level 2 and should not be used in new applications.</p> <p>The <code>tgetent()</code> routine looks up the termcap entry for <i>name</i>. The emulation ignores the buffer pointer <i>bp</i>.</p> <p>The <code>tgetflag()</code> routine gets the boolean entry for <i>id</i>.</p> <p>The <code>tgetnum()</code> routine gets the numeric entry for <i>id</i>.</p> <p>The <code>tgetstr()</code> routine returns the string entry for <i>id</i>. Use <code>tputs()</code> to output the returned string.</p> <p>The <code>tgoto()</code> routine instantiates the parameters into the given capability. The output from this routine is to be passed to <code>tputs()</code>.</p> <p>The <code>tputs()</code> routine is described on the <code>curs_terminfo(3CURSES)</code> manual page.</p> |                |                 |          |        |
| RETURN VALUES  | <p>Routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion.</p> <p>Routines that return pointers return NULL on error.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |

| <b>PARAMETERS</b>    | <p><i>bp</i> Is a pointer to a buffer. This parameter is ignored.</p> <p><i>name</i> Is the termcap entry to look up.</p> <p><i>cap</i> Is the pointer to a termcap capability.</p> <p><i>area</i> Is a pointer to the area where tgetstr() stores the decoded string.</p> <p><i>col</i> Is the column placement of the new cursor.</p> <p><i>row</i> Is the row placement of the new cursor.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b>   | <p>The tgetent() function looks up the termcap entry for <i>name</i>. The emulation ignores the buffer pointer <i>bp</i>.</p> <p>The tgetflag() function gets the Boolean entry for <i>id</i>.</p> <p>The tgetnum() function gets the numeric entry for <i>id</i>.</p> <p>The tgetstr() function gets the string entry for <i>id</i>. If <i>area</i> is not a null pointer and does not point to a null pointer, tgetstr() copies the string entry into the buffer pointed to by <i>*area</i> and advances the variable pointed to by <i>area</i> to the first byte after the copy of the string entry.</p> <p>The tgoto() function instantiates the parameters <i>col</i> and <i>row</i> into the capability <i>cap</i> and returns a pointer to the resulting string.</p> <p>All of the information available in the terminfo database need not be available through these functions.</p> |
| <b>RETURN VALUES</b> | <p>Upon successful completion, those functions that return integers return OK. Otherwise, they return ERR.</p> <p>Those functions that return pointers return a null pointer when an error occurs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

tgetent(3XCURSES)

**USAGE** | These functions are included as a conversion aid for programs that use the `termcap` library. Their arguments are the same and the functions are emulated using the `terminfo` database.

These functions are only guaranteed to operate reliably on character sets in which each character fits into a single byte, whose attributes can be expressed using only constants with the `A_` prefix.

Any terminal capabilities from the `terminfo` database that cannot be retrieved using these functions can be retrieved using the functions described on the `tigetflag(3XCURSES)` manual page.

Portable applications must use `tputs(3XCURSES)` to output the strings returned by `tgetstr()` and `tgoto()`.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO** | `libcurses(3XCURSES)`, `putp(3XCURSES)`, `setupterm(3XCURSES)`, `tigetflag(3XCURSES)`, `attributes(5)`, `standards(5)`

| NAME           | curs_termcap, tgetent, tgetflag, tgetnum, tgetstr, tgoto, tputs – curses interfaces (emulated) to the termcap library                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |          |        |

| DESCRIPTION    | <p>These routines are included as a conversion aid for programs that use the <i>termcap</i> library. Their parameters are the same and the routines are emulated using the <i>terminfo</i> database. These routines are supported at Level 2 and should not be used in new applications.</p> <p>The <code>tgetent()</code> routine looks up the termcap entry for <i>name</i>. The emulation ignores the buffer pointer <i>bp</i>.</p> <p>The <code>tgetflag()</code> routine gets the boolean entry for <i>id</i>.</p> <p>The <code>tgetnum()</code> routine gets the numeric entry for <i>id</i>.</p> <p>The <code>tgetstr()</code> routine returns the string entry for <i>id</i>. Use <code>tputs()</code> to output the returned string.</p> <p>The <code>tgoto()</code> routine instantiates the parameters into the given capability. The output from this routine is to be passed to <code>tputs()</code>.</p> <p>The <code>tputs()</code> routine is described on the <code>curs_terminfo(3CURSES)</code> manual page.</p> |                |                 |          |        |
| RETURN VALUES  | <p>Routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion.</p> <p>Routines that return pointers return NULL on error.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |

| <b>PARAMETERS</b>    | <p><i>bp</i> Is a pointer to a buffer. This parameter is ignored.</p> <p><i>name</i> Is the termcap entry to look up.</p> <p><i>cap</i> Is the pointer to a termcap capability.</p> <p><i>area</i> Is a pointer to the area where tgetstr() stores the decoded string.</p> <p><i>col</i> Is the column placement of the new cursor.</p> <p><i>row</i> Is the row placement of the new cursor.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b>   | <p>The tgetent() function looks up the termcap entry for <i>name</i>. The emulation ignores the buffer pointer <i>bp</i>.</p> <p>The tgetflag() function gets the Boolean entry for <i>id</i>.</p> <p>The tgetnum() function gets the numeric entry for <i>id</i>.</p> <p>The tgetstr() function gets the string entry for <i>id</i>. If <i>area</i> is not a null pointer and does not point to a null pointer, tgetstr() copies the string entry into the buffer pointed to by <i>*area</i> and advances the variable pointed to by <i>area</i> to the first byte after the copy of the string entry.</p> <p>The tgoto() function instantiates the parameters <i>col</i> and <i>row</i> into the capability <i>cap</i> and returns a pointer to the resulting string.</p> <p>All of the information available in the terminfo database need not be available through these functions.</p> |
| <b>RETURN VALUES</b> | <p>Upon successful completion, those functions that return integers return OK. Otherwise, they return ERR.</p> <p>Those functions that return pointers return a null pointer when an error occurs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## tgetflag(3XCURSES)

**USAGE** These functions are included as a conversion aid for programs that use the `termcap` library. Their arguments are the same and the functions are emulated using the `terminfo` database.

These functions are only guaranteed to operate reliably on character sets in which each character fits into a single byte, whose attributes can be expressed using only constants with the `A_` prefix.

Any terminal capabilities from the `terminfo` database that cannot be retrieved using these functions can be retrieved using the functions described on the `tigetflag(3XCURSES)` manual page.

Portable applications must use `tputs(3XCURSES)` to output the strings returned by `tgetstr()` and `tgoto()`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO** `libcurses(3XCURSES)`, `putp(3XCURSES)`, `setupterm(3XCURSES)`, `tigetflag(3XCURSES)`, `attributes(5)`, `standards(5)`

| NAME           | curs_termcap, tgetent, tgetflag, tgetnum, tgetstr, tgoto, tputs – curses interfaces (emulated) to the termcap library                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |          |        |

| DESCRIPTION    | <p>These routines are included as a conversion aid for programs that use the <i>termcap</i> library. Their parameters are the same and the routines are emulated using the <i>terminfo</i> database. These routines are supported at Level 2 and should not be used in new applications.</p> <p>The <code>tgetent()</code> routine looks up the termcap entry for <i>name</i>. The emulation ignores the buffer pointer <i>bp</i>.</p> <p>The <code>tgetflag()</code> routine gets the boolean entry for <i>id</i>.</p> <p>The <code>tgetnum()</code> routine gets the numeric entry for <i>id</i>.</p> <p>The <code>tgetstr()</code> routine returns the string entry for <i>id</i>. Use <code>tputs()</code> to output the returned string.</p> <p>The <code>tgoto()</code> routine instantiates the parameters into the given capability. The output from this routine is to be passed to <code>tputs()</code>.</p> <p>The <code>tputs()</code> routine is described on the <code>curs_terminfo(3CURSES)</code> manual page.</p> |                |                 |          |        |
| RETURN VALUES  | <p>Routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion.</p> <p>Routines that return pointers return NULL on error.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |

| <b>PARAMETERS</b>    | <p><i>bp</i> Is a pointer to a buffer. This parameter is ignored.</p> <p><i>name</i> Is the termcap entry to look up.</p> <p><i>cap</i> Is the pointer to a termcap capability.</p> <p><i>area</i> Is a pointer to the area where tgetstr() stores the decoded string.</p> <p><i>col</i> Is the column placement of the new cursor.</p> <p><i>row</i> Is the row placement of the new cursor.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b>   | <p>The tgetent() function looks up the termcap entry for <i>name</i>. The emulation ignores the buffer pointer <i>bp</i>.</p> <p>The tgetflag() function gets the Boolean entry for <i>id</i>.</p> <p>The tgetnum() function gets the numeric entry for <i>id</i>.</p> <p>The tgetstr() function gets the string entry for <i>id</i>. If <i>area</i> is not a null pointer and does not point to a null pointer, tgetstr() copies the string entry into the buffer pointed to by <i>*area</i> and advances the variable pointed to by <i>area</i> to the first byte after the copy of the string entry.</p> <p>The tgoto() function instantiates the parameters <i>col</i> and <i>row</i> into the capability <i>cap</i> and returns a pointer to the resulting string.</p> <p>All of the information available in the terminfo database need not be available through these functions.</p> |
| <b>RETURN VALUES</b> | <p>Upon successful completion, those functions that return integers return OK. Otherwise, they return ERR.</p> <p>Those functions that return pointers return a null pointer when an error occurs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

tgetnum(3XCURSES)

**USAGE** These functions are included as a conversion aid for programs that use the `termcap` library. Their arguments are the same and the functions are emulated using the `terminfo` database.

These functions are only guaranteed to operate reliably on character sets in which each character fits into a single byte, whose attributes can be expressed using only constants with the `A_` prefix.

Any terminal capabilities from the `terminfo` database that cannot be retrieved using these functions can be retrieved using the functions described on the `tigetflag(3XCURSES)` manual page.

Portable applications must use `tputs(3XCURSES)` to output the strings returned by `tgetstr()` and `tgoto()`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO** `libcurses(3XCURSES)`, `putp(3XCURSES)`, `setupterm(3XCURSES)`, `tigetflag(3XCURSES)`, `attributes(5)`, `standards(5)`

| NAME           | curs_termcap, tgetent, tgetflag, tgetnum, tgetstr, tgoto, tputs – curses interfaces (emulated) to the termcap library                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |          |        |

| DESCRIPTION    | <p>These routines are included as a conversion aid for programs that use the <i>termcap</i> library. Their parameters are the same and the routines are emulated using the <i>terminfo</i> database. These routines are supported at Level 2 and should not be used in new applications.</p> <p>The <code>tgetent()</code> routine looks up the termcap entry for <i>name</i>. The emulation ignores the buffer pointer <i>bp</i>.</p> <p>The <code>tgetflag()</code> routine gets the boolean entry for <i>id</i>.</p> <p>The <code>tgetnum()</code> routine gets the numeric entry for <i>id</i>.</p> <p>The <code>tgetstr()</code> routine returns the string entry for <i>id</i>. Use <code>tputs()</code> to output the returned string.</p> <p>The <code>tgoto()</code> routine instantiates the parameters into the given capability. The output from this routine is to be passed to <code>tputs()</code>.</p> <p>The <code>tputs()</code> routine is described on the <code>curs_terminfo(3CURSES)</code> manual page.</p> |                |                 |          |        |
| RETURN VALUES  | <p>Routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion.</p> <p>Routines that return pointers return NULL on error.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |

| <b>PARAMETERS</b>    | <p><i>bp</i> Is a pointer to a buffer. This parameter is ignored.</p> <p><i>name</i> Is the termcap entry to look up.</p> <p><i>cap</i> Is the pointer to a termcap capability.</p> <p><i>area</i> Is a pointer to the area where tgetstr() stores the decoded string.</p> <p><i>col</i> Is the column placement of the new cursor.</p> <p><i>row</i> Is the row placement of the new cursor.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b>   | <p>The tgetent() function looks up the termcap entry for <i>name</i>. The emulation ignores the buffer pointer <i>bp</i>.</p> <p>The tgetflag() function gets the Boolean entry for <i>id</i>.</p> <p>The tgetnum() function gets the numeric entry for <i>id</i>.</p> <p>The tgetstr() function gets the string entry for <i>id</i>. If <i>area</i> is not a null pointer and does not point to a null pointer, tgetstr() copies the string entry into the buffer pointed to by <i>*area</i> and advances the variable pointed to by <i>area</i> to the first byte after the copy of the string entry.</p> <p>The tgoto() function instantiates the parameters <i>col</i> and <i>row</i> into the capability <i>cap</i> and returns a pointer to the resulting string.</p> <p>All of the information available in the terminfo database need not be available through these functions.</p> |
| <b>RETURN VALUES</b> | <p>Upon successful completion, those functions that return integers return OK. Otherwise, they return ERR.</p> <p>Those functions that return pointers return a null pointer when an error occurs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

tgetstr(3XCURSES)

**USAGE** These functions are included as a conversion aid for programs that use the `termcap` library. Their arguments are the same and the functions are emulated using the `terminfo` database.

These functions are only guaranteed to operate reliably on character sets in which each character fits into a single byte, whose attributes can be expressed using only constants with the `A_` prefix.

Any terminal capabilities from the `terminfo` database that cannot be retrieved using these functions can be retrieved using the functions described on the `tigetflag(3XCURSES)` manual page.

Portable applications must use `tputs(3XCURSES)` to output the strings returned by `tgetstr()` and `tgoto()`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| DESCRIPTION    | <p>These routines are included as a conversion aid for programs that use the <i>termcap</i> library. Their parameters are the same and the routines are emulated using the <i>terminfo</i> database. These routines are supported at Level 2 and should not be used in new applications.</p> <p>The <code>tgetent()</code> routine looks up the termcap entry for <i>name</i>. The emulation ignores the buffer pointer <i>bp</i>.</p> <p>The <code>tgetflag()</code> routine gets the boolean entry for <i>id</i>.</p> <p>The <code>tgetnum()</code> routine gets the numeric entry for <i>id</i>.</p> <p>The <code>tgetstr()</code> routine returns the string entry for <i>id</i>. Use <code>tputs()</code> to output the returned string.</p> <p>The <code>tgoto()</code> routine instantiates the parameters into the given capability. The output from this routine is to be passed to <code>tputs()</code>.</p> <p>The <code>tputs()</code> routine is described on the <code>curs_terminfo(3CURSES)</code> manual page.</p> |                |                 |          |        |
| RETURN VALUES  | <p>Routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion.</p> <p>Routines that return pointers return NULL on error.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |

| <b>PARAMETERS</b>    | <p><i>bp</i> Is a pointer to a buffer. This parameter is ignored.</p> <p><i>name</i> Is the termcap entry to look up.</p> <p><i>cap</i> Is the pointer to a termcap capability.</p> <p><i>area</i> Is a pointer to the area where tgetstr() stores the decoded string.</p> <p><i>col</i> Is the column placement of the new cursor.</p> <p><i>row</i> Is the row placement of the new cursor.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b>   | <p>The tgetent() function looks up the termcap entry for <i>name</i>. The emulation ignores the buffer pointer <i>bp</i>.</p> <p>The tgetflag() function gets the Boolean entry for <i>id</i>.</p> <p>The tgetnum() function gets the numeric entry for <i>id</i>.</p> <p>The tgetstr() function gets the string entry for <i>id</i>. If <i>area</i> is not a null pointer and does not point to a null pointer, tgetstr() copies the string entry into the buffer pointed to by <i>*area</i> and advances the variable pointed to by <i>area</i> to the first byte after the copy of the string entry.</p> <p>The tgoto() function instantiates the parameters <i>col</i> and <i>row</i> into the capability <i>cap</i> and returns a pointer to the resulting string.</p> <p>All of the information available in the terminfo database need not be available through these functions.</p> |
| <b>RETURN VALUES</b> | <p>Upon successful completion, those functions that return integers return OK. Otherwise, they return ERR.</p> <p>Those functions that return pointers return a null pointer when an error occurs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

tgoto(3XCURSES)

**USAGE** These functions are included as a conversion aid for programs that use the `termcap` library. Their arguments are the same and the functions are emulated using the `terminfo` database.

These functions are only guaranteed to operate reliably on character sets in which each character fits into a single byte, whose attributes can be expressed using only constants with the `A_` prefix.

Any terminal capabilities from the `terminfo` database that cannot be retrieved using these functions can be retrieved using the functions described on the `tigetflag(3XCURSES)` manual page.

Portable applications must use `tputs(3XCURSES)` to output the strings returned by `tgetstr()` and `tgoto()`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO** `libcurses(3XCURSES)`, `putp(3XCURSES)`, `setupterm(3XCURSES)`, `tigetflag(3XCURSES)`, `attributes(5)`, `standards(5)`

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| DESCRIPTION | <p>These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, curses routines are more suitable and their use is recommended.</p> <p>Initially, <code>setupterm()</code> should be called. Note that <code>setupterm()</code> is automatically called by <code>initscr()</code> and <code>newterm()</code>. This defines the set of terminal-dependent variables (listed in <code>terminfo(4)</code>). The <i>terminfo</i> variables <code>lines</code> and <code>columns</code> are initialized by <code>setupterm()</code> as follows: If <code>use_env(FALSE)</code> has been called, values for <code>lines</code> and <code>columns</code> specified in <i>terminfo</i> are used. Otherwise, if the environment variables <code>LINES</code> and <code>COLUMNS</code> exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database are used.</p> <p>The headers <code>&lt;curses.h&gt;</code> and <code>&lt;term.h&gt;</code> should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through <code>tparm()</code> to instantiate them. All <i>terminfo</i> strings (including the output</p> |

## tigetflag(3CURSES)

of `tparm()` should be printed with `tputs()` or `putp()`. Call the `reset_shell_mode()` routine to restore the tty modes before exiting (see `curs_kernel(3CURSES)`). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call `reset_shell_mode` and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call `reset_prog_mode` after returning from the shell.

The `setupterm()` routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fildef* which is initialized for output. If *errret* is not null, then `setupterm()` returns OK or ERR and stores a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo* database could not be found. If *errret* is null, `setupterm()` prints an error message upon finding an error and exits. Thus, the simplest call is:

`setupterm((char *)0, 1, (int *)0);` which uses all the defaults and sends the output to `stdout`.

The `setterm()` routine is being replaced by `setupterm()`. The call:

`setupterm(term, 1, (int *)0)` provides the same functionality as `setterm(term)`. The `setterm()` routine is included here for compatibility and is supported at Level 2.

The `set_curterm()` routine sets the variable `cur_term` to *nterm*, and makes all of the *terminfo* boolean, numeric, and string variables use the values from *nterm*.

The `del_curterm()` routine frees the space pointed to by *oterm* and makes it available for further use. If *oterm* is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another `setupterm()` has been called.

The `restartterm()` routine is similar to `setupterm()` and `initscr()`, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The `tparm()` routine instantiates the string *str* with parameters *pi*. A pointer is returned to the result of *str* with the parameters applied.

The `tputs()` routine applies padding information to the string *str* and outputs it. The *str* must be a *terminfo* string variable or the return value from `tparm()`, `tgetstr()`, or `tgoto()`. *affcnt* is the number of lines affected, or 1 if not applicable. *putc* is a `putchar()`-like routine to which the characters are passed, one at a time.

tigetflag(3CURSES)

The `putp()` routine calls `tputs(str, 1, putchar)`. Note that the output of `putpA()` always goes to `stdout`, not to the *fil*des specified in `setupterm()`.

The `vidputs()` routine displays the string on the terminal in the video attribute mode *attrs*, which is any combination of the attributes listed in `curses(3CURSES)`. The characters are passed to the `putchar()`-like routine `putc()`.

The `vidattr()` routine is like the `vidputs()` routine, except that it outputs through `putchar()`.

The `mvcur()` routine provides low-level cursor motion.

The `tigetflag()`, `tigetnum()` and `tigetstr()` routines return the value of the capability corresponding to the *terminfo capname* passed to them, such as `xenl`.

With the `tigetflag()` routine, the value `-1` is returned if *capname* is not a boolean capability.

With the `tigetnum()` routine, the value `-2` is returned if *capname* is not a numeric capability.

With the `tigetstr()` routine, the value `(char *)-1` is returned if *capname* is not a string capability.

The *capname* for each capability is given in the table column entitled *capname* code in the capabilities section of `terminfo(4)`.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

## RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

## SEE ALSO

`curs_initscr(3CURSES)`, `curs_kernel(3CURSES)`, `curs_termcap(3CURSES)`, `curses(3CURSES)`, `putc(3C)`, `terminfo(4)`, `attributes(5)`

`tigetflag(3CURSES)`

**NOTES** | The header `< curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

The `setupterm()` routine should be used in place of `setterm()`.

Note that `vidattr()` and `vidputs()` may be macros.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                         |

| <b>NAME</b>          | tigetflag, tigetnum, tigetstr, tparm – return the value of a terminfo capability                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                                         |
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;term.h&gt;  int <b>tigetflag</b>(char *capname);  int <b>tigetnum</b>(char *capname);  char *<b>tigetstr</b>(char *capname);  char *<b>tparm</b>(char *cap, long p1, long p2, long p3, long p4, long p5,             long p6, long p7, long p8, long p9);</pre>                                                                                                                                                                                                             |                                                                         |
| <b>PARAMETERS</b>    | <i>capname</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Is the name of the terminfo capability for which the value is required. |
|                      | <i>cap</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Is a pointer to a string capability.                                    |
|                      | <i>p1...p9</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Are the parameters to be instantiated.                                  |
| <b>DESCRIPTION</b>   | <p>The <code>tigetflag()</code>, <code>tigetnum()</code>, and <code>tigetstr()</code> functions return values for terminfo capabilities passed to them.</p> <p>The following null-terminated arrays contain the <i>capnames</i>, the termcap codes and full C names for each of the terminfo variables.</p> <pre>char *boolnames, *boolcodes, *boolfnames char *numnames, *numcodes, *numfnames char *strnames, *strcodes, *strfnames</pre> <p>The <code>tparm()</code> function instantiates a parameterized string using nine arguments. The string is suitable for output processing by <code>tputs()</code>.</p>                                    |                                                                         |
| <b>RETURN VALUES</b> | <p>On success, the <code>tigetflg()</code>, <code>tigetnum()</code>, and <code>tigetstr()</code> functions return the specified terminfo capability.</p> <p><code>tigetflag()</code> returns <code>-1</code> if <i>capname</i> is not a Boolean capability.</p> <p><code>tigetnum()</code> returns <code>-2</code> if <i>capname</i> is not a numeric capability.</p> <p><code>tigetstr()</code> returns <code>(char *)-1</code> if <i>capname</i> is not a string capability.</p> <p>On success, the <code>tparm()</code> function returns <i>cap</i> in a static buffer with the parameterization resolved. Otherwise, it returns a null pointer.</p> |                                                                         |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                         |

| DESCRIPTION | <p>These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, curses routines are more suitable and their use is recommended.</p> <p>Initially, <code>setupterm()</code> should be called. Note that <code>setupterm()</code> is automatically called by <code>initscr()</code> and <code>newterm()</code>. This defines the set of terminal-dependent variables (listed in <code>terminfo(4)</code>). The <i>terminfo</i> variables <code>lines</code> and <code>columns</code> are initialized by <code>setupterm()</code> as follows: If <code>use_env(FALSE)</code> has been called, values for <code>lines</code> and <code>columns</code> specified in <i>terminfo</i> are used. Otherwise, if the environment variables <code>LINES</code> and <code>COLUMNS</code> exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database are used.</p> <p>The headers <code>&lt;curses.h&gt;</code> and <code>&lt;term.h&gt;</code> should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through <code>tparm()</code> to instantiate them. All <i>terminfo</i> strings (including the output</p> |

tigetnum(3CURSES)

of `tparm()` should be printed with `tputs()` or `putp()`. Call the `reset_shell_mode()` routine to restore the tty modes before exiting (see `curs_kernel(3CURSES)`). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call `reset_shell_mode` and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call `reset_prog_mode` after returning from the shell.

The `setupterm()` routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fildef* which is initialized for output. If *errret* is not null, then `setupterm()` returns OK or ERR and stores a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo* database could not be found. If *errret* is null, `setupterm()` prints an error message upon finding an error and exits. Thus, the simplest call is:

`setupterm((char *)0, 1, (int *)0);` which uses all the defaults and sends the output to `stdout`.

The `setterm()` routine is being replaced by `setupterm()`. The call:

`setupterm(term, 1, (int *)0)` provides the same functionality as `setterm(term)`. The `setterm()` routine is included here for compatibility and is supported at Level 2.

The `set_curterm()` routine sets the variable `cur_term` to *nterm*, and makes all of the *terminfo* boolean, numeric, and string variables use the values from *nterm*.

The `del_curterm()` routine frees the space pointed to by *oterm* and makes it available for further use. If *oterm* is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another `setupterm()` has been called.

The `restartterm()` routine is similar to `setupterm()` and `initscr()`, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The `tparm()` routine instantiates the string *str* with parameters *pi*. A pointer is returned to the result of *str* with the parameters applied.

The `tputs()` routine applies padding information to the string *str* and outputs it. The *str* must be a *terminfo* string variable or the return value from `tparm()`, `tgetstr()`, or `tgoto()`. *affcnt* is the number of lines affected, or 1 if not applicable. *putc* is a `putchar()`-like routine to which the characters are passed, one at a time.

tigetnum(3CURSES)

The `putp()` routine calls `tputs(str, 1, putchar)`. Note that the output of `putpA()` always goes to `stdout`, not to the *fil*des specified in `setupterm()`.

The `vidputs()` routine displays the string on the terminal in the video attribute mode *attrs*, which is any combination of the attributes listed in `curses(3CURSES)`. The characters are passed to the `putchar()`-like routine `putc()`.

The `vidattr()` routine is like the `vidputs()` routine, except that it outputs through `putchar()`.

The `mvcur()` routine provides low-level cursor motion.

The `tigetflag()`, `tigetnum()` and `tigetstr()` routines return the value of the capability corresponding to the *terminfo capname* passed to them, such as `xenl`.

With the `tigetflag()` routine, the value `-1` is returned if *capname* is not a boolean capability.

With the `tigetnum()` routine, the value `-2` is returned if *capname* is not a numeric capability.

With the `tigetstr()` routine, the value `(char *)-1` is returned if *capname* is not a string capability.

The *capname* for each capability is given in the table column entitled *capname* code in the capabilities section of `terminfo(4)`.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

## RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

| NAME          | <p> <b>tigetflag</b>, <b>tigetnum</b>, <b>tigetstr</b>, <b>tparm</b> – return the value of a terminfo capability </p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| SYNOPSIS      | <pre> cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;term.h&gt;  int <b>tigetflag</b>(char *capname); int <b>tigetnum</b>(char *capname); char *<b>tigetstr</b>(char *capname); char *<b>tparm</b>(char *cap, long p1, long p2, long p3, long p4, long p5,             long p6, long p7, long p8, long p9); </pre>                                                                                                                                                     |
| PARAMETERS    | <p> <i>capname</i>                      Is the name of the terminfo capability for which the value is required. </p> <p> <i>cap</i>                              Is a pointer to a string capability. </p> <p> <i>p1...p9</i>                      Are the parameters to be instantiated. </p>                                                                                                                                                                                                                                                                                                 |
| DESCRIPTION   | <p> The <b>tigetflag()</b>, <b>tigetnum()</b>, and <b>tigetstr()</b> functions return values for terminfo capabilities passed to them. </p> <p> The following null-terminated arrays contain the <i>capnames</i>, the termcap codes and full C names for each of the terminfo variables. </p> <pre> char *boolnames, *boolcodes, *boolfnames char *numnames, *numcodes, *numfnames char *strnames, *strcodes, *strfnames </pre> <p> The <b>tparm()</b> function instantiates a parameterized string using nine arguments. The string is suitable for output processing by <b>tputs()</b>. </p> |
| RETURN VALUES | <p> On success, the <b>tigetflg()</b>, <b>tigetnum()</b>, and <b>tigetstr()</b> functions return the specified terminfo capability. </p> <p> <b>tigetflag()</b> returns -1 if <i>capname</i> is not a Boolean capability. </p> <p> <b>tigetnum()</b> returns -2 if <i>capname</i> is not a numeric capability. </p> <p> <b>tigetstr()</b> returns (char *)-1 if <i>capname</i> is not a string capability. </p> <p> On success, the <b>tparm()</b> function returns <i>cap</i> in a static buffer with the parameterization resolved. Otherwise, it returns a null pointer. </p>               |
| ERRORS        | <p> None. </p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| DESCRIPTION | <p>These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, curses routines are more suitable and their use is recommended.</p> <p>Initially, <code>setupterm()</code> should be called. Note that <code>setupterm()</code> is automatically called by <code>initscr()</code> and <code>newterm()</code>. This defines the set of terminal-dependent variables (listed in <code>terminfo(4)</code>). The <i>terminfo</i> variables <code>lines</code> and <code>columns</code> are initialized by <code>setupterm()</code> as follows: If <code>use_env(FALSE)</code> has been called, values for <code>lines</code> and <code>columns</code> specified in <i>terminfo</i> are used. Otherwise, if the environment variables <code>LINES</code> and <code>COLUMNS</code> exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database are used.</p> <p>The headers <code>&lt;curses.h&gt;</code> and <code>&lt;term.h&gt;</code> should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through <code>tparm()</code> to instantiate them. All <i>terminfo</i> strings (including the output</p> |

tigetstr(3CURSES)

of `tparm()` should be printed with `tputs()` or `putp()`. Call the `reset_shell_mode()` routine to restore the tty modes before exiting (see `curs_kernel(3CURSES)`). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call `reset_shell_mode` and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call `reset_prog_mode` after returning from the shell.

The `setupterm()` routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fildef* which is initialized for output. If *errret* is not null, then `setupterm()` returns OK or ERR and stores a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo* database could not be found. If *errret* is null, `setupterm()` prints an error message upon finding an error and exits. Thus, the simplest call is:

`setupterm((char *)0, 1, (int *)0);` which uses all the defaults and sends the output to `stdout`.

The `setterm()` routine is being replaced by `setupterm()`. The call:

`setupterm(term, 1, (int *)0)` provides the same functionality as `setterm(term)`. The `setterm()` routine is included here for compatibility and is supported at Level 2.

The `set_curterm()` routine sets the variable `cur_term` to *nterm*, and makes all of the *terminfo* boolean, numeric, and string variables use the values from *nterm*.

The `del_curterm()` routine frees the space pointed to by *oterm* and makes it available for further use. If *oterm* is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another `setupterm()` has been called.

The `restartterm()` routine is similar to `setupterm()` and `initscr()`, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The `tparm()` routine instantiates the string *str* with parameters *pi*. A pointer is returned to the result of *str* with the parameters applied.

The `tputs()` routine applies padding information to the string *str* and outputs it. The *str* must be a *terminfo* string variable or the return value from `tparm()`, `tgetstr()`, or `tgoto()`. *affcnt* is the number of lines affected, or 1 if not applicable. *putc* is a `putchar()`-like routine to which the characters are passed, one at a time.

tigetstr(3CURSES)

The `putp()` routine calls `tputs(str, 1, putchar)`. Note that the output of `putpA()` always goes to `stdout`, not to the *fil*des specified in `setupterm()`.

The `vidputs()` routine displays the string on the terminal in the video attribute mode *attrs*, which is any combination of the attributes listed in `curses(3CURSES)`. The characters are passed to the `putchar()`-like routine `putc()`.

The `vidattr()` routine is like the `vidputs()` routine, except that it outputs through `putchar()`.

The `mvcur()` routine provides low-level cursor motion.

The `tigetflag()`, `tigetnum()` and `tigetstr()` routines return the value of the capability corresponding to the *terminfo capname* passed to them, such as `xenl`.

With the `tigetflag()` routine, the value `-1` is returned if *capname* is not a boolean capability.

With the `tigetnum()` routine, the value `-2` is returned if *capname* is not a numeric capability.

With the `tigetstr()` routine, the value `(char *)-1` is returned if *capname* is not a string capability.

The *capname* for each capability is given in the table column entitled *capname* code in the capabilities section of `terminfo(4)`.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

## RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

## ATTRIBUTES

| NAME          | tigetflag, tigetnum, tigetstr, tparm – return the value of a terminfo capability                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| SYNOPSIS      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;term.h&gt;  int <b>tigetflag</b>(char *capname); int <b>tigetnum</b>(char *capname); char *<b>tigetstr</b>(char *capname); char *<b>tparm</b>(char *cap, long p1, long p2, long p3, long p4, long p5,             long p6, long p7, long p8, long p9);</pre>                                                                                                                                                                                                                |
| PARAMETERS    | <p><i>capname</i>                      Is the name of the terminfo capability for which the value is required.</p> <p><i>cap</i>                              Is a pointer to a string capability.</p> <p><i>p1...p9</i>                        Are the parameters to be instantiated.</p>                                                                                                                                                                                                                                                                                                                                                              |
| DESCRIPTION   | <p>The <code>tigetflag()</code>, <code>tigetnum()</code>, and <code>tigetstr()</code> functions return values for terminfo capabilities passed to them.</p> <p>The following null-terminated arrays contain the <i>capnames</i>, the termcap codes and full C names for each of the terminfo variables.</p> <pre>char *boolnames, *boolcodes, *boolfnames char *numnames, *numcodes, *numfnames char *strnames, *strcodes, *strfnames</pre> <p>The <code>tparm()</code> function instantiates a parameterized string using nine arguments. The string is suitable for output processing by <code>tputs()</code>.</p>                                    |
| RETURN VALUES | <p>On success, the <code>tigetflg()</code>, <code>tigetnum()</code>, and <code>tigetstr()</code> functions return the specified terminfo capability.</p> <p><code>tigetflag()</code> returns <code>-1</code> if <i>capname</i> is not a Boolean capability.</p> <p><code>tigetnum()</code> returns <code>-2</code> if <i>capname</i> is not a numeric capability.</p> <p><code>tigetstr()</code> returns <code>(char *)-1</code> if <i>capname</i> is not a string capability.</p> <p>On success, the <code>tparm()</code> function returns <i>cap</i> in a static buffer with the parameterization resolved. Otherwise, it returns a null pointer.</p> |
| ERRORS        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| DESCRIPTION | <p>The <code>cbreak()</code> and <code>nocbreak()</code> routines put the terminal into and out of <code>cbreak()</code> mode, respectively. In this mode, characters typed by the user are immediately available to the program, and erase/kill character-processing is not performed. When out of this mode, the tty driver buffers the typed characters until a newline or carriage return is typed. Interrupt and flow control characters are unaffected by this mode. Initially the terminal may or may not be in <code>cbreak()</code> mode, as the mode is inherited; therefore, a program should call <code>cbreak()</code> or <code>nocbreak()</code> explicitly. Most interactive programs using curses set the <code>cbreak()</code> mode.</p> <p>Note that <code>cbreak()</code> overrides <code>raw()</code>. (See <code>curs_getch(3CURSES)</code> for a discussion of how these routines interact with <code>echo()</code> and <code>noecho()</code>.)</p> <p>The <code>echo()</code> and <code>noecho()</code> routines control whether characters typed by the user are echoed by <code>getch()</code> as they are typed. Echoing by the tty driver is always disabled, but initially <code>getch()</code> is in echo mode, so characters typed are echoed. Authors of</p> |

timeout(3CURSES)

most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling `noecho()`. (See `curs_getch(3CURSES)` for a discussion of how these routines interact with `cbreak()` and `nocbreak()`.)

The `halfdelay()` routine is used for half-delay mode, which is similar to `cbreak()` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, `ERR` is returned if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

If the `intrflush()` option is enabled, (*bf* is `TRUE`), when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing `curses` to have the wrong idea of what is on the screen. Disabling (*bf* is `FALSE`), the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.

The `keypad()` option enables the keypad of the user's terminal. If enabled (*bf* is `TRUE`), the user can press a function key (such as an arrow key) and `wgetch()` returns a single value representing the function key, as in `KEY_LEFT`. If disabled (*bf* is `FALSE`), `curses` does not treat function keys specially and the program has to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option causes the terminal keypad to be turned on when `wgetch()` is called. The default value for keypad is false.

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the tty driver (see `termio(7I)`). To force 8 bits to be returned, invoke `meta(win, TRUE)`. To force 7 bits to be returned, invoke `meta(win, FALSE)`. The window argument, *win*, is always ignored. If the terminfo capabilities `smm` (`meta_on`) and `rmm` (`meta_off`) are defined for the terminal, `smm` is sent to the terminal when `meta(win, TRUE)` is called and `rmm` is sent when `meta(win, FALSE)` is called.

The `nodelay()` option causes `getch()` to be a non-blocking call. If no input is ready, `getch()` returns `ERR`. If disabled (*bf* is `FALSE`), `getch()` waits until a key is pressed.

While interpreting an input escape sequence, `wgetch()` sets a timer while waiting for the next character. If `notimeout(win, TRUE)` is called, then `wgetch()` does not set a timer. The purpose of the timeout is to differentiate between sequences received from a function key and those typed by a user.

With the `raw()` and `noraw()` routines, the terminal is placed into or out of raw mode. Raw mode is similar to `cbreak()` mode, in that characters typed are immediately passed through to the user program. The differences are that in raw mode, the interrupt, quit, suspend, and flow control characters are all passed through uninterpreted, instead of generating a signal. The behavior of the `BREAK` key depends on other bits in the tty driver that are not set by `curses`.

timeout(3CURSES)

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the INTR, QUIT and SUSP characters will not be done (see `termio(7I)`). When `qiflush()` is called, the queues will be flushed when these control characters are read.

The `timeout()` and `wtimeout()` routines set blocking or non-blocking read for a given window. If *delay* is negative, blocking read is used (that is, waits indefinitely for input). If *delay* is zero, then non-blocking read is used (that is, read returns ERR if no input is waiting). If *delay* is positive, then read blocks for *delay* milliseconds, and returns ERR if there is still no input. Hence, these routines provide the same functionality as `nodelay()`, plus the additional capability of being able to block for only *delay* milliseconds (where *delay* is positive).

`curses` does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh()` or `doupdate()` is called again. This allows faster response to commands typed in advance. Normally, the input FILE pointer passed to `newterm()`, or `stdin` in the case that `initscr()` was used, will be used to do this typeahead checking. The `typeahead()` routine specifies that the file descriptor *fildev* is to be used to check for typeahead instead. If *fildev* is `-1`, then no typeahead checking is done.

**RETURN VALUES** All routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_getch(3CURSES)`, `curs_initscr(3CURSES)`, `curses(3CURSES)`, `attributes(5)`, `termio(7I)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `echo()`, `noecho()`, `halfdelay()`, `intrflush()`, `meta()`, `nodelay()`, `notimeout()`, `noqiflush()`, `qiflush()`, `timeout()`, and `wtimeout()` may be macros.

## timeout(3XCURSES)

| NAME           | panel_top, top_panel, bottom_panel – panels deck manipulation routines                                                                                                                                                                                                                                               |                |                 |          |        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lpanel -lcurses [ library .. ] #include &lt;panel.h&gt;  int top_panel (PANEL *panel) ; int bottom_panel (PANEL *panel) ;</pre>                                                                                                                                                       |                |                 |          |        |
| DESCRIPTION    | <p>top_panel () pulls <i>panel</i> to the top of the desk of panels. It leaves the size, location, and contents of its associated window unchanged.</p> <p>bottom_panel () puts <i>panel</i> at the bottom of the deck of panels. It leaves the size, location, and contents of its associated window unchanged.</p> |                |                 |          |        |
| RETURN VALUES  | All of these routines return the integer OK upon successful completion or ERR upon error.                                                                                                                                                                                                                            |                |                 |          |        |
| ATTRIBUTES     | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                      |                |                 |          |        |
|                | <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>MT-Level</td><td>Unsafe</td></tr></table>                                                                                                                                                                                                     | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE                                                                                                                                                                                                                                                                                                      |                |                 |          |        |
| MT-Level       | Unsafe                                                                                                                                                                                                                                                                                                               |                |                 |          |        |

| NOTES          | The header <panel.h> automatically includes the header <curses.h>.                                                                                                                                                                                                                                                   |                |                 |          |        |

top\_row(3CURSES)

**NAME** menu\_item\_current, set\_current\_item, current\_item, set\_top\_row, top\_row, item\_index  
– set and get current menus items

**SYNOPSIS**

```
cc [flag...] file... -lmenu -lcurses [library...]
#include <menu.h>

int set_current_item(MENU *menu, ITEM *item);
ITEM *current_item(MENU *menu);
int set_top_row(MENU *menu, int row);
int top_row(MENU *menu);
int item_index(ITEM *item);
```

**DESCRIPTION**

The current item of a menu is the item where the cursor is currently positioned. set\_current\_item() sets the current item of *menu* to *item*. current\_item() returns a pointer to the the current item in *menu*.

set\_top\_row() sets the top row of *menu* to *row*. The left-most item on the new top row becomes the current item. top\_row() returns the number of the menu row currently displayed at the top of *menu*.

item\_index() returns the index to the *item* in the item pointer array. The value of this index ranges from 0 through *N*-1, where *N* is the total number of items connected to the menu.

**RETURN VALUES**

current\_item() returns NULL on error.

top\_row() and index\_item() return -1 on error.

set\_current\_item() and set\_top\_row() return one of the following:

|                 |                                                                        |
|-----------------|------------------------------------------------------------------------|
| E_OK            | The routine returned successfully.                                     |
| E_SYSTEM_ERROR  | System error.                                                          |
| E_BAD_ARGUMENT  | An incorrect argument was passed to the routine.                       |
| E_BAD_STATE     | The routine was called from an initialization or termination function. |
| E_NOT_CONNECTED | No items are connected to the menu.                                    |

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curses(3CURSES), menus(3CURSES), attributes(5)

`top_row(3CURSES)`

**NOTES**

The header `<menu.h>` automatically includes the headers `<eti.h>` and `<curses.h>`.

| <b>NAME</b>          | curs_touch, touchwin, touchline, untouchwin, wtouchln, is_linetouched, is_wintouched – curses refresh control routines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int touchwin(WINDOW *win); int touchline(WINDOW *win, int start, int count); int untouchwin(WINDOW *win); int wtouchln(WINDOW *win, int y, int n, int changed); int is_linetouched(WINDOW *win, int line); int is_wintouched(WINDOW *win);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>The touchwin() and touchline() routines throw away all optimization information about which parts of the window have been touched, by pretending that the entire window has been drawn on. This is sometimes necessary when using overlapping windows, since a change to one window affects the other window, but the records of which lines have been changed in the other window do not reflect the change. The routine touchline() only pretends that <i>count</i> lines have been changed, beginning with line <i>start</i>.</p> <p>The untouchwin() routine marks all lines in the window as unchanged since the last call to wrefresh().</p> <p>The wtouchln() routine makes <i>n</i> lines in the window, starting at line <i>y</i>, look as if they have (<i>changed</i>=1) or have not (<i>changed</i>=0) been changed since the last call to wrefresh().</p> <p>The is_linetouched() and is_wintouched() routines return TRUE if the specified line/window was modified since the last call to wrefresh(); otherwise they return FALSE. In addition, is_linetouched() returns ERR if line is not valid for the given window.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |
