| <b>SYNOPSIS</b>           | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  chtype <b>inch</b>(void); chtype <b>winch</b>(WINDOW *win); chtype <b>mvinch</b>(int y, int x); chtype <b>mvwinch</b>(WINDOW *win, int y, int x);</pre>                                                                                                                                                 |                         |                               |                           |                                |                      |                                                  |
| <b>DESCRIPTION</b>        | With these routines, the character, of type <code>chtype</code> , at the current position in the named window is returned. If any attributes are set for that position, their values are OR-ed into the value returned. Constants defined in <code>&lt;curses.h&gt;</code> can be used with the logical AND ( <code>&amp;</code> ) operator to extract the character or attributes alone. |                         |                               |                           |                                |                      |                                                  |

| <b>DESCRIPTION</b>   | <p>The <code>inch()</code> and <code>winch()</code> functions return the <code>chtype</code> character located at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively. The <code>mvinch()</code> and <code>mvwinch()</code> functions return the <code>chtype</code> character located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The complete character/attribute pair will be returned. The character or attributes can be extracted by performing a bitwise AND on the returned value, using the constants <code>A_CHARTEXT</code>, <code>A_ATTRIBUTES</code>, and <code>A_COLOR</code>.</p> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>y</i>           Is the <i>y</i> (row) coordinate of the position of the character to be returned.</p> <p><i>x</i>           Is the <i>x</i> (column) coordinate of the position of the character to be returned.</p> <p><i>win</i>          Is a pointer to the window that contains the character to be returned.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return the specified character and rendition. Otherwise, they return <code>ERR</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |                     |          |          |        |

## mvinchnstr(3CURSES)

| <b>NAME</b>          | <code>curs_inchstr</code> , <code>inchstr</code> , <code>inchnstr</code> , <code>winchstr</code> , <code>winchnstr</code> , <code>mvinchstr</code> , <code>mvinchnstr</code> , <code>mvwinchstr</code> , <code>mvwinchnstr</code> – get a string of characters (and attributes) from a curses window                                                                                                                                                                                                                                          |                |                 |          |        |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>inchstr</b>(chtype *chstr); int <b>inchnstr</b>(chtype *chstr, int n); int <b>winchstr</b>(WINDOW *win, chtype *chstr); int <b>winchnstr</b>(WINDOW *win, chtype *chstr, int n); int <b>mvinchstr</b>(int y, int x, chtype *chstr); int <b>mvinchnstr</b>(int y, int x, chtype *chstr, int n); int <b>mvwinchstr</b>(WINDOW *win, int y, int x, chtype *chstr); int <b>mvwinchnstr</b>(WINDOW *win, int y, int x, chtype *chstr, int n);</pre>       |                |                 |          |        |
| <b>DESCRIPTION</b>   | With these routines, a string of type <code>chtype</code> , starting at the current cursor position in the named window and ending at the right margin of the window, is returned. The four functions with <i>n</i> as the last argument, return the string at most <i>n</i> characters long. Constants defined in <code>&lt;curses.h&gt;</code> can be used with the <code>&amp;</code> (logical AND) operator to extract the character or the attribute alone from any position in the <i>chstr</i> (see <code>curs_inch(3CURSES)</code> ). |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |
| <b>ATTRIBUTES</b>    | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |          |        |

| <b>NAME</b>        | inchstr, inchstr, mvinchstr, mvinchstr, mvwinchnstr, mvwinchnstr, winchnstr, winchnstr – retrieve a single-byte character string (with rendition)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>inchstr</b>(chtype *chstr, int n); int <b>inchstr</b>(chtype *chstr); int <b>mvinchstr</b>(int y, int x, chtype *chstr, int n); int <b>mvinchstr</b>(int y, int x, chtype *chstr); int <b>mvwinchnstr</b>(WINDOW *win, int y, int x, chtype *chstr, int n); int <b>mvwinchnstr</b>(WINDOW *win, int y, int x, chtype *chstr); int <b>winchnstr</b>(WINDOW *win, chtype *chstr, int n); int <b>winchnstr</b>(WINDOW *win, chtype *chstr);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>The <code>inchstr()</code> and <code>winchnstr()</code> functions retrieve the character string (with rendition) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinchstr()</code> and <code>mvwinchnstr()</code> functions retrieve the character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>inchstr()</code>, <code>winchnstr()</code>, <code>mvinchstr()</code>, and <code>mvwinchnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All these functions store the retrieved character string in the object pointed to by <i>chstr</i>.</p> <p>The complete character/attribute pair is retrieved. The character or attributes can be extracted by performing a bitwise AND on the retrieved value, using the constants <code>A_CHARTEXT</code>, <code>A_ATTRIBUTES</code>, and <code>A_COLOR</code>. The character string can also be retrieved without attributes by using <code>instr(3XCURSES)</code> set of functions.</p> |
| <b>PARAMETERS</b>  | <p><i>chstr</i> Is a pointer to an object that can hold the retrieved character string.</p> <p><i>n</i> Is the number of characters not to exceed when retrieving <i>chstr</i>.</p> <p><i>y</i> Is the <i>y</i> (row) coordinate of the starting position of the string to be retrieved.</p> <p><i>x</i> Is the <i>x</i> (column) coordinate of the starting position of the string to be retrieved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`mvinchnstr(3XCURSES)`

*win*      Is a pointer to the window in which the string is to be retrieved.

**RETURN VALUES**      On success, these functions return OK. Otherwise, they return ERR.

**ERRORS**      None.

**ATTRIBUTES**      See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO**      `inch(3XCURSES)`, `innstr(3XCURSES)`, `libcurses(3XCURSES)`, `attributes(5)`, `standards(5)`

| NAME           | curs_inchstr, inchstr, inchnstr, winchstr, winchnstr, mvinchstr, mvinchnstr, mvwinchstr, mvwinchnstr – get a string of characters (and attributes) from a curses window                                                                                                                                                                                                                                                                                                                 |                |                 |          |        |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int  inchstr(chtype *chstr); int  inchnstr(chtype *chstr, int n); int  winchstr(WINDOW *win, chtype *chstr); int  winchnstr(WINDOW *win, chtype *chstr, int n); int  mvinchstr(int y, int x, chtype *chstr); int  mvinchnstr(int y, int x, chtype *chstr, int n); int  mvwinchstr(WINDOW *win, int y, int x, chtype *chstr); int  mvwinchnstr(WINDOW *win, int y, int x, chtype *chstr, int n);</pre> |                |                 |          |        |
| DESCRIPTION    | With these routines, a string of type chtype, starting at the current cursor position in the named window and ending at the right margin of the window, is returned. The four functions with <i>n</i> as the last argument, return the string at most <i>n</i> characters long. Constants defined in <curses.h> can be used with the & (logical AND) operator to extract the character or the attribute alone from any position in the <i>chstr</i> (see curs_inch(3CURSES)).           |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |

| <b>DESCRIPTION</b> | <p>The <code>inchstr()</code> and <code>winchstr()</code> functions retrieve the character string (with rendition) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinchstr()</code> and <code>mvwinchstr()</code> functions retrieve the character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>inchstr()</code>, <code>winchstr()</code>, <code>mvinchstr()</code>, and <code>mvwinchstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All these functions store the retrieved character string in the object pointed to by <i>chstr</i>.</p> <p>The complete character/attribute pair is retrieved. The character or attributes can be extracted by performing a bitwise AND on the retrieved value, using the constants <code>A_CHARTEXT</code>, <code>A_ATTRIBUTES</code>, and <code>A_COLOR</code>. The character string can also be retrieved without attributes by using <code>instr(3XCURSES)</code> set of functions.</p> |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |

| <i>chstr</i>       | Is a pointer to an object that can hold the retrieved character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |
| <i>n</i>           | Is the number of characters not to exceed when retrieving <i>chstr</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |
| <i>y</i>           | Is the <i>y</i> (row) coordinate of the starting position of the string to be retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |
| <i>x</i>           | Is the <i>x</i> (column) coordinate of the starting position of the string to be retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |

`mvinchstr(3XCURSES)`

*win* Is a pointer to the window in which the string is to be retrieved.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>DESCRIPTION</b>   | These routines return a string of characters in <i>str</i> , starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with <i>n</i> as the last argument return the string at most <i>n</i> characters long.                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| <b>PARAMETERS</b>  | <p><i>str</i> Is a pointer to an object that can hold the retrieved multibyte character string.</p> <p><i>n</i> Is the number of characters not to exceed when retrieving <i>str</i>.</p> <p><i>y</i> Is the y (row) coordinate of the starting position of the string to be retrieved.</p> <p><i>x</i> Is the x (column) coordinate of the starting position of the string to be retrieved.</p> <p><i>win</i> Is a pointer to the window in which the string is to be retrieved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |  |
| <b>DESCRIPTION</b> | <p>The <code>instr()</code> and <code>winstr()</code> functions retrieve a multibyte character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinstr()</code> and <code>mvwinstr()</code> functions retrieve a multibyte character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>innstr()</code>, <code>winnstr()</code>, <code>mvinnstr()</code>, and <code>mvwinnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> |  |

mvinnstr(3XCURSES)

All these functions store the retrieved string in the object pointed to by *str*. They only store complete multibyte characters. If the area pointed to by *str* is not large enough to hold at least one character, these functions fail.

Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use `winchstr()`.

**ERRORS** OK Successful completion.

ERR An error occurred.

**USAGE** All functions except `winnstr()` may be macros.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses[library .. ] #include &lt;curses.h&gt;  int inwstr(wchar_t *wstr); int innwstr(wchar_t *wstr, int n); int winwstr(WINDOW *win, wchar_t *wstr); int winnwstr(WINDOW *win, wchar_t *wstr, int n); int mvinwstr(int y, int x, wchar_t *wstr); int mvinnwstr(int y, int x, wchar_t *wstr, int n); int mvwinwstr(WINDOW *win, int y, int x, wchar_t *wstr); int mvwinnwstr(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre> |                |                 |          |        |
| <b>DESCRIPTION</b>   | These routines return the string of <code>wchar_t</code> characters in <code>wstr</code> starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with <code>n</code> as the last argument return the string at most <code>n</code> <code>wchar_t</code> characters long.                                                                           |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |

| PARAMETERS  | <p><i>wstr</i> Is a pointer to an object that can hold the retrieved multibyte character string.</p> <p><i>n</i> Is the number of characters not to exceed when retrieving <i>wstr</i>.</p> <p><i>y</i> Is the y (row) coordinate of the starting position of the string to be retrieved.</p> <p><i>x</i> Is the x (column) coordinate of the starting position of the string to be retrieved.</p> <p><i>win</i> Is a pointer to the window in which the string is to be retrieved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DESCRIPTION | <p>The <code>inwstr()</code> and <code>winwstr()</code> functions retrieve a wide character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinwstr()</code> and <code>mvwinwstr()</code> functions retrieve a wide character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>innwstr()</code>, <code>winnwstr()</code>, <code>mvinnwstr()</code>, and <code>mvwinnwstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All these functions store the retrieved string in the object pointed to by <i>wstr</i>. They only store complete wide characters. If the area pointed to by <i>wstr</i> is not large enough to hold at least one character, these functions fail.</p> |

`mvinnwstr(3XCURSES)`

**RETURN VALUES** Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use `win_wchstr(3XCURSES)`.

On success, the `inwstr()`, `mvinwstr()`, `mvwinwstr()`, and `winwstr()` functions return OK. Otherwise, they return ERR.

On success, the `innwstr()`, `mvinnwstr()`, `mvwinnwstr()`, and `winnwstr()` functions return the number of characters read into the string. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

mvinsch(3CURSES)

| NAME           | curs_insch, insch, winsch, mvinsch, mvwinsch – insert a character before the character under the cursor in a curses window                                                                                                                                                                                                                                                                                        |                |                 |          |        |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>insch</b>(chtype <i>ch</i>) ; int <b>winsch</b>(WINDOW *<i>win</i>, chtype <i>ch</i>) ; int <b>mvinsch</b>(int <i>y</i>, int <i>x</i>, chtype <i>ch</i>) ; int <b>mvwinsch</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, chtype <i>ch</i>) ;</pre>                                                                  |                |                 |          |        |
| DESCRIPTION    | With these routines, the character <i>ch</i> is inserted before the character under the cursor. All characters to the right of the cursor are moved one space to the right, with the possibility of the rightmost character on the line being lost. The cursor position does not change (after moving to <i>y</i> , <i>x</i> , if specified). (This does not imply use of the hardware insert character feature.) |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                  |                |                 |          |        |

| <i>ch</i>            | Is the character to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| <i>y</i>             | Is the y (row) coordinate of the position of the character.                                                                                                                                                                                                                                                                                                                                                                                                  |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| <i>x</i>             | Is the x (column) coordinate of the position of the character.                                                                                                                                                                                                                                                                                                                                                                                               |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| <i>win</i>           | Is a pointer to the window in which the character is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                         |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| <b>DESCRIPTION</b>   | <p>These functions insert the character and rendition from <i>ch</i> into the current or specified window at the current or specified position.</p> <p>These functions do not perform wrapping and do not advance the cursor position. These functions perform special-character processing, with the exception that if a newline is inserted into the last line of a window and scrolling is not enabled, the behavior is unspecified.</p>                  |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| <b>RETURN VALUES</b> | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                           |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| <b>USAGE</b>         | These functions are only guaranteed to operate reliably on character sets in which each character fits into a single byte, whose attributes can be expressed using only constants with the A_ prefix.                                                                                                                                                                                                                                                        |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |

| DESCRIPTION    | <p>With these routines, a character string (as many characters as will fit on the line) is inserted before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <i>y, x</i>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <i>n</i> as the last argument insert at most <i>n</i> characters. If <i>n</i> ≤ 0, then the entire string is inserted.</p> <p>If a character in <i>str</i> is a tab, newline, carriage return or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol()</code> before moving. Tabs are considered to be at every eighth column. If a character in <i>str</i> is another control character, it is drawn in the ^X notation. Calling <code>winch()</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |          |        |

If <i>n</i> is less than 1, the entire string is inserted. | <i>y</i> | Is the y (row) coordinate of the starting position of the string. | <i>x</i> | Is the x (column) coordinate of the starting position of the string. | <i>win</i> | Is a pointer to the window in which the string is to be inserted. |
| <i>str</i>  | Is a pointer to the string to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>n</i>    | Is the number of characters not to exceed when inserting <i>str</i> . If <i>n</i> is less than 1, the entire string is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>y</i>    | Is the y (row) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>x</i>    | Is the x (column) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>win</i>  | Is a pointer to the window in which the string is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| DESCRIPTION | <p>The <code>insstr()</code> function inserts <i>str</i> at the current cursor position of the <code>stdscr</code> window. The <code>winsstr()</code> function performs the identical action, but in window <i>win</i>. The <code>mvinsstr()</code> and <code>mvwinsstr()</code> functions insert the character string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The <code>insnstr()</code>, <code>winsnstr()</code>, <code>mvinsnstr()</code>, and <code>mvwinsnstr()</code> functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.</p> |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |

mvinsnstr(3XCURSES)

If a character in *str* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using  $\wedge x$  notation, where  $x$  is a printable character. `clrtoeol(3XCURSES)` is automatically done before a newline.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>DESCRIPTION</b>  | <p>These routines insert a <code>wchar_t</code> character string (as many <code>wchar_t</code> characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <code>y, x</code>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <code>n</code> as the last argument insert at most <code>n</code> <code>wchar_t</code> characters. If <code>n</code> ≤ 0, then the entire string is inserted.</p> <p>If a character in <code>wstr</code> is a tab, newline, carriage return, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol(3CURSES)</code> before moving. Tabs are considered to be at every eighth column. If a character in <code>wstr</code> is another control character, it is drawn in the <code>^X</code> notation. Calling <code>winwch(3CURSES)</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |
| <b>ATTRIBUTES</b>   | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |

If <i>n</i> is less than 1, the entire string is inserted. | <i>y</i> | Is the y (row) coordinate of the starting position of the string. | <i>x</i> | Is the x (column) coordinate of the starting position of the string. | <i>win</i> | Is a pointer to the window in which the string is to be inserted. |
| <i>wstr</i> | Is a pointer to the string to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>n</i>    | Is the number of characters not to exceed when inserting <i>wstr</i> . If <i>n</i> is less than 1, the entire string is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>y</i>    | Is the y (row) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>x</i>    | Is the x (column) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>win</i>  | Is a pointer to the window in which the string is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| DESCRIPTION | <p>The <code>ins_wstr()</code> function inserts <i>wstr</i> at the current cursor position of the <code>stdscr</code> window. The <code>wins_wstr()</code> function performs the identical action, but in window <i>win</i>. The <code>mvins_wstr()</code> and <code>mvwins_wstr()</code> functions insert <i>wstr</i> string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>ins_nwstr()</code>, <code>wins_nwstr()</code>, <code>mvins_nwstr()</code>, and <code>mvwins_nwstr()</code> functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |

mvins\_nwstr(3XCURSES)

All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.

If a character in *wstr* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using *^x* notation, where *x* is a printable character. `clrtoeol(3XCURSES)` is automatically done before a newline.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| DESCRIPTION    | <p>With these routines, a character string (as many characters as will fit on the line) is inserted before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <i>y</i>, <i>x</i>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <i>n</i> as the last argument insert at most <i>n</i> characters. If <i>n</i> ≤ 0, then the entire string is inserted.</p> <p>If a character in <i>str</i> is a tab, newline, carriage return or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol()</code> before moving. Tabs are considered to be at every eighth column. If a character in <i>str</i> is another control character, it is drawn in the ^X notation. Calling <code>winch()</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

If <i>n</i> is less than 1, the entire string is inserted. | <i>y</i> | Is the y (row) coordinate of the starting position of the string. | <i>x</i> | Is the x (column) coordinate of the starting position of the string. | <i>win</i> | Is a pointer to the window in which the string is to be inserted. |
| <i>str</i>  | Is a pointer to the string to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>n</i>    | Is the number of characters not to exceed when inserting <i>str</i> . If <i>n</i> is less than 1, the entire string is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>y</i>    | Is the y (row) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>x</i>    | Is the x (column) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>win</i>  | Is a pointer to the window in which the string is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| DESCRIPTION | <p>The <code>insstr()</code> function inserts <i>str</i> at the current cursor position of the <code>stdscr</code> window. The <code>winsstr()</code> function performs the identical action, but in window <i>win</i>. The <code>mvinsstr()</code> and <code>mvwinsstr()</code> functions insert the character string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The <code>insnstr()</code>, <code>winsnstr()</code>, <code>mvinsnstr()</code>, and <code>mvwinsnstr()</code> functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.</p> |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |

mvinsstr(3XCURSES)

If a character in *str* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using  $\wedge x$  notation, where  $x$  is a printable character. `clrtoeol(3XCURSES)` is automatically done before a newline.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int instr(char *str); int innstr(char *str, int n); int winstr(WINDOW *win, char *str); int winnstr(WINDOW *win, char *str, int n); int mvinstr(int y, int x, char *str); int mvinnstr(int y, int x, char *str, int n); int mvwinstr(WINDOW *win, int y, int x, char *str); int mvwinnstr(WINDOW *win, int y, int x, char *str, int n);</pre> |                |                 |          |        |
| DESCRIPTION    | These routines return a string of characters in <i>str</i> , starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with <i>n</i> as the last argument return the string at most <i>n</i> characters long.                                                                                                   |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                |                |                 |          |        |
| ATTRIBUTES     | See attributes(5) for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>Unsafe</td></tr></tbody></table>                                                                                                                                                                                                                  | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| NAME        | innstr, instr, mvinnstr, mvinstr, mvwinnstr, mvwinstr, winstr – retrieve a multibyte character string (without rendition)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |  |
| SYNOPSIS    | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int innstr(char *str, int n); int instr(char *str); int mvinnstr(int y, int x, char *str, int n); int mvinstr(int y, int x, char *str); int mvwinnstr(WINDOW *win, int y, int x, char *str, int n); int mvwinstr(WINDOW *win, int y, int x, char *str); int winstr(WINDOW *win, char *str); int winnstr(WINDOW *win, char *str, int n);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |
| PARAMETERS  | <p><i>str</i> Is a pointer to an object that can hold the retrieved multibyte character string.</p> <p><i>n</i> Is the number of characters not to exceed when retrieving <i>str</i>.</p> <p><i>y</i> Is the y (row) coordinate of the starting position of the string to be retrieved.</p> <p><i>x</i> Is the x (column) coordinate of the starting position of the string to be retrieved.</p> <p><i>win</i> Is a pointer to the window in which the string is to be retrieved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |  |
| DESCRIPTION | <p>The <code>instr()</code> and <code>winstr()</code> functions retrieve a multibyte character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinstr()</code> and <code>mvwinstr()</code> functions retrieve a multibyte character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>innstr()</code>, <code>winnstr()</code>, <code>mvinnstr()</code>, and <code>mvwinnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> |  |

`mvinstr(3XCURSES)`

All these functions store the retrieved string in the object pointed to by *str*. They only store complete multibyte characters. If the area pointed to by *str* is not large enough to hold at least one character, these functions fail.

Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use `winchstr()`.

**ERRORS**    `OK`                      Successful completion.

`ERR`                      An error occurred.

**USAGE**    All functions except `winnstr()` may be macros.

**ATTRIBUTES**    See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>NAME</b>         | <p> <code> curs_inswch, inswch, winswch, mvinswch, mvwinswch </code> – insert a <code>wchar_t</code> character before the character under the cursor in a curses window </p>                                                                                                                                                                                                                                                                            |                |                 |          |        |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>     | <pre> cc [ flag ... ] file ... -lcurses [ library .. ] #include &lt;curses.h&gt;  int <b>inswch</b>(chtype <i>wch</i>) ; int <b>winswch</b>(WINDOW *<i>win</i>, chtype <i>wch</i>) ; int <b>mvinswch</b>(int <i>y</i>, int <i>x</i>, chtype <i>wch</i>) ; int <b>mvwinswch</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, chtype <i>wch</i>) ; </pre>                                                                                              |                |                 |          |        |
| <b>DESCRIPTION</b>  | <p>These routines insert the character <i>wch</i>, holding a <code>wchar_t</code> character, before the character under the cursor. All characters to the right of the cursor are moved one space to the right, with the possibility of the rightmost character on the line being lost. The cursor position does not change (after moving to <i>y</i>, <i>x</i>, if specified). (This does not imply use of the hardware insert character feature.)</p> |                |                 |          |        |
| <b>RETURN VALUE</b> | <p>All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.</p>                                                                                                                                                                                                                                                                                                       |                |                 |          |        |

| <b>DESCRIPTION</b>  | <p> These routines insert a <code>wchar_t</code> character string (as many <code>wchar_t</code> characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <code>y, x</code>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <code>n</code> as the last argument insert at most <code>n</code> <code>wchar_t</code> characters. If <code>n ≤ 0</code>, then the entire string is inserted. </p> <p> If a character in <code>wstr</code> is a tab, newline, carriage return, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol(3CURSES)</code> before moving. Tabs are considered to be at every eighth column. If a character in <code>wstr</code> is another control character, it is drawn in the <code>^X</code> notation. Calling <code>winwch(3CURSES)</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character. </p> |                |                 |          |        |
| <b>RETURN VALUE</b> | <p> All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion. </p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |

| <i>n</i>           | Is the number of characters not to exceed when inserting <i>wstr</i> . If <i>n</i> is less than 1, the entire string is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>y</i>           | Is the y (row) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>x</i>           | Is the x (column) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>win</i>         | Is a pointer to the window in which the string is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <b>DESCRIPTION</b> | <p>The <code>ins_wstr()</code> function inserts <i>wstr</i> at the current cursor position of the <code>stdscr</code> window. The <code>wins_wstr()</code> function performs the identical action, but in window <i>win</i>. The <code>mvins_wstr()</code> and <code>mvwins_wstr()</code> functions insert <i>wstr</i> string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>ins_nwstr()</code>, <code>wins_nwstr()</code>, <code>mvins_nwstr()</code>, and <code>mvwins_nwstr()</code> functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |

mvins\_wstr(3XCURSES)

All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.

If a character in *wstr* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using *^x* notation, where *x* is a printable character. `clrtoeol(3XCURSES)` is automatically done before a newline.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

## mvinwch(3CURSES)

| <b>NAME</b>                | <code> curs_inwch</code> , <code>inwch</code> , <code>winwch</code> , <code>mvinwch</code> , <code>mvwinwch</code> – get a <code>wchar_t</code> character and its attributes from a curses window                                                                                                                                                                               |                          |                               |                            |                                |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|-------------------------------|----------------------------|--------------------------------|
| <b>SYNOPSIS</b>            | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lcurses [ <i>library</i> .. ] #include &lt;curses.h&gt;  ctype <b>inwch</b>(void); ctype <b>winwch</b>(WINDOW *<i>win</i>); ctype <b>mvinwch</b>(int <i>y</i>, int <i>x</i>); ctype <b>mvwinwch</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>);</pre>                                                                         |                          |                               |                            |                                |
| <b>DESCRIPTION</b>         | These routines return the <code>wchar_t</code> character, of type <code>ctype</code> , at the current position in the named window. If any attributes are set for that position, their values are OR-ed into the value returned. Constants defined in <code>&lt;curses.h&gt;</code> can be used with the logical AND (&) operator to extract the character or attributes alone. |                          |                               |                            |                                |
| <b>Attributes</b>          | The following bit-masks may be AND-ed with characters returned by <code>winwch()</code> .<br><br><table><tr><td><code>A_WCHARTEXT</code></td><td>Bit-mask to extract character</td></tr><tr><td><code>A_WATTRIBUTES</code></td><td>Bit-mask to extract attributes</td></tr></table>                                                                                             | <code>A_WCHARTEXT</code> | Bit-mask to extract character | <code>A_WATTRIBUTES</code> | Bit-mask to extract attributes |
| <code>A_WCHARTEXT</code>   | Bit-mask to extract character                                                                                                                                                                                                                                                                                                                                                   |                          |                               |                            |                                |

| DESCRIPTION         | <p>The <code>in_wch()</code> and <code>win_wch()</code> functions retrieve the complex character and its rendition located at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively. The <code>mvin_wch()</code> and <code>mvwin_wch()</code> functions retrieve the complex character and its rendition located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>All these functions store the retrieved character and its rendition in the object pointed to by <i>wcv</i>.</p> |                                                                                      |  |                |                 |                     |          |          |        |
| PARAMETERS          | <i>wcv</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Is a pointer to an object that can store a complex character and its rendition.      |  |                |                 |                     |          |          |        |
|                     | <i>y</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Is the <i>y</i> (row) coordinate of the position of the character to be returned.    |  |                |                 |                     |          |          |        |
|                     | <i>x</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Is the <i>x</i> (column) coordinate of the position of the character to be returned. |  |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>  | These routines return a string of type <code>chtype</code> , holding <code>wchar_t</code> characters, starting at the current cursor position in the named window and ending at the right margin of the window. The four functions with <i>n</i> as the last argument, return the string at most <i>n</i> <code>wchar_t</code> characters long. Constants defined in <code>&lt;curses.h&gt;</code> can be used with the logical AND (&) operator to extract the <code>wchar_t</code> character or the attribute alone from any position in the <i>wchstr</i> (see <code>curs_inwch(3CURSES)</code> ). |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |          |        |

| <b>DESCRIPTION</b> | <p>The <code>in_wchstr()</code> and <code>win_wchstr()</code> functions retrieve a complex character string (with rendition) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvin_wchstr()</code> and <code>mvwin_wchstr()</code> functions retrieve a complex character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>in_wchnstr()</code>, <code>win_wchnstr()</code>, <code>mvin_wchnstr()</code>, and <code>mvwin_wchnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>The retrieved character string (with renditions) is stored in the object pointed to by <i>wcval</i>.</p> |                                                                                             |

| <b>NAME</b>         | curs_inwchstr, inwchstr, inwchnstr, winwchstr, winwchnstr, mvinwchstr, mvinwchnstr, mvwinwchstr, mvwinwchnstr – get a string of wchar_t characters (and attributes) from a curses window                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>     | <pre>cc [ flag ... ] file ... -lcurses [ library .. ] #include &lt;curses.h&gt;  int inwchstr(chtype *wchstr); int inwchnstr(chtype *wchstr, int n); int winwchstr(WINDOW *win, chtype *wchstr); int winwchnstr(WINDOW *win, chtype *wchstr, int n); int mvinwchstr(int y, int x, chtype *wchstr); int mvinwchnstr(int y, int x, chtype *wchstr, int n); int mvwinwchstr(WINDOW *win, int y, int x, chtype *wchstr); int mvwinwchnstr(WINDOW *win, int y, int x, chtype *wchstr, int n);</pre>                  |                |                 |          |        |
| <b>DESCRIPTION</b>  | These routines return a string of type chtype, holding wchar_t characters, starting at the current cursor position in the named window and ending at the right margin of the window. The four functions with <i>n</i> as the last argument, return the string at most <i>n</i> wchar_t characters long. Constants defined in <curses.h> can be used with the logical AND (&) operator to extract the wchar_t character or the attribute alone from any position in the <i>wchstr</i> (see curs_inwch(3CURSES)). |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |

| <b>DESCRIPTION</b> | <p>The <code>in_wchstr()</code> and <code>win_wchstr()</code> functions retrieve a complex character string (with rendition) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvin_wchstr()</code> and <code>mvwin_wchstr()</code> functions retrieve a complex character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>in_wchnstr()</code>, <code>win_wchnstr()</code>, <code>mvin_wchnstr()</code>, and <code>mvwin_wchnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>The retrieved character string (with renditions) is stored in the object pointed to by <i>wcval</i>.</p> |                                                                                             |
| <b>PARAMETERS</b>  | <i>wchstr</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Is a pointer to an object where the retrieved complex character string can be stored.       |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [library .. ] #include &lt;curses.h&gt;  int inwstr(wchar_t *wstr); int innwstr(wchar_t *wstr, int n); int winwstr(WINDOW *win, wchar_t *wstr); int winnwstr(WINDOW *win, wchar_t *wstr, int n); int mvinwstr(int y, int x, wchar_t *wstr); int mvinnwstr(int y, int x, wchar_t *wstr, int n); int mvwinwstr(WINDOW *win, int y, int x, wchar_t *wstr); int mvwinnwstr(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre> |                |                 |          |        |
| DESCRIPTION    | These routines return the string of wchar_t characters in <i>wstr</i> starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with <i>n</i> as the last argument return the string at most <i>n</i> wchar_t characters long.                                                                                                                        |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                      |                |                 |          |        |

| <b>PARAMETERS</b>  | <p><i>wstr</i>        Is a pointer to an object that can hold the retrieved multibyte character string.</p> <p><i>n</i>            Is the number of characters not to exceed when retrieving <i>wstr</i>.</p> <p><i>y</i>            Is the y (row) coordinate of the starting position of the string to be retrieved.</p> <p><i>x</i>            Is the x (column) coordinate of the starting position of the string to be retrieved.</p> <p><i>win</i>          Is a pointer to the window in which the string is to be retrieved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The <code>inwstr()</code> and <code>winwstr()</code> functions retrieve a wide character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinwstr()</code> and <code>mvwinwstr()</code> functions retrieve a wide character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>innwstr()</code>, <code>winnwstr()</code>, <code>mvinnwstr()</code>, and <code>mvwinnwstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All these functions store the retrieved string in the object pointed to by <i>wstr</i>. They only store complete wide characters. If the area pointed to by <i>wstr</i> is not large enough to hold at least one character, these functions fail.</p> |

`mvinwstr(3XCURSES)`

Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use `win_wchstr(3XCURSES)`.

**RETURN VALUES**

On success, the `inwstr()`, `mvinwstr()`, `mvwinwstr()`, and `winwstr()` functions return OK. Otherwise, they return ERR.

On success, the `innwstr()`, `mvinnwstr()`, `mvwinnwstr()`, and `winnwstr()` functions return the number of characters read into the string. Otherwise, they return ERR.

**ERRORS**

None.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |

| NAME           | curs_printw, printw, wprintw, mvprintw, mvwprintw, vwprintw – print formatted output in curses windows                                                                                                                                                                                                                                                                                                                                                                              |                |                 |          |        |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int printw(char *fmt, /* arg */ ... ); int wprintw(WINDOW *win, char *fmt, /* arg */ ... ); int mvprintw(int y, int x, char *fmt, /* arg */ ... ); int mvwprintw(WINDOW *win, int y, int x, char *fmt, /* arg */ ... ); #include &lt;varargs.h&gt; int vwprintw(WINDOW *win, char *fmt, /* varglist */ ... );</pre>                                                                               |                |                 |          |        |
| DESCRIPTION    | <p>The printw(), wprintw(), mvprintw(), and mvwprintw() routines are analogous to printf() (see printf(3C)). In effect, the string that would be output by printf() is output instead as though waddstr() were used on the given window.</p> <p>The vwprintw() routine is analogous to vprintf() (see vprintf(3C)) and performs a wprintw() using a variable argument list. The third argument is a va_list, a pointer to a list of arguments, as defined in &lt;varargs.h&gt;.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |
| ATTRIBUTES     | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| MT-Level       | Unsafe                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |          |        |
| SEE ALSO       | curses(3CURSES), printf(3C), vprintf(3C), attributes(5)                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |          |        |
| NOTES          | The header <curses.h> automatically includes the headers <stdio.h> and <unctrl.h>.                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |          |        |

## mvprintw(3XCURSES)

| <b>NAME</b>          | mvprintw, mvwprintw, printw, wprintw – print formatted output window                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>mvprintw</b>(int <i>y</i>, int <i>x</i>, char *<i>fmt</i>, ...); int <b>mvwprintw</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, char *<i>fmt</i>, ...); int <b>printw</b>(char *<i>fmt</i>, ...); int <b>wprintw</b>(WINDOW *<i>win</i>, char *<i>fmt</i>, ...);</pre> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>y</i> Is the y (row) coordinate position of the string's placement in the window.</p> <p><i>x</i> Is the x (column) coordinate position of the string's placement in the window.</p> <p><i>fmt</i> Is a printf() format string.</p> <p><i>win</i> Is a pointer to the window in which the string is to be written.</p>                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | The mvprintw(), mvwprintw(), printw(), and wprintw() functions are analogous to printf(3C). The effect of these functions is as though sprintf() were used to format the string, and then waddstr(3XCURSES) were used to add that multi-byte string to the current or specified window at the current or specified cursor position.                                                                                                                                           |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>scanw</b>(char *fmt, /* arg */ ...); int <b>wscanw</b>(WINDOW *win, char *fmt, /* arg */ ...); int <b>mvscanw</b>(int y, int x, char *fmt, /* arg */ ...); int <b>mvwscanw</b>(WINDOW *win, int y, int x, char *fmt, /* arg */...); int <b>vwscanw</b>(WINDOW *win, char *fmt, va_list varlist);</pre>                                                                                                                                                                                                                                                                               |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>scanw()</code>, <code>wscanw()</code>, and <code>mvscanw()</code> routines correspond to <code>scanf()</code> (see <code>scanf(3C)</code>). The effect of these routines is as though <code>wgetstr()</code> were called on the window, and the resulting line used as input for the scan. Fields which do not map to a variable in the <code>fmt</code> field are lost.</p> <p>The <code>vwscanw()</code> routine is similar to <code>vwprintw()</code> in that it performs a <code>wscanw()</code> using a variable argument list. The third argument is a <i>va_list</i>, a pointer to a list of arguments, as defined in <code>&lt;varargs.h&gt;</code>.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | <p><code>vwscanw()</code> returns <code>ERR</code> on failure and an integer equal to the number of fields scanned on success.</p> <p>Applications may interrogate the return value from the <code>scanw</code>, <code>wscanw()</code>, <code>mvscanw()</code>, and <code>mvwscanw()</code> routines to determine the number of fields which were mapped in the call.</p>                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| <b>NOTES</b>         | The header <code>&lt;curses.h&gt;</code> automatically includes the headers <code>&lt;stdio.h&gt;</code> and <code>&lt;unctrl.h&gt;</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |          |        |

## mvscanw(3XCURSES)

| <b>NAME</b>          | mvscanw, mvwscanw, scanw, wscanw – convert formatted input from a window                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int mvscanw(int y, int x, char *fmt, ...); int mvwscanw(WINDOW *win, int y, int x, char *fmt, ...); int scanw(char *fmt, ...); int wscanw(WINDOW *win, char *fmt, ...);</pre> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>y</i> Is the y (row) coordinate of the position of the character to be read.</p> <p><i>x</i> Is the x (column) coordinate of the position of the character to be read.</p> <p><i>fmt</i> Is a scanf ( ) format string.</p> <p><i>win</i> Is a pointer to the window in which the character is to be read.</p>                                                     |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | These functions are similar to scanf(3C). Their effect is as though mvwgetstr(3XCURSES) were called to get a multi-byte character string from the current or specified window at the current or specified cursor position, and then sscanf ( ) were used to interpret and convert that string.                                                                          |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>   | <p>The <code>hline()</code>, <code>vline()</code>, <code>whline()</code>, <code>wvline()</code> functions draw a horizontal or vertical line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>ch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>ch</code> is 0 (zero), the default horizontal or vertical character is used.</p> <p>The <code>mvhline()</code>, <code>mvvline()</code>, <code>mvwhline()</code>, <code>mvwvline()</code> functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code>.</p> <p>The functions with names ending with <code>hline()</code> draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with <code>vline()</code> draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |

| <b>DESCRIPTION</b>   | <p>The <code>hline_set()</code>, <code>vline_set()</code>, <code>whline_set()</code>, <code>wvline_set()</code> functions draw a line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>wch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>wch</code> is a null pointer, the default horizontal or vertical character is used.</p> <p>The <code>mvhline_set()</code>, <code>mvvline_set()</code>, <code>mvwhline_set()</code>, <code>mvwvline_set()</code> functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code>.</p> <p>The functions with names ending with <code>hline_set()</code> draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with <code>vline_set()</code> draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |
| <b>PARAMETERS</b>    | <p><i>wch</i>        Is the complex character used to draw the line.</p> <p><i>n</i>         Is the maximum number of characters in the line.</p> <p><i>y</i>         Is the y (row) coordinate for the start of the line.</p> <p><i>x</i>         Is the x (column) coordinate for the start of the line.</p> <p><i>win</i>        Is a pointer to a window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>DESCRIPTION</b>   | <p>With the <code>addch()</code>, <code>waddch()</code>, <code>mvaddch()</code>, and <code>mvwaddch()</code> routines, the character <i>ch</i> is put into the window at the current cursor position of the window and the position of the window cursor is advanced. Its function is similar to that of <code>putchar()</code>. At the right margin, an automatic newline is performed. At the bottom of the scrolling region, if <code>scrollok()</code> is enabled, the scrolling region is scrolled up one line.</p> <p>If <i>ch</i> is a tab, newline, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol()</code> before moving. Tabs are considered to be at every eighth column. If <i>ch</i> is another control character, it is drawn in the ^X notation. Calling <code>winch()</code> after adding a control character does not return the control character, but instead returns the representation of the control character. See <code>curs_inch(3CURSES)</code>.</p> <p>Video attributes can be combined with a character by OR-ing them into the parameter. This results in these attributes also being set. (The intent here is that text, including attributes, can be copied from one place to another using <code>inch()</code> and <code>addch()</code>.) (see <code>standout()</code>, predefined video attribute constants, on the <code>curs_attr(3CURSES)</code> page).</p> <p>The <code>echochar()</code> and <code>wechochar()</code> routines are functionally equivalent to a call to <code>addch()</code> followed by a call to <code>refresh()</code>, or a call to <code>waddch</code> followed by a call to <code>wrefresh()</code>. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents.</p> |
| <b>Line Graphics</b> | <p>The following variables may be used to add line drawing characters to the screen with routines of the <code>addch()</code> family. When variables are defined for the terminal, the <code>A_ALTCHARSET</code> bit is turned on (see <code>curs_attr(3CURSES)</code>). Otherwise, the default character listed below is stored in the variable. The names chosen are consistent with the VT100 nomenclature.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

mvwaddch(3CURSES)

| Name         | Default | Glyph Description       |
|--------------|---------|-------------------------|
| ACS_ULCORNER | +       | upper left-hand corner  |
| ACS_LLCORNER | +       | lower left-hand corner  |
| ACS_URCORNER | +       | upper right-hand corner |
| ACS_LRCORNER | +       | lower right-hand corner |
| ACS_RTEE     | +       | right tee               |
| ACS_LTEE     | +       | left tee                |
| ACS_BTEE     | +       | bottom tee              |
| ACS_TTEE     | +       | top tee                 |
| ACS_HLINE    | -       | horizontal line         |
| ACS_VLINE    |         | vertical line           |
| ACS_PLUS     | +       | plus                    |
| ACS_S1       | -       | scan line 1             |
| ACS_S9       | -       | scan line 9             |
| ACS_DIAMOND  | +       | diamond                 |
| ACS_CKBOARD  | :       | checker board (stipple) |
| ACS_DEGREE   | '       | degree symbol           |
| ACS_PLMINUS  | #       | plus/minus              |
| ACS_BULLET   | o       | bullet                  |
| ACS_LARROW   | <       | arrow pointing left     |
| ACS_RARROW   | >       | arrow pointing right    |
| ACS_DARROW   | v       | arrow pointing down     |
| ACS_UARROW   | ^       | arrow pointing up       |
| ACS_BOARD    | #       | board of squares        |
| ACS_LANTERN  | #       | lantern symbol          |
| ACS_BLOCK    | #       | solid square block      |

## RETURN VALUES

All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.

`mvwaddch(3CURSES)`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curl_attr(3CURSES)`, `curl_clear(3CURSES)`, `curl_inch(3CURSES)`, `curl_outopts(3CURSES)`, `curl_refresh(3CURSES)`, `curses(3CURSES)`, `putc(3C)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `addch()`, `mvaddch()`, `mvwaddch()`, and `echochar()` may be macros.

| <b>DESCRIPTION</b>   | <p>The addch() function writes a character to the stdscr window at the current cursor position. The mvaddch() and mvwaddch() functions write the character to the position indicated by the x (column) and y (row) parameters. The mvaddch() function writes the character to the stdscr window, while mvwaddch() writes the character to the window specified by win. The waddch() function is identical to addch(), but writes the character to the window specified by win.</p> <p>These functions advance the cursor after writing the character. Characters that do not fit on the end of the current line are wrapped to the beginning of the next line unless the current line is the last line of the window and scrolling is disabled. In that situation, characters which extend beyond the end of the line are discarded.</p> <p>When ch is a backspace, carriage return, newline, or tab, X/Open Curses moves the cursor appropriately. Each tab character moves the cursor to the next tab stop. By default, tab stops occur every eight columns. When ch is a control character other than backspace, carriage return, newline, or tab, it is written using ^x notation, where x is a printable character. When X/Open Curses writes ch to the last character position on a line, it automatically generates a newline. When ch is written to the last character position of a scrolling region and scrolllok() is enabled, X/Open Curses scrolls the scrolling region up one line (see clearok(3XCURSES)).</p> |        |                                                                |   |                                                                                                                                                       |   |                                                                             |   |                                                                                |     |                                                                 |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int  addchstr(chtype *chstr); int  addchnstr(chtype *chstr, int n); int  waddchstr(WINDOW *win, chtype *chstr); int  waddchnstr(WINDOW *win, chtype *chstr, int n); int  mvaddchstr(int y, int x, chtype *chstr); int  mvaddchnstr(int y, int x, chtype *chstr, int n); int  mvwaddchstr(WINDOW *win, int y, int x, chtype *chstr); int  mvwaddchnstr(WINDOW *win, int y, int x, chtype *chstr, int n);</pre>                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>All of these routines copy <i>chstr</i> directly into the window image structure starting at the current cursor position. The four routines with <i>n</i> as the last argument copy at most <i>n</i> elements, but no more than will fit on the line. If <i>n</i>=-1 then the whole string is copied, to the maximum number that fit on the line.</p> <p>The position of the window cursor is not advanced. These routines works faster than <code>waddnstr()</code> (see <code>curs_addstr(3CURSES)</code>) because they merely copy <i>chstr</i> into the window image structure. On the other hand, care must be taken when using these functions because they do not perform any kind of checking (such as for the newline character), they do not advance the current cursor position, and they truncate the string, rather than wrapping it around to the next line.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |

| DESCRIPTION   | <p>The <code>addchstr()</code> function copies the <code>chtype</code> character string to the <code>stdscr</code> window at the current cursor position. The <code>mvaddchstr()</code> and <code>mvwaddchstr()</code> functions copy the character string to the starting position indicated by the <code>x</code> (column) and <code>y</code> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <code>win</code>). The <code>waddchstr()</code> is identical to <code>addchstr()</code>, but writes to the window specified by <code>win</code>.</p> <p>The <code>addchnstr()</code>, <code>waddchnstr()</code>, <code>mvaddchnstr()</code>, and <code>mvwaddchnstr()</code> functions write <code>n</code> characters to the window, or as many as will fit on the line. If <code>n</code> is less than 0, the entire string is written, or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <code>x</code> and <code>y</code> parameters.</p> <p>These functions differ from the <code>addstr(3XCURSES)</code> set of functions in two important respects. First, these functions do <i>not</i> advance the cursor after writing the string to the window. Second, the current window rendition is not combined with the character; only the attributes that are already part of the <code>chtype</code> character are used.</p> |
| PARAMETERS    | <p><i>chstr</i> Is a pointer to the <code>chtype</code> string to be copied to the window.</p> <p><i>n</i> Is the maximum number of characters to be copied from <i>chstr</i>. If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line.</p> <p><i>y</i> Is the <i>y</i> (row) coordinate of the starting position of <i>chstr</i> in the window.</p> <p><i>x</i> Is the <i>x</i> (column) coordinate of the starting position of <i>chstr</i> in the window.</p> <p><i>win</i> Is a pointer to the window to which the string is to be copied.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| RETURN VALUES | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

mvwaddchnstr(3XCURSES)

**ERRORS** None.

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int addchstr(chtype *chstr); int addchnstr(chtype *chstr, int n); int waddchstr(WINDOW *win, chtype *chstr); int waddchnstr(WINDOW *win, chtype *chstr, int n); int mvaddchstr(int y, int x, chtype *chstr); int mvaddchnstr(int y, int x, chtype *chstr, int n); int mvwaddchstr(WINDOW *win, int y, int x, chtype *chstr); int mvwaddchnstr(WINDOW *win, int y, int x, chtype *chstr, int n);</pre>                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |
| DESCRIPTION    | <p>All of these routines copy <i>chstr</i> directly into the window image structure starting at the current cursor position. The four routines with <i>n</i> as the last argument copy at most <i>n</i> elements, but no more than will fit on the line. If <i>n</i>=-1 then the whole string is copied, to the maximum number that fit on the line.</p> <p>The position of the window cursor is not advanced. These routines works faster than <code>waddnstr()</code> (see <code>curs_addstr(3CURSES)</code>) because they merely copy <i>chstr</i> into the window image structure. On the other hand, care must be taken when using these functions because they do not perform any kind of checking (such as for the newline character), they do not advance the current cursor position, and they truncate the string, rather than wrapping it around to the next line.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |

| <b>DESCRIPTION</b>   | <p>The <code>addchstr()</code> function copies the <code>chtype</code> character string to the <code>stdscr</code> window at the current cursor position. The <code>mvaddchstr()</code> and <code>mvwaddchstr()</code> functions copy the character string to the starting position indicated by the <code>x</code> (column) and <code>y</code> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <code>win</code>). The <code>waddchstr()</code> is identical to <code>addchstr()</code>, but writes to the window specified by <code>win</code>.</p> <p>The <code>addchnstr()</code>, <code>waddchnstr()</code>, <code>mvaddchnstr()</code>, and <code>mvwaddchnstr()</code> functions write <code>n</code> characters to the window, or as many as will fit on the line. If <code>n</code> is less than 0, the entire string is written, or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <code>x</code> and <code>y</code> parameters.</p> <p>These functions differ from the <code>addstr(3XCURSES)</code> set of functions in two important respects. First, these functions do <i>not</i> advance the cursor after writing the string to the window. Second, the current window rendition is not combined with the character; only the attributes that are already part of the <code>chtype</code> character are used.</p> |              |                                                                            |          |                                                                                                                                                                     |          |                                                                                          |          |                                                                                             |            |                                                                 |

| <b>DESCRIPTION</b>   | All of these routines write all the characters of the null terminated character string <i>str</i> on the given window. It is similar to calling <code>waddch()</code> once for each character in the string. The four routines with <i>n</i> as the last argument write at most <i>n</i> characters. If <i>n</i> is negative, then the entire string will be added.                                                                                                                                                                                                                                                                                                                                  |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |
| <b>ATTRIBUTES</b>    | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |          |        |

| DESCRIPTION | <p>The <code>addstr()</code> function writes a null-terminated string of multi-byte characters to the <code>stdscr</code> window at the current cursor position. The <code>waddstr()</code> function performs an identical action, but writes the character to the window specified by <i>win</i>. The <code>mvaddstr()</code> and <code>mvwaddstr()</code> functions write the string to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The <code>addnstr()</code>, <code>waddnstr()</code>, <code>mvaddnstr()</code>, and <code>mvwaddnstr()</code> functions are similar but write at most <i>n</i> characters to the window. If <i>n</i> is less than 0, the entire string is written.</p> <p>All of these functions advance the cursor after writing the string.</p> <p>These functions are functionally equivalent to calling the corresponding function from the <code>addch(3XCURSES)</code> set of functions once for each character in the string. Refer to the <code>curses(3XCURSES)</code> man page for a complete description of special character handling and of the interaction between the window rendition (or background character and rendition) and the character written.</p> <p>Note that these functions differ from the <code>addchstr()</code> set of functions in that the <code>addchstr(3XCURSES)</code> functions copy the string as is (without combining each character with the window rendition or the background character and rendition).</p> |
| PARAMETERS  | <p><i>str</i>        Is a pointer to the character string that is to be written to the window.</p> <p><i>n</i>         Is the maximum number of characters to be copied from <i>str</i>. If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line.</p> <p><i>y</i>         Is the <i>y</i> (row) coordinate of the starting position of <i>str</i> in the window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

mvwaddnstr(3XCURSES)

*x* Is the x (column) coordinate of the starting position of *str* in the window.  
*win* Is a pointer to the window in which the string is to be written.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>NAME</b>         | curs_addwstr, addwstr, addnwstr, waddwstr, waddnwstr, mvaddwstr, mvaddnwstr, mvwaddwstr, mvwaddnwstr – add a string of wchar_t characters to a curses window and advance cursor                                                                                                                                                                                                                                                                                          |                |                 |          |        |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>     | <pre>cc [flag...] file... -lcurses [library...]  #include&lt;curses.h&gt;  int addwstr(wchar_t *wstr); int addnwstr(wchar_t *wstr, int n); int waddwstr(WINDOW *win, wchar_t *wstr); int waddnwstr(WINDOW *win, wchar_t *wstr, int n); int mvaddwstr(int y, int x, wchar_t *wstr); int mvaddnwstr(int y, int x, wchar_t *wstr, int n); int mvwaddwstr(WINDOW *win, int y, int x, wchar_t *wstr); int mvwaddnwstr(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre> |                |                 |          |        |
| <b>DESCRIPTION</b>  | All of these routines write all the characters of the null-terminated wchar_t character string wstr on the given window. The effect is similar to calling waddwch(3CURSES) once for each wchar_t character in the string. The four routines with n as the last argument write at most n wchar_t characters. If n is negative, then the entire string will be added.                                                                                                      |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                         |                |                 |          |        |
| <b>ATTRIBUTES</b>   | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |

| DESCRIPTION | <p>The <code>addwstr()</code> function writes a null-terminated wide-character string to the <code>stdscr</code> window at the current cursor position. The <code>waddwstr()</code> function performs an identical action, but writes the string to the window specified by <i>win</i>. The <code>mvaddwstr()</code> and <code>mvwaddwstr()</code> functions write the string to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The <code>addnwstr()</code>, <code>waddnwstr()</code>, <code>mvaddnwstr()</code>, and <code>mvwaddnwstr()</code> functions write at most <i>n</i> characters to the window. If <i>n</i> is less than 0, the entire string is written. The former two functions place the characters at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All of these functions advance the cursor after writing the string.</p> <p>These functions are functionally equivalent to building a <code>cchar_t</code> from the <code>wchar_t</code> and the window rendition (or background character and rendition) and calling the <code>wadd_wch(3XCURSES)</code> function once for each <code>wchar_t</code> in the string. Refer to the <code>curses(3XCURSES)</code> man page for a complete description of special character handling and of the interaction between the window rendition (or background character and rendition) and the character written.</p> <p>Note that these functions differ from the <code>add_wchnstr(3XCURSES)</code> set of functions in that the latter copy the string as is (without combining each character with the foreground and background attributes of the window).</p> |
| PARAMETERS  | <p><i>wstr</i>      Is a pointer to the wide-character string that is to be written to the window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

mvwaddnwstr(3XCURSES)

*n* Is the maximum number of characters to be copied from *wstr*. If *n* is less than 0, the entire string is written or as much of it as fits on the line.

*y* Is the y (row) coordinate of the starting position of *wstr* in the window.

*x* Is the x (column) coordinate of the starting position of *wstr* in the window.

*win* Is a pointer to the window in which the string is to be written.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>SYNOPSIS</b>      | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lcurses [ <i>library</i> ... ] #include &lt;curses.h&gt;  int <b>addstr</b>(char *<i>str</i>) ; int <b>addnstr</b>(char *<i>str</i>, int <i>n</i>) ; int <b>waddstr</b>(WINDOW *<i>win</i>, char *<i>str</i>) ; int <b>waddnstr</b>(WINDOW *<i>win</i>, char *<i>str</i>, int <i>n</i>) ; int <b>mvaddstr</b>(int <i>y</i>, int <i>x</i>, char *<i>str</i>) ; int <b>mvaddnstr</b>(int <i>y</i>, int <i>x</i>, char *<i>str</i>, int <i>n</i>) ; int <b>mvwaddstr</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, char *<i>str</i>) ; int <b>mvwaddnstr</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, char *<i>str</i>, int <i>n</i>) ;</pre> |                |                 |          |        |
| <b>DESCRIPTION</b>   | All of these routines write all the characters of the null terminated character string <i>str</i> on the given window. It is similar to calling <code>waddch()</code> once for each character in the string. The four routines with <i>n</i> as the last argument write at most <i>n</i> characters. If <i>n</i> is negative, then the entire string will be added.                                                                                                                                                                                                                                                                                                                                  |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |

| DESCRIPTION | <p>The <code>addstr()</code> function writes a null-terminated string of multi-byte characters to the <code>stdscr</code> window at the current cursor position. The <code>waddstr()</code> function performs an identical action, but writes the character to the window specified by <i>win</i>. The <code>mvaddstr()</code> and <code>mvwaddstr()</code> functions write the string to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The <code>addnstr()</code>, <code>waddnstr()</code>, <code>mvaddnstr()</code>, and <code>mvwaddnstr()</code> functions are similar but write at most <i>n</i> characters to the window. If <i>n</i> is less than 0, the entire string is written.</p> <p>All of these functions advance the cursor after writing the string.</p> <p>These functions are functionally equivalent to calling the corresponding function from the <code>addch(3XCURSES)</code> set of functions once for each character in the string. Refer to the <code>curses(3XCURSES)</code> man page for a complete description of special character handling and of the interaction between the window rendition (or background character and rendition) and the character written.</p> <p>Note that these functions differ from the <code>addchstr()</code> set of functions in that the <code>addchstr(3XCURSES)</code> functions copy the string as is (without combining each character with the window rendition or the background character and rendition).</p> |
| PARAMETERS  | <p><i>str</i>        Is a pointer to the character string that is to be written to the window.</p> <p><i>n</i>         Is the maximum number of characters to be copied from <i>str</i>. If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line.</p> <p><i>y</i>         Is the <i>y</i> (row) coordinate of the starting position of <i>str</i> in the window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

mvwaddstr(3XCURSES)

*x* Is the x (column) coordinate of the starting position of *str* in the window.  
*win* Is a pointer to the window in which the string is to be written.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| DESCRIPTION | <p>           The <code>addwch()</code>, <code>waddwch()</code>, <code>mvaddwch()</code>, and <code>mvwaddwch()</code> routines put the character <i>wch</i>, holding a <code>wchar_t</code> character, into the window at the current cursor position of the window and advance the position of the window cursor. Their function is similar to that of <code>putwchar(3C)</code> in the C multibyte library. At the right margin, an automatic newline is performed. At the bottom of the scrolling region, if <code>scrollok</code> is enabled, the scrolling region is scrolled up one line.         </p> <p>           If <i>wch</i> is a tab, newline, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol(3CURSES)</code> before moving. Tabs are considered to be at every eighth column. If <i>wch</i> is another control character, it is drawn in the <code>^X</code> notation. Calling <code>winwch(3CURSES)</code> after adding a control character does not return the control character, but instead returns the representation of the control character.         </p> <p>           Video attributes can be combined with a <code>wchar_t</code> character by OR-ing them into the parameter. This results in these attributes also being set. (The intent here is that text, including attributes, can be copied from one place to another using <code>inwch()</code> and <code>addwch()</code>.) See <code>standout(3CURSES)</code>, predefined video attribute constants.         </p> <p>           The <code>echowchar()</code> and <code>wechowchar()</code> routines are functionally equivalent to a call to <code>addwch()</code> followed by a call to <code>refresh(3CURSES)</code>, or a call to <code>waddwch()</code> followed by a call to <code>wrefresh(3CURSES)</code>. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents.         </p> <p> <b>Line Graphics</b> The following variables may be used to add line drawing characters to the screen with routines of the <code>addwch()</code> family. When variables are defined for the terminal, the <code>A_ALTCHARSET</code> bit is turned on. (See <code>curs_attr(3CURSES)</code>). Otherwise, the default character listed below is stored in the variable. The names chosen are consistent with the VT100 nomenclature.         </p> |

mvwaddwch(3CURSES)

#### RETURN VALUE

All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.

`mvwaddwch(3CURSES)`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `putwchar(3C)`, `clrtoeol(3CURSES)`, `curses(3CURSES)`, `curs_attr(3CURSES)`, `curs_inwch(3CURSES)`, `curs_outopts(3CURSES)`, `refresh(3CURSES)`, `standout(3CURSES)`, `winwch(3CURSES)`, `wrefresh(3CURSES)`, `attributes(5)`

**NOTES** The header file `<curses.h>` automatically includes the header files `<stdio.h>`, `<unctrl.h>` and `<wdec.h>`.

Note that `addwch()`, `mvaddwch()`, `mvwaddwch()`, and `echowchar()` may be macros.

None of these routines can use the color attribute in `chtype`.

## mvwadd\_wch(3XCURSES)

| <b>DESCRIPTION</b> | <p>The add_wch() function writes a complex character to the stdscr window at the current cursor position. The mvadd_wch() and mvwadd_wch() functions write the character to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters. The mvadd_wch() function writes the character to the stdscr window, while mvwadd_wch() writes the character to the window specified by <i>win</i>. The wadd_wch() function is identical to add_wch(), but writes the character to the window specified by <i>win</i>. These functions advance the cursor after writing the character.</p> <p>If <i>wch</i> is a spacing complex character, X/Open Curses replaces any previous character at the specified location with <i>wch</i> (and its rendition). If <i>wch</i> is a non-spacing complex character, X/Open Curses preserves all existing characters at the specified location and adds the non-spacing characters of <i>wch</i> to the spacing complex character. It ignores the rendition associated with <i>wch</i>.</p> <p>Characters that do not fit on the end of the current line are wrapped to the beginning of the next line unless the current line is the last line of the window and scrolling is disabled. In that situation, X/Open Curses discards characters which extend beyond the end of the line.</p> <p>When <i>wch</i> is a backspace, carriage return, newline, or tab, X/Open Curses moves the cursor appropriately as described in the curses(3XCURSES) man page. Each tab character moves the cursor to the next tab stop. By default, tab stops occur every eight columns. When <i>wch</i> is a control character other than a backspace, carriage return, newline, or tab, it is written using ^<i>x</i> notation, where <i>x</i> is a printable character. When X/Open Curses writes <i>wch</i> to the last character position on a line, it automatically generates a newline. When <i>wch</i> is written to the last character position of a scrolling region and scrolllok() is enabled, X/Open Curses scrolls the scrolling region up one line (see clearok(3XCURSES)).</p> |
| <b>PARAMETERS</b>  | <p><i>wch</i>        Is the character/attribute pair (rendition) to be written to the window.</p> <p><i>win</i>        Is a pointer to the window in which the character is to be written.</p> <p><i>y</i>           Is the <i>y</i> (row) coordinate of the character's position in the window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

`mvwadd_wch(3XCURSES)`

`x` Is the `x` (column) coordinate of the character's position in the window.

**RETURN VALUES** On success, these functions return `OK`. Otherwise, they return `ERR`.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|

| <b>SYNOPSIS</b>     | <pre>cc [flag...] file... -lcurses [library...]  #include&lt;curses.h&gt;  int addwchstr(chtype *wchstr); int addwchnstr(chtype *wchstr, int n); int waddwchstr(WINDOW *win, chtype *wchstr); int waddwchnstr(WINDOW *win, chtype *wchstr, int n); int mvaddwchstr(int y, int x, chtype *wchstr); int mvaddwchnstr(int y, int x, chtype *wchstr, int n); int mvwaddwchstr(WINDOW *win, int y, int x, chtype *wchstr); int mvwaddwchnstr(WINDOW *win, int y, int x, chtype *wchstr, int n);</pre>                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |
| <b>DESCRIPTION</b>  | <p>All of these routines copy <i>wchstr</i>, which points to a string of wchar_t characters, directly into the window image structure starting at the current cursor position. The four routines with <i>n</i> as the last argument copy at most <i>n</i> elements, but no more than will fit on the line. If <i>n</i>=-1 then the whole string is copied, to the maximum number that fit on the line.</p> <p>The position of the window cursor is not advanced. These routines work faster than waddnwstr(3CURSES) because they merely copy <i>wchstr</i> into the window image structure. On the other hand, care must be taken when using these functions because they don't perform any kind of checking (such as for the newline character), they do not advance the current cursor position, and they truncate the string, rather than wrapping it around to the new line.</p> |                |                 |          |        |
| <b>RETURN VALUE</b> | <p>All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |

| DESCRIPTION   | <p>The <code>add_wchstr()</code> function copies the string of <code>cchar_t</code> characters to the <code>stdscr</code> window at the current cursor position. The <code>mvadd_wchstr()</code> and <code>mvwadd_wchstr()</code> functions copy the string to the starting position indicated by the <code>x</code> (column) and <code>y</code> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <code>win</code>). The <code>wadd_wchstr()</code> is identical to <code>add_wchstr()</code>, but writes to the window specified by <code>win</code>.</p> <p>The <code>add_wchnstr()</code>, <code>wadd_wchnstr()</code>, <code>mvadd_wchnstr()</code>, and <code>mvwadd_wchnstr()</code> functions write <code>n</code> characters to the window, or as many as will fit on the line. If <code>n</code> is less than 0, the entire string is written, or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <code>x</code> and <code>y</code> parameters.</p> <p>These functions differ from the <code>addwstr(3XCURSES)</code> set of functions in two important respects. First, these functions do <i>not</i> advance the cursor after writing the string to the window. Second, the current window rendition (that is, the combination of attributes and color pair) is not combined with the character; only those attributes that are already part of the <code>cchar_t</code> character are used.</p> |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |

| <i>wchstr</i> | Is a pointer to the <code>cchar_t</code> string to be copied to the window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |
| <i>n</i>      | Is the maximum number of characters to be copied from <i>wchstr</i> . If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |
| <i>y</i>      | Is the <i>y</i> (row) coordinate of the starting position of <i>wchstr</i> in the window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |

mvwadd\_wchnstr(3XCURSES)

*x* Is the x (column) coordinate of the starting position of *wchstr* in the window.

*win* Is a pointer to the window to which the string is to be copied.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>SYNOPSIS</b>     | <pre>cc [flag...] file... -lcurses [library...]  #include&lt;curses.h&gt;  int addwchstr(chtype *wchstr); int addwchnstr(chtype *wchstr, int n); int waddwchstr(WINDOW *win, chtype *wchstr); int waddwchnstr(WINDOW *win, chtype *wchstr, int n); int mvaddwchstr(int y, int x, chtype *wchstr); int mvaddwchnstr(int y, int x, chtype *wchstr, int n); int mvwaddwchstr(WINDOW *win, int y, int x, chtype *wchstr); int mvwaddwchnstr(WINDOW *win, int y, int x, chtype *wchstr, int n);</pre>                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |
| <b>DESCRIPTION</b>  | <p>All of these routines copy <i>wchstr</i>, which points to a string of wchar_t characters, directly into the window image structure starting at the current cursor position. The four routines with <i>n</i> as the last argument copy at most <i>n</i> elements, but no more than will fit on the line. If <i>n</i>=-1 then the whole string is copied, to the maximum number that fit on the line.</p> <p>The position of the window cursor is not advanced. These routines work faster than waddnwstr(3CURSES) because they merely copy <i>wchstr</i> into the window image structure. On the other hand, care must be taken when using these functions because they don't perform any kind of checking (such as for the newline character), they do not advance the current cursor position, and they truncate the string, rather than wrapping it around to the new line.</p> |                |                 |          |        |
| <b>RETURN VALUE</b> | <p>All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |

| DESCRIPTION   | <p>The <code>add_wchstr()</code> function copies the string of <code>cchar_t</code> characters to the <code>stdscr</code> window at the current cursor position. The <code>mvadd_wchstr()</code> and <code>mvwadd_wchstr()</code> functions copy the string to the starting position indicated by the <code>x</code> (column) and <code>y</code> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <code>win</code>). The <code>wadd_wchstr()</code> is identical to <code>add_wchstr()</code>, but writes to the window specified by <code>win</code>.</p> <p>The <code>add_wchnstr()</code>, <code>wadd_wchnstr()</code>, <code>mvadd_wchnstr()</code>, and <code>mvwadd_wchnstr()</code> functions write <code>n</code> characters to the window, or as many as will fit on the line. If <code>n</code> is less than 0, the entire string is written, or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <code>x</code> and <code>y</code> parameters.</p> <p>These functions differ from the <code>addwstr(3XCURSES)</code> set of functions in two important respects. First, these functions do <i>not</i> advance the cursor after writing the string to the window. Second, the current window rendition (that is, the combination of attributes and color pair) is not combined with the character; only those attributes that are already part of the <code>cchar_t</code> character are used.</p> |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |

| <i>y</i>      | Is the <i>y</i> (row) coordinate of the starting position of <i>wchstr</i> in the window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |

mvwadd\_wchstr(3XCURSES)

*x* Is the x (column) coordinate of the starting position of *wchstr* in the window.

*win* Is a pointer to the window to which the string is to be copied.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>SYNOPSIS</b>     | <pre> <b>cc</b> [<i>flag...</i>] <i>file...</i> -lcurses [<i>library...</i>]  #include&lt;curses.h&gt;  int <b>addwstr</b>(wchar_t *wstr); int <b>addnwstr</b>(wchar_t *wstr, int n); int <b>waddwstr</b>(WINDOW *win, wchar_t *wstr); int <b>waddnwstr</b>(WINDOW *win, wchar_t *wstr, int n); int <b>mvaddwstr</b>(int y, int x, wchar_t *wstr); int <b>mvaddnwstr</b>(int y, int x, wchar_t *wstr, int n); int <b>mvwaddwstr</b>(WINDOW *win, int y, int x, wchar_t *wstr); int <b>mvwaddnwstr</b>(WINDOW *win, int y, int x, wchar_t *wstr, int n); </pre> |                |                 |          |        |
| <b>DESCRIPTION</b>  | All of these routines write all the characters of the null-terminated <code>wchar_t</code> character string <code>wstr</code> on the given window. The effect is similar to calling <code>waddwch(3CURSES)</code> once for each <code>wchar_t</code> character in the string. The four routines with <code>n</code> as the last argument write at most <code>n</code> <code>wchar_t</code> characters. If <code>n</code> is negative, then the entire string will be added.                                                                                    |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| NAME        | addnwstr, addwstr, mvaddnwstr, mvaddwstr, mvwaddnwstr, mvwaddwstr, waddnwstr, waddwstr – add a wide-character string to a window                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| DESCRIPTION | <p>The <code>addwstr()</code> function writes a null-terminated wide-character string to the <code>stdscr</code> window at the current cursor position. The <code>waddwstr()</code> function performs an identical action, but writes the string to the window specified by <code>win</code>. The <code>mvaddwstr()</code> and <code>mvwaddwstr()</code> functions write the string to the position indicated by the <code>x</code> (column) and <code>y</code> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <code>win</code>).</p> <p>The <code>addnwstr()</code>, <code>waddnwstr()</code>, <code>mvaddnwstr()</code>, and <code>mvwaddnwstr()</code> functions write at most <code>n</code> characters to the window. If <code>n</code> is less than 0, the entire string is written. The former two functions place the characters at the current cursor position; the latter two commands use the position specified by the <code>x</code> and <code>y</code> parameters.</p> <p>All of these functions advance the cursor after writing the string.</p> <p>These functions are functionally equivalent to building a <code>cchar_t</code> from the <code>wchar_t</code> and the window rendition (or background character and rendition) and calling the <code>wadd_wch(3XCURSES)</code> function once for each <code>wchar_t</code> in the string. Refer to the <code>curses(3XCURSES)</code> man page for a complete description of special character handling and of the interaction between the window rendition (or background character and rendition) and the character written.</p> <p>Note that these functions differ from the <code>add_wchnstr(3XCURSES)</code> set of functions in that the latter copy the string as is (without combining each character with the foreground and background attributes of the window).</p> |
| PARAMETERS  | <p><i>wstr</i>        Is a pointer to the wide-character string that is to be written to the window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

mvwaddwstr(3XCURSES)

|            |                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>   | Is the maximum number of characters to be copied from <i>wstr</i> . If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line. |
| <i>y</i>   | Is the y (row) coordinate of the starting position of <i>wstr</i> in the window.                                                                                   |
| <i>x</i>   | Is the x (column) coordinate of the starting position of <i>wstr</i> in the window.                                                                                |
| <i>win</i> | Is a pointer to the window in which the string is to be written.                                                                                                   |

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| DESCRIPTION   | <p>These functions change the renditions of the next <i>n</i> characters in the current or specified window (or of the remaining characters on the current or specified line, if <i>n</i> is -1), beginning at the current or specified cursor position. The attributes and colors are specified by <i>attr</i> and <i>color</i> as for <code>setcchar(3XCURSES)</code>.</p> <p>These function neither update the cursor nor perform wrapping.</p> <p>A value of <i>n</i> that is greater than the remaining characters on a line is not an error.</p> <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, the application must provide a null pointer for <i>opts</i>.</p>                                                                                |          |                                                               |             |                                                            |              |                                                         |             |                                                                     |          |                                                                   |          |                                                                                             |            |                                                                                   |

| <b>NAME</b>          | curs_delch, delch, wdelch, mvdelch, mvwdelch – delete character under cursor in a curses window                                                                                                                                                                                                                                                                                           |                |                 |          |        |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>delch</b>(void); int <b>wdelch</b>(WINDOW *win); int <b>mvdelch</b>(int y, int x); int <b>mvwdelch</b>(WINDOW *win, int y, int x);</pre>                                                                                                                                                         |                |                 |          |        |
| <b>DESCRIPTION</b>   | With these routines the character under the cursor in the window is deleted; all characters to the right of the cursor on the same line are moved to the left one position and the last character on the line is filled with a blank. The cursor position does not change (after moving to <i>y, x</i> , if specified). This does not imply use of the hardware delete character feature. |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                          |                |                 |          |        |

| <b>DESCRIPTION</b>   | <p>The <code>delch()</code> and <code>wdelch()</code> functions delete the character at the current cursor position from <code>stdscr</code> and <i>win</i>, respectively. All remaining characters after cursor through to the end of the line are shifted one character towards the start of the line. The last character on the line becomes a space; characters on other lines are not affected.</p> <p>The <code>mvdelch()</code> and <code>mvwdelch()</code> functions delete the character at the position specified by the <i>x</i> and <i>y</i> parameters; the former deletes the character from <code>stdscr</code>; the latter from <i>win</i>.</p> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>y</i> Is the <i>y</i> (row) coordinate of the position of the character to be removed.</p> <p><i>x</i> Is the <i>x</i> (column) coordinate of the position of the character to be removed.</p> <p><i>win</i> Is a pointer to the window containing the character to be removed.</p>                                                                                                                                                                                                                                                                                                                                                                       |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |                     |          |          |        |

| DESCRIPTION   | <p>With the <code>getch()</code>, <code>wgetch()</code>, <code>mvgetch()</code>, and <code>mvwgetch()</code> routines a character is read from the terminal associated with the window. In no-delay mode, if no input is waiting, the value <code>ERR</code> is returned. In delay mode, the program waits until the system passes text through to the program. Depending on the setting of <code>cbreak()</code>, this is after one character (<code>cbreak</code> mode), or after the first newline (<code>nocbreak</code> mode). In half-delay mode, the program waits until a character is typed or the specified timeout has been reached. Unless <code>noecho()</code> has been set, the character will also be echoed into the designated window.</p> <p>If the window is not a pad, and it has been moved or modified since the last call to <code>wrefresh()</code>, <code>wrefresh()</code> will be called before another character is read.</p> <p>If <code>keypad()</code> is <code>TRUE</code>, and a function key is pressed, the token for that function key is returned instead of the raw characters. Possible function keys are defined in <code>&lt;curses.h&gt;</code> with integers beginning with 0401, whose names begin with <code>KEY_</code>. If a character that could be the beginning of a function key (such as escape) is received, <code>curses</code> sets a timer. If the remainder of the sequence does not come in within the designated time, the character is passed through; otherwise, the function key value is returned. For this reason, many terminals experience a delay between the time a user presses the escape key and the escape is returned to the program. Since tokens returned by these routines are outside the ASCII range, they are not printable.</p> <p>The <code>ungetch()</code> routine places <code>ch</code> back onto the input queue to be returned by the next call to <code>wgetch()</code>.</p> |      |          |           |           |
| Function Keys | <p>The following function keys, defined in <code>&lt;curses.h&gt;</code>, might be returned by <code>getch()</code> if <code>keypad()</code> has been enabled. Note that not all of these may be supported on a particular terminal if the terminal does not transmit a unique code when the key is pressed or if the definition for the key is not present in the <i>terminfo</i> database.</p> <table> <tr> <th>Name</th><th>Key name</th></tr> <tr> <td>KEY_BREAK</td><td>Break key</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Name | Key name | KEY_BREAK | Break key |

| KEY_PREVIOUS  | Previous object key   |
| KEY_REDO      | Redo key              |
| KEY_REFERENCE | Reference key         |
| KEY_REFRESH   | Refresh key           |
| KEY_REPLACE   | Replace key           |
| KEY_RESTART   | Restart key           |
| KEY_RESUME    | Resume key            |

## mvwgetch(3CURSES)

| <i>Name</i>   | <i>Key name</i>         |
|---------------|-------------------------|
| KEY_SAVE      | Save key                |
| KEY_SBEG      | Shifted beginning key   |
| KEY_SCANCEL   | Shifted cancel key      |
| KEY_SCOMMAND  | Shifted command key     |
| KEY_SCOPY     | Shifted copy key        |
| KEY_SCREATE   | Shifted create key      |
| KEY_SDC       | Shifted delete char key |
| KEY_SDL       | Shifted delete line key |
| KEY_SELECT    | Select key              |
| KEY_SEND      | Shifted end key         |
| KEY_SEOL      | Shifted clear line key  |
| KEY_SEXIT     | Shifted exit key        |
| KEY_SFIND     | Shifted find key        |
| KEY_SHELP     | Shifted help key        |
| KEY_SHOME     | Shifted home key        |
| KEY_SIC       | Shifted input key       |
| KEY_SLEFT     | Shifted left arrow key  |
| KEY_SMESSAGE  | Shifted message key     |
| KEY_SMOVE     | Shifted move key        |
| KEY_SNEXT     | Shifted next key        |
| KEY_SOPTIONS  | Shifted options key     |
| KEY_SPREVIOUS | Shifted prev key        |
| KEY_SPRINT    | Shifted print key       |
| KEY_SREDO     | Shifted redo key        |
| KEY_SREPLACE  | Shifted replace key     |
| KEY_SRIGHT    | Shifted right arrow     |
| KEY_SRSUME    | Shifted resume key      |
| KEY_SSAVE     | Shifted save key        |
| KEY_SSUSPEND  | Shifted suspend key     |

mvwgetch(3CURSES)

| <i>Name</i> | <i>Key name</i>  |
|-------------|------------------|
| KEY_SUNDO   | Shifted undo key |
| KEY_SUSPEND | Suspend key      |
| KEY_UNDO    | Undo key         |

**RETURN VALUES** All routines return the integer ERR upon failure. The `ungetch()` routine returns an integer value other than ERR upon successful completion. The other routines return the next input character or function key code upon successful completion.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_inopts(3CURSES)`, `curs_move(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Use of the escape key for a single character function is discouraged.

When using `getch()`, `wgetch()`, `mvgetch()`, or `mvwgetch()`, nocbreak mode (`nocbreak()`) and echo mode (`echo()`) should not be used at the same time. Depending on the state of the tty driver when each character is typed, the program may produce undesirable results.

Note that `getch()`, `mvgetch()`, and `mvwgetch()` may be macros.

| <b>PARAMETERS</b>                        | <p><i>win</i> Is a pointer to the window associated with the terminal from which the character is to be read.</p> <p><i>y</i> Is the y (row) coordinate for the position of the character to be read.</p> <p><i>x</i> Is the x (column) coordinate for the position of the character to be read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b>                       | <p>These functions read a single-byte character from the terminal associated with the current or specified window. The results are unspecified if the input is not a single-byte character. If keypad(3XCURSES) is enabled, these functions respond to the pressing of a function key by returning the corresponding <code>KEY_</code> value defined in <code>&lt;curses.h&gt;</code></p> <p>Processing of terminal input is subject to the general rules described on the keypad(3XCURSES) manual page.</p> <p>If echoing is enabled, then the character is echoed as though it were provided as an input argument to <code>addch(3XCURSES)</code>, except for the following characters:</p> <p><code>&lt;backspace&gt;</code> The input is interpreted as follows: unless the cursor already was in column 0, <code>&lt;backspace&gt;</code> moves the cursor one column toward the start of the current line and any characters after the <code>&lt;backspace&gt;</code> are added or inserted starting there. The character at the resulting cursor position is then deleted as though <code>delch(3XCURSES)</code> were called, except that if the cursor was originally in the first column of the line, the user is alerted as though <code>beep(3XCURSES)</code> were called.</p> <p>Function keys The user is alerted as though <code>beep()</code> were called. Information concerning the function keys is not returned to the caller.</p> <p>If the current or specified window is not a pad, and it has been moved modified since the last refresh operation, then it will be refreshed before another character is read.</p> |
| <b>Constant Values for Function Keys</b> | The following is a list of tokens for function keys that are returned by the <code>getch()</code> set of functions if keypad handling is enabled (some terminals may not support all tokens).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Constant          | Description                                   |
|-------------------|-----------------------------------------------|
| KEY_BREAK         | Break key                                     |
| KEY_DOWN          | The down arrow key                            |
| KEY_UP            | The up arrow key                              |
| KEY_LEFT          | The left arrow key                            |
| KEY_RIGHT         | The right arrow key                           |
| KEY_HOME          | Home key                                      |
| KEY_BACKSPACE     | Backspace                                     |
| KEY_F0            | Function keys. Space for 64 keys is reserved. |
| KEY_F( <i>n</i> ) | For $0 \leq n \leq 63$                        |
| KEY_DL            | Delete line                                   |
| KEY_IL            | Insert line                                   |
| KEY_DC            | Delete character                              |
| KEY_IC            | Insert char or enter insert mode              |
| KEY_EIC           | Exit insert char mode                         |
| KEY_CLEAR         | Clear screen                                  |
| KEY_EOS           | Clear to end of screen                        |
| KEY_EOL           | Clear to end of line                          |
| KEY_SF            | Scroll 1 line forward                         |
| KEY_SR            | Scroll 1 line backwards                       |
| KEY_NPAGE         | Next page                                     |
| KEY_PPAGE         | Previous page                                 |
| KEY_STAB          | Set tab                                       |
| KEY_CTAB          | Clear tab                                     |
| KEY_CATAB         | Clear all tabs                                |
| KEY_ENTER         | Enter or send                                 |
| KEY_SRESET        | Soft (partial) reset                          |
| KEY_RESET         | Reset or hard reset                           |
| KEY_PRINT         | Print or copy                                 |
| KEY_LL            | Home down or bottom (lower left)              |

## mvwgetch(3XCURSES)

| Constant      | Description           |
|---------------|-----------------------|
| KEY_A1        | Upper left of keypad  |
| KEY_A3        | Upper right of keypad |
| KEY_B2        | Center of keypad      |
| KEY_C1        | Lower left of keypad  |
| KEY_C3        | Lower right of keypad |
| KEY_BTAB      | Back tab              |
| KEY_BEG       | Beginning key         |
| KEY_CANCEL    | Cancel key            |
| KEY_CLOSE     | Close key             |
| KEY_COMMAND   | Cmd (command) key     |
| KEY_COPY      | Copy key              |
| KEY_CREATE    | Create key            |
| KEY_END       | End key               |
| KEY_EXIT      | Exit key              |
| KEY_FIND      | Find key              |
| KEY_HELP      | Help key              |
| KEY_MARK      | Mark key              |
| KEY_MESSAGE   | Message key           |
| KEY_MOVE      | Move key              |
| KEY_NEXT      | Next object key       |
| KEY_OPEN      | Open key              |
| KEY_OPTIONS   | Options key           |
| KEY_PREVIOUS  | Previous object key   |
| KEY_REDO      | Redo key              |

| KEY_SMESSAGES | Shifted messages key    |
| KEY_SMOVE     | Shifted move key        |
| KEY_SNEXT     | Shifted next key        |
| KEY_SOPTIONS  | Shifted options key     |
| KEY_SPREVIOUS | Shifted previous key    |
| KEY_SPRINT    | Shifted print key       |
| KEY_SREDO     | Shifted redo key        |
| KEY_SREPLACE  | Shifted replace key     |
| KEY_SRIGHT    | Shifted right arrow key |
| KEY_SRSUME    | Shifted resume key      |
| KEY_SSAVE     | Shifted save key        |
| KEY_SSUSPEND  | Shifted suspend key     |

mvwgetch(3XCURSES)

| Constant    | Description      |
|-------------|------------------|
| KEY_SUNDO   | Shifted undo key |
| KEY_SUSPEND | Suspend key      |
| KEY_UNDO    | Undo key         |

**RETURN VALUES** Upon successful completion, these functions return the single-byte character, `KEY_` value, or `ERR`. When in the nodelay mode and no data is available, `ERR` is returned.

**ERRORS** No errors are defined.

**USAGE** Applications should not define the escape key by itself as a single-character function.

When using these functions, nocbreak mode (`cbreak(3XCURSES)`) and echo mode (`echo(3XCURSES)`) should not be used at the same time. Depending on the state of the terminal when each character is typed, the application may produce undesirable results.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| DESCRIPTION | <p>The <code>getstr()</code> and <code>wgetstr()</code> functions get a character string from the terminal associated with the window <code>stdscr</code> or window <i>win</i>, respectively. The <code>mvgetstr()</code> and <code>mvwgetstr()</code> functions move the cursor to the position specified in <code>stdscr</code> or <i>win</i>, respectively, then get a character string.</p> <p>These functions call <code>wgetch(3XCURSES)</code> and place each received character in <i>str</i> until a newline is received, which is also placed in <i>str</i>. The erase and kill characters set by the user are processed.</p> <p>The <code>getnstr()</code>, <code>mvgetnstr()</code>, <code>mvwgetnstr()</code> and <code>wgetnstr()</code> functions read at most <i>n</i> characters. These functions are used to prevent overflowing the input buffer.</p> <p>The <code>getnstr()</code>, <code>wgetnstr()</code>, <code>mvgetnstr()</code>, and <code>mvwgetnstr()</code> functions only return complete multibyte characters. If the area pointed to by <i>str</i> is not large enough to hold at least one character, these functions fail.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PARAMETERS  | <p><i>str</i></p> <p><i>n</i></p> <p><i>y</i></p> <p><i>x</i></p> <p><i>win</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <p>Is a pointer to the area where the character string is to be placed.</p> <p>Is the maximum number of characters to read from input.</p> <p>Is the y (row) coordinate of starting position of character string to be read.</p> <p>Is the x (column) coordinate of starting position of character string to be read.</p> <p>Points to the window associated with the terminal from which the character is to be read.</p> |

mvwgetnstr(3XCURSES)

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |

| <b>NAME</b>         | curs_getwstr, getwstr, getnwstr, wgetwstr, wgetnwstr, mvgetwstr, mvgetnwstr, mvwgetwstr, mvwgetnwstr – get wchar_t character strings from curses terminal keyboard                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>     | <pre>cc [ flag ... ] file ... -lcurses [ library .. ] #include &lt;curses.h&gt;  int <b>getwstr</b>(wchar_t *wstr); int <b>getnwstr</b>(wchar_t *wstr, int n); int <b>wgetwstr</b>(WINDOW *win, wchar_t *wstr); int <b>wgetnwstr</b>(WINDOW *win, wchar_t *wstr, int n); int <b>mvgetwstr</b>(int y, int x, wchar_t *wstr); int <b>mvgetnwstr</b>(int y, int x, wchar_t *wstr, int n); int <b>mvwgetwstr</b>(WINDOW *win, int y, int x, wchar_t *wstr); int <b>mvwgetnwstr</b>(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre> |                |                 |          |        |
| <b>DESCRIPTION</b>  | The effect of getwstr() is as though a series of calls to getch(3CURSES) were made, until a newline and carriage return is received. The resulting value is placed in the area pointed to by the wchar_t pointer wstr. getnwstr() reads at most n wchar_t characters, thus preventing a possible overflow of the input buffer. The user's erase and kill characters are interpreted, as well as any special keys (such as function keys, HOME key, CLEAR key, etc.).                                                                   |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |          |        |

| <b>DESCRIPTION</b>   | <p>The <code>get_wstr()</code> and <code>wget_wstr()</code> functions get a wide character string from the terminal associated with the window <code>stdscr</code> or window <code>win</code>, respectively. The <code>mvget_wstr()</code> and <code>mvwget_wstr()</code> functions move the cursor to the position specified in <code>stdscr</code> or <code>win</code>, respectively, then get a wide character string.</p> <p>These functions call <code>wget_wch(3XCURSES)</code> and place each received character in <code>wstr</code> until a newline character, end-of-line character, or end-of-file character is received, which is also placed in <code>wstr</code>. The erase and kill characters set by the user are processed.</p> <p>The <code>getn_wstr()</code>, <code>mvgetn_wstr()</code>, <code>mvwgetn_wstr()</code> and <code>wgetn_wstr()</code> functions read at most <code>n</code> characters. These functions are used to prevent overflowing the input buffer.</p> |
| <b>PARAMETERS</b>    | <p><i>wstr</i> Is a pointer to the area where the character string is to be placed.</p> <p><i>n</i> Is the maximum number of characters to read from input.</p> <p><i>y</i> Is the y (row) coordinate of starting position of character string to be read.</p> <p><i>x</i> Is the x (column) coordinate of starting position of character string to be read.</p> <p><i>win</i> points to the window associated with the terminal from which the character is to be read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int  getstr(char *str); int  wgetstr(WINDOW *win, char *str); int  mvgetstr(int y, int x, char *str); int  mvwgetstr(WINDOW *win, int y, int x, char *str); int  wgetnstr(WINDOW *win, char *str, int n);</pre>                                                                                                                                                                                                                    |                |                 |          |        |
| DESCRIPTION    | The effect of <code>getstr()</code> is as though a series of calls to <code>getch()</code> were made, until a newline or carriage return is received. The resulting value is placed in the area pointed to by the character pointer <code>str</code> . <code>wgetnstr()</code> reads at most <code>n</code> characters, thus preventing a possible overflow of the input buffer. The user's erase and kill characters are interpreted, as well as any special keys (such as function keys, HOME key, and CLEAR key.) |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| DESCRIPTION | <p>The <code>getstr()</code> and <code>wgetstr()</code> functions get a character string from the terminal associated with the window <code>stdscr</code> or window <i>win</i>, respectively. The <code>mvgetstr()</code> and <code>mvwgetstr()</code> functions move the cursor to the position specified in <code>stdscr</code> or <i>win</i>, respectively, then get a character string.</p> <p>These functions call <code>wgetch(3XCURSES)</code> and place each received character in <i>str</i> until a newline is received, which is also placed in <i>str</i>. The erase and kill characters set by the user are processed.</p> <p>The <code>getnstr()</code>, <code>mvgetnstr()</code>, <code>mvwgetnstr()</code> and <code>wgetnstr()</code> functions read at most <i>n</i> characters. These functions are used to prevent overflowing the input buffer.</p> <p>The <code>getnstr()</code>, <code>wgetnstr()</code>, <code>mvgetnstr()</code>, and <code>mvwgetnstr()</code> functions only return complete multibyte characters. If the area pointed to by <i>str</i> is not large enough to hold at least one character, these functions fail.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PARAMETERS  | <p><i>str</i></p> <p><i>n</i></p> <p><i>y</i></p> <p><i>x</i></p> <p><i>win</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <p>Is a pointer to the area where the character string is to be placed.</p> <p>Is the maximum number of characters to read from input.</p> <p>Is the y (row) coordinate of starting position of character string to be read.</p> <p>Is the x (column) coordinate of starting position of character string to be read.</p> <p>Points to the window associated with the terminal from which the character is to be read.</p> |

mvwgetstr(3XCURSES)

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |

| <b>DESCRIPTION</b>     | <p>The <code>getwch()</code>, <code>wgetwch()</code>, <code>mvgetwch()</code>, and <code>mvwgetwch()</code> routines read an EUC character from the terminal associated with the window, transform it into a <code>wchar_t</code> character, and return a <code>wchar_t</code> character. In no-delay mode, if no input is waiting, the value <code>ERR</code> is returned. In delay mode, the program waits until the system passes text through to the program. Depending on the setting of <code>cbreak</code>, this is after one character ( <code>cbreak</code> mode ), or after the first newline ( <code>nocbreak</code> mode ). In half-delay mode, the program waits until a character is typed or the specified timeout has been reached. Unless <code>noecho</code> has been set, the character will also be echoed into the designated window.</p> <p>If the window is not a pad, and it has been moved or modified since the last call to <code>wrefresh(3CURSES)</code>, <code>wrefresh</code> will be called before another character is read.</p> <p>If <code>keypad</code> is <code>TRUE</code>, and a function key is pressed, the token for that function key is returned instead of the raw characters. Possible function keys are defined in <code>&lt;curses.h&gt;</code> with integers beginning with 0401, whose names begin with <code>KEY_</code>. If a character that could be the beginning of a function key (such as escape) is received, <code>curses(3CURSES)</code> sets a timer. If the remainder of the sequence does not come in within the designated time, the character is passed through; otherwise, the function key value is returned. For this reason, many terminals experience a delay between the time a user presses the escape key and the escape is returned to the program.</p> <p>The <code>ungetwch()</code> routine places <code>wch</code> back onto the input queue to be returned by the next call to <code>wgetwch()</code>.</p> |      |          |                        |           |
| <b>Function Keys</b>   | <p>The following function keys, defined in <code>&lt;curses.h&gt;</code>, might be returned by <code>getwch()</code> if <code>keypad</code> has been enabled. Note that not all of these may be supported on a particular terminal if the terminal does not transmit a unique code when the key is pressed or if the definition for the key is not present in the <code>terminfo(4)</code> database.</p> <table border="1"> <thead> <tr> <th>Name</th><th>Key name</th></tr> </thead> <tbody> <tr> <td><code>KEY_BREAK</code></td><td>Break key</td></tr> </tbody> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Name | Key name | <code>KEY_BREAK</code> | Break key |

| KEY_ENTER         | Enter or send                                                                                     |
| KEY_SRESET        | Soft (partial) reset                                                                              |
| KEY_RESET         | Reset or hard reset                                                                               |
| KEY_PRINT         | Print or copy                                                                                     |
| KEY_LL            | Home down or bottom (lower left). Keypad is arranged like this: A1 up A3 left B2 right C1 down C3 |

| <i>Name</i>   | <i>Key name</i>       |
|---------------|-----------------------|
| KEY_A1        | Upper left of keypad  |
| KEY_A3        | Upper right of keypad |
| KEY_B2        | Center of keypad      |
| KEY_C1        | Lower left of keypad  |
| KEY_C3        | Lower right of keypad |
| KEY_BTAB      | Back tab key          |
| KEY_BEG       | Beg(inning) key       |
| KEY_CANCEL    | Cancel key            |
| KEY_CLOSE     | Close key             |
| KEY_COMMAND   | Cmd (command) key     |
| KEY_COPY      | Copy key              |
| KEY_CREATE    | Create key            |
| KEY_END       | End key               |
| KEY_EXIT      | Exit key              |
| KEY_FIND      | Find key              |
| KEY_HELP      | Help key              |
| KEY_MARK      | Mark key              |
| KEY_MESSAGE   | Message key           |
| KEY_MOVE      | Move key              |
| KEY_NEXT      | Next object key       |
| KEY_OPEN      | Open key              |
| KEY_OPTIONS   | Options key           |
| KEY_PREVIOUS  | Previous object key   |
| KEY_REDO      | Redo key              |
| KEY_REFERENCE | Reference key         |
| KEY_REFRESH   | Refresh key           |
| KEY_REPLACE   | Replace key           |
| KEY_RESTART   | Restart key           |
| KEY_RESUME    | Resume key            |

## mvwgetwch(3CURSES)

| <i>Name</i>   | <i>Key name</i>         |
|---------------|-------------------------|
| KEY_SAVE      | Save key                |
| KEY_SBEG      | Shifted beginning key   |
| KEY_SCANCEL   | Shifted cancel key      |
| KEY_SCOMMAND  | Shifted command key     |
| KEY_SCOPY     | Shifted copy key        |
| KEY_SCREATE   | Shifted create key      |
| KEY_SDC       | Shifted delete char key |
| KEY_SDL       | Shifted delete line key |
| KEY_SELECT    | Select key              |
| KEY_SEND      | Shifted end key         |
| KEY_SEOL      | Shifted clear line key  |
| KEY_SEXIT     | Shifted exit key        |
| KEY_SFIND     | Shifted find key        |
| KEY_SHELP     | Shifted help key        |
| KEY_SHOME     | Shifted home key        |
| KEY_SIC       | Shifted input key       |
| KEY_SLEFT     | Shifted left arrow key  |
| KEY_SMESSAGE  | Shifted message key     |
| KEY_SMOVE     | Shifted move key        |
| KEY_SNEXT     | Shifted next key        |
| KEY_SOPTIONS  | Shifted options key     |
| KEY_SPREVIOUS | Shifted prev key        |
| KEY_SPRINT    | Shifted print key       |
| KEY_SREDO     | Shifted redo key        |
| KEY_SREPLACE  | Shifted replace key     |
| KEY_SRIGHT    | Shifted right arrow     |
| KEY_SRSUME    | Shifted resume key      |
| KEY_SSAVE     | Shifted save key        |
| KEY_SSUSPEND  | Shifted suspend key     |

mvwgetwch(3CURSES)

| <i>Name</i> | <i>Key name</i>  |
|-------------|------------------|
| KEY_SUNDO   | Shifted undo key |
| KEY_SUSPEND | Suspend key      |
| KEY_UNDO    | Undo key         |

**RETURN VALUE** All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curses(3CURSES), curs\_inopts(3CURSES), curs\_move(3CURSES), wrefresh(3CURSES), terminfo(4), attributes(5)

**NOTES** The header file <curses.h> automatically includes the header files <stdio.h>, <unctrl.h> and <wdec.h>.

Use of the escape key by a programmer for a single character function is discouraged.

When using getch(), wgetch(), mvgetch(), or mvwgetch(), nocbreak mode and echo mode should not be used at the same time. Depending on the state of the tty driver when each character is typed, the program may produce undesirable results.

Note that getch(), mvgetch(), and mvwgetch() may be macros.

| NAME        | get_wch, wget_wch, mvget_wch, mvwget_wch – get a wide character from terminal                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| DESCRIPTION | <p>The <code>get_wch()</code> and <code>wget_wch()</code> functions get a wide character from the terminal associated with the window <code>stdscr</code> or window <code>win</code>, respectively. The <code>mvget_wch()</code> and <code>mvwget_wch()</code> functions move the cursor to the position specified in <code>stdscr</code> or <code>win</code>, respectively, then get a character.</p> <p>If the window is not a pad and has been changed since the last call to <code>refresh(3XCURSES)</code>, <code>get_wch()</code> calls <code>refresh()</code> to update the window before the next character is read.</p> <p>The setting of certain functions affects the behavior of the <code>get_wch()</code> set of functions. For example, if <code>cbreak(3XCURSES)</code> is set, characters typed by the user are immediately processed. If <code>halfdelay(3XCURSES)</code> is set, <code>get_wch()</code> waits until a character is typed or returns <code>ERR</code> if no character is typed within the specified timeout period. This timeout can also be specified for individual windows with the <i>delay</i> parameter of <code>timeout(3XCURSES)</code>. A negative value waits for input; a value of 0 returns <code>ERR</code> if no input is ready; a positive value blocks until input arrives or the time specified expires (in which case <code>ERR</code> is returned). If <code>nodelay(3XCURSES)</code> is set, <code>ERR</code> is returned if no input is waiting; if not set, <code>get_wch()</code> waits until input arrives. Each character will be echoed to the window unless <code>noecho(3XCURSES)</code> has been set.</p> <p>If keypad handling is enabled ( <code>keypad(3XCURSES)</code> is <code>TRUE</code>), the token for the function key (a <code>KEY_</code> value) is stored in the object pointed to by <code>ch</code> and <code>KEY_CODE_YES</code> is returned. If a character is received that could be the beginning of a function key (for example, <code>ESC</code>), an inter-byte timer is set. If the remainder of the sequence is not received before the time expires, the character is passed through; otherwise, the value of the function key is returned. If <code>notimeout()</code> is set, the inter-byte timer is not used.</p> <p>The <code>ESC</code> key is typically a prefix key used with function keys and should not be used as a single character.</p> <p>See the <code>getch(3XCURSES)</code> manual page for a list of tokens for function keys that are returned by the <code>get_wch()</code> set of functions if keypad handling is enabled (Some terminals may not support all tokens).</p> |

`mvwget_wch(3XCURSES)`

**PARAMETERS**

|            |                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------|
| <i>ch</i>  | Is a pointer to a wide integer where the returned wide character or <code>KEY_</code> value can be stored. |
| <i>win</i> | Is a pointer to the window associated with the terminal from which the character is to be read.            |
| <i>y</i>   | Is the y (row) coordinate for the position of the character to be read.                                    |
| <i>x</i>   | Is the x (column) coordinate for the position of the character to be read.                                 |

**RETURN VALUES** When these functions successfully report the pressing of a function key, they return `KEY_CODE_YES`. When they successfully report a wide character, they return `OK`. Otherwise, they return `ERR`.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

## mvwgetwstr(3CURSES)

| NAME           | curs_getwstr, getwstr, getnwstr, wgetwstr, wgetnwstr, mvgetwstr, mvgetnwstr, mvwgetwstr, mvwgetnwstr – get wchar_t character strings from curses terminal keyboard                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library .. ] #include &lt;curses.h&gt;  int  getwstr(wchar_t *wstr); int  getnwstr(wchar_t *wstr, int n); int  wgetwstr(WINDOW *win, wchar_t *wstr); int  wgetnwstr(WINDOW *win, wchar_t *wstr, int n); int  mvgetwstr(int y, int x, wchar_t *wstr); int  mvgetnwstr(int y, int x, wchar_t *wstr, int n); int  mvwgetwstr(WINDOW *win, int y, int x, wchar_t *wstr); int  mvwgetnwstr(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre>                                                                            |                |                 |          |        |
| DESCRIPTION    | The effect of <code>getwstr()</code> is as though a series of calls to <code>getwch(3CURSES)</code> were made, until a newline and carriage return is received. The resulting value is placed in the area pointed to by the <code>wchar_t</code> pointer <code>wstr</code> . <code>getnwstr()</code> reads at most <code>n</code> <code>wchar_t</code> characters, thus preventing a possible overflow of the input buffer. The user's erase and kill characters are interpreted, as well as any special keys (such as function keys, HOME key, CLEAR key, etc.). |                |                 |          |        |
| RETURN VALUE   | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |

| DESCRIPTION   | <p>The <code>get_wstr()</code> and <code>wget_wstr()</code> functions get a wide character string from the terminal associated with the window <code>stdscr</code> or window <code>win</code>, respectively. The <code>mvget_wstr()</code> and <code>mvwget_wstr()</code> functions move the cursor to the position specified in <code>stdscr</code> or <code>win</code>, respectively, then get a wide character string.</p> <p>These functions call <code>wget_wch(3XCURSES)</code> and place each received character in <code>wstr</code> until a newline character, end-of-line character, or end-of-file character is received, which is also placed in <code>wstr</code>. The erase and kill characters set by the user are processed.</p> <p>The <code>getn_wstr()</code>, <code>mvgetn_wstr()</code>, <code>mvwgetn_wstr()</code> and <code>wgetn_wstr()</code> functions read at most <code>n</code> characters. These functions are used to prevent overflowing the input buffer.</p> |
| PARAMETERS    | <p><i>wstr</i> Is a pointer to the area where the character string is to be placed.</p> <p><i>n</i> Is the maximum number of characters to read from input.</p> <p><i>y</i> Is the y (row) coordinate of starting position of character string to be read.</p> <p><i>x</i> Is the x (column) coordinate of starting position of character string to be read.</p> <p><i>win</i> points to the window associated with the terminal from which the character is to be read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| RETURN VALUES | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>DESCRIPTION</b>   | <p>The <code>hline()</code>, <code>vline()</code>, <code>whline()</code>, <code>wvline()</code> functions draw a horizontal or vertical line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>ch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>ch</code> is 0 (zero), the default horizontal or vertical character is used.</p> <p>The <code>mvhline()</code>, <code>mvvline()</code>, <code>mvwhline()</code>, <code>mvwvline()</code> functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code>.</p> <p>The functions with names ending with <code>hline()</code> draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with <code>vline()</code> draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |
| <b>PARAMETERS</b>    | <p><code>ch</code> Is the character used to draw the line.</p> <p><code>n</code> Is the maximum number of characters in the line.</p> <p><code>y</code> Is the y (row) coordinate for the start of the line.</p> <p><code>x</code> Is the x (column) coordinate for the start of the line.</p> <p><code>win</code> Is a pointer to a window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>RETURN VALUES</b> | On success, these functions return OK. | <b>DESCRIPTION</b>   | <p>The <code>hline_set()</code>, <code>vline_set()</code>, <code>whline_set()</code>, <code>wvline_set()</code> functions draw a line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>wch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>wch</code> is a null pointer, the default horizontal or vertical character is used.</p> <p>The <code>mvhline_set()</code>, <code>mvvline_set()</code>, <code>mvwhline_set()</code>, <code>mvwvline_set()</code> functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code>.</p> <p>The functions with names ending with <code>hline_set()</code> draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with <code>vline_set()</code> draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |
| <b>PARAMETERS</b>    | <p><i>wch</i> Is the complex character used to draw the line.</p> <p><i>n</i> Is the maximum number of characters in the line.</p> <p><i>y</i> Is the y (row) coordinate for the start of the line.</p> <p><i>x</i> Is the x (column) coordinate for the start of the line.</p> <p><i>win</i> Is a pointer to a window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| DESCRIPTION | <p>The <code>newwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The upper left-hand corner of the window is at line <i>begin_y</i>, column <i>begin_x</i>. If either <i>nlines</i> or <i>ncols</i> is zero, they default to <code>LINES</code> — <i>begin_y</i> and <code>COLS</code> — <i>begin_x</i>. A new full-screen window is created by calling <code>newwin(0, 0, 0, 0)</code>.</p> <p>The <code>delwin()</code> routine deletes the named window, freeing all memory associated with it. Subwindows must be deleted before the main window can be deleted.</p> <p>The <code>mvwin()</code> routine moves the window so that the upper left-hand corner is at position (<i>x</i>, <i>y</i>). If the move would cause the window to be off the screen, it is an error and the window is not moved. Moving subwindows is allowed, but should be avoided.</p> <p>The <code>subwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The window is at position (<i>begin_y</i>, <i>begin_x</i>) on the screen. (This position is relative to the screen, and not to the window <i>orig</i>.) The window is made in the middle of the window <i>orig</i>, so that changes made to one window will affect both windows. The subwindow shares memory with the window <i>orig</i>. When using this routine, it is necessary to call <code>touchwin()</code> or <code>touchline()</code> on <i>orig</i> before calling <code>wrefresh()</code> on the subwindow.</p> <p>The <code>derwin()</code> routine is the same as <code>subwin()</code>, except that <i>begin_y</i> and <i>begin_x</i> are relative to the origin of the window <i>orig</i> rather than the screen. There is no difference between the subwindows and the derived windows.</p> |

## mvwin(3CURSES)

The `mvderwin()` routine moves a derived window (or subwindow) inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

The `dupwin()` routine creates an exact duplicate of the window *win*.

Each `curses` window maintains two data structures: the character image structure and the status structure. The character image structure is shared among all windows in the window hierarchy (that is, the window with all subwindows). The status structure, which contains information about individual line changes in the window, is private to each window. The routine `wrefresh()` uses the status data structure when performing screen updating. Since status structures are not shared, changes made to one window in the hierarchy may not be properly reflected on the screen.

The routine `wsyncup()` causes the changes in the status structure of a window to be reflected in the status structures of its ancestors. If `syncok()` is called with second argument `TRUE` then `wsyncup()` is called automatically whenever there is a change in the window.

The routine `wcursyncup()` updates the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

The routine `wsyncdown()` updates the status structure of the window to reflect the changes in the status structures of its ancestors. Applications seldom call this routine because it is called automatically by `wrefresh()`.

### RETURN VALUES

Routines that return an integer return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`delwin()` returns the integer `ERR` upon failure and `OK` upon successful completion.

Routines that return pointers return `NULL` on error.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

### SEE ALSO

`curs_refresh(3CURSES)`, `curs_touch(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

If many small changes are made to the window, the `wsyncup()` option could degrade performance.

`mvwin(3CURSES)`

Note that `syncok()` may be a macro.

## mvwin(3XCURSES)

| NAME                | mvwin – move window                                                                                                                                                                                                                                                                                                                             |                |                                     |                     |                                                                   |          |                                                                      |

| <i>win</i>          | Is a pointer to the window to move.                                                                                                                                                                                                                                                                                                             |                |                                     |                     |                                                                   |          |                                                                      |
| <i>y</i>            | Is the y (row) coordinate of the upper left corner of the window.                                                                                                                                                                                                                                                                               |                |                                     |                     |                                                                   |          |                                                                      |
| <i>x</i>            | Is the x (column) coordinate of the upper left corner of the window.                                                                                                                                                                                                                                                                            |                |                                     |                     |                                                                   |          |                                                                      |
| DESCRIPTION         | The mvwin() function moves the specified window (or subwindow), placing its upper left corner at the positions specified by <i>x</i> and <i>y</i> . The entire window must fit within the physical boundaries of the screen or an error results. In the case of a subwindow, the window must remain within the boundaries of the parent window. |                |                                     |                     |                                                                   |          |                                                                      |
| RETURN VALUES       | On success, the mvwin() function returns OK. Otherwise, it returns ERR.                                                                                                                                                                                                                                                                         |                |                                     |                     |                                                                   |          |                                                                      |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                                                           |                |                                     |                     |                                                                   |          |                                                                      |

| <b>SYNOPSIS</b>    | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  chtype <b>inch</b>(void); chtype <b>winch</b>(WINDOW *win); chtype <b>mvinch</b>(int y, int x); chtype <b>mvwinch</b>(WINDOW *win, int y, int x);</pre>                                                                                             |                |                               |              |                                |         |                                                  |
| <b>DESCRIPTION</b> | With these routines, the character, of type chtype, at the current position in the named window is returned. If any attributes are set for that position, their values are OR-ed into the value returned. Constants defined in <curses.h> can be used with the logical AND (&) operator to extract the character or attributes alone. |                |                               |              |                                |         |                                                  |

| <b>SYNOPSIS</b>      | <pre>cc [ <i>flag...</i> ] <i>file...</i> -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ <i>library...</i> ]  c89 [ <i>flag...</i> ] <i>file...</i> -lcurses [ <i>library...</i> ]</pre> <pre>#include &lt;curses.h&gt;  chtype <b>inch</b>(void);  chtype <b>mvinch</b>(int <i>y</i>, int <i>x</i>);  chtype <b>mvwinch</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>);  chtype <b>winch</b>(WINDOW *<i>win</i>);</pre>                                                                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>inch()</code> and <code>winch()</code> functions return the <code>chtype</code> character located at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively. The <code>mvinch()</code> and <code>mvwinch()</code> functions return the <code>chtype</code> character located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The complete character/attribute pair will be returned. The character or attributes can be extracted by performing a bitwise AND on the returned value, using the constants <code>A_CHARTEXT</code>, <code>A_ATTRIBUTES</code>, and <code>A_COLOR</code>.</p> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>y</i>           Is the <i>y</i> (row) coordinate of the position of the character to be returned.</p> <p><i>x</i>           Is the <i>x</i> (column) coordinate of the position of the character to be returned.</p> <p><i>win</i>          Is a pointer to the window that contains the character to be returned.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return the specified character and rendition. Otherwise, they return <code>ERR</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>   | With these routines, a string of type <code>chtype</code> , starting at the current cursor position in the named window and ending at the right margin of the window, is returned. The four functions with <i>n</i> as the last argument, return the string at most <i>n</i> characters long. Constants defined in <code>&lt;curses.h&gt;</code> can be used with the <code>&amp;</code> (logical AND) operator to extract the character or the attribute alone from any position in the <i>chstr</i> (see <code>curs_inch(3CURSES)</code> ).                                                                                                                                                                                                |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |
| <b>ATTRIBUTES</b>    | See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1" data-bbox="461 1247 1430 1335"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>MT-Level</td><td>Unsafe</td></tr> </tbody> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                               | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| DESCRIPTION  | <p>The <code>inchstr()</code> and <code>winchstr()</code> functions retrieve the character string (with rendition) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinchnstr()</code> and <code>mvwinchstr()</code> functions retrieve the character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>inchstr()</code>, <code>winchnstr()</code>, <code>mvinchnstr()</code>, and <code>mvwinchnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All these functions store the retrieved character string in the object pointed to by <i>chstr</i>.</p> <p>The complete character/attribute pair is retrieved. The character or attributes can be extracted by performing a bitwise AND on the retrieved value, using the constants <code>A_CHARTEXT</code>, <code>A_ATTRIBUTES</code>, and <code>A_COLOR</code>. The character string can also be retrieved without attributes by using <code>instr(3XCURSES)</code> set of functions.</p> |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |

| <i>chstr</i> | Is a pointer to an object that can hold the retrieved character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |
| <i>n</i>     | Is the number of characters not to exceed when retrieving <i>chstr</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |
| <i>y</i>     | Is the <i>y</i> (row) coordinate of the starting position of the string to be retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |
| <i>x</i>     | Is the <i>x</i> (column) coordinate of the starting position of the string to be retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |

`mvwinchnstr(3XCURSES)`

*win* Is a pointer to the window in which the string is to be retrieved.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>inchstr</b>(chtype *chstr); int <b>inchnstr</b>(chtype *chstr, int n); int <b>winchstr</b>(WINDOW *win, chtype *chstr); int <b>winchnstr</b>(WINDOW *win, chtype *chstr, int n); int <b>mvinchstr</b>(int y, int x, chtype *chstr); int <b>mvinchnstr</b>(int y, int x, chtype *chstr, int n); int <b>mvwinchstr</b>(WINDOW *win, int y, int x, chtype *chstr); int <b>mvwinchnstr</b>(WINDOW *win, int y, int x, chtype *chstr, int n);</pre>       |                |                 |          |        |
| <b>DESCRIPTION</b>   | With these routines, a string of type <code>chtype</code> , starting at the current cursor position in the named window and ending at the right margin of the window, is returned. The four functions with <i>n</i> as the last argument, return the string at most <i>n</i> characters long. Constants defined in <code>&lt;curses.h&gt;</code> can be used with the <code>&amp;</code> (logical AND) operator to extract the character or the attribute alone from any position in the <i>chstr</i> (see <code>curs_inch(3CURSES)</code> ). |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |
| <b>ATTRIBUTES</b>    | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |          |        |

| DESCRIPTION | <p>The <code>inchstr()</code> and <code>winchstr()</code> functions retrieve the character string (with rendition) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinchstr()</code> and <code>mvwinchstr()</code> functions retrieve the character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>inchnstr()</code>, <code>winchnstr()</code>, <code>mvinchnstr()</code>, and <code>mvwinchnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All these functions store the retrieved character string in the object pointed to by <i>chstr</i>.</p> <p>The complete character/attribute pair is retrieved. The character or attributes can be extracted by performing a bitwise AND on the retrieved value, using the constants <code>A_CHARTEXT</code>, <code>A_ATTRIBUTES</code>, and <code>A_COLOR</code>. The character string can also be retrieved without attributes by using <code>instr(3XCURSES)</code> set of functions.</p> |
| PARAMETERS  | <p><i>chstr</i>      Is a pointer to an object that can hold the retrieved character string.</p> <p><i>n</i>          Is the number of characters not to exceed when retrieving <i>chstr</i>.</p> <p><i>y</i>          Is the <i>y</i> (row) coordinate of the starting position of the string to be retrieved.</p> <p><i>x</i>          Is the <i>x</i> (column) coordinate of the starting position of the string to be retrieved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

mvwinchstr(3XCURSES)

*win* Is a pointer to the window in which the string is to be retrieved.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>DESCRIPTION</b>   | These routines return a string of characters in <i>str</i> , starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with <i>n</i> as the last argument return the string at most <i>n</i> characters long.                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |          |        |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |          |        |

| NAME        | innstr, instr, mvinnstr, mvinstr, mvwinnstr, mvwinstr, winnstr, winstr – retrieve a multibyte character string (without rendition)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| SYNOPSIS    | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int innstr(char *str, int n); int instr(char *str); int mvinnstr(int y, int x, char *str, int n); int mvinstr(int y, int x, char *str); int mvwinnstr(WINDOW *win, int y, int x, char *str, int n); int mvwinstr(WINDOW *win, int y, int x, char *str); int winstr(WINDOW *win, char *str); int winnstr(WINDOW *win, char *str, int n);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PARAMETERS  | <p><i>str</i> Is a pointer to an object that can hold the retrieved multibyte character string.</p> <p><i>n</i> Is the number of characters not to exceed when retrieving <i>str</i>.</p> <p><i>y</i> Is the y (row) coordinate of the starting position of the string to be retrieved.</p> <p><i>x</i> Is the x (column) coordinate of the starting position of the string to be retrieved.</p> <p><i>win</i> Is a pointer to the window in which the string is to be retrieved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| DESCRIPTION | <p>The <code>instr()</code> and <code>winstr()</code> functions retrieve a multibyte character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinstr()</code> and <code>mvwinstr()</code> functions retrieve a multibyte character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>innstr()</code>, <code>winnstr()</code>, <code>mvinnstr()</code>, and <code>mvwinnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> |

`mvwinnstr(3XCURSES)`

All these functions store the retrieved string in the object pointed to by *str*. They only store complete multibyte characters. If the area pointed to by *str* is not large enough to hold at least one character, these functions fail.

Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use `winchstr()`.

**ERRORS**    `OK`                      Successful completion.  
              `ERR`                     An error occurred.

**USAGE**     All functions except `winnstr()` may be macros.

**ATTRIBUTES**   See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

## mvwinnwstr(3CURSES)

| <b>NAME</b>          | <code> curs_inwstr, inwstr, innwstr, winwstr, winnwstr, mvinwstr, mvinnwstr, mvwinwstr, mvwinnwstr </code> – get a string of <code>wchar_t</code> characters from a curses window                                                                                                                                                                                                                                                                                                                                             |                |                 |          |        |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [library .. ] #include &lt;curses.h&gt;  int <b>inwstr</b>(wchar_t *wstr); int <b>innwstr</b>(wchar_t *wstr, int n); int <b>winwstr</b>(WINDOW *win, wchar_t *wstr); int <b>winnwstr</b>(WINDOW *win, wchar_t *wstr, int n); int <b>mvinwstr</b>(int y, int x, wchar_t *wstr); int <b>mvinnwstr</b>(int y, int x, wchar_t *wstr, int n); int <b>mvwinwstr</b>(WINDOW *win, int y, int x, wchar_t *wstr); int <b>mvwinnwstr</b>(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre> |                |                 |          |        |
| <b>DESCRIPTION</b>   | These routines return the string of <code>wchar_t</code> characters in <code>wstr</code> starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with <code>n</code> as the last argument return the string at most <code>n</code> <code>wchar_t</code> characters long.                                                                                                                                    |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |
| <b>ATTRIBUTES</b>    | See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>MT-Level</td><td>Unsafe</td></tr> </tbody> </table>                                                                                                                                                                                                                                                                               | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| <b>PARAMETERS</b>  | <p><i>wstr</i> Is a pointer to an object that can hold the retrieved multibyte character string.</p> <p><i>n</i> Is the number of characters not to exceed when retrieving <i>wstr</i>.</p> <p><i>y</i> Is the y (row) coordinate of the starting position of the string to be retrieved.</p> <p><i>x</i> Is the x (column) coordinate of the starting position of the string to be retrieved.</p> <p><i>win</i> Is a pointer to the window in which the string is to be retrieved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>The <code>inwstr()</code> and <code>winwstr()</code> functions retrieve a wide character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinwstr()</code> and <code>mvwinwstr()</code> functions retrieve a wide character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>innwstr()</code>, <code>winnwstr()</code>, <code>mvinnwstr()</code>, and <code>mvwinnwstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All these functions store the retrieved string in the object pointed to by <i>wstr</i>. They only store complete wide characters. If the area pointed to by <i>wstr</i> is not large enough to hold at least one character, these functions fail.</p> |

mvwinnwstr(3XCURSES)

|                      | Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use <code>win_wchstr(3XCURSES)</code> .                                                                                                                                                                                                                                           |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>RETURN VALUES</b> | <p>On success, the <code>innwstr()</code>, <code>mvinwstr()</code>, <code>mvwinnwstr()</code>, and <code>winnwstr()</code> functions return OK. Otherwise, they return ERR.</p> <p>On success, the <code>innwstr()</code>, <code>mvinwstr()</code>, <code>mvwinnwstr()</code>, and <code>winnwstr()</code> functions return the number of characters read into the string. Otherwise, they return ERR.</p> |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |

| <b>NAME</b>          | <p> <code> curs_insch, insch, winsch, mvinsch, mvwinsch </code> – insert a character before the character under the cursor in a curses window </p>                                                                                                                                                                                                                                                                     |                |                 |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>      | <pre> cc [ flag ... ] file... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>insch</b>(chtype <i>ch</i>) ; int <b>winsch</b>(WINDOW *<i>win</i>, chtype <i>ch</i>) ; int <b>mvinsch</b>(int <i>y</i>, int <i>x</i>, chtype <i>ch</i>) ; int <b>mvwinsch</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, chtype <i>ch</i>) ; </pre>                                                                     |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>With these routines, the character <i>ch</i> is inserted before the character under the cursor. All characters to the right of the cursor are moved one space to the right, with the possibility of the rightmost character on the line being lost. The cursor position does not change (after moving to <i>y</i>, <i>x</i>, if specified). (This does not imply use of the hardware insert character feature.)</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | <p>All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.</p>                                                                                                                                                                                                                                                                                                |                |                 |          |        |

## mvwinsch(3XCURSES)

| <b>NAME</b>          | insch, winsch, mvinsch, mvwinsch – insert a character                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |                     |          |          |        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>insch</b>(chtype <i>ch</i>);  int <b>mvinsch</b>(int <i>y</i>, int <i>x</i>, chtype <i>ch</i>);  int <b>mvwinsch</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, chtype <i>ch</i>);  int <b>winsch</b>(WINDOW *<i>win</i>, chtype <i>ch</i>);</pre> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>ch</i> Is the character to be inserted.</p> <p><i>y</i> Is the y (row) coordinate of the position of the character.</p> <p><i>x</i> Is the x (column) coordinate of the position of the character.</p> <p><i>win</i> Is a pointer to the window in which the character is to be inserted.</p>                                                                                                                                                      |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>These functions insert the character and rendition from <i>ch</i> into the current or specified window at the current or specified position.</p> <p>These functions do not perform wrapping and do not advance the cursor position. These functions perform special-character processing, with the exception that if a newline is inserted into the last line of a window and scrolling is not enabled, the behavior is unspecified.</p>              |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                       |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |                     |          |          |        |
| <b>USAGE</b>         | These functions are only guaranteed to operate reliably on character sets in which each character fits into a single byte, whose attributes can be expressed using only constants with the A_ prefix.                                                                                                                                                                                                                                                    |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>   | <p>With these routines, a character string (as many characters as will fit on the line) is inserted before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <i>y</i>, <i>x</i>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <i>n</i> as the last argument insert at most <i>n</i> characters. If <i>n</i> ≤ 0, then the entire string is inserted.</p> <p>If a character in <i>str</i> is a tab, newline, carriage return or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol()</code> before moving. Tabs are considered to be at every eighth column. If a character in <i>str</i> is another control character, it is drawn in the ^X notation. Calling <code>winch()</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| <i>str</i>  | Is a pointer to the string to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>n</i>    | Is the number of characters not to exceed when inserting <i>str</i> . If <i>n</i> is less than 1, the entire string is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>y</i>    | Is the y (row) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>x</i>    | Is the x (column) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>win</i>  | Is a pointer to the window in which the string is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| DESCRIPTION | <p>The <code>insstr()</code> function inserts <i>str</i> at the current cursor position of the <code>stdscr</code> window. The <code>winsstr()</code> function performs the identical action, but in window <i>win</i>. The <code>mvinsstr()</code> and <code>mvwinsstr()</code> functions insert the character string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The <code>insnstr()</code>, <code>winsnstr()</code>, <code>mvinsnstr()</code>, and <code>mvwinsnstr()</code> functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.</p> |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |

mvwinsnstr(3XCURSES)

If a character in *str* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using  $\wedge x$  notation, where  $x$  is a printable character. `clrtoeol(3XCURSES)` is automatically done before a newline.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| <b>DESCRIPTION</b>  | <p>These routines insert a <code>wchar_t</code> character string (as many <code>wchar_t</code> characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <code>y, x</code>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <code>n</code> as the last argument insert at most <code>n</code> <code>wchar_t</code> characters. If <code>n</code> ≤ 0, then the entire string is inserted.</p> <p>If a character in <code>wstr</code> is a tab, newline, carriage return, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol(3CURSES)</code> before moving. Tabs are considered to be at every eighth column. If a character in <code>wstr</code> is another control character, it is drawn in the <code>^X</code> notation. Calling <code>winch(3CURSES)</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |

If <i>n</i> is less than 1, the entire string is inserted. | <i>y</i> | Is the y (row) coordinate of the starting position of the string. | <i>x</i> | Is the x (column) coordinate of the starting position of the string. | <i>win</i> | Is a pointer to the window in which the string is to be inserted. |
| <i>wstr</i> | Is a pointer to the string to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>n</i>    | Is the number of characters not to exceed when inserting <i>wstr</i> . If <i>n</i> is less than 1, the entire string is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>y</i>    | Is the y (row) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>x</i>    | Is the x (column) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>win</i>  | Is a pointer to the window in which the string is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| DESCRIPTION | <p>The <code>ins_wstr()</code> function inserts <i>wstr</i> at the current cursor position of the <code>stdscr</code> window. The <code>wins_wstr()</code> function performs the identical action, but in window <i>win</i>. The <code>mvins_wstr()</code> and <code>mvwins_wstr()</code> functions insert <i>wstr</i> string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>ins_nwstr()</code>, <code>wins_nwstr()</code>, <code>mvins_nwstr()</code>, and <code>mvwins_nwstr()</code> functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |

mvwins\_nwstr(3XCURSES)

All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.

If a character in *wstr* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using *^x* notation, where *x* is a printable character. `clrtoeol(3XCURSES)` is automatically done before a newline.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>DESCRIPTION</b>   | <p>With these routines, a character string (as many characters as will fit on the line) is inserted before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <i>y</i>, <i>x</i>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <i>n</i> as the last argument insert at most <i>n</i> characters. If <i>n</i> ≤ 0, then the entire string is inserted.</p> <p>If a character in <i>str</i> is a tab, newline, carriage return or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol()</code> before moving. Tabs are considered to be at every eighth column. If a character in <i>str</i> is another control character, it is drawn in the ^X notation. Calling <code>winch()</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

If <i>n</i> is less than 1, the entire string is inserted. | <i>y</i> | Is the y (row) coordinate of the starting position of the string. | <i>x</i> | Is the x (column) coordinate of the starting position of the string. | <i>win</i> | Is a pointer to the window in which the string is to be inserted. |
| <i>str</i>  | Is a pointer to the string to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>n</i>    | Is the number of characters not to exceed when inserting <i>str</i> . If <i>n</i> is less than 1, the entire string is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>y</i>    | Is the y (row) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>x</i>    | Is the x (column) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>win</i>  | Is a pointer to the window in which the string is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| DESCRIPTION | <p>The <code>insstr()</code> function inserts <i>str</i> at the current cursor position of the <code>stdscr</code> window. The <code>winsstr()</code> function performs the identical action, but in window <i>win</i>. The <code>mvinsstr()</code> and <code>mvwinsstr()</code> functions insert the character string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The <code>insnstr()</code>, <code>winsnstr()</code>, <code>mvinsnstr()</code>, and <code>mvwinsnstr()</code> functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.</p> |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |

mvwinsstr(3XCURSES)

If a character in *str* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using  $\wedge x$  notation, where *x* is a printable character. `clrtoeol(3XCURSES)` is automatically done before a newline.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>SYNOPSIS</b>      | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lcurses [ <i>library</i> ... ] #include &lt;curses.h&gt;  int <b>instr</b>(char *<i>str</i>); int <b>innstr</b>(char *<i>str</i>, int <i>n</i>); int <b>winstr</b>(WINDOW *<i>win</i>, char *<i>str</i>); int <b>winnstr</b>(WINDOW *<i>win</i>, char *<i>str</i>, int <i>n</i>); int <b>mvinstr</b>(int <i>y</i>, int <i>x</i>, char *<i>str</i>); int <b>mvinnstr</b>(int <i>y</i>, int <i>x</i>, char *<i>str</i>, int <i>n</i>); int <b>mvwinstr</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, char *<i>str</i>); int <b>mvwinnstr</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, char *<i>str</i>, int <i>n</i>);</pre> |                |                 |          |        |
| <b>DESCRIPTION</b>   | These routines return a string of characters in <i>str</i> , starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with <i>n</i> as the last argument return the string at most <i>n</i> characters long.                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| <b>PARAMETERS</b>  | <i>str</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Is a pointer to an object that can hold the retrieved multibyte character string.    |
|                    | <i>n</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Is the number of characters not to exceed when retrieving <i>str</i> .               |
|                    | <i>y</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Is the y (row) coordinate of the starting position of the string to be retrieved.    |
|                    | <i>x</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Is the x (column) coordinate of the starting position of the string to be retrieved. |
|                    | <i>win</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Is a pointer to the window in which the string is to be retrieved.                   |
| <b>DESCRIPTION</b> | <p>The <code>instr()</code> and <code>winstr()</code> functions retrieve a multibyte character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinstr()</code> and <code>mvwinstr()</code> functions retrieve a multibyte character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>innstr()</code>, <code>winnstr()</code>, <code>mvinnstr()</code>, and <code>mvwinnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> |                                                                                      |

`mvwinstr(3XCURSES)`

All these functions store the retrieved string in the object pointed to by *str*. They only store complete multibyte characters. If the area pointed to by *str* is not large enough to hold at least one character, these functions fail.

Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use `winchstr()`.

**ERRORS**    `OK`                      Successful completion.  
              `ERR`                     An error occurred.

**USAGE**    All functions except `winnstr()` may be macros.

**ATTRIBUTES**    See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO**    `inch(3XCURSES)`, `inchstr(3XCURSES)`, `libcurses(3XCURSES)`, `attributes(5)`,  
              `standards(5)`

## mvwinswch(3CURSES)

| NAME           | curs_inswch, inswch, winswch, mvinswch, mvwinswch – insert a wchar_t character before the character under the cursor in a curses window                                                                                                                                                                                                                                                                                                |                |                 |          |        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library .. ] #include &lt;curses.h&gt;  int inswch(chtype wch); int winswch(WINDOW *win, chtype wch); int mvinswch(int y, int x, chtype wch); int mvwinswch(WINDOW *win, int y, int x, chtype wch);</pre>                                                                                                                                                                                     |                |                 |          |        |
| DESCRIPTION    | These routines insert the character <i>wch</i> , holding a wchar_t character, before the character under the cursor. All characters to the right of the cursor are moved one space to the right, with the possibility of the rightmost character on the line being lost. The cursor position does not change (after moving to <i>y</i> , <i>x</i> , if specified). (This does not imply use of the hardware insert character feature.) |                |                 |          |        |
| RETURN VALUE   | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                       |                |                 |          |        |

| <b>PARAMETERS</b>    | <p><i>wch</i> Is the complex character to be inserted.</p> <p><i>y</i> Is the y (row) coordinate of the position of the character.</p> <p><i>x</i> Is the x (column) coordinate of the position of the character.</p> <p><i>win</i> Is a pointer to the window in which the character is to be inserted.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b>   | <p>The <code>ins_wch()</code> function inserts the complex character <i>wch</i> at the current cursor position of the <code>stdscr</code> window. The <code>wins_wch()</code> function performs the identical action but in window <i>win</i>. The <code>mvins_wch()</code> and <code>mvwins_wch()</code> functions insert the character at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>). The cursor position does not change.</p> <p>All characters to the right of the inserted character are moved right one character. The last character on the line is deleted.</p> <p>Insertions and deletions occur at the character level. The cursor is adjusted to the first column of the character prior to the the operation.</p> |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>DESCRIPTION</b>  | <p>These routines insert a <code>wchar_t</code> character string (as many <code>wchar_t</code> characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <code>y, x</code>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <code>n</code> as the last argument insert at most <code>n</code> <code>wchar_t</code> characters. If <code>n</code> ≤ 0, then the entire string is inserted.</p> <p>If a character in <code>wstr</code> is a tab, newline, carriage return, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol(3CURSES)</code> before moving. Tabs are considered to be at every eighth column. If a character in <code>wstr</code> is another control character, it is drawn in the <code>^X</code> notation. Calling <code>winch(3CURSES)</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |

If <i>n</i> is less than 1, the entire string is inserted. | <i>y</i> | Is the y (row) coordinate of the starting position of the string. | <i>x</i> | Is the x (column) coordinate of the starting position of the string. | <i>win</i> | Is a pointer to the window in which the string is to be inserted. |
| <i>wstr</i> | Is a pointer to the string to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>n</i>    | Is the number of characters not to exceed when inserting <i>wstr</i> . If <i>n</i> is less than 1, the entire string is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>y</i>    | Is the y (row) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>x</i>    | Is the x (column) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>win</i>  | Is a pointer to the window in which the string is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| DESCRIPTION | <p>The <code>ins_wstr()</code> function inserts <i>wstr</i> at the current cursor position of the <code>stdscr</code> window. The <code>wins_wstr()</code> function performs the identical action, but in window <i>win</i>. The <code>mvins_wstr()</code> and <code>mvwins_wstr()</code> functions insert <i>wstr</i> string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>ins_nwstr()</code>, <code>wins_nwstr()</code>, <code>mvins_nwstr()</code>, and <code>mvwins_nwstr()</code> functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |

mvwins\_wstr(3XCURSES)

All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.

If a character in *wstr* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using *^x* notation, where *x* is a printable character. `clrtoeol(3XCURSES)` is automatically done before a newline.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>NAME</b>        | curs_inwch, inwch, winwch, mvwinwch, mvwinwch – get a wchar_t character and its attributes from a curses window                                                                                                                                                                                                                    |                |                               |               |                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-------------------------------|---------------|--------------------------------|
| <b>SYNOPSIS</b>    | <pre>cc [ flag ... ] file ... -lcurses [ library .. ] #include &lt;curses.h&gt;  chtype inwch(void); chtype winwch(WINDOW *win); chtype mvwinwch(int y, int x); chtype mvwinwch(WINDOW *win, int y, int x);</pre>                                                                                                                  |                |                               |               |                                |
| <b>DESCRIPTION</b> | These routines return the wchar_t character, of type chtype, at the current position in the named window. If any attributes are set for that position, their values are OR-ed into the value returned. Constants defined in <curses.h> can be used with the logical AND (&) operator to extract the character or attributes alone. |                |                               |               |                                |
| <b>Attributes</b>  | <p>The following bit-masks may be AND-ed with characters returned by winwch().</p> <table> <tr> <td>A_WCHARTEXT</td><td>Bit-mask to extract character</td></tr> <tr> <td>A_WATTRIBUTES</td><td>Bit-mask to extract attributes</td></tr> </table>                                                                                   | A_WCHARTEXT    | Bit-mask to extract character | A_WATTRIBUTES | Bit-mask to extract attributes |
| A_WCHARTEXT        | Bit-mask to extract character                                                                                                                                                                                                                                                                                                      |                |                               |               |                                |

| <b>DESCRIPTION</b>   | <p>The in_wch() and win_wch() functions retrieve the complex character and its rendition located at the current cursor position of the stdscr window and window win, respectively. The mvin_wch() and mvwin_wch() functions retrieve the complex character and its rendition located at the position indicated by the x (column) and y (row) parameters (the former in the stdscr window; the latter in window win).</p> <p>All these functions store the retrieved character and its rendition in the object pointed to by wcv.</p> |                |                                                                                 |                     |                                                                            |          |                                                                               |     |                                                                        |
| <b>PARAMETERS</b>    | <table> <tr> <td>wcv</td><td>Is a pointer to an object that can store a complex character and its rendition.</td></tr> <tr> <td>y</td><td>Is the y (row) coordinate of the position of the character to be returned.</td></tr> <tr> <td>x</td><td>Is the x (column) coordinate of the position of the character to be returned.</td></tr> <tr> <td>win</td><td>Is a pointer to the window that contains the character to be returned.</td></tr> </table>                                                                             | wcv            | Is a pointer to an object that can store a complex character and its rendition. | y                   | Is the y (row) coordinate of the position of the character to be returned. | x        | Is the x (column) coordinate of the position of the character to be returned. | win | Is a pointer to the window that contains the character to be returned. |
| wcv                  | Is a pointer to an object that can store a complex character and its rendition.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                                                                                 |                     |                                                                            |          |                                                                               |     |                                                                        |
| y                    | Is the y (row) coordinate of the position of the character to be returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                                                                                 |                     |                                                                            |          |                                                                               |     |                                                                        |
| x                    | Is the x (column) coordinate of the position of the character to be returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                                                                                 |                     |                                                                            |          |                                                                               |     |                                                                        |
| win                  | Is a pointer to the window that contains the character to be returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                                                                                 |                     |                                                                            |          |                                                                               |     |                                                                        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                                                                                 |                     |                                                                            |          |                                                                               |     |                                                                        |

| <b>DESCRIPTION</b>  | These routines return a string of type <code>chtype</code> , holding <code>wchar_t</code> characters, starting at the current cursor position in the named window and ending at the right margin of the window. The four functions with <i>n</i> as the last argument, return the string at most <i>n</i> <code>wchar_t</code> characters long. Constants defined in <code>&lt;curses.h&gt;</code> can be used with the logical AND (&) operator to extract the <code>wchar_t</code> character or the attribute alone from any position in the <i>wchstr</i> (see <code>curs_inwch(3CURSES)</code> ).                                                                                                                                                       |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |          |        |
| <b>ATTRIBUTES</b>   | See <code>attributes(5)</code> for a description of the following attributes: <table border="1" data-bbox="461 1247 1430 1335"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>MT-Level</td><td>Unsafe</td></tr> </tbody> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| <b>DESCRIPTION</b> | <p>The in_wchstr() and win_wchstr() functions retrieve a complex character string (with rendition) starting at the current cursor position of the stdscr window and window win, respectively, and ending at the right margin. The mvin_wchstr() and mvwin_wchstr() functions retrieve a complex character string located at the position indicated by the x (column) and y (row) parameters (the former in the stdscr window; the latter in window win).</p> <p>The in_wchnstr(), win_wchnstr(), mvin_wchnstr(), and mvwin_wchnstr() functions retrieve at most n characters from the window stdscr and win, respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the x and y parameters.</p> <p>The retrieved character string (with renditions) is stored in the object pointed to by wcvval.</p> |                                                                                       |

## mvwinwchstr(3CURSES)

| <b>NAME</b>         | <code> curs_inwchstr, inwchstr, inwchnstr, winwchstr, winwchnstr, mvinwchstr, mvinwchnstr, mvwinwchstr, mvwinwchnstr </code> – get a string of <code>wchar_t</code> characters (and attributes) from a curses window                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |          |        |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>     | <pre>cc [ flag ... ] file ... -lcurses [ library .. ] #include &lt;curses.h&gt;  int <b>inwchstr</b>(chtype *wchstr); int <b>inwchnstr</b>(chtype *wchstr, int n); int <b>winwchstr</b>(WINDOW *win, chtype *wchstr); int <b>winwchnstr</b>(WINDOW *win, chtype *wchstr, int n); int <b>mvinwchstr</b>(int y, int x, chtype *wchstr); int <b>mvinwchnstr</b>(int y, int x, chtype *wchstr, int n); int <b>mvwinwchstr</b>(WINDOW *win, int y, int x, chtype *wchstr); int <b>mvwinwchnstr</b>(WINDOW *win, int y, int x, chtype *wchstr, int n);</pre>                                                |                |                 |          |        |
| <b>DESCRIPTION</b>  | These routines return a string of type <code>chtype</code> , holding <code>wchar_t</code> characters, starting at the current cursor position in the named window and ending at the right margin of the window. The four functions with <i>n</i> as the last argument, return the string at most <i>n</i> <code>wchar_t</code> characters long. Constants defined in <code>&lt;curses.h&gt;</code> can be used with the logical AND (&) operator to extract the <code>wchar_t</code> character or the attribute alone from any position in the <i>wchstr</i> (see <code>curs_inwch(3CURSES)</code> ). |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |          |        |

| DESCRIPTION | <p>The <code>in_wchstr()</code> and <code>win_wchstr()</code> functions retrieve a complex character string (with rendition) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvin_wchstr()</code> and <code>mvwin_wchstr()</code> functions retrieve a complex character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>in_wchnstr()</code>, <code>win_wchnstr()</code>, <code>mvin_wchnstr()</code>, and <code>mvwin_wchnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>The retrieved character string (with renditions) is stored in the object pointed to by <i>wcval</i>.</p> |                                                                                             |
| PARAMETERS  | <i>wchstr</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Is a pointer to an object where the retrieved complex character string can be stored.       |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses[library .. ] #include &lt;curses.h&gt;  int inwstr(wchar_t *wstr); int innwstr(wchar_t *wstr, int n); int winwstr(WINDOW *win, wchar_t *wstr); int winnwstr(WINDOW *win, wchar_t *wstr, int n); int mvinwstr(int y, int x, wchar_t *wstr); int mvinnwstr(int y, int x, wchar_t *wstr, int n); int mvwinwstr(WINDOW *win, int y, int x, wchar_t *wstr); int mvwinnwstr(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre> |                |                 |          |        |
| DESCRIPTION    | These routines return the string of wchar_t characters in <i>wstr</i> starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with <i>n</i> as the last argument return the string at most <i>n</i> wchar_t characters long.                                                                                                                       |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| PARAMETERS  | <p><i>wstr</i> Is a pointer to an object that can hold the retrieved multibyte character string.</p> <p><i>n</i> Is the number of characters not to exceed when retrieving <i>wstr</i>.</p> <p><i>y</i> Is the y (row) coordinate of the starting position of the string to be retrieved.</p> <p><i>x</i> Is the x (column) coordinate of the starting position of the string to be retrieved.</p> <p><i>win</i> Is a pointer to the window in which the string is to be retrieved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DESCRIPTION | <p>The <code>inwstr()</code> and <code>winwstr()</code> functions retrieve a wide character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinwstr()</code> and <code>mvwinwstr()</code> functions retrieve a wide character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>innwstr()</code>, <code>winnwstr()</code>, <code>mvinnwstr()</code>, and <code>mvwinnwstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All these functions store the retrieved string in the object pointed to by <i>wstr</i>. They only store complete wide characters. If the area pointed to by <i>wstr</i> is not large enough to hold at least one character, these functions fail.</p> |

`mvwinwstr(3XCURSES)`

**RETURN VALUES** Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use `win_wchstr(3XCURSES)`.

On success, the `inwstr()`, `mvinwstr()`, `mvwinwstr()`, and `winwstr()` functions return OK. Otherwise, they return ERR.

On success, the `innwstr()`, `mvinnwstr()`, `mvwinnwstr()`, and `winnwstr()` functions return the number of characters read into the string. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO** `in_wch(3XCURSES)`, `in_wchnstr(3XCURSES)`, `libcurses(3XCURSES)`, `attributes(5)`, `standards(5)`

## mvwprintw(3CURSES)

| NAME           | <code> curs_printw, printw, wprintw, mvprintw, mvwprintw, vwprintw </code> – print formatted output in curses windows                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| SYNOPSIS       | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lcurses [ <i>library</i> ... ] #include &lt;curses.h&gt;  int <b>printw</b>(char *<i>fmt</i>, /* <i>arg</i> */ ... ); int <b>wprintw</b>(WINDOW *<i>win</i>, char *<i>fmt</i>, /* <i>arg</i> */ ... ); int <b>mvprintw</b>(int <i>y</i>, int <i>x</i>, char *<i>fmt</i>, /* <i>arg</i> */ ... ); int <b>mvwprintw</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, char *<i>fmt</i>, /* <i>arg</i> */ ... ); #include &lt;varargs.h&gt; int <b>vwprintw</b>(WINDOW *<i>win</i>, char *<i>fmt</i>, /* <i>varglist</i> */ ... );</pre>                                                                                      |                |                 |          |        |
| DESCRIPTION    | <p>The <code>printw()</code>, <code>wprintw()</code>, <code>mvprintw()</code>, and <code>mvwprintw()</code> routines are analogous to <code>printf()</code> (see <code>printf(3C)</code>). In effect, the string that would be output by <code>printf()</code> is output instead as though <code>waddstr()</code> were used on the given window.</p> <p>The <code>vwprintw()</code> routine is analogous to <code>vprintf()</code> (see <code>vprintf(3C)</code>) and performs a <code>wprintw()</code> using a variable argument list. The third argument is a <code>va_list</code>, a pointer to a list of arguments, as defined in <code>&lt;varargs.h&gt;</code>.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |
| ATTRIBUTES     | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |          |        |

|                     | win                                                                                                                                                                                                                                                                                                                                                                            | Is a pointer to the window in which the string is to be written.               |                |                 |                     |          |          |        |
| DESCRIPTION         | The mvprintw(), mvwprintw(), printw(), and wprintw() functions are analogous to printf(3C). The effect of these functions is as though sprintf() were used to format the string, and then waddstr(3XCURSES) were used to add that multi-byte string to the current or specified window at the current or specified cursor position.                                            |                                                                                |                |                 |                     |          |          |        |
| RETURN VALUES       | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                             |                                                                                |                |                 |                     |          |          |        |
| ERRORS              | No errors are defined.                                                                                                                                                                                                                                                                                                                                                         |                                                                                |                |                 |                     |          |          |        |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>scanw</b>(char *fmt, /* arg */ ...); int <b>wscanw</b>(WINDOW *win, char *fmt, /* arg */ ...); int <b>mvscanw</b>(int y, int x, char *fmt, /* arg */ ...); int <b>mvwscanw</b>(WINDOW *win, int y, int x, char *fmt, /* arg */...); int <b>vwscanw</b>(WINDOW *win, char *fmt, va_list varglist);</pre>                                                                                                                                                                                                                                                                              |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>scanw()</code>, <code>wscanw()</code>, and <code>mvscanw()</code> routines correspond to <code>scanf()</code> (see <code>scanf(3C)</code>). The effect of these routines is as though <code>wgetstr()</code> were called on the window, and the resulting line used as input for the scan. Fields which do not map to a variable in the <code>fmt</code> field are lost.</p> <p>The <code>vwscanw()</code> routine is similar to <code>vwprintw()</code> in that it performs a <code>wscanw()</code> using a variable argument list. The third argument is a <i>va_list</i>, a pointer to a list of arguments, as defined in <code>&lt;varargs.h&gt;</code>.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | <p><code>vwscanw()</code> returns <code>ERR</code> on failure and an integer equal to the number of fields scanned on success.</p> <p>Applications may interrogate the return value from the <code>scanw</code>, <code>wscanw()</code>, <code>mvscanw()</code>, and <code>mvwscanw()</code> routines to determine the number of fields which were mapped in the call.</p>                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

|                     | win                                                                                                                                                                                                                                                                                                                                                                        | Is a pointer to the window in which the character is to be read.          |                |                 |                     |          |          |        |
| DESCRIPTION         | These functions are similar to scanf(3C). Their effect is as though mvwgetstr(3XCURSES) were called to get a multi-byte character string from the current or specified window at the current or specified cursor position, and then sscanf ( ) were used to interpret and convert that string.                                                                             |                                                                           |                |                 |                     |          |          |        |
| RETURN VALUES       | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                         |                                                                           |                |                 |                     |          |          |        |
| ERRORS              | No errors are defined.                                                                                                                                                                                                                                                                                                                                                     |                                                                           |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>   | <p>The <code>hline()</code>, <code>vline()</code>, <code>whline()</code>, <code>wvline()</code> functions draw a horizontal or vertical line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>ch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>ch</code> is 0 (zero), the default horizontal or vertical character is used.</p> <p>The <code>mvhline()</code>, <code>mvvline()</code>, <code>mvwhline()</code>, <code>mvwvline()</code> functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code>.</p> <p>The functions with names ending with <code>hline()</code> draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with <code>vline()</code> draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |
| <b>PARAMETERS</b>    | <p><code>ch</code> Is the character used to draw the line.</p> <p><code>n</code> Is the maximum number of characters in the line.</p> <p><code>y</code> Is the y (row) coordinate for the start of the line.</p> <p><code>x</code> Is the x (column) coordinate for the start of the line.</p> <p><code>win</code> Is a pointer to a window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>RETURN VALUES</b> | On success, these functions return OK. | <b>DESCRIPTION</b>   | <p>The <code>hline_set()</code>, <code>vline_set()</code>, <code>whline_set()</code>, <code>wvline_set()</code> functions draw a line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>wch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>wch</code> is a null pointer, the default horizontal or vertical character is used.</p> <p>The <code>mvhline_set()</code>, <code>mvvline_set()</code>, <code>mvwhline_set()</code>, <code>mvwvline_set()</code> functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code>.</p> <p>The functions with names ending with <code>hline_set()</code> draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with <code>vline_set()</code> draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |
| <b>PARAMETERS</b>    | <p><i>wch</i> Is the complex character used to draw the line.</p> <p><i>n</i> Is the maximum number of characters in the line.</p> <p><i>y</i> Is the y (row) coordinate for the start of the line.</p> <p><i>x</i> Is the x (column) coordinate for the start of the line.</p> <p><i>win</i> Is a pointer to a window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>DESCRIPTION</b> | <p>The following routines give low-level access to various curses functionality. These routines typically are used inside library routines.</p> <p>The <code>def_prog_mode()</code> and <code>def_shell_mode()</code> routines save the current terminal modes as the “program” (in curses) or “shell” (not in curses) state for use by the <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines. This is done automatically by <code>initscr()</code>.</p> <p>The <code>reset_prog_mode()</code> and <code>reset_shell_mode()</code> routines restore the terminal to “program” (in curses) or “shell” (out of curses) state. These are done automatically by <code>endwin()</code> and, after an <code>endwin()</code>, by <code>doupdate()</code>, so they normally are not called.</p> <p>The <code>resetty()</code> and <code>savetty()</code> routines save and restore the state of the terminal modes. <code>savetty()</code> saves the current state in a buffer and <code>resetty()</code> restores the state to what it was at the last call to <code>savetty()</code>.</p> <p>With the <code>getsyx()</code> routine, the current coordinates of the virtual screen cursor are returned in <code>y</code> and <code>x</code>. If <code>leaveok()</code> is currently TRUE, then <code>-1,-1</code> is returned. If lines have been removed from the top of the screen, using <code>ripoffline()</code>, <code>y</code> and <code>x</code> include these lines; therefore, <code>y</code> and <code>x</code> should be used only as arguments for <code>setsyx()</code>.</p> <p>With the <code>setsyx()</code> routine, the virtual screen cursor is set to <code>y, x</code>. If <code>y</code> and <code>x</code> are both <code>-1</code>, then <code>leaveok()</code> is set. The two routines <code>getsyx()</code> and <code>setsyx()</code> are designed to be used by a library routine, which manipulates curses windows but does not</p> |

napms(3CURSES)

want to change the current position of the program's cursor. The library routine would call getsyx() at the beginning, do its manipulation of its own windows, do a wnoutrefresh() on its windows, call setsyx(), and then call doupdate().

The ripoffline() routine provides access to the same facility that slk\_init() (see curs\_slk(3CURSES)) uses to reduce the size of the screen. ripoffline() must be called before initscr() or newterm() is called. If line is positive, a line is removed from the top of stdscr(); if line is negative, a line is removed from the bottom. When this is done inside initscr(), the routine init() (supplied by the user) is called with two arguments: a window pointer to the one-line window that has been allocated and an integer with the number of columns in the window. Inside this initialization routine, the integer variables LINES and COLS (defined in <curses.h>) are not guaranteed to be accurate and wrefresh() or doupdate() must not be called. It is allowable to call wnoutrefresh() during the initialization routine.

ripoffline() can be called up to five times before calling initscr() or newterm().

With the curs\_set() routine, the cursor state is set to invisible, normal, or very visible for *visibility* equal to 0, 1, or 2 respectively. If the terminal supports the *visibility* requested, the previous *cursor* state is returned; otherwise, ERR is returned.

The napms() routine is used to sleep for *ms* milliseconds.

#### RETURN VALUES

Except for curs\_set(), these routines always return OK. curs\_set() returns the previous cursor state, or ERR if the requested *visibility* is not supported.

#### ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

#### SEE ALSO

curs\_initscr(3CURSES), curs\_outopts(3CURSES), curs\_refresh(3CURSES), curs\_scr\_dump(3CURSES), curs\_slk(3CURSES), curses(3CURSES), attributes(5)

#### NOTES

The header <curses.h> automatically includes the headers <stdio.h> and <unctrl.h>.

Note that getsyx() is a macro, so an ampersand (&) is not necessary before the variables *y* and *x*.

## napms(3XCURSES)

| NAME                | napms – sleep process for a specified length of time                                                                                                                                                                                                                              |                |                 |                     |          |          |        |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| SYNOPSIS            | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>napms</b>(int <i>ms</i>);</pre>                                                  |                |                 |                     |          |          |        |
| PARAMETERS          | <i>ms</i> Is the number of milliseconds to sleep.                                                                                                                                                                                                                                 |                |                 |                     |          |          |        |
| DESCRIPTION         | The <code>napms()</code> function sleeps for at least <i>ms</i> milliseconds.                                                                                                                                                                                                     |                |                 |                     |          |          |        |
| RETURN VALUES       | The <code>napms()</code> function always returns OK.                                                                                                                                                                                                                              |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                             |                |                 |                     |          |          |        |

new\_field(3CURSES)

| NAME           | form_field_new, new_field, dup_field, link_field, free_field – create and destroy forms fields                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                                     |             |                                           |                |               |                |                           |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-------------------------------------|-------------|-------------------------------------------|----------------|---------------|----------------|---------------------------|
| SYNOPSIS       | <pre>cc [ flag... ] file... -lform -lcurses [ library... ] #include &lt;form.h&gt;  FIELD *new_field(int r, int c, int frow, int fcol, int nrow, int ncol); FIELD *dup_field(FIELD *field, int frow, int fcol); FIELD *link_field(FIELD *field, int frow, int fcol); int free_field(FIELD *field);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                                     |             |                                           |                |               |                |                           |
| DESCRIPTION    | <p>new_field() creates a new field with <i>r</i> rows and <i>c</i> columns, starting at <i>frow</i>, <i>fcol</i>, in the subwindow of a form. <i>nrow</i> is the number of off-screen rows and <i>nbuf</i> is the number of additional working buffers. This routine returns a pointer to the new field.</p> <p>dup_field() duplicates <i>field</i> at the specified location. All field attributes are duplicated, including the current contents of the field buffers.</p> <p>link_field() also duplicates <i>field</i> at the specified location. However, unlike dup_field(), the new field shares the field buffers with the original field. After creation, the attributes of the new field can be changed without affecting the original field.</p> <p>free_field() frees the storage allocated for <i>field</i>.</p> |                |                                     |             |                                           |                |               |                |                           |
| RETURN VALUES  | <p>Routines that return pointers return NULL on error. free_field() returns one of the following:</p> <table><tr><td>E_OK</td><td>The function returned successfully.</td></tr><tr><td>E_CONNECTED</td><td>The field is already connected to a form.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error.</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                               | E_OK           | The function returned successfully. | E_CONNECTED | The field is already connected to a form. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An argument is incorrect. |
| E_OK           | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                                     |             |                                           |                |               |                |                           |

| <b>DESCRIPTION</b>   | <p>new_fieldtype() creates a new field type. The application programmer must write the function <i>field_check</i>, which validates the field value, and the function <i>char_check</i>, which validates each character. free_fieldtype() frees the space allocated for the field type.</p> <p>By associating function pointers with a field type, set_fieldtype_arg() connects to the field type additional arguments necessary for a set_field_type() call. Function <i>mak_arg</i> allocates a structure for the field specific parameters to set_field_type() and returns a pointer to the saved data. Function <i>copy_arg</i> duplicates the structure created by <i>make_arg</i>. Function <i>free_arg</i> frees any storage allocated by <i>make_arg</i> or <i>copy_arg</i>.</p> <p>The form_driver() requests REQ_NEXT_CHOICE and REQ_PREV_CHOICE let the user request the next or previous value of a field type comprising an ordered set of values. set_fieldtype_choice() allows the application programmer to implement these requests for the given field type. It associates with the given field type those application-defined functions that return pointers to the next or previous choice for the field.</p> <p>link_fieldtype() returns a pointer to the field type built from the two given types. The constituent types may be any application-defined or pre-defined types.</p> |      |                                     |                |               |                |                           |             |                                          |
| <b>RETURN VALUES</b> | <p>Routines that return pointers always return NULL on error. Routines that return an integer return one of the following:</p> <table> <tr> <td>E_OK</td><td>The function returned successfully.</td></tr> <tr> <td>E_SYSTEM_ERROR</td><td>System error.</td></tr> <tr> <td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr> <tr> <td>E_CONNECTED</td><td>Type is connected to one or more fields.</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | E_OK | The function returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An argument is incorrect. | E_CONNECTED | Type is connected to one or more fields. |

| SYNOPSIS       | <pre>cc [ flag... ] file... -lform -lcurses [ library... ] #include &lt;form.h&gt;  FORM *new_form(FIELD **fields) ; int free_form(FORM *form) ;</pre>                                                                                                                                              |                |                                     |                |                           |          |                     |
| DESCRIPTION    | <p>new_form() creates a new form connected to the designated fields and returns a pointer to the form.</p> <p>free_form() disconnects the <i>form</i> from its associated field pointer array and deallocates the space for the form.</p>                                                           |                |                                     |                |                           |          |                     |
| RETURN VALUES  | <p>new_form() always returns NULL on error. free_form() returns one of the following:</p> <table><tr><td>E_OK</td><td>The function returned successfully.</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr><tr><td>E_POSTED</td><td>The form is posted.</td></tr></table> | E_OK           | The function returned successfully. | E_BAD_ARGUMENT | An argument is incorrect. | E_POSTED | The form is posted. |
| E_OK           | The function returned successfully.                                                                                                                                                                                                                                                                 |                |                                     |                |                           |          |                     |
| E_BAD_ARGUMENT | An argument is incorrect.                                                                                                                                                                                                                                                                           |                |                                     |                |                           |          |                     |
| E_POSTED       | The form is posted.                                                                                                                                                                                                                                                                                 |                |                                     |                |                           |          |                     |

| NAME        | curs_pad, newpad, subpad, prefresh, pnoutrefresh, pechochar, pechowchar – create and display curses pads                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| DESCRIPTION | <p>The <code>newpad()</code> routine creates and returns a pointer to a new pad data structure with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (for example, from scrolling or echoing of input) do not occur. It is not legal to call <code>wrefresh(3CURSES)</code> with a <i>pad</i> as an argument; the routines <code>prefresh()</code> or <code>pnoutrefresh()</code> should be called instead. Note that these routines require additional parameters to specify the part of the pad to be displayed and the location on the screen to be used for the display.</p> <p>The <code>subpad()</code> routine creates and returns a pointer to a subwindow within a pad with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. Unlike <code>subwin(3CURSES)</code>, which uses screen coordinates, the window is at position (<i>begin_x</i>, <i>begin_y</i>) on the pad. The window is made in the middle of the window <i>orig</i>, so that changes made to one window affect both windows. During the use of this routine, it will often be necessary to call <code>touchwin(3CURSES)</code> or <code>touchline(3CURSES)</code> on <i>orig</i> before calling <code>prefresh()</code>.</p> <p>The <code>prefresh()</code> and <code>pnoutrefresh()</code> routines are analogous to <code>wrefresh(3CURSES)</code> and <code>wnoutrefresh(3CURSES)</code> except that they relate to pads instead of windows. The additional parameters are needed to indicate what part of the pad and screen are involved. <i>pminrow</i> and <i>pmincol</i> specify the upper left-hand corner of the rectangle to be displayed in the pad. <i>sminrow</i>, <i>smincol</i>, <i>smaxrow</i>, and <i>smaxcol</i> specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of <i>pminrow</i>, <i>pmincol</i>, <i>sminrow</i>, or <i>smincol</i> are treated as if they were zero.</p> |

newpad(3CURSES)

The `pechochar()` routine is functionally equivalent to a call to `addch(3CURSES)` followed by a call to `refresh(3CURSES)`, a call to `waddch(3CURSES)` followed by a call to `wrefresh(3CURSES)`, or a call to `waddch(3CURSES)` followed by a call to `prefresh()`. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents. In the case of `pechochar()`, the last location of the pad on the screen is reused for the arguments to `prefresh()`.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

Routines that return pointers return `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `addch(3CURSES)`, `curses(3CURSES)`, `refresh(3CURSES)`, `subwin(3CURSES)`, `touchline(3CURSES)`, `touchwin(3CURSES)`, `waddch(3CURSES)`, `wnoutrefresh(3CURSES)`, `wrefresh(3CURSES)`, `attributes(5)`

**NOTES** The header file `<curses.h>` automatically includes the header files `<stdio.h>`, `<unctrl.h>` and `<wider.h>`.

Note that `pechochar()` may be a macro.

| NAME        | newpad, pnoutrefresh, prefresh, subpad – create or refresh a pad or subpad                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |
| SYNOPSIS    | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  WINDOW *newpad(int nlines, int ncols);  int pnoutrefresh(WINDOW *pad, int pminrow, int pmincol, int sminrow, int smincol, int smaxrow, int smaxcol);  int prefresh(WINDOW *pad, int pminrow, int pmincol, int sminrow, int smincol, int smaxrow, int smaxcol);  WINDOW *subpad(WINDOW *orig, int nlines, int ncols);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |
| PARAMETERS  | <p><i>nlines</i> Is the number of lines in the pad to be created.</p> <p><i>ncols</i> Is the number of columns in the pad to be created.</p> <p><i>pad</i> Is a pointer to the pad to refresh.</p> <p><i>pminrow</i> Is the row coordinate of the upper left corner of the pad rectangle to be copied</p> <p><i>pmincol</i> Is the column coordinate of the upper left corner of the pad rectangle to be copied.</p> <p><i>sminrow</i> Is the row coordinate of the upper left corner of the rectangle on the physical screen where pad is to be positioned.</p> <p><i>smincol</i> Is the column coordinate of the upper left corner of the rectangle on the physical screen where pad is to be positioned.</p> <p><i>smaxrow</i> Is the row coordinate of the lower right corner of the rectangle on the physical screen where the pad is to be positioned.</p> <p><i>smaxcol</i> Is the column coordinate of the lower right corner of the rectangle on the physical screen where the pad is to be positioned.</p> <p><i>orig</i> Is a pointer to the parent pad within which a sub-pad is created.</p> |  |
| DESCRIPTION | <p>The newpad() function creates a new pad with the specified number of lines and columns. A pointer to the new pad structure is returned. A pad differs from a window in that it is not restricted to the size of the physical screen. It is useful when only part of a large window will be displayed at any one time.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |  |

## newpad(3XCURSES)

Automatic refreshes by scrolling or echoing of input do not take place when pads are used. Pads have their own refresh commands, `prefresh()` and `pnoutrefresh()`.

The `prefresh()` function copies the specified portion of the logical pad to the terminal screen. The parameters *pmincol* and *pminrow* specify the upper left corner of the rectangular area of the pad to be displayed. The lower right coordinate of the rectangular area of the pad that is to be displayed is calculated from the screen parameters (*sminrow*, *smincol*, *smaxrow*, *smaxcol*).

This function calls the `pnoutrefresh()` function to copy the specified portion of *pad* to the terminal screen and the `doupdate(3XCURSES)` function to do the actual update. The logical cursor is copied to the same location in the physical window unless `leaveok(3XCURSES)` is enabled (in which case, the cursor is placed in a position that the program finds convenient).

When outputting several pads at once, it is often more efficient to call the `pnoutrefresh()` and `doupdate()` functions directly. A call to `pnoutrefresh()` for each pad first, followed by only one call to `doupdate()` to update the screen, results in one burst of output, fewer characters sent, and less CPU time used.

The `subpad()` function creates a sub-pad within the pad *orig* with the specified number of lines and columns. A pointer to the new pad structure is returned. The sub-pad is positioned in the middle of *orig*. Any changes made to one pad affect the other. `touchwin(3XCURSES)` or `touchline(3XCURSES)` will likely have to be called on pad *orig* to correctly update the window.

### RETURN VALUES

On success, the `newpad()` and `subpad()` functions return a pointer to the new pad data structure. Otherwise, they return a null pointer.

On success, the `pnoutrefresh()` and `prefresh()` functions return `OK`. Otherwise, they return `ERR`.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| NAME           | panel_new, new_panel, del_panel – create and destroy panels                                                                                                                                                                   |                |                 |          |        |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lpanel -lcurses [ library .. ] #include &lt;panel.h&gt;  PANEL *new_panel (WINDOW *win) ; int del_panel (PANEL *panel) ;</pre>                                                                 |                |                 |          |        |
| DESCRIPTION    | <p>new_panel () creates a new panel associated with <i>win</i> and returns the panel pointer. The new panel is placed on top of the panel deck.</p> <p>del_panel () destroys <i>panel</i>, but not its associated window.</p> |                |                 |          |        |
| RETURN VALUES  | <p>new_panel () returns NULL if an error occurs.</p> <p>del_win () returns OK if successful, ERR otherwise.</p>                                                                                                               |                |                 |          |        |

| NAME        | curs_initscr, initscr, newterm, endwin, isendwin, set_term, delscreen – curses screen initialization and manipulation routines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| SYNOPSIS    | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  WINDOW *initscr(void);  int endwin(void);  int isendwin(void);  SCREEN *newterm(char *type, FILE *outfd, FILE *infd);  SCREEN *set_term(SCREEN *new);  void delscreen(SCREEN *sp);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| DESCRIPTION | <p><code>initscr()</code> is almost always the first routine that should be called (the exceptions are <code>slk_init()</code>, <code>filter()</code>, <code>ripline()</code>, <code>use_env()</code> and, for multiple-terminal applications, <code>newterm()</code>.) This determines the terminal type and initializes all curses data structures. <code>initscr()</code> also causes the first call to <code>refresh()</code> to clear the screen. If errors occur, <code>initscr()</code> writes an appropriate error message to standard error and exits; otherwise, a pointer is returned to <code>stdscr()</code>. If the program needs an indication of error conditions, <code>newterm()</code> should be used instead of <code>initscr()</code>; <code>initscr()</code> should only be called once per application.</p> <p>A program that outputs to more than one terminal should use the <code>newterm()</code> routine for each terminal instead of <code>initscr()</code>. A program that needs an indication of error conditions, so it can continue to run in a line-oriented mode if the terminal cannot support a screen-oriented program, would also use this routine. The routine <code>newterm()</code> should be called once for each terminal. It returns a variable of type <code>SCREEN *</code> which should be saved as a reference to that terminal. The arguments are the <i>type</i> of the terminal to be used in place of <code>\$TERM</code>, a file pointer for output to the terminal, and another file pointer for input from the terminal (if <i>type</i> is <code>NULL</code>, <code>\$TERM</code> will be used). The program must also call <code>endwin()</code> for each terminal being used before exiting from curses. If <code>newterm()</code> is called more than once for the same terminal, the first terminal referred to must be the last one for which <code>endwin()</code> is called.</p> <p>A program should always call <code>endwin()</code> before exiting or escaping from curses mode temporarily. This routine restores tty modes, moves the cursor to the lower left-hand corner of the screen and resets the terminal into the proper non-visual mode. Calling <code>refresh()</code> or <code>doupdate()</code> after a temporary escape causes the program to resume visual mode.</p> <p>The <code>isendwin()</code> routine returns <code>TRUE</code> if <code>endwin()</code> has been called without any subsequent calls to <code>wrefresh()</code>, and <code>FALSE</code> otherwise.</p> |

newterm(3CURSES)

The `set_term()` routine is used to switch between different terminals. The screen reference `new` becomes the new current terminal. The previous terminal is returned by the routine. This is the only routine which manipulates `SCREEN` pointers; all other routines affect only the current terminal.

The `delscreen()` routine frees storage associated with the `SCREEN` data structure. The `endwin()` routine does not do this, so `delscreen()` should be called after `endwin()` if a particular `SCREEN` is no longer needed.

**RETURN VALUES** `endwin()` returns the integer `ERR` upon failure and `OK` upon successful completion.

Routines that return pointers always return `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curl_kernel(3CURSES)`, `curl_refresh(3CURSES)`, `curl_slk(3CURSES)`, `curl_util(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `initscr()` and `newterm()` may be macros.

| <b>DESCRIPTION</b>                                                                                                                                                                                                         | <p>The <code>initscr()</code> function initializes X/Open Curses data structures, determines the terminal type, and ensures the first call to <code>refresh(3XCURSES)</code> clears the screen.</p> <p>The <code>newterm()</code> function opens a new terminal with each call. It should be used instead of <code>initscr()</code> when the program interacts with more than one terminal. It returns a variable of type <code>SCREEN</code>, which should be used for later reference to that terminal. Before program termination, <code>endwin()</code> should be called for each terminal.</p> <p>The only functions that you can call before calling <code>initscr()</code> or <code>newterm()</code> are <code>filter(3XCURSES)</code>, <code>ripcoffline(3XCURSES)</code>, <code>slk_init(3XCURSES)</code>, and <code>use_env(3XCURSES)</code>.</p> |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The <code>newwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The upper left-hand corner of the window is at line <i>begin_y</i>, column <i>begin_x</i>. If either <i>nlines</i> or <i>ncols</i> is zero, they default to <code>LINES</code> — <i>begin_y</i> and <code>COLS</code> — <i>begin_x</i>. A new full-screen window is created by calling <code>newwin(0,0,0,0)</code>.</p> <p>The <code>delwin()</code> routine deletes the named window, freeing all memory associated with it. Subwindows must be deleted before the main window can be deleted.</p> <p>The <code>mvwin()</code> routine moves the window so that the upper left-hand corner is at position (<i>x</i>, <i>y</i>). If the move would cause the window to be off the screen, it is an error and the window is not moved. Moving subwindows is allowed, but should be avoided.</p> <p>The <code>subwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The window is at position (<i>begin_y</i>, <i>begin_x</i>) on the screen. (This position is relative to the screen, and not to the window <i>orig</i>.) The window is made in the middle of the window <i>orig</i>, so that changes made to one window will affect both windows. The subwindow shares memory with the window <i>orig</i>. When using this routine, it is necessary to call <code>touchwin()</code> or <code>touchline()</code> on <i>orig</i> before calling <code>wrefresh()</code> on the subwindow.</p> <p>The <code>derwin()</code> routine is the same as <code>subwin()</code>, except that <i>begin_y</i> and <i>begin_x</i> are relative to the origin of the window <i>orig</i> rather than the screen. There is no difference between the subwindows and the derived windows.</p> |

## newwin(3CURSES)

The `mvderwin()` routine moves a derived window (or subwindow) inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

The `dupwin()` routine creates an exact duplicate of the window *win*.

Each `curses` window maintains two data structures: the character image structure and the status structure. The character image structure is shared among all windows in the window hierarchy (that is, the window with all subwindows). The status structure, which contains information about individual line changes in the window, is private to each window. The routine `wrefresh()` uses the status data structure when performing screen updating. Since status structures are not shared, changes made to one window in the hierarchy may not be properly reflected on the screen.

The routine `wsyncup()` causes the changes in the status structure of a window to be reflected in the status structures of its ancestors. If `syncok()` is called with second argument `TRUE` then `wsyncup()` is called automatically whenever there is a change in the window.

The routine `wcursyncup()` updates the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

The routine `wsyncdown()` updates the status structure of the window to reflect the changes in the status structures of its ancestors. Applications seldom call this routine because it is called automatically by `wrefresh()`.

### RETURN VALUES

Routines that return an integer return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`delwin()` returns the integer `ERR` upon failure and `OK` upon successful completion.

Routines that return pointers return `NULL` on error.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

### SEE ALSO

`curs_refresh(3CURSES)`, `curs_touch(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

If many small changes are made to the window, the `wsyncup()` option could degrade performance.

`newwin(3CURSES)`

Note that `syncok()` may be a macro.

| <b>DESCRIPTION</b> | <p>The <code>derwin()</code> function creates a subwindow within window <i>orig</i>, with the specified number of lines and columns, and upper left corner positioned at <i>begin_x</i>, <i>begin_y</i> relative to window <i>orig</i>. A pointer to the new window structure is returned.</p> <p>The <code>newwin()</code> function creates a new window with the specified number of lines and columns and upper left corner positioned at <i>begin_x</i>, <i>begin_y</i>. A pointer to the new window structure is returned. A full-screen window can be created by calling <code>newwin(0,0,0,0)</code>.</p> <p>If the number of lines specified is zero, <code>newwin()</code> uses a default value of <code>LINES</code> minus <i>begin_y</i>; if the number of columns specified is zero, <code>newwin()</code> uses the default value of <code>COLS</code> minus <i>begin_x</i>.</p> <p>The <code>subwin()</code> function creates a subwindow within window <i>orig</i>, with the specified number of lines and columns, and upper left corner positioned at <i>begin_x</i>, <i>begin_y</i> (relative to the physical screen, <i>not</i> to window <i>orig</i>). A pointer to the new window structure is returned.</p> <p>The original window and subwindow share character storage of the overlapping area (each window maintains its own pointers, cursor location, and other items). This means that characters and attributes are identical in overlapping areas regardless of which window characters are written to.</p> <p>When using subwindows, it is often necessary to call <code>touchwin(3XCURSES)</code> before <code>wrefresh(3XCURSES)</code> to maintain proper screen contents.</p> |             |                                                                    |               |                                          |              |                                            |                |                                                                                                     |

| <i>orig</i>        | Is a pointer to the parent window for the newly created subwindow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |             |                                                                    |               |                                          |              |                                            |                |                                                                                                     |
| <i>nlines</i>      | Is the number of lines in the subwindow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |             |                                                                    |               |                                          |              |                                            |                |                                                                                                     |
| <i>ncols</i>       | Is the number of columns in the subwindow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                                                                    |               |                                          |              |                                            |                |                                                                                                     |
| <i>begin_y</i>     | Is the y (row) coordinate of the upper left corner of the subwindow, relative to the parent window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |             |                                                                    |               |                                          |              |                                            |                |                                                                                                     |

`newwin(3XCURSES)`

*begin\_x* Is the x (column) coordinate of the upper left corner of the subwindow, relative to the parent window.

**RETURN VALUES** On success, these functions return a pointer to the newly-created window. Otherwise, they return `ERR`.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO** `doupdate(3XCURSES)`, `is_linetouched(3XCURSES)`, `libcurses(3XCURSES)`, `attributes(5)`, `standards(5)`

| <b>DESCRIPTION</b> | <p>These routines set options that deal with output within curses. All options are initially FALSE, unless otherwise stated. It is not necessary to turn these options off before calling <code>endwin()</code>.</p> <p>With the <code>clearok()</code> routine, if enabled (<i>bf</i> is TRUE), the next call to <code>wrefresh()</code> with this window will clear the screen completely and redraw the entire screen from scratch. This is useful when the contents of the screen are uncertain, or in some cases for a more pleasing visual effect. If the <i>win</i> argument to <code>clearok()</code> is the global variable <code>curscr()</code>, the next call to <code>wrefresh()</code> with any window causes the screen to be cleared and repainted from scratch.</p> <p>With the <code>idlok()</code> routine, if enabled (<i>bf</i> is TRUE), curses considers using the hardware insert/delete line feature of terminals so equipped. If disabled (<i>bf</i> is FALSE), curses very seldom uses this feature. (The insert/delete character feature is always considered.) This option should be enabled only if the application needs insert/delete line, for example, for a screen editor. It is disabled by default because insert/delete line tends to be visually annoying when used in applications where it isn't really needed. If insert/delete line cannot be used, curses redraws the changed portions of all lines.</p> <p>With the <code>idcok()</code> routine, if enabled (<i>bf</i> is TRUE), curses considers using the hardware insert/delete character feature of terminals so equipped. This is enabled by default.</p> <p>With the <code>immedok()</code> routine, if enabled (<i>bf</i> is TRUE), any change in the window image, such as the ones caused by <code>waddch()</code>, <code>wclrtoeol()</code>, <code>wscrl()</code>, etc., automatically cause a call to <code>wrefresh()</code>. However, it may degrade the performance considerably, due to repeated calls to <code>wrefresh()</code>. It is disabled by default.</p> |

nl(3CURSES)

Normally, the hardware cursor is left at the location of the window cursor being refreshed. The `leaveok()` option allows the cursor to be left wherever the update happens to leave it. It is useful for applications where the cursor is not used, since it reduces the need for cursor motions. If possible, the cursor is made invisible when this option is enabled.

The `setscrreg()` and `wsetscrreg()` routines allow the application programmer to set a software scrolling region in a window. *top* and *bot* are the line numbers of the top and bottom margin of the scrolling region. (Line 0 is the top line of the window.) If this option and `scrollok()` are enabled, an attempt to move off the bottom margin line causes all lines in the scrolling region to scroll up one line. Only the text of the window is scrolled. (Note that this has nothing to do with the use of a physical scrolling region capability in the terminal, like that in the VT100. If `idlok()` is enabled and the terminal has either a scrolling region or insert/delete line capability, they will probably be used by the output routines.)

The `scrollok()` option controls what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If disabled, (*bf* is FALSE), the cursor is left on the bottom line. If enabled, (*bf* is TRUE), `wrefresh()` is called on the window, and the physical terminal and window are scrolled up one line. (Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call `idlok()`.)

The `nl()` and `nonl()` routines control whether newline is translated into carriage return and linefeed on output, and whether return is translated into newline on input. Initially, the translations do occur. By disabling these translations using `nonl()`, `curses` is able to make better use of the linefeed capability, resulting in faster cursor motion.

**RETURN VALUES** `setscrreg()` and `wsetscrreg()` return OK upon success and ERR upon failure. All other routines that return an integer always return OK.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_addch(3CURSES)`, `curs_clear(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curs_scroll(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `clearok()`, `leaveok()`, `scrollok()`, `idcok()`, `nl()`, `nonl()`, and `setscrreg()` may be macros.

nl(3CURSES)

The `immedok()` routine is useful for windows that are used as terminal emulators.

| <b>NAME</b>          | nl, nonl – enable/disable newline control                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The <code>cbreak()</code> and <code>nocbreak()</code> routines put the terminal into and out of <code>cbreak()</code> mode, respectively. In this mode, characters typed by the user are immediately available to the program, and erase/kill character-processing is not performed. When out of this mode, the tty driver buffers the typed characters until a newline or carriage return is typed. Interrupt and flow control characters are unaffected by this mode. Initially the terminal may or may not be in <code>cbreak()</code> mode, as the mode is inherited; therefore, a program should call <code>cbreak()</code> or <code>nocbreak()</code> explicitly. Most interactive programs using curses set the <code>cbreak()</code> mode.</p> <p>Note that <code>cbreak()</code> overrides <code>raw()</code>. (See <code>curs_getch(3CURSES)</code> for a discussion of how these routines interact with <code>echo()</code> and <code>noecho()</code>.)</p> <p>The <code>echo()</code> and <code>noecho()</code> routines control whether characters typed by the user are echoed by <code>getch()</code> as they are typed. Echoing by the tty driver is always disabled, but initially <code>getch()</code> is in echo mode, so characters typed are echoed. Authors of</p> |

most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling `noecho()`. (See `curs_getch(3CURSES)` for a discussion of how these routines interact with `cbreak()` and `nocbreak()`.)

The `halfdelay()` routine is used for half-delay mode, which is similar to `cbreak()` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, `ERR` is returned if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

If the `intrflush()` option is enabled, (*bf* is `TRUE`), when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing `curses` to have the wrong idea of what is on the screen. Disabling (*bf* is `FALSE`), the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.

The `keypad()` option enables the keypad of the user's terminal. If enabled (*bf* is `TRUE`), the user can press a function key (such as an arrow key) and `wgetch()` returns a single value representing the function key, as in `KEY_LEFT`. If disabled (*bf* is `FALSE`), `curses` does not treat function keys specially and the program has to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option causes the terminal keypad to be turned on when `wgetch()` is called. The default value for keypad is false.

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the tty driver (see `termio(7I)`). To force 8 bits to be returned, invoke `meta(win, TRUE)`. To force 7 bits to be returned, invoke `meta(win, FALSE)`. The window argument, *win*, is always ignored. If the terminfo capabilities `smm` (`meta_on`) and `rmm` (`meta_off`) are defined for the terminal, `smm` is sent to the terminal when `meta(win, TRUE)` is called and `rmm` is sent when `meta(win, FALSE)` is called.

The `nodelay()` option causes `getch()` to be a non-blocking call. If no input is ready, `getch()` returns `ERR`. If disabled (*bf* is `FALSE`), `getch()` waits until a key is pressed.

While interpreting an input escape sequence, `wgetch()` sets a timer while waiting for the next character. If `notimeout(win, TRUE)` is called, then `wgetch()` does not set a timer. The purpose of the timeout is to differentiate between sequences received from a function key and those typed by a user.

With the `raw()` and `noraw()` routines, the terminal is placed into or out of raw mode. Raw mode is similar to `cbreak()` mode, in that characters typed are immediately passed through to the user program. The differences are that in raw mode, the interrupt, quit, suspend, and flow control characters are all passed through uninterpreted, instead of generating a signal. The behavior of the `BREAK` key depends on other bits in the tty driver that are not set by `curses`.

## nocbreak(3CURSES)

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done (see `termio(7I)`). When `qiflush()` is called, the queues will be flushed when these control characters are read.

The `timeout()` and `wtimeout()` routines set blocking or non-blocking read for a given window. If *delay* is negative, blocking read is used (that is, waits indefinitely for input). If *delay* is zero, then non-blocking read is used (that is, read returns `ERR` if no input is waiting). If *delay* is positive, then read blocks for *delay* milliseconds, and returns `ERR` if there is still no input. Hence, these routines provide the same functionality as `nodelay()`, plus the additional capability of being able to block for only *delay* milliseconds (where *delay* is positive).

`curses` does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh()` or `doupdate()` is called again. This allows faster response to commands typed in advance. Normally, the input FILE pointer passed to `newterm()`, or `stdin` in the case that `initscr()` was used, will be used to do this typeahead checking. The `typeahead()` routine specifies that the file descriptor *fildev* is to be used to check for typeahead instead. If *fildev* is `-1`, then no typeahead checking is done.

### RETURN VALUES

All routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

### SEE ALSO

`curs_getch(3CURSES)`, `curs_initscr(3CURSES)`, `curses(3CURSES)`, `attributes(5)`, `termio(7I)`

### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `echo()`, `noecho()`, `halfdelay()`, `intrflush()`, `meta()`, `nodelay()`, `notimeout()`, `noqiflush()`, `qiflush()`, `timeout()`, and `wtimeout()` may be macros.

| DESCRIPTION         | <p>The <code>cbreak()</code> function enables the character input mode. This overrides any previous call to the <code>raw()</code> function and turns the <code>stty</code> flag <code>ICANON</code> off.</p> <p>The <code>nocbreak()</code> function sets the line canonical mode and turns the <code>stty</code> flag <code>ICANON</code> on without touching the <code>ISIG</code> or <code>IXON</code> flags.</p> <p>The <code>noraw()</code> function sets the line canonical mode and turns the the <code>stty</code> flags <code>ICANON</code>, <code>ISIG</code>, and <code>IXON</code> all on.</p> <p>The <code>raw()</code> function sets the character input mode and turns the <code>stty</code> flags <code>ICANON</code>, <code>ISIG</code>, and <code>IXON</code> all off. This mode provides maximum control over input.</p> <p>It is important to remember that the terminal may or may not be in character mode operation initially. Most interactive programs require <code>cbreak()</code> to be enabled.</p> |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return <code>OK</code> . Otherwise, they return <code>ERR</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The <code>cbreak()</code> and <code>nocbreak()</code> routines put the terminal into and out of <code>cbreak()</code> mode, respectively. In this mode, characters typed by the user are immediately available to the program, and erase/kill character-processing is not performed. When out of this mode, the tty driver buffers the typed characters until a newline or carriage return is typed. Interrupt and flow control characters are unaffected by this mode. Initially the terminal may or may not be in <code>cbreak()</code> mode, as the mode is inherited; therefore, a program should call <code>cbreak()</code> or <code>nocbreak()</code> explicitly. Most interactive programs using curses set the <code>cbreak()</code> mode.</p> <p>Note that <code>cbreak()</code> overrides <code>raw()</code>. (See <code>curs_getch(3CURSES)</code> for a discussion of how these routines interact with <code>echo()</code> and <code>noecho()</code>.)</p> <p>The <code>echo()</code> and <code>noecho()</code> routines control whether characters typed by the user are echoed by <code>getch()</code> as they are typed. Echoing by the tty driver is always disabled, but initially <code>getch()</code> is in echo mode, so characters typed are echoed. Authors of</p> |

most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling `noecho()`. (See `curs_getch(3CURSES)` for a discussion of how these routines interact with `cbreak()` and `nocbreak()`.)

The `halfdelay()` routine is used for half-delay mode, which is similar to `cbreak()` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, `ERR` is returned if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

If the `intrflush()` option is enabled, (*bf* is `TRUE`), when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing `curses` to have the wrong idea of what is on the screen. Disabling (*bf* is `FALSE`), the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.

The `keypad()` option enables the keypad of the user's terminal. If enabled (*bf* is `TRUE`), the user can press a function key (such as an arrow key) and `wgetch()` returns a single value representing the function key, as in `KEY_LEFT`. If disabled (*bf* is `FALSE`), `curses` does not treat function keys specially and the program has to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option causes the terminal keypad to be turned on when `wgetch()` is called. The default value for keypad is false.

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the tty driver (see `termio(7I)`). To force 8 bits to be returned, invoke `meta(win, TRUE)`. To force 7 bits to be returned, invoke `meta(win, FALSE)`. The window argument, *win*, is always ignored. If the terminfo capabilities `smm` (`meta_on`) and `rmm` (`meta_off`) are defined for the terminal, `smm` is sent to the terminal when `meta(win, TRUE)` is called and `rmm` is sent when `meta(win, FALSE)` is called.

The `nodelay()` option causes `getch()` to be a non-blocking call. If no input is ready, `getch()` returns `ERR`. If disabled (*bf* is `FALSE`), `getch()` waits until a key is pressed.

While interpreting an input escape sequence, `wgetch()` sets a timer while waiting for the next character. If `notimeout(win, TRUE)` is called, then `wgetch()` does not set a timer. The purpose of the timeout is to differentiate between sequences received from a function key and those typed by a user.

With the `raw()` and `noraw()` routines, the terminal is placed into or out of raw mode. Raw mode is similar to `cbreak()` mode, in that characters typed are immediately passed through to the user program. The differences are that in raw mode, the interrupt, quit, suspend, and flow control characters are all passed through uninterpreted, instead of generating a signal. The behavior of the `BREAK` key depends on other bits in the tty driver that are not set by `curses`.

## nodelay(3CURSES)

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done (see `termio(7I)`). When `qiflush()` is called, the queues will be flushed when these control characters are read.

The `timeout()` and `wtimeout()` routines set blocking or non-blocking read for a given window. If *delay* is negative, blocking read is used (that is, waits indefinitely for input). If *delay* is zero, then non-blocking read is used (that is, read returns `ERR` if no input is waiting). If *delay* is positive, then read blocks for *delay* milliseconds, and returns `ERR` if there is still no input. Hence, these routines provide the same functionality as `nodelay()`, plus the additional capability of being able to block for only *delay* milliseconds (where *delay* is positive).

`curses` does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh()` or `doupdate()` is called again. This allows faster response to commands typed in advance. Normally, the input FILE pointer passed to `newterm()`, or `stdin` in the case that `initscr()` was used, will be used to do this typeahead checking. The `typeahead()` routine specifies that the file descriptor *fildes* is to be used to check for typeahead instead. If *fildes* is `-1`, then no typeahead checking is done.

### RETURN VALUES

All routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

### SEE ALSO

`curs_getch(3CURSES)`, `curs_initscr(3CURSES)`, `curses(3CURSES)`, `attributes(5)`, `termio(7I)`

### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `echo()`, `noecho()`, `halfdelay()`, `intrflush()`, `meta()`, `nodelay()`, `notimeout()`, `noqiflush()`, `qiflush()`, `timeout()`, and `wtimeout()` may be macros.

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>nodelay</b>(WINDOW *win, bool bf);</pre>                                                                      |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>win</i> Is a pointer to the window in which to enable non-blocking.</p> <p><i>bf</i> Is a Boolean expression.</p>                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | If enabled, ( <i>bf</i> is TRUE), the <code>nodelay()</code> function causes <code>getch(3XCURSES)</code> to return ERR if no input is ready. When disabled, <code>getch()</code> blocks until a key is pressed.                                                                                               |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, the <code>nodelay()</code> function returns OK. Otherwise, it returns ERR.                                                                                                                                                                                                                         |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The <code>cbreak()</code> and <code>nocbreak()</code> routines put the terminal into and out of <code>cbreak()</code> mode, respectively. In this mode, characters typed by the user are immediately available to the program, and erase/kill character-processing is not performed. When out of this mode, the tty driver buffers the typed characters until a newline or carriage return is typed. Interrupt and flow control characters are unaffected by this mode. Initially the terminal may or may not be in <code>cbreak()</code> mode, as the mode is inherited; therefore, a program should call <code>cbreak()</code> or <code>nocbreak()</code> explicitly. Most interactive programs using curses set the <code>cbreak()</code> mode.</p> <p>Note that <code>cbreak()</code> overrides <code>raw()</code>. (See <code>curs_getch(3CURSES)</code> for a discussion of how these routines interact with <code>echo()</code> and <code>noecho()</code>.)</p> <p>The <code>echo()</code> and <code>noecho()</code> routines control whether characters typed by the user are echoed by <code>getch()</code> as they are typed. Echoing by the tty driver is always disabled, but initially <code>getch()</code> is in echo mode, so characters typed are echoed. Authors of</p> |

most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling `noecho()`. (See `curs_getch(3CURSES)` for a discussion of how these routines interact with `cbreak()` and `nocbreak()`.)

The `halfdelay()` routine is used for half-delay mode, which is similar to `cbreak()` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, `ERR` is returned if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

If the `intrflush()` option is enabled, (*bf* is `TRUE`), when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing `curses` to have the wrong idea of what is on the screen. Disabling (*bf* is `FALSE`), the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.

The `keypad()` option enables the keypad of the user's terminal. If enabled (*bf* is `TRUE`), the user can press a function key (such as an arrow key) and `wgetch()` returns a single value representing the function key, as in `KEY_LEFT`. If disabled (*bf* is `FALSE`), `curses` does not treat function keys specially and the program has to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option causes the terminal keypad to be turned on when `wgetch()` is called. The default value for keypad is false.

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the tty driver (see `termio(7I)`). To force 8 bits to be returned, invoke `meta(win, TRUE)`. To force 7 bits to be returned, invoke `meta(win, FALSE)`. The window argument, *win*, is always ignored. If the terminfo capabilities `smm` (`meta_on`) and `rmm` (`meta_off`) are defined for the terminal, `smm` is sent to the terminal when `meta(win, TRUE)` is called and `rmm` is sent when `meta(win, FALSE)` is called.

The `nodelay()` option causes `getch()` to be a non-blocking call. If no input is ready, `getch()` returns `ERR`. If disabled (*bf* is `FALSE`), `getch()` waits until a key is pressed.

While interpreting an input escape sequence, `wgetch()` sets a timer while waiting for the next character. If `notimeout(win, TRUE)` is called, then `wgetch()` does not set a timer. The purpose of the timeout is to differentiate between sequences received from a function key and those typed by a user.

With the `raw()` and `noraw()` routines, the terminal is placed into or out of raw mode. Raw mode is similar to `cbreak()` mode, in that characters typed are immediately passed through to the user program. The differences are that in raw mode, the interrupt, quit, suspend, and flow control characters are all passed through uninterpreted, instead of generating a signal. The behavior of the `BREAK` key depends on other bits in the tty driver that are not set by `curses`.

## noecho(3CURSES)

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done (see `termio(7I)`). When `qiflush()` is called, the queues will be flushed when these control characters are read.

The `timeout()` and `wtimeout()` routines set blocking or non-blocking read for a given window. If *delay* is negative, blocking read is used (that is, waits indefinitely for input). If *delay* is zero, then non-blocking read is used (that is, read returns `ERR` if no input is waiting). If *delay* is positive, then read blocks for *delay* milliseconds, and returns `ERR` if there is still no input. Hence, these routines provide the same functionality as `nodelay()`, plus the additional capability of being able to block for only *delay* milliseconds (where *delay* is positive).

`curses` does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh()` or `doupdate()` is called again. This allows faster response to commands typed in advance. Normally, the input FILE pointer passed to `newterm()`, or `stdin` in the case that `initscr()` was used, will be used to do this typeahead checking. The `typeahead()` routine specifies that the file descriptor *fildes* is to be used to check for typeahead instead. If *fildes* is `-1`, then no typeahead checking is done.

### RETURN VALUES

All routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

### SEE ALSO

`curs_getch(3CURSES)`, `curs_initscr(3CURSES)`, `curses(3CURSES)`, `attributes(5)`, `termio(7I)`

### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `echo()`, `noecho()`, `halfdelay()`, `intrflush()`, `meta()`, `nodelay()`, `notimeout()`, `noqiflush()`, `qiflush()`, `timeout()`, and `wtimeout()` may be macros.

| SYNOPSIS      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int echo(void);  int noecho(void);</pre>                                                                                                                                                                         |
| DESCRIPTION   | The echo() function enables Echo mode for the current screen. The noecho() function disables Echo mode for the current screen. Initially, curses software echo mode is enabled and hardware echo mode of the tty driver is disabled. The echo() and noecho() functions control software echo only. Hardware echo must remain disabled for the duration of the application, else the behavior is undefined. |
| RETURN VALUES | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                         |
| ERRORS        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                     |
| ATTRIBUTES    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                            |

| DESCRIPTION | <p>These routines set options that deal with output within curses. All options are initially FALSE, unless otherwise stated. It is not necessary to turn these options off before calling <code>endwin()</code>.</p> <p>With the <code>clearok()</code> routine, if enabled (<i>bf</i> is TRUE), the next call to <code>wrefresh()</code> with this window will clear the screen completely and redraw the entire screen from scratch. This is useful when the contents of the screen are uncertain, or in some cases for a more pleasing visual effect. If the <i>win</i> argument to <code>clearok()</code> is the global variable <code>curscr()</code>, the next call to <code>wrefresh()</code> with any window causes the screen to be cleared and repainted from scratch.</p> <p>With the <code>idlok()</code> routine, if enabled (<i>bf</i> is TRUE), curses considers using the hardware insert/delete line feature of terminals so equipped. If disabled (<i>bf</i> is FALSE), curses very seldom uses this feature. (The insert/delete character feature is always considered.) This option should be enabled only if the application needs insert/delete line, for example, for a screen editor. It is disabled by default because insert/delete line tends to be visually annoying when used in applications where it isn't really needed. If insert/delete line cannot be used, curses redraws the changed portions of all lines.</p> <p>With the <code>idcok()</code> routine, if enabled (<i>bf</i> is TRUE), curses considers using the hardware insert/delete character feature of terminals so equipped. This is enabled by default.</p> <p>With the <code>immedok()</code> routine, if enabled (<i>bf</i> is TRUE), any change in the window image, such as the ones caused by <code>waddch()</code>, <code>wclrtoeol()</code>, <code>wscrl()</code>, etc., automatically cause a call to <code>wrefresh()</code>. However, it may degrade the performance considerably, due to repeated calls to <code>wrefresh()</code>. It is disabled by default.</p> |

nonl(3CURSES)

Normally, the hardware cursor is left at the location of the window cursor being refreshed. The `leaveok()` option allows the cursor to be left wherever the update happens to leave it. It is useful for applications where the cursor is not used, since it reduces the need for cursor motions. If possible, the cursor is made invisible when this option is enabled.

The `setscrreg()` and `wsetscrreg()` routines allow the application programmer to set a software scrolling region in a window. *top* and *bot* are the line numbers of the top and bottom margin of the scrolling region. (Line 0 is the top line of the window.) If this option and `scrollok()` are enabled, an attempt to move off the bottom margin line causes all lines in the scrolling region to scroll up one line. Only the text of the window is scrolled. (Note that this has nothing to do with the use of a physical scrolling region capability in the terminal, like that in the VT100. If `idlok()` is enabled and the terminal has either a scrolling region or insert/delete line capability, they will probably be used by the output routines.)

The `scrollok()` option controls what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If disabled, (*bf* is FALSE), the cursor is left on the bottom line. If enabled, (*bf* is TRUE), `wrefresh()` is called on the window, and the physical terminal and window are scrolled up one line. (Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call `idlok()`.)

The `nl()` and `nonl()` routines control whether newline is translated into carriage return and linefeed on output, and whether return is translated into newline on input. Initially, the translations do occur. By disabling these translations using `nonl()`, `curses` is able to make better use of the linefeed capability, resulting in faster cursor motion.

**RETURN VALUES** `setscrreg()` and `wsetscrreg()` return OK upon success and ERR upon failure. All other routines that return an integer always return OK.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_addch(3CURSES)`, `curs_clear(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curs_scroll(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `clearok()`, `leaveok()`, `scrollok()`, `idcok()`, `nl()`, `nonl()`, and `setscrreg()` may be macros.

`nonl(3CURSES)`

The `immedok()` routine is useful for windows that are used as terminal emulators.

| <b>NAME</b>          | nl, nonl – enable/disable newline control                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int nl(void);  int nonl(void);</pre>                                                                                                                                                                                                                 |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The nl ( ) function enables the handling of newlines. The nl ( ) function converts newline into carriage return and line feed on output and converts carriage return into newline on input. nonl ( ) disables the handling of newlines.</p> <p>The handling of newlines is initially enabled. Disabling the handling of newlines results in faster cursor motion since X/Open Curses can use the line-feed capability more efficiently.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                             |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The <code>cbreak()</code> and <code>nocbreak()</code> routines put the terminal into and out of <code>cbreak()</code> mode, respectively. In this mode, characters typed by the user are immediately available to the program, and erase/kill character-processing is not performed. When out of this mode, the tty driver buffers the typed characters until a newline or carriage return is typed. Interrupt and flow control characters are unaffected by this mode. Initially the terminal may or may not be in <code>cbreak()</code> mode, as the mode is inherited; therefore, a program should call <code>cbreak()</code> or <code>nocbreak()</code> explicitly. Most interactive programs using curses set the <code>cbreak()</code> mode.</p> <p>Note that <code>cbreak()</code> overrides <code>raw()</code>. (See <code>curs_getch(3CURSES)</code> for a discussion of how these routines interact with <code>echo()</code> and <code>noecho()</code>.)</p> <p>The <code>echo()</code> and <code>noecho()</code> routines control whether characters typed by the user are echoed by <code>getch()</code> as they are typed. Echoing by the tty driver is always disabled, but initially <code>getch()</code> is in echo mode, so characters typed are echoed. Authors of</p> |

most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling `noecho()`. (See `curs_getch(3CURSES)` for a discussion of how these routines interact with `cbreak()` and `nocbreak()`.)

The `halfdelay()` routine is used for half-delay mode, which is similar to `cbreak()` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, `ERR` is returned if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

If the `intrflush()` option is enabled, (*bf* is `TRUE`), when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing `curses` to have the wrong idea of what is on the screen. Disabling (*bf* is `FALSE`), the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.

The `keypad()` option enables the keypad of the user's terminal. If enabled (*bf* is `TRUE`), the user can press a function key (such as an arrow key) and `wgetch()` returns a single value representing the function key, as in `KEY_LEFT`. If disabled (*bf* is `FALSE`), `curses` does not treat function keys specially and the program has to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option causes the terminal keypad to be turned on when `wgetch()` is called. The default value for keypad is false.

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the tty driver (see `termio(7I)`). To force 8 bits to be returned, invoke `meta(win, TRUE)`. To force 7 bits to be returned, invoke `meta(win, FALSE)`. The window argument, *win*, is always ignored. If the terminfo capabilities `smm` (`meta_on`) and `rmm` (`meta_off`) are defined for the terminal, `smm` is sent to the terminal when `meta(win, TRUE)` is called and `rmm` is sent when `meta(win, FALSE)` is called.

The `nodelay()` option causes `getch()` to be a non-blocking call. If no input is ready, `getch()` returns `ERR`. If disabled (*bf* is `FALSE`), `getch()` waits until a key is pressed.

While interpreting an input escape sequence, `wgetch()` sets a timer while waiting for the next character. If `notimeout(win, TRUE)` is called, then `wgetch()` does not set a timer. The purpose of the timeout is to differentiate between sequences received from a function key and those typed by a user.

With the `raw()` and `noraw()` routines, the terminal is placed into or out of raw mode. Raw mode is similar to `cbreak()` mode, in that characters typed are immediately passed through to the user program. The differences are that in raw mode, the interrupt, quit, suspend, and flow control characters are all passed through uninterpreted, instead of generating a signal. The behavior of the `BREAK` key depends on other bits in the tty driver that are not set by `curses`.

## noqiflush(3CURSES)

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done (see `termio(7I)`). When `qiflush()` is called, the queues will be flushed when these control characters are read.

The `timeout()` and `wtimeout()` routines set blocking or non-blocking read for a given window. If *delay* is negative, blocking read is used (that is, waits indefinitely for input). If *delay* is zero, then non-blocking read is used (that is, read returns `ERR` if no input is waiting). If *delay* is positive, then read blocks for *delay* milliseconds, and returns `ERR` if there is still no input. Hence, these routines provide the same functionality as `nodelay()`, plus the additional capability of being able to block for only *delay* milliseconds (where *delay* is positive).

`curses` does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh()` or `doupdate()` is called again. This allows faster response to commands typed in advance. Normally, the input FILE pointer passed to `newterm()`, or `stdin` in the case that `initscr()` was used, will be used to do this typeahead checking. The `typeahead()` routine specifies that the file descriptor *fildes* is to be used to check for typeahead instead. If *fildes* is `-1`, then no typeahead checking is done.

### RETURN VALUES

All routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

### SEE ALSO

`curs_getch(3CURSES)`, `curs_initscr(3CURSES)`, `curses(3CURSES)`, `attributes(5)`, `termio(7I)`

### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `echo()`, `noecho()`, `halfdelay()`, `intrflush()`, `meta()`, `nodelay()`, `notimeout()`, `noqiflush()`, `qiflush()`, `timeout()`, and `wtimeout()` may be macros.

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  void <b>noqiflush</b>(void);  void <b>qiflush</b>(void);</pre> |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | The qiflush() function enables the flushing of input and output queues when an interrupt, quit, or suspend character is sent to the terminal. The noqiflush() function disables this flushing.                                                           |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | These functions do not return a value.                                                                                                                                                                                                                   |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None                                                                                                                                                                                                                                                     |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The <code>cbreak()</code> and <code>nocbreak()</code> routines put the terminal into and out of <code>cbreak()</code> mode, respectively. In this mode, characters typed by the user are immediately available to the program, and erase/kill character-processing is not performed. When out of this mode, the tty driver buffers the typed characters until a newline or carriage return is typed. Interrupt and flow control characters are unaffected by this mode. Initially the terminal may or may not be in <code>cbreak()</code> mode, as the mode is inherited; therefore, a program should call <code>cbreak()</code> or <code>nocbreak()</code> explicitly. Most interactive programs using curses set the <code>cbreak()</code> mode.</p> <p>Note that <code>cbreak()</code> overrides <code>raw()</code>. (See <code>curs_getch(3CURSES)</code> for a discussion of how these routines interact with <code>echo()</code> and <code>noecho()</code>.)</p> <p>The <code>echo()</code> and <code>noecho()</code> routines control whether characters typed by the user are echoed by <code>getch()</code> as they are typed. Echoing by the tty driver is always disabled, but initially <code>getch()</code> is in echo mode, so characters typed are echoed. Authors of</p> |

most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling `noecho()`. (See `curs_getch(3CURSES)` for a discussion of how these routines interact with `cbreak()` and `nocbreak()`.)

The `halfdelay()` routine is used for half-delay mode, which is similar to `cbreak()` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, `ERR` is returned if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

If the `intrflush()` option is enabled, (*bf* is `TRUE`), when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing `curses` to have the wrong idea of what is on the screen. Disabling (*bf* is `FALSE`), the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.

The `keypad()` option enables the keypad of the user's terminal. If enabled (*bf* is `TRUE`), the user can press a function key (such as an arrow key) and `wgetch()` returns a single value representing the function key, as in `KEY_LEFT`. If disabled (*bf* is `FALSE`), `curses` does not treat function keys specially and the program has to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option causes the terminal keypad to be turned on when `wgetch()` is called. The default value for keypad is false.

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the tty driver (see `termio(7I)`). To force 8 bits to be returned, invoke `meta(win, TRUE)`. To force 7 bits to be returned, invoke `meta(win, FALSE)`. The window argument, *win*, is always ignored. If the terminfo capabilities `smm` (`meta_on`) and `rmm` (`meta_off`) are defined for the terminal, `smm` is sent to the terminal when `meta(win, TRUE)` is called and `rmm` is sent when `meta(win, FALSE)` is called.

The `nodelay()` option causes `getch()` to be a non-blocking call. If no input is ready, `getch()` returns `ERR`. If disabled (*bf* is `FALSE`), `getch()` waits until a key is pressed.

While interpreting an input escape sequence, `wgetch()` sets a timer while waiting for the next character. If `notimeout(win, TRUE)` is called, then `wgetch()` does not set a timer. The purpose of the timeout is to differentiate between sequences received from a function key and those typed by a user.

With the `raw()` and `noraw()` routines, the terminal is placed into or out of raw mode. Raw mode is similar to `cbreak()` mode, in that characters typed are immediately passed through to the user program. The differences are that in raw mode, the interrupt, quit, suspend, and flow control characters are all passed through uninterpreted, instead of generating a signal. The behavior of the `BREAK` key depends on other bits in the tty driver that are not set by `curses`.

noraw(3CURSES)

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done (see `termio(7I)`). When `qiflush()` is called, the queues will be flushed when these control characters are read.

The `timeout()` and `wtimeout()` routines set blocking or non-blocking read for a given window. If *delay* is negative, blocking read is used (that is, waits indefinitely for input). If *delay* is zero, then non-blocking read is used (that is, read returns `ERR` if no input is waiting). If *delay* is positive, then read blocks for *delay* milliseconds, and returns `ERR` if there is still no input. Hence, these routines provide the same functionality as `nodelay()`, plus the additional capability of being able to block for only *delay* milliseconds (where *delay* is positive).

`curses` does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh()` or `doupdate()` is called again. This allows faster response to commands typed in advance. Normally, the input FILE pointer passed to `newterm()`, or `stdin` in the case that `initscr()` was used, will be used to do this typeahead checking. The `typeahead()` routine specifies that the file descriptor *fildes* is to be used to check for typeahead instead. If *fildes* is `-1`, then no typeahead checking is done.

#### RETURN VALUES

All routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

#### SEE ALSO

`curs_getch(3CURSES)`, `curs_initscr(3CURSES)`, `curses(3CURSES)`, `attributes(5)`, `termio(7I)`

#### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `echo()`, `noecho()`, `halfdelay()`, `intrflush()`, `meta()`, `nodelay()`, `notimeout()`, `noqiflush()`, `qiflush()`, `timeout()`, and `wtimeout()` may be macros.

| <b>NAME</b>          | cbreak, nocbreak, noraw, raw – set input mode controls                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>   | <p>The <code>cbreak()</code> function enables the character input mode. This overrides any previous call to the <code>raw()</code> function and turns the <code>stty</code> flag <code>ICANON</code> off.</p> <p>The <code>nocbreak()</code> function sets the line canonical mode and turns the <code>stty</code> flag <code>ICANON</code> on without touching the <code>ISIG</code> or <code>IXON</code> flags.</p> <p>The <code>noraw()</code> function sets the line canonical mode and turns the the <code>stty</code> flags <code>ICANON</code>, <code>ISIG</code>, and <code>IXON</code> all on.</p> <p>The <code>raw()</code> function sets the character input mode and turns the <code>stty</code> flags <code>ICANON</code>, <code>ISIG</code>, and <code>IXON</code> all off. This mode provides maximum control over input.</p> <p>It is important to remember that the terminal may or may not be in character mode operation initially. Most interactive programs require <code>cbreak()</code> to be enabled.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return <code>OK</code> . Otherwise, they return <code>ERR</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |                     |          |          |        |
| <b>ATTRIBUTES</b>    | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The <code>cbreak()</code> and <code>nocbreak()</code> routines put the terminal into and out of <code>cbreak()</code> mode, respectively. In this mode, characters typed by the user are immediately available to the program, and erase/kill character-processing is not performed. When out of this mode, the tty driver buffers the typed characters until a newline or carriage return is typed. Interrupt and flow control characters are unaffected by this mode. Initially the terminal may or may not be in <code>cbreak()</code> mode, as the mode is inherited; therefore, a program should call <code>cbreak()</code> or <code>nocbreak()</code> explicitly. Most interactive programs using curses set the <code>cbreak()</code> mode.</p> <p>Note that <code>cbreak()</code> overrides <code>raw()</code>. (See <code>curs_getch(3CURSES)</code> for a discussion of how these routines interact with <code>echo()</code> and <code>noecho()</code>.)</p> <p>The <code>echo()</code> and <code>noecho()</code> routines control whether characters typed by the user are echoed by <code>getch()</code> as they are typed. Echoing by the tty driver is always disabled, but initially <code>getch()</code> is in echo mode, so characters typed are echoed. Authors of</p> |

notimeout(3CURSES)

most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling `noecho()`. (See `curs_getch(3CURSES)` for a discussion of how these routines interact with `cbreak()` and `nocbreak()`.)

The `halfdelay()` routine is used for half-delay mode, which is similar to `cbreak()` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, `ERR` is returned if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

If the `intrflush()` option is enabled, (*bf* is `TRUE`), when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing `curses` to have the wrong idea of what is on the screen. Disabling (*bf* is `FALSE`), the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.

The `keypad()` option enables the keypad of the user's terminal. If enabled (*bf* is `TRUE`), the user can press a function key (such as an arrow key) and `wgetch()` returns a single value representing the function key, as in `KEY_LEFT`. If disabled (*bf* is `FALSE`), `curses` does not treat function keys specially and the program has to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option causes the terminal keypad to be turned on when `wgetch()` is called. The default value for keypad is false.

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the tty driver (see `termio(7I)`). To force 8 bits to be returned, invoke `meta(win, TRUE)`. To force 7 bits to be returned, invoke `meta(win, FALSE)`. The window argument, *win*, is always ignored. If the terminfo capabilities `smm` (`meta_on`) and `rmm` (`meta_off`) are defined for the terminal, `smm` is sent to the terminal when `meta(win, TRUE)` is called and `rmm` is sent when `meta(win, FALSE)` is called.

The `nodelay()` option causes `getch()` to be a non-blocking call. If no input is ready, `getch()` returns `ERR`. If disabled (*bf* is `FALSE`), `getch()` waits until a key is pressed.

While interpreting an input escape sequence, `wgetch()` sets a timer while waiting for the next character. If `notimeout(win, TRUE)` is called, then `wgetch()` does not set a timer. The purpose of the timeout is to differentiate between sequences received from a function key and those typed by a user.

With the `raw()` and `noraw()` routines, the terminal is placed into or out of raw mode. Raw mode is similar to `cbreak()` mode, in that characters typed are immediately passed through to the user program. The differences are that in raw mode, the interrupt, quit, suspend, and flow control characters are all passed through uninterpreted, instead of generating a signal. The behavior of the `BREAK` key depends on other bits in the tty driver that are not set by `curses`.

## notimeout(3CURSES)

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done (see `termio(7I)`). When `qiflush()` is called, the queues will be flushed when these control characters are read.

The `timeout()` and `wtimeout()` routines set blocking or non-blocking read for a given window. If *delay* is negative, blocking read is used (that is, waits indefinitely for input). If *delay* is zero, then non-blocking read is used (that is, read returns `ERR` if no input is waiting). If *delay* is positive, then read blocks for *delay* milliseconds, and returns `ERR` if there is still no input. Hence, these routines provide the same functionality as `nodelay()`, plus the additional capability of being able to block for only *delay* milliseconds (where *delay* is positive).

`curses` does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh()` or `doupdate()` is called again. This allows faster response to commands typed in advance. Normally, the input FILE pointer passed to `newterm()`, or `stdin` in the case that `initscr()` was used, will be used to do this typeahead checking. The `typeahead()` routine specifies that the file descriptor *fildes* is to be used to check for typeahead instead. If *fildes* is `-1`, then no typeahead checking is done.

### RETURN VALUES

All routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

### SEE ALSO

`curs_getch(3CURSES)`, `curs_initscr(3CURSES)`, `curses(3CURSES)`, `attributes(5)`, `termio(7I)`

### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `echo()`, `noecho()`, `halfdelay()`, `intrflush()`, `meta()`, `nodelay()`, `notimeout()`, `noqiflush()`, `qiflush()`, `timeout()`, and `wtimeout()` may be macros.

| PARAMETERS    | <p><i>win</i> Is a pointer to the window in which to set the timed blocking.</p> <p><i>bf</i> Is a Boolean expression.</p> <p><i>delay</i> Is the number of milliseconds to block or wait for input.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| DESCRIPTION   | <p>If <i>bool</i> is TRUE, the notimeout() function disables a timer used by getch(3XCURSES) when handling multibyte function key sequences.</p> <p>When <i>bool</i> is FALSE and keypad handling is enabled, a timer is set by getch() to handle bytes received that could be the beginning of a function key (for example, ESC). If the remainder of the sequence is not received before the time expires, the first byte is returned; otherwise, the value of the function key is returned. Subsequent calls to the getch() function will return the other bytes received for the incomplete key sequence.</p> <p>The timeout() and wtimeout() functions set the length of time getch() waits for input for windows stdscr and <i>win</i>, respectively. These functions are similar to nodelay(3XCURSES) except the time to block or wait for input can be specified.</p> <p>A negative <i>delay</i> causes the program to wait indefinitely for input; a <i>delay</i> of 0 returns ERR if no input is ready; and a positive <i>delay</i> blocks until input arrives or the time specified expires, (in which case, ERR is returned).</p> |
| RETURN VALUES | <p>On success, the notimeout() function returns OK. Otherwise, it returns ERR.</p> <p>The timeout() and wtimeout() functions do not return a value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| DESCRIPTION | <p>These functions generate graphics output for a set of output devices. The format of the output is dependent upon which link editor option is used when the program is compiled and linked (see Link Editor).</p> <p>The term "current point" refers to the current setting for the <math>x</math> and <math>y</math> coordinates.</p> <p>The <code>arc()</code> function specifies a circular arc. The coordinates <math>(x0, y0)</math> specify the center of the arc. The coordinates <math>(x1, y1)</math> specify the starting point of the arc. The coordinates <math>(x2, y2)</math> specify the end point of the circular arc.</p> <p>The <code>box()</code> function specifies a rectangle with coordinates <math>(x0, y0)</math>, <math>(x0, y1)</math>, <math>(x1, y0)</math>, and <math>(x1, y1)</math>. The current point is set to <math>(x1, y1)</math>.</p> <p>The <code>circle()</code> function specifies a circle with a center at the coordinates <math>(x, y)</math> and a radius of <math>r</math>.</p> <p>The <code>closevt()</code> and <code>closepl()</code> functions flush the output.</p> <p>The <code>cont()</code> function specifies a line beginning at the current point and ending at the coordinates <math>(x, y)</math>. The current point is set to <math>(x, y)</math>.</p> |

## openpl(3PLOT)

The `erase()` function starts another frame of output.

The `label()` function places the null terminated string `s` so that the first character falls on the current point. The string is then terminated by a NEWLINE character.

The `line()` function draws a line starting at the coordinates  $(x0, y0)$  and ending at the coordinates  $(x1, y1)$ . The current point is set to  $(x1, y1)$ .

The `linemod()` function specifies the style for drawing future lines. `s` may contain one of the following: `dotted`, `solid`, `longdashed`, `shortdashed`, or `dotdashed`.

The `move()` function sets the current point to the coordinates  $(x, y)$ .

The `openpl()` or `openvt()` function must be called to open the device before any other plot functions are called.

The `point()` function plots the point given by the coordinates  $(x, y)$ . The current point is set to  $(x, y)$ .

The `space()` function specifies the size of the plotting area. The plot will be reduced or enlarged as necessary to fit the area specified. The coordinates  $(x0, y0)$  specify the lower left hand corner of the plotting area. The coordinates  $(x1, y1)$  specify the upper right hand corner of the plotting area.

### Link Editor

Various flavors of these functions exist for different output devices. They are obtained by using the following `ld(1)` options:

|                     |                                                                                                        |

| DESCRIPTION | <p>These functions generate graphics output for a set of output devices. The format of the output is dependent upon which link editor option is used when the program is compiled and linked (see Link Editor).</p> <p>The term "current point" refers to the current setting for the <i>x</i> and <i>y</i> coordinates.</p> <p>The <code>arc()</code> function specifies a circular arc. The coordinates <i>(x0, y0)</i> specify the center of the arc. The coordinates <i>(x1, y1)</i> specify the starting point of the arc. The coordinates <i>(x2, y2)</i> specify the end point of the circular arc.</p> <p>The <code>box()</code> function specifies a rectangle with coordinates <i>(x0, y0)</i>, <i>(x0, y1)</i>, <i>(x1, y0)</i>, and <i>(x1, y1)</i>. The current point is set to <i>(x1, y1)</i>.</p> <p>The <code>circle()</code> function specifies a circle with a center at the coordinates <i>(x, y)</i> and a radius of <i>r</i>.</p> <p>The <code>closevt()</code> and <code>closepl()</code> functions flush the output.</p> <p>The <code>cont()</code> function specifies a line beginning at the current point and ending at the coordinates <i>(x, y)</i>. The current point is set to <i>(x, y)</i>.</p> |

The `erase()` function starts another frame of output.

The `label()` function places the null terminated string `s` so that the first character falls on the current point. The string is then terminated by a NEWLINE character.

The `line()` function draws a line starting at the coordinates  $(x0, y0)$  and ending at the coordinates  $(x1, y1)$ . The current point is set to  $(x1, y1)$ .

The `linemod()` function specifies the style for drawing future lines. `s` may contain one of the following: `dotted`, `solid`, `longdashed`, `shortdashed`, or `dotdashed`.

The `move()` function sets the current point to the coordinates  $(x, y)$ .

The `openpl()` or `openvt()` function must be called to open the device before any other plot functions are called.

The `point()` function plots the point given by the coordinates  $(x, y)$ . The current point is set to  $(x, y)$ .

The `space()` function specifies the size of the plotting area. The plot will be reduced or enlarged as necessary to fit the area specified. The coordinates  $(x0, y0)$  specify the lower left hand corner of the plotting area. The coordinates  $(x1, y1)$  specify the upper right hand corner of the plotting area.

**Link Editor** Various flavors of these functions exist for different output devices. They are obtained by using the following `ld(1)` options:

|                     |                                                                                                        |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>overlay</b>(WINDOW *srcwin, WINDOW *dstwin); int <b>overwrite</b>(WINDOW *srcwin, WINDOW *dstwin); int <b>copywin</b>(WINDOW *srcwin, WINDOW *dstwin, int sminrow, int smincol,             int dminrow, int dmincol, int dmaxrow, int dmaxcol, int overlay);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |
| DESCRIPTION    | <p>The <code>overlay()</code> and <code>overwrite()</code> routines overlay <i>srcwin</i> on top of <i>dstwin</i>. <i>srcwin</i> and <i>dstwin</i> are not required to be the same size; only text where the two windows overlap is copied. The difference is that <code>overlay()</code> is non-destructive (blanks are not copied) whereas <code>overwrite()</code> is destructive.</p> <p>The <code>copywin()</code> routine provides a finer granularity of control over the <code>overlay()</code> and <code>overwrite()</code> routines. Like in the <code>prefresh()</code> routine, a rectangle is specified in the destination window, (<i>dminrow</i>, <i>dmincol</i>) and (<i>dmaxrow</i>, <i>dmaxcol</i>), and the upper-left-corner coordinates of the source window, (<i>sminrow</i>, <i>smincol</i>). If the argument <i>overlay</i> is true, then copying is non-destructive, as in <code>overlay()</code>.</p> |                |                 |          |        |
| RETURN VALUES  | Routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |          |        |

| <b>NAME</b>          | overlay, overwrite – copy overlapped windows                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]</pre> <pre>#include &lt;curses.h&gt;  int <b>overlay</b>(const WINDOW *srcwin, WINDOW *dstwin);  int <b>overwrite</b>(const WINDOW *srcwin, WINDOW *dstwin);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>PARAMETERS</b>    | <p><i>srcwin</i> Is a pointer to the source window to be copied.</p> <p><i>dstwin</i> Is a pointer to the destination window to be overlaid or overwritten.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b>   | <p>The <code>overwrite()</code> and <code>overlay()</code> functions overlay <i>srcwin</i> on top of <i>dstwin</i>. The <i>srcwin</i> and <i>dstwin</i> arguments do not have to be the same size; only text where the two windows overlap is copied.</p> <p>The <code>overwrite()</code> function copies characters as though a sequence of <code>win_wch(3XCURSES)</code> and <code>wadd_wch(3XCURSES)</code> were performed with the destination window's attributes and background attributes cleared.</p> <p>The <code>overlay()</code> function does the same thing, except that, whenever a character to be copied is the background character of the source window, <code>overlay()</code> does not copy the character but merely moves the destination cursor the width of the source background character.</p> <p>If any portion of the overlaying window border is not the first column of a multi-column character, then all the column positions will be replaced with the background character and rendition before the overlay is done. If the default background character is a multi-column character when this occurs, then these functions fail.</p> |
| <b>RETURN VALUES</b> | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>EXAMPLES</b>      | <p><b>EXAMPLE 1</b> Implement a pop-up dialog</p> <p>The following example demonstrates the use of <code>overwrite()</code> to implement a pop-up dialog box.</p> <pre>#include &lt;curses.h&gt; /*  *   Pop-up a window on top of curscr.  If row and/or col  *   are -1 then that dimension will be centered within  *   curscr.  Return 0 for success or -1 if malloc( ) failed.  *   Pass back the working window and the saved window for the  *   pop-up.  The saved window should not be modified.  */</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**EXAMPLE 1** Implement a pop-up dialog      *(Continued)*

```

int
popup(work, save, nrows, ncols, row, col)
WINDOW **work, **save;
int nrows, ncols, row, col;
{
 int mr, mc;
 getmaxyx(curscr, mr, mc);
 /* Windows are limited to the size of curscr. */
 if (mr < nrows)
 nrows = mr;
 if (mc < ncols)
 ncols = mc;
 /* Center dimensions. */
 if (row == -1)
 row = (mr-nrows)/2;
 if (col == -1)
 col = (mc-ncols)/2;
 /* The window must fit entirely in curscr. */
 if (mr < row+nrows)
 row = 0;
 if (mc < col+ncols)
 col = 0;
 *work = newwin(nrows, ncols, row, col);
 if (*work == NULL)
 return (-1);
 if ((*save = dupwin(*work)) == NULL) {
 delwin(*work);
 return (-1);
 }
 overwrite(curscr, *save);
 return (0);
}
/*
 * Restore the region covered by a pop-up window.
 * Delete the working window and the saved window.
 * This function is the complement to popup(). Return
 * 0 for success or -1 for an error.
 */
int
popdown(work, save)
WINDOW *work, *save;
{
 (void) wnoutrefresh(save);
 (void) delwin(save);
 (void) delwin(work);
 return (0);
}
/*
 * Compute the size of a dialog box that would fit around
 * the string.
 */
void
dialsize(str, nrows, ncols)
char *str;

```

**EXAMPLE 1** Implement a pop-up dialog      *(Continued)*

```

int *nrows, *ncols;
{
 int rows, cols, col;
 for (rows = 1, cols = col = 0; *str != '\0'; ++str) {
 if (*str == '\n') {
 if (cols < col)
 cols = col;
 col = 0;
 ++rows;
 } else {
 ++col;
 }
 }
 if (cols < col)
 cols = col;
 *nrows = rows;
 *ncols = cols;
}
/*
 * Write a string into a dialog box.
 */
void
dialfill(w, s)
WINDOW *w;
char *s;
{
 int row;
 (void) wmove(w, 1, 1);
 for (row = 1; *s != '\0'; ++s) {
 (void) waddch(w, *((unsigned char*) s));
 if (*s == '\n')
 wmove(w, ++row, 1);
 }
 box(w, 0, 0);
}
void
dialog(str)
char *str;
{
 WINDOW *work, *save;
 int nrows, ncols, row, col;
 /* Figure out size of window. */
 dialsize(str, &nrows, &ncols);
 /* Create a centered working window with extra */
 /* room for a border. */
 (void) popup(&work, &save, nrows+2, ncols+2, -1, -1);
 /* Write text into the working window. */
 dialfill(work, str);
 /* Pause. Remember that wgetch() will do a wrefresh() */
 /* for us. */
 (void) wgetch(work);
 /* Restore curscr and free windows. */
 (void) popdown(work, save);
 /* Redraw curscr to remove window from physical screen. */
}

```

**EXAMPLE 1** Implement a pop-up dialog      *(Continued)*

```
(void) douupdate();
}
```

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int overlay(WINDOW *srcwin, WINDOW *dstwin); int overwrite(WINDOW *srcwin, WINDOW *dstwin); int copywin(WINDOW *srcwin, WINDOW *dstwin, int sminrow, int smincol,             int dminrow, int dmincol, int dmaxrow, int dmaxcol, int overlay);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |
| DESCRIPTION    | <p>The overlay() and overwrite() routines overlay <i>srcwin</i> on top of <i>dstwin</i>. <i>srcwin</i> and <i>dstwin</i> are not required to be the same size; only text where the two windows overlap is copied. The difference is that overlay() is non-destructive (blanks are not copied) whereas overwrite() is destructive.</p> <p>The copywin() routine provides a finer granularity of control over the overlay() and overwrite() routines. Like in the prefresh() routine, a rectangle is specified in the destination window, (<i>dminrow</i>, <i>dmincol</i>) and (<i>dmaxrow</i>, <i>dmaxcol</i>), and the upper-left-corner coordinates of the source window, (<i>sminrow</i>, <i>smincol</i>). If the argument <i>overlay</i> is true, then copying is non-destructive, as in overlay().</p> |                |                 |          |        |
| RETURN VALUES  | Routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |
| ATTRIBUTES     | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |          |        |

| <b>PARAMETERS</b>    | <p><i>srcwin</i> Is a pointer to the source window to be copied.</p> <p><i>dstwin</i> Is a pointer to the destination window to be overlaid or overwritten.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b>   | <p>The <code>overwrite()</code> and <code>overlay()</code> functions overlay <i>srcwin</i> on top of <i>dstwin</i>. The <i>srcwin</i> and <i>dstwin</i> arguments do not have to be the same size; only text where the two windows overlap is copied.</p> <p>The <code>overwrite()</code> function copies characters as though a sequence of <code>win_wch(3XCURSES)</code> and <code>wadd_wch(3XCURSES)</code> were performed with the destination window's attributes and background attributes cleared.</p> <p>The <code>overlay()</code> function does the same thing, except that, whenever a character to be copied is the background character of the source window, <code>overlay()</code> does not copy the character but merely moves the destination cursor the width of the source background character.</p> <p>If any portion of the overlaying window border is not the first column of a multi-column character, then all the column positions will be replaced with the background character and rendition before the overlay is done. If the default background character is a multi-column character when this occurs, then these functions fail.</p> |
| <b>RETURN VALUES</b> | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Overview             | <p>curses provides routines that manipulate color on color alphanumeric terminals. To use these routines <code>start_color()</code> must be called, usually right after <code>initscr()</code>. See <code>curs_initscr(3CURSES)</code>. Colors are always used in pairs (referred to as color-pairs). A color-pair consists of a foreground color (for characters) and a background color (for the field on which the characters are displayed). A programmer initializes a color-pair with the routine <code>init_pair</code>. After it has been initialized, <code>COLOR_PAIR(<i>n</i>)</code>, a macro defined in <code>&lt;curses.h&gt;</code>, can be used in the same ways other video attributes can be used. If a terminal is capable of redefining colors, the programmer can use the routine <code>init_color()</code> to change the definition of a color. The routines <code>has_colors()</code> and <code>can_change_color()</code> return <code>TRUE</code> or <code>FALSE</code>, depending on whether the terminal has color capabilities and whether the programmer can change the colors. The routine <code>color_content()</code> allows a programmer to identify the amounts of red, green, and blue components in an initialized color. The routine <code>pair_content()</code> allows a programmer to find out how a given color-pair is currently defined.</p> |
| Routine Descriptions | <p>The <code>start_color()</code> routine requires no arguments. It must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after <code>initscr()</code>. <code>start_color()</code> initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables, <code>COLORS</code> and <code>COLOR_PAIRS</code> (respectively defining the maximum number of colors and color-pairs the terminal can support). It also restores the colors on the terminal to the values they had when the terminal was just turned on.</p> <p>The <code>init_pair()</code> routine changes the definition of a color-pair. It takes three arguments: the number of the color-pair to be changed, the foreground color number, and the background color number. The value of the first argument must be between 1 and <code>COLOR_PAIRS-1</code>. The value of the second and third arguments must be between 0 and <code>COLORS</code>. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair is changed to the new definition.</p>                                                                                                                                                       |

pair\_content(3CURSES)

The `init_color()` routine changes the definition of a color. It takes four arguments: the number of the color to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of the first argument must be between 0 and `COLORS`. (See the section `COLORS` for the default color index.) Each of the last three arguments must be a value between 0 and 1000. When `init_color()` is used, all occurrences of that color on the screen immediately change to the new definition.

The `has_colors()` routine requires no arguments. It returns `TRUE` if the terminal can manipulate colors; otherwise, it returns `FALSE`. This routine facilitates writing terminal-independent programs. For example, a programmer can use it to decide whether to use color or some other video attribute.

The `can_change_color()` routine requires no arguments. It returns `TRUE` if the terminal supports colors and can change their definitions; other, it returns `FALSE`. This routine facilitates writing terminal-independent programs.

The `color_content()` routine gives users a way to find the intensity of the red, green, and blue (RGB) components in a color. It requires four arguments: the color number, and three addresses of `shorts` for storing the information about the amounts of red, green, and blue components in the given color. The value of the first argument must be between 0 and `COLORS`. The values that are stored at the addresses pointed to by the last three arguments are between 0 (no component) and 1000 (maximum amount of component).

The `pair_content()` routine allows users to find out what colors a given color-pair consists of. It requires three arguments: the color-pair number, and two addresses of `shorts` for storing the foreground and the background color numbers. The value of the first argument must be between 1 and `COLOR_PAIRS-1`. The values that are stored at the addresses pointed to by the second and third arguments are between 0 and `COLORS`.

#### Colors

In `< curses.h >` the following macros are defined. These are the default colors. `curses` also assumes that `COLOR_BLACK` is the default background color for all terminals.

```
COLOR_BLACK
COLOR_RED
COLOR_GREEN
COLOR_YELLOW
COLOR_BLUE
COLOR_MAGENTA
COLOR_CYAN
COLOR_WHITE
```

#### RETURN VALUES

All routines that return an integer return `ERR` upon failure and `OK` upon successful completion.

| <b>NAME</b>                  | can_change_color, color_content, COLOR_PAIR, has_colors, init_color, init_pair, pair_content, PAIR_NUMBER, start_color, COLOR_PAIRS, COLORS – manipulate color information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>              | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  bool can_change_color(void);  int color_content(short color, short *red, short *green, short *blue);  int COLOR_PAIR(int n);  bool has_colors(void);  int init_color(short color, short red, short green, short blue);  int init_pair(short pair, short f, short b);  int pair_content(short pair, short *f, short *b);  int PAIR_NUMBER(int value);  int start_color(void);  extern int COLOR_PAIRS;  extern int COLORS;</pre>                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b>           | These functions manipulate color on terminals that support color.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Querying Capabilities</b> | The has_colors() function indicates whether the terminal is a color terminal. The can_change_color() function indicates whether the terminal is a color terminal on which colors can be redefined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Initialization</b>        | <p>The start_color() function must be called to enable use of colors and before any color manipulation function is called. The function initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white) that can be specified by the color macros (such as COLOR_BLACK) defined in &lt;curses.h&gt;. The initial appearance of these colors is unspecified.</p> <p>The function also initializes two global external variables:</p> <ul style="list-style-type: none"> <li>■ COLORS defines the number of colors that the terminal supports. See Color Identification below. If COLORS is 0, the terminal does not support redefinition of colors and can_change_color() will return FALSE.</li> <li>■ COLOR_PAIRS defines the maximum number of color-pairs that the terminal supports. See User-defined Color Pairs below.</li> </ul> |

pair\_content(3XCURSES)

|                          |                                                                                                                                                                                                                                                                                                                                                                    |                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Color Identification     | The start_color() function also restores the colors on the terminal to terminal-specific initial values. The initial background color is assumed to be black for all terminals.                                                                                                                                                                                    |                                                                                        |
|                          | The init_color() function redefines color number <i>color</i> , on terminals that support the redefinition of colors, to have the red, green, and blue intensity components specified by <i>red</i> , <i>green</i> , and <i>blue</i> , respectively. Calling init_color() also changes all occurrences of the specified color on the screen to the new definition. |                                                                                        |
| User-defined Color Pairs | The color_content() function identifies the intensity components of color number <i>color</i> . It stores the red, green, and blue intensity components of this color in the addresses pointed to by <i>red</i> , <i>green</i> , and <i>blue</i> , respectively.                                                                                                   |                                                                                        |
|                          | For both functions, the <i>color</i> argument must be in the range from 0 to and including COLORS-1. Valid intensity value range from 0 (no intensity component) up to and including 1000 (maximum intensity in that component).                                                                                                                                   |                                                                                        |
|                          | Calling init_pair() defines or redefines color-pair number <i>pair</i> to have foreground color <i>f</i> and background color <i>b</i> . Calling init_pair() changes any characters that were displayed in the color pair's old definition to the new definition and refreshes the screen.                                                                         |                                                                                        |
|                          | After defining the color pair, the macro COLOR_PAIR( <i>n</i> ) returns the value of color pair <i>n</i> . This value is the color attribute as it would be extracted from a chtype. Controversy, the macro COLOR_NUMBER( <i>value</i> ) returns the color pair number associated with the color attribute <i>value</i> .                                          |                                                                                        |
| PARAMETERS               | The pair_content() retrieves the component colors of a color-pair number <i>pair</i> . It stores the foreground and background color numbers in the variables pointed to by <i>f</i> and <i>b</i> , respectively.                                                                                                                                                  |                                                                                        |
|                          | With init_pair() and pair_content(), the value of <i>pair</i> must be in a range from 0 to and including COLOR_PAIRS-1. Valid values for <i>f</i> and <i>b</i> are the range from 0 to and including COLORS-1.                                                                                                                                                     |                                                                                        |
|                          | <i>color</i>                                                                                                                                                                                                                                                                                                                                                       | Is the number of the color for which to provide information (0 to COLORS-1).           |
|                          | <i>red</i>                                                                                                                                                                                                                                                                                                                                                         | Is a pointer to the RGB value for the amount of red in <i>color</i> .                  |
|                          | <i>green</i>                                                                                                                                                                                                                                                                                                                                                       | Is a pointer to the RGB value for the amount of green in <i>color</i> .                |
|                          | <i>blue</i>                                                                                                                                                                                                                                                                                                                                                        | Is a pointer to the RGB value for the amount of blue in <i>color</i> .                 |
|                          | <i>n</i>                                                                                                                                                                                                                                                                                                                                                           | Is the number of a color pair.                                                         |

pair\_content(3XCURSES)

|              |                                                                                     |
|--------------|-------------------------------------------------------------------------------------|
| <i>b</i>     | Is a pointer to the number of the background color (0 to COLORS-1) in <i>pair</i> . |
| <i>value</i> | Is a color attribute value.                                                         |

**RETURN VALUES** The `has_colors()` function returns `TRUE` if the terminal can manipulate colors. Otherwise, it returns `FALSE`.

The `can_change_color()` function returns `TRUE` if the terminal supports colors and is able to change their definitions. Otherwise, it returns `FALSE`.

Upon successful completion, the other functions return `OK`. Otherwise, they return `ERR`.

**ERRORS** No errors are defined.

**USAGE** To use these functions, `start_color()` must be called, usually right after `initscr(3XCURSES)`.

The `can_change_color()` and `has_colors()` functions facilitate writing terminal-independent applications. For example, a programmer can use them to decide whether to use color or some other video attribute.

On color terminals, a typical value of `COLORS` is 8 and the macros such as `COLOR_BLACK` return a value within the range from 0 to and including 7. However, applications cannot rely on this to be true.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO** `attroff(3XCURSES)`, `delscreen(3XCURSES)`, `initscr(3XCURSES)`, `libcurses(3XCURSES)`, `attributes(5)`, `standards(5)`

| <b>DESCRIPTION</b>           | These functions manipulate color on terminals that support color.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Querying Capabilities</b> | The <code>has_colors()</code> function indicates whether the terminal is a color terminal. The <code>can_change_color()</code> function indicates whether the terminal is a color terminal on which colors can be redefined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Initialization</b>        | <p>The <code>start_color()</code> function must be called to enable use of colors and before any color manipulation function is called. The function initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white) that can be specified by the color macros (such as <code>COLOR_BLACK</code>) defined in <code>&lt;curses.h&gt;</code>. The initial appearance of these colors is unspecified.</p> <p>The function also initializes two global external variables:</p> <ul style="list-style-type: none"> <li>■ <code>COLORS</code> defines the number of colors that the terminal supports. See <a href="#">Color Identification</a> below. If <code>COLORS</code> is 0, the terminal does not support redefinition of colors and <code>can_change_color()</code> will return <code>FALSE</code>.</li> <li>■ <code>COLOR_PAIRS</code> defines the maximum number of color-pairs that the terminal supports. See <a href="#">User-defined Color Pairs</a> below.</li> </ul> |

## PAIR\_NUMBER(3XCURSES)

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |              |                                                                                            |            |                                                                       |              |                                                                         |             |                                                                        |          |                                |             |                                                                                                      |          |                                                                                                   |

|                                        | <p>The <code>start_color()</code> function also restores the colors on the terminal to terminal-specific initial values. The initial background color is assumed to be black for all terminals.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |              |                                                                                            |            |                                                                       |              |                                                                         |             |                                                                        |          |                                |             |                                                                                                      |          |                                                                                                   |
| <p><b>Color Identification</b></p>     | <p>The <code>init_color()</code> function redefines color number <i>color</i>, on terminals that support the redefinition of colors, to have the red, green, and blue intensity components specified by <i>red</i>, <i>green</i>, and <i>blue</i>, respectively. Calling <code>init_color()</code> also changes all occurrences of the specified color on the screen to the new definition.</p> <p>The <code>color_content()</code> function identifies the intensity components of color number <i>color</i>. It stores the red, green, and blue intensity components of this color in the addresses pointed to by <i>red</i>, <i>green</i>, and <i>blue</i>, respectively.</p> <p>For both functions, the <i>color</i> argument must be in the range from 0 to and including <code>COLORS-1</code>. Valid intensity value range from 0 (no intensity component) up to and including 1000 (maximum intensity in that component).</p>                                                                                                                                                                                                                                                        |              |                                                                                            |            |                                                                       |              |                                                                         |             |                                                                        |          |                                |             |                                                                                                      |          |                                                                                                   |
| <p><b>User-defined Color Pairs</b></p> | <p>Calling <code>init_pair()</code> defines or redefines color-pair number <i>pair</i> to have foreground color <i>f</i> and background color <i>b</i>. Calling <code>init_pair()</code> changes any characters that were displayed in the color pair's old definition to the new definition and refreshes the screen.</p> <p>After defining the color pair, the macro <code>COLOR_PAIR(n)</code> returns the value of color pair <i>n</i>. This value is the color attribute as it would be extracted from a <code>chtype</code>. Controversy, the macro <code>COLOR_NUMBER(value)</code> returns the color pair number associated with the color attribute <i>value</i>.</p> <p>The <code>pair_content()</code> retrieves the component colors of a color-pair number <i>pair</i>. It stores the foreground and background color numbers in the variables pointed to by <i>f</i> and <i>b</i>, respectively.</p> <p>With <code>init_pair()</code> and <code>pair_content()</code>, the value of <i>pair</i> must be in a range from 0 to and including <code>COLOR_PAIRS-1</code>. Valid values for <i>f</i> and <i>b</i> are the range from 0 to and including <code>COLORS-1</code>.</p> |              |                                                                                            |            |                                                                       |              |                                                                         |             |                                                                        |          |                                |             |                                                                                                      |          |                                                                                                   |

Otherwise, it returns FALSE.</p> <p>The <code>can_change_color()</code> function returns TRUE if the terminal supports colors and is able to change their definitions. Otherwise, it returns FALSE.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                 |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |                     |          |          |        |
| <b>USAGE</b>         | <p>To use these functions, <code>start_color()</code> must be called, usually right after <code>initscr(3XCURSES)</code>.</p> <p>The <code>can_change_color()</code> and <code>has_colors()</code> functions facilitate writing terminal-independent applications. For example, a programmer can use them to decide whether to use color or some other video attribute.</p> <p>On color terminals, a typical value of <code>COLORS</code> is 8 and the macros such as <code>COLOR_BLACK</code> return a value within the range from 0 to and including 7. However, applications cannot rely on this to be true.</p> |                |                 |                     |          |          |        |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lpanel -lcurses [ library .. ] #include &lt;panel.h&gt;  PANEL *panel_above (PANEL *panel) ; PANEL *panel_below (PANEL *panel) ;</pre>                                                                                                                                                                                                                                                       |                |                 |          |        |
| DESCRIPTION    | <p>panel_above () returns a pointer to the panel just above <i>panel</i>, or NULL if <i>panel</i> is the top panel. panel_below () returns a pointer to the panel just below <i>panel</i>, or NULL if <i>panel</i> is the bottom panel.</p> <p>If NULL is passed for <i>panel</i>, panel_above () returns a pointer to the bottom panel in the deck, and panel_below () returns a pointer to the top panel in the deck.</p> |                |                 |          |        |
| RETURN VALUES  | NULL is returned if an error occurs.                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |

| NAME           | panel_above, panel_below – panels deck traversal primitives                                                                                                                                                                                                                                                                                                                                                                 |                |                 |          |        |
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lpanel -lcurses [ library .. ] #include &lt;panel.h&gt;  PANEL *panel_above (PANEL *panel) ; PANEL *panel_below (PANEL *panel) ;</pre>                                                                                                                                                                                                                                                       |                |                 |          |        |
| DESCRIPTION    | <p>panel_above () returns a pointer to the panel just above <i>panel</i>, or NULL if <i>panel</i> is the top panel. panel_below () returns a pointer to the panel just below <i>panel</i>, or NULL if <i>panel</i> is the bottom panel.</p> <p>If NULL is passed for <i>panel</i>, panel_above () returns a pointer to the bottom panel in the deck, and panel_below () returns a pointer to the top panel in the deck.</p> |                |                 |          |        |
| RETURN VALUES  | NULL is returned if an error occurs.                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |

## panel\_hidden(3CURSES)

| NAME           | panel_show, show_panel, hide_panel, panel_hidden – panels deck manipulation routines                                                                                                                                                                                                                                                                                                     |                |                 |          |        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lpanel -lcurses [ library .. ] #include &lt;panel.h&gt;  int show_panel (PANEL *panel) ; int hide_panel (PANEL *panel) ; int panel_hidden (PANEL *panel) ;</pre>                                                                                                                                                                                          |                |                 |          |        |
| DESCRIPTION    | <p>show_panel () makes <i>panel</i>, previously hidden, visible and places it on top of the deck of panels.</p> <p>hide_panel () removes <i>panel</i> from the panel deck and, thus, hides it from view. The internal data structure of the panel is retained.</p> <p>panel_hidden () returns TRUE (1) or FALSE (0) indicating whether or not <i>panel</i> is in the deck of panels.</p> |                |                 |          |        |
| RETURN VALUES  | show_panel () and hide_panel () return the integer OK upon successful completion or ERR upon error.                                                                                                                                                                                                                                                                                      |                |                 |          |        |

| SEE ALSO       | curses(3CURSES), panel_update(3CURSES), panels(3CURSES), attributes(5)                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |
| NOTES          | The header <panel.h> automatically includes the header <curses.h>.                                                                                                                                                                                                                                                                                                                       |                |                 |          |        |

| <b>NAME</b>          | panel_move, move_panel – move a panels window on the virtual screen                                                                                                                                                                              |                |                 |          |        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lpanel -lcurses [ library .. ] #include &lt;panel.h&gt;  int move_panel(PANEL *panel, int starty, int startx);</pre>                                                                                              |                |                 |          |        |
| <b>DESCRIPTION</b>   | move_panel() moves the curses window associated with <i>panel</i> so that its upper left-hand corner is at <i>starty</i> , <i>startx</i> . See usage note, below.                                                                                |                |                 |          |        |
| <b>RETURN VALUES</b> | OK is returned if the routine completes successfully, otherwise ERR is returned.                                                                                                                                                                 |                |                 |          |        |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                  |                |                 |          |        |
|                      | <table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>MT-Level</td><td>Unsafe</td></tr> </table>                                                                                                                            | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |
| ATTRIBUTE TYPE       | ATTRIBUTE VALUE                                                                                                                                                                                                                                  |                |                 |          |        |
| MT-Level             | Unsafe                                                                                                                                                                                                                                           |                |                 |          |        |
| <b>SEE ALSO</b>      | curses(3CURSES), panel_update(3CURSES), panels(3CURSES), attributes(5)                                                                                                                                                                           |                |                 |          |        |
| <b>NOTES</b>         | <p>For panels windows, use move_panel() instead of the mvwin() curses routine. Otherwise, update_panels() will not properly update the virtual screen.</p> <p>The header &lt;panel.h&gt; automatically includes the header &lt;curses.h&gt;.</p> |                |                 |          |        |

panel\_new(3CURSES)

| NAME           | panel_new, new_panel, del_panel – create and destroy panels                                                                                                                                                                   |                |                 |          |        |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lpanel -lcurses [ library .. ] #include &lt;panel.h&gt;  PANEL *new_panel (WINDOW *win) ; int del_panel (PANEL *panel) ;</pre>                                                                 |                |                 |          |        |
| DESCRIPTION    | <p>new_panel () creates a new panel associated with <i>win</i> and returns the panel pointer. The new panel is placed on top of the panel deck.</p> <p>del_panel () destroys <i>panel</i>, but not its associated window.</p> |                |                 |          |        |
| RETURN VALUES  | <p>new_panel () returns NULL if an error occurs.</p> <p>del_win () returns OK if successful, ERR otherwise.</p>                                                                                                               |                |                 |          |        |
| ATTRIBUTES     | See attributes(5) for descriptions of the following attributes:                                                                                                                                                               |                |                 |          |        |

| <b>SYNOPSIS</b>                | <code>#include &lt;panel.h&gt;</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                     |                  |                           |                                 |                        |                                 |                         |                                  |                         |                                  |                        |                                 |                          |                                   |                          |                                   |                           |                                  |                            |                                     |                           |                                    |                            |                                    |                                |                                     |                         |                                  |                        |                                 |                            |                                    |
| <b>DESCRIPTION</b>             | <p>The <code>panel</code> library is built using the <code>curses</code> library, and any program using <code>panels</code> routines must call one of the <code>curses</code> initialization routines such as <code>initscr</code>. A program using these routines must be compiled with <code>-lpanel</code> and <code>-lcurses</code> on the <code>cc</code> command line.</p> <p>The <code>panels</code> package gives the applications programmer a way to have depth relationships between <code>curses</code> windows; a <code>curses</code> window is associated with every panel. The <code>panels</code> routines allow <code>curses</code> windows to overlap without making visible the overlapped portions of underlying windows. The initial <code>curses</code> window, <code>stdscr</code>, lies beneath all panels. The set of currently visible panels is the <i>deck</i> of panels.</p> <p>The <code>panels</code> package allows the applications programmer to create panels, fetch and set their associated windows, shuffle panels in the deck, and manipulate panels in other ways.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                          |                     |                  |                           |                                 |                        |                                 |                         |                                  |                         |                                  |                        |                                 |                          |                                   |                          |                                   |                           |                                  |                            |                                     |                           |                                    |                            |                                    |                                |                                     |                         |                                  |                        |                                 |                            |                                    |

panels(3CURSES)

**RETURN VALUES** Each `panels` routine that returns a pointer to an object returns NULL if an error occurs. Each panel routine that returns an integer, returns OK if it executes successfully and ERR if it does not.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curses(3CURSES)`, `attributes(5)` and 3X pages whose names begin “panel\_” for detailed routine descriptions.

**NOTES** The header `<panel.h>` automatically includes the header `<curses.h>`.

| NAME           | panel_show, show_panel, hide_panel, panel_hidden – panels deck manipulation routines                                                                                                                                                                                                                                                                                                  |                |                 |          |        |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lpanel -lcurses [ library .. ] #include &lt;panel.h&gt;  int show_panel (PANEL *panel) ; int hide_panel (PANEL *panel) ; int panel_hidden (PANEL *panel) ;</pre>                                                                                                                                                                                       |                |                 |          |        |
| DESCRIPTION    | <p>show_panel() makes <i>panel</i>, previously hidden, visible and places it on top of the deck of panels.</p> <p>hide_panel() removes <i>panel</i> from the panel deck and, thus, hides it from view. The internal data structure of the panel is retained.</p> <p>panel_hidden() returns TRUE (1) or FALSE (0) indicating whether or not <i>panel</i> is in the deck of panels.</p> |                |                 |          |        |
| RETURN VALUES  | show_panel() and hide_panel() return the integer OK upon successful completion or ERR upon error.                                                                                                                                                                                                                                                                                     |                |                 |          |        |
| ATTRIBUTES     | <p>See attributes(5) for descriptions of the following attributes:</p> <table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>MT-Level</td><td>Unsafe</td></tr> </table>                                                                                                                                                                                          | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE                                                                                                                                                                                                                                                                                                                                                                       |                |                 |          |        |

## panel\_top(3CURSES)

| NAME           | panel_top, top_panel, bottom_panel – panels deck manipulation routines                                                                                                                                                                                                                                             |                |                 |          |        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lpanel -lcurses [ library .. ] #include &lt;panel.h&gt;  int top_panel (PANEL *panel) ; int bottom_panel (PANEL *panel) ;</pre>                                                                                                                                                     |                |                 |          |        |
| DESCRIPTION    | <p>top_panel() pulls <i>panel</i> to the top of the desk of panels. It leaves the size, location, and contents of its associated window unchanged.</p> <p>bottom_panel() puts <i>panel</i> at the bottom of the deck of panels. It leaves the size, location, and contents of its associated window unchanged.</p> |                |                 |          |        |
| RETURN VALUES  | All of these routines return the integer OK upon successful completion or ERR upon error.                                                                                                                                                                                                                          |                |                 |          |        |
| ATTRIBUTES     | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                    |                |                 |          |        |
|                | <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>MT-Level</td><td>Unsafe</td></tr></table>                                                                                                                                                                                                   | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE                                                                                                                                                                                                                                                                                                    |                |                 |          |        |
| MT-Level       | Unsafe                                                                                                                                                                                                                                                                                                             |                |                 |          |        |

panel\_update(3CURSES)

| NAME           | panel_update, update_panels – panels virtual screen refresh routine                                                                                                                                                              |                |                 |          |        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lpanel -lcurses [ library .. ] #include &lt;panel.h&gt;  void <b>update_panels</b>(void);</pre>                                                                                                   |                |                 |          |        |
| DESCRIPTION    | update_panels() refreshes the virtual screen to reflect the depth relationships between the panels in the deck. The user must use the curses library call doupdate() (see curs_refresh(3CURSES)) to refresh the physical screen. |                |                 |          |        |
| ATTRIBUTES     | See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>MT-Level</td><td>Unsafe</td></tr></table>                                                 | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE                                                                                                                                                                                                                  |                |                 |          |        |
| MT-Level       | Unsafe                                                                                                                                                                                                                           |                |                 |          |        |
| SEE ALSO       | curs_refresh(3CURSES), curses(3CURSES), panels(3CURSES), attributes(5)                                                                                                                                                           |                |                 |          |        |
| NOTES          | The header <panel.h> automatically includes the header <curses.h>.                                                                                                                                                               |                |                 |          |        |

## panel\_userptr(3CURSES)

| NAME           | panel_userptr, set_panel_userptr – associate application data with a panels panel                                                                                                                                                     |                |                 |          |        |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lpanel -lcurses [ library .. ] #include &lt;panel.h&gt;  int set_panel_userptr(PANEL *panel, char *ptr); char * panel_userptr(PANEL *panel);</pre>                                                     |                |                 |          |        |
| DESCRIPTION    | <p>Each panel has a user pointer available for maintaining relevant information.</p> <p>set_panel_userptr() sets the user pointer of <i>panel</i> to <i>ptr</i>.</p> <p>panel_userptr() returns the user pointer of <i>panel</i>.</p> |                |                 |          |        |
| RETURN VALUES  | <p>set_panel_userptr returns OK if successful, ERR otherwise.</p> <p>panel_userptr returns NULL if there is no user pointer assigned to <i>panel</i>.</p>                                                                             |                |                 |          |        |
| ATTRIBUTES     | <p>See attributes(5) for descriptions of the following attributes:</p> <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>Unsafe</td></tr></tbody></table>                 | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |
| ATTRIBUTE TYPE | ATTRIBUTE VALUE                                                                                                                                                                                                                       |                |                 |          |        |

| <b>DESCRIPTION</b> | <p>The <code>newpad()</code> routine creates and returns a pointer to a new pad data structure with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (for example, from scrolling or echoing of input) do not occur. It is not legal to call <code>wrefresh(3CURSES)</code> with a <i>pad</i> as an argument; the routines <code>prefresh()</code> or <code>pnoutrefresh()</code> should be called instead. Note that these routines require additional parameters to specify the part of the pad to be displayed and the location on the screen to be used for the display.</p> <p>The <code>subpad()</code> routine creates and returns a pointer to a subwindow within a pad with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. Unlike <code>subwin(3CURSES)</code>, which uses screen coordinates, the window is at position (<i>begin_x</i>, <i>begin_y</i>) on the pad. The window is made in the middle of the window <i>orig</i>, so that changes made to one window affect both windows. During the use of this routine, it will often be necessary to call <code>touchwin(3CURSES)</code> or <code>touchline(3CURSES)</code> on <i>orig</i> before calling <code>prefresh()</code>.</p> <p>The <code>prefresh()</code> and <code>pnoutrefresh()</code> routines are analogous to <code>wrefresh(3CURSES)</code> and <code>wnoutrefresh(3CURSES)</code> except that they relate to pads instead of windows. The additional parameters are needed to indicate what part of the pad and screen are involved. <i>pminrow</i> and <i>pmincol</i> specify the upper left-hand corner of the rectangle to be displayed in the pad. <i>sminrow</i>, <i>smincol</i>, <i>smaxrow</i>, and <i>smaxcol</i> specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of <i>pminrow</i>, <i>pmincol</i>, <i>sminrow</i>, or <i>smincol</i> are treated as if they were zero.</p> |

pechochar(3CURSES)

The `pechochar()` routine is functionally equivalent to a call to `addch(3CURSES)` followed by a call to `refresh(3CURSES)`, a call to `waddch(3CURSES)` followed by a call to `wrefresh(3CURSES)`, or a call to `waddch(3CURSES)` followed by a call to `prefresh()`. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents. In the case of `pechochar()`, the last location of the pad on the screen is reused for the arguments to `prefresh()`.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

Routines that return pointers return `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `addch(3CURSES)`, `curses(3CURSES)`, `refresh(3CURSES)`, `subwin(3CURSES)`, `touchline(3CURSES)`, `touchwin(3CURSES)`, `waddch(3CURSES)`, `wnoutrefresh(3CURSES)`, `wrefresh(3CURSES)`, `attributes(5)`

**NOTES** The header file `<curses.h>` automatically includes the header files `<stdio.h>`, `<unctrl.h>` and `<widec.h>`.

Note that `pechochar()` may be a macro.

## pechochar(3XCURSES)

| NAME                | pechochar, pecho_wchar – add character and refresh window                                                                                                                                                                                                                                                         |                |                                                                |                     |                                                         |            |                                                                 |

| <i>pad</i>          | Is a pointer to the pad in which the character is to be added.                                                                                                                                                                                                                                                    |                |                                                                |                     |                                                         |            |                                                                 |
| <i>ch</i>           | Is a pointer to the character to be written to the pad.                                                                                                                                                                                                                                                           |                |                                                                |                     |                                                         |            |                                                                 |
| <i>wch</i>          | Is a pointer to the complex character to be written to the pad.                                                                                                                                                                                                                                                   |                |                                                                |                     |                                                         |            |                                                                 |
| DESCRIPTION         | The pechochar() function is equivalent to calling waddch(3XCURSES) followed by a call to prefresh(3XCURSES). The pecho_wchar() function is equivalent to calling wadd_wch(3XCURSES) followed by a call to prefresh(). prefresh() reuses the last position of the pad on the screen for its parameters.            |                |                                                                |                     |                                                         |            |                                                                 |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                |                |                                                                |                     |                                                         |            |                                                                 |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                             |                |                                                                |                     |                                                         |            |                                                                 |

| DESCRIPTION | <p>The <code>newpad()</code> routine creates and returns a pointer to a new pad data structure with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (for example, from scrolling or echoing of input) do not occur. It is not legal to call <code>wrefresh(3CURSES)</code> with a <i>pad</i> as an argument; the routines <code>prefresh()</code> or <code>pnoutrefresh()</code> should be called instead. Note that these routines require additional parameters to specify the part of the pad to be displayed and the location on the screen to be used for the display.</p> <p>The <code>subpad()</code> routine creates and returns a pointer to a subwindow within a pad with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. Unlike <code>subwin(3CURSES)</code>, which uses screen coordinates, the window is at position (<i>begin_x</i>, <i>begin_y</i>) on the pad. The window is made in the middle of the window <i>orig</i>, so that changes made to one window affect both windows. During the use of this routine, it will often be necessary to call <code>touchwin(3CURSES)</code> or <code>touchline(3CURSES)</code> on <i>orig</i> before calling <code>prefresh()</code>.</p> <p>The <code>prefresh()</code> and <code>pnoutrefresh()</code> routines are analogous to <code>wrefresh(3CURSES)</code> and <code>wnoutrefresh(3CURSES)</code> except that they relate to pads instead of windows. The additional parameters are needed to indicate what part of the pad and screen are involved. <i>pminrow</i> and <i>pmincol</i> specify the upper left-hand corner of the rectangle to be displayed in the pad. <i>sminrow</i>, <i>smincol</i>, <i>smaxrow</i>, and <i>smaxcol</i> specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of <i>pminrow</i>, <i>pmincol</i>, <i>sminrow</i>, or <i>smincol</i> are treated as if they were zero.</p> |

pechochar(3CURSES)

The `pechochar()` routine is functionally equivalent to a call to `addch(3CURSES)` followed by a call to `refresh(3CURSES)`, a call to `waddch(3CURSES)` followed by a call to `wrefresh(3CURSES)`, or a call to `waddch(3CURSES)` followed by a call to `prefresh()`. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents. In the case of `pechochar()`, the last location of the pad on the screen is reused for the arguments to `prefresh()`.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

Routines that return pointers return `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `addch(3CURSES)`, `curses(3CURSES)`, `refresh(3CURSES)`, `subwin(3CURSES)`, `touchline(3CURSES)`, `touchwin(3CURSES)`, `waddch(3CURSES)`, `wnoutrefresh(3CURSES)`, `wrefresh(3CURSES)`, `attributes(5)`

**NOTES** The header file `<curses.h>` automatically includes the header files `<stdio.h>`, `<unctrl.h>` and `<wider.h>`.

Note that `pechochar()` may be a macro.

| <b>NAME</b>          | pechochar, pecho_wchar – add character and refresh window                                                                                                                                                                                                                                              |                |                 |                     |          |          |        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int pechochar(WINDOW *pad, chtype ch);  int pecho_wchar(WINDOW *pad, const chtype *wch);</pre>               |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>pad</i> Is a pointer to the pad in which the character is to be added.</p> <p><i>ch</i> Is a pointer to the character to be written to the pad.</p> <p><i>wch</i> Is a pointer to the complex character to be written to the pad.</p>                                                            |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | The pechochar() function is equivalent to calling waddch(3XCURSES) followed by a call to prefresh(3XCURSES). The pecho_wchar() function is equivalent to calling wadd_wch(3XCURSES) followed by a call to prefresh(). prefresh() reuses the last position of the pad on the screen for its parameters. |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                     |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |

| DESCRIPTION | <p>These functions generate graphics output for a set of output devices. The format of the output is dependent upon which link editor option is used when the program is compiled and linked (see Link Editor).</p> <p>The term "current point" refers to the current setting for the <i>x</i> and <i>y</i> coordinates.</p> <p>The <code>arc()</code> function specifies a circular arc. The coordinates <i>(x0, y0)</i> specify the center of the arc. The coordinates <i>(x1, y1)</i> specify the starting point of the arc. The coordinates <i>(x2, y2)</i> specify the end point of the circular arc.</p> <p>The <code>box()</code> function specifies a rectangle with coordinates <i>(x0, y0)</i>, <i>(x0, y1)</i>, <i>(x1, y0)</i>, and <i>(x1, y1)</i>. The current point is set to <i>(x1, y1)</i>.</p> <p>The <code>circle()</code> function specifies a circle with a center at the coordinates <i>(x, y)</i> and a radius of <i>r</i>.</p> <p>The <code>closevt()</code> and <code>closepl()</code> functions flush the output.</p> <p>The <code>cont()</code> function specifies a line beginning at the current point and ending at the coordinates <i>(x, y)</i>. The current point is set to <i>(x, y)</i>.</p> |

The `erase()` function starts another frame of output.

The `label()` function places the null terminated string `s` so that the first character falls on the current point. The string is then terminated by a NEWLINE character.

The `line()` function draws a line starting at the coordinates  $(x0, y0)$  and ending at the coordinates  $(x1, y1)$ . The current point is set to  $(x1, y1)$ .

The `linemod()` function specifies the style for drawing future lines. `s` may contain one of the following: `dotted`, `solid`, `longdashed`, `shortdashed`, or `dotdashed`.

The `move()` function sets the current point to the coordinates  $(x, y)$ .

The `openpl()` or `openvt()` function must be called to open the device before any other plot functions are called.

The `point()` function plots the point given by the coordinates  $(x, y)$ . The current point is set to  $(x, y)$ .

The `space()` function specifies the size of the plotting area. The plot will be reduced or enlarged as necessary to fit the area specified. The coordinates  $(x0, y0)$  specify the lower left hand corner of the plotting area. The coordinates  $(x1, y1)$  specify the upper right hand corner of the plotting area.

**Link Editor** Various flavors of these functions exist for different output devices. They are obtained by using the following `ld(1)` options:

| NAME        | curs_pad, newpad, subpad, prefresh, pnoutrefresh, pechochar, pechowchar – create and display curses pads                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| DESCRIPTION | <p>The <code>newpad()</code> routine creates and returns a pointer to a new pad data structure with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (for example, from scrolling or echoing of input) do not occur. It is not legal to call <code>wrefresh(3CURSES)</code> with a <i>pad</i> as an argument; the routines <code>prefresh()</code> or <code>pnoutrefresh()</code> should be called instead. Note that these routines require additional parameters to specify the part of the pad to be displayed and the location on the screen to be used for the display.</p> <p>The <code>subpad()</code> routine creates and returns a pointer to a subwindow within a pad with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. Unlike <code>subwin(3CURSES)</code>, which uses screen coordinates, the window is at position (<i>begin_x</i>, <i>begin_y</i>) on the pad. The window is made in the middle of the window <i>orig</i>, so that changes made to one window affect both windows. During the use of this routine, it will often be necessary to call <code>touchwin(3CURSES)</code> or <code>touchline(3CURSES)</code> on <i>orig</i> before calling <code>prefresh()</code>.</p> <p>The <code>prefresh()</code> and <code>pnoutrefresh()</code> routines are analogous to <code>wrefresh(3CURSES)</code> and <code>wnoutrefresh(3CURSES)</code> except that they relate to pads instead of windows. The additional parameters are needed to indicate what part of the pad and screen are involved. <i>pminrow</i> and <i>pmincol</i> specify the upper left-hand corner of the rectangle to be displayed in the pad. <i>sminrow</i>, <i>smincol</i>, <i>smaxrow</i>, and <i>smaxcol</i> specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of <i>pminrow</i>, <i>pmincol</i>, <i>sminrow</i>, or <i>smincol</i> are treated as if they were zero.</p> |

pnoutrefresh(3CURSES)

The `pechochar()` routine is functionally equivalent to a call to `addch(3CURSES)` followed by a call to `refresh(3CURSES)`, a call to `waddch(3CURSES)` followed by a call to `wrefresh(3CURSES)`, or a call to `waddch(3CURSES)` followed by a call to `prefresh()`. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents. In the case of `pechochar()`, the last location of the pad on the screen is reused for the arguments to `prefresh()`.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

Routines that return pointers return `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `addch(3CURSES)`, `curses(3CURSES)`, `refresh(3CURSES)`, `subwin(3CURSES)`, `touchline(3CURSES)`, `touchwin(3CURSES)`, `waddch(3CURSES)`, `wnoutrefresh(3CURSES)`, `wrefresh(3CURSES)`, `attributes(5)`

**NOTES** The header file `<curses.h>` automatically includes the header files `<stdio.h>`, `<unctrl.h>` and `<wider.h>`.

Note that `pechochar()` may be a macro.

| NAME        | newpad, pnoutrefresh, prefresh, subpad – create or refresh a pad or subpad                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |
| SYNOPSIS    | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  WINDOW *newpad(int nlines, int ncols);  int pnoutrefresh(WINDOW *pad, int pminrow, int pmincol, int sminrow, int smincol, int smaxrow, int smaxcol);  int prefresh(WINDOW *pad, int pminrow, int pmincol, int sminrow, int smincol, int smaxrow, int smaxcol);  WINDOW *subpad(WINDOW *orig, int nlines, int ncols);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |
| PARAMETERS  | <p><i>nlines</i> Is the number of lines in the pad to be created.</p> <p><i>ncols</i> Is the number of columns in the pad to be created.</p> <p><i>pad</i> Is a pointer to the pad to refresh.</p> <p><i>pminrow</i> Is the row coordinate of the upper left corner of the pad rectangle to be copied</p> <p><i>pmincol</i> Is the column coordinate of the upper left corner of the pad rectangle to be copied.</p> <p><i>sminrow</i> Is the row coordinate of the upper left corner of the rectangle on the physical screen where pad is to be positioned.</p> <p><i>smincol</i> Is the column coordinate of the upper left corner of the rectangle on the physical screen where pad is to be positioned.</p> <p><i>smaxrow</i> Is the row coordinate of the lower right corner of the rectangle on the physical screen where the pad is to be positioned.</p> <p><i>smaxcol</i> Is the column coordinate of the lower right corner of the rectangle on the physical screen where the pad is to be positioned.</p> <p><i>orig</i> Is a pointer to the parent pad within which a sub-pad is created.</p> |  |
| DESCRIPTION | <p>The <code>newpad()</code> function creates a new pad with the specified number of lines and columns. A pointer to the new pad structure is returned. A pad differs from a window in that it is not restricted to the size of the physical screen. It is useful when only part of a large window will be displayed at any one time.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |

## pnoutrefresh(3XCURSES)

Automatic refreshes by scrolling or echoing of input do not take place when pads are used. Pads have their own refresh commands, `prefresh()` and `pnoutrefresh()`.

The `prefresh()` function copies the specified portion of the logical pad to the terminal screen. The parameters *pmincol* and *pminrow* specify the upper left corner of the rectangular area of the pad to be displayed. The lower right coordinate of the rectangular area of the pad that is to be displayed is calculated from the screen parameters (*sminrow*, *smincol*, *smaxrow*, *smaxcol*).

This function calls the `pnoutrefresh()` function to copy the specified portion of *pad* to the terminal screen and the `doupdate(3XCURSES)` function to do the actual update. The logical cursor is copied to the same location in the physical window unless `leaveok(3XCURSES)` is enabled (in which case, the cursor is placed in a position that the program finds convenient).

When outputting several pads at once, it is often more efficient to call the `pnoutrefresh()` and `doupdate()` functions directly. A call to `pnoutrefresh()` for each pad first, followed by only one call to `doupdate()` to update the screen, results in one burst of output, fewer characters sent, and less CPU time used.

The `subpad()` function creates a sub-pad within the pad *orig* with the specified number of lines and columns. A pointer to the new pad structure is returned. The sub-pad is positioned in the middle of *orig*. Any changes made to one pad affect the other. `touchwin(3XCURSES)` or `touchline(3XCURSES)` will likely have to be called on pad *orig* to correctly update the window.

### RETURN VALUES

On success, the `newpad()` and `subpad()` functions return a pointer to the new pad data structure. Otherwise, they return a null pointer.

On success, the `pnoutrefresh()` and `prefresh()` functions return `OK`. Otherwise, they return `ERR`.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| DESCRIPTION | <p>These functions generate graphics output for a set of output devices. The format of the output is dependent upon which link editor option is used when the program is compiled and linked (see Link Editor).</p> <p>The term "current point" refers to the current setting for the <math>x</math> and <math>y</math> coordinates.</p> <p>The <code>arc()</code> function specifies a circular arc. The coordinates <math>(x0, y0)</math> specify the center of the arc. The coordinates <math>(x1, y1)</math> specify the starting point of the arc. The coordinates <math>(x2, y2)</math> specify the end point of the circular arc.</p> <p>The <code>box()</code> function specifies a rectangle with coordinates <math>(x0, y0)</math>, <math>(x0, y1)</math>, <math>(x1, y0)</math>, and <math>(x1, y1)</math>. The current point is set to <math>(x1, y1)</math>.</p> <p>The <code>circle()</code> function specifies a circle with a center at the coordinates <math>(x, y)</math> and a radius of <math>r</math>.</p> <p>The <code>closevt()</code> and <code>closepl()</code> functions flush the output.</p> <p>The <code>cont()</code> function specifies a line beginning at the current point and ending at the coordinates <math>(x, y)</math>. The current point is set to <math>(x, y)</math>.</p> |

## point(3PLOT)

The `erase()` function starts another frame of output.

The `label()` function places the null terminated string `s` so that the first character falls on the current point. The string is then terminated by a NEWLINE character.

The `line()` function draws a line starting at the coordinates  $(x0, y0)$  and ending at the coordinates  $(x1, y1)$ . The current point is set to  $(x1, y1)$ .

The `linemod()` function specifies the style for drawing future lines. `s` may contain one of the following: `dotted`, `solid`, `longdashed`, `shortdashed`, or `dotdashed`.

The `move()` function sets the current point to the coordinates  $(x, y)$ .

The `openpl()` or `openvt()` function must be called to open the device before any other plot functions are called.

The `point()` function plots the point given by the coordinates  $(x, y)$ . The current point is set to  $(x, y)$ .

The `space()` function specifies the size of the plotting area. The plot will be reduced or enlarged as necessary to fit the area specified. The coordinates  $(x0, y0)$  specify the lower left hand corner of the plotting area. The coordinates  $(x1, y1)$  specify the upper right hand corner of the plotting area.

**Link Editor** Various flavors of these functions exist for different output devices. They are obtained by using the following `ld(1)` options:

|                     |                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------|
| <code>-lplot</code> | device-independent graphics stream on standard output in the format described in <code>plot(4B)</code> |

## pos\_form\_cursor(3CURSES)

| NAME           | form_cursor, pos_form_cursor – position forms window cursor                                                                                                                                                                                                                                                                |                |                                     |                |               |                |                           |              |                         |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-------------------------------------|----------------|---------------|----------------|---------------------------|--------------|-------------------------|
| SYNOPSIS       | <pre>cc [ <i>flag...</i> ] <i>file...</i> -lform -lcurses [ <i>library...</i> ]<br/>#include &lt;form.h&gt;<br/><br/>int <b>pos_form_cursor</b>(FORM *<i>form</i>) ;</pre>                                                                                                                                                 |                |                                     |                |               |                |                           |              |                         |
| DESCRIPTION    | pos_form_cursor() moves the form window cursor to the location required by the form driver to resume form processing. This may be needed after the application calls a curses library I/O routine.                                                                                                                         |                |                                     |                |               |                |                           |              |                         |
| RETURN VALUES  | pos_form_cursor() returns one of the following:<br><table><tr><td>E_OK</td><td>The function returned successfully.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error.</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr><tr><td>E_NOT_POSTED</td><td>The form is not posted.</td></tr></table> | E_OK           | The function returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An argument is incorrect. | E_NOT_POSTED | The form is not posted. |
| E_OK           | The function returned successfully.                                                                                                                                                                                                                                                                                        |                |                                     |                |               |                |                           |              |                         |
| E_SYSTEM_ERROR | System error.                                                                                                                                                                                                                                                                                                              |                |                                     |                |               |                |                           |              |                         |
| E_BAD_ARGUMENT | An argument is incorrect.                                                                                                                                                                                                                                                                                                  |                |                                     |                |               |                |                           |              |                         |
| E_NOT_POSTED   | The form is not posted.                                                                                                                                                                                                                                                                                                    |                |                                     |                |               |                |                           |              |                         |

| SYNOPSIS       | <pre>cc [ flag... ] file... -lmenu -lcurses [ library... ] #include &lt;menu.h&gt;  int pos_menu_cursor(MENU *menu) ;</pre>                                                                                                                                                                                                                           |                |                                    |                |               |                |                                                  |              |                               |
| DESCRIPTION    | pos_menu_cursor() moves the cursor in the window of <i>menu</i> to the correct position to resume menu processing. This is needed after the application calls a curses library I/O routine.                                                                                                                                                           |                |                                    |                |               |                |                                                  |              |                               |
| RETURN VALUES  | <p>This routine returns one of the following:</p> <table><tr><td>E_OK</td><td>The routine returned successfully.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error.</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An incorrect argument was passed to the routine.</td></tr><tr><td>E_NOT_POSTED</td><td>The menu has not been posted.</td></tr></table> | E_OK           | The routine returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An incorrect argument was passed to the routine. | E_NOT_POSTED | The menu has not been posted. |
| E_OK           | The routine returned successfully.                                                                                                                                                                                                                                                                                                                    |                |                                    |                |               |                |                                                  |              |                               |
| E_SYSTEM_ERROR | System error.                                                                                                                                                                                                                                                                                                                                         |                |                                    |                |               |                |                                                  |              |                               |
| E_BAD_ARGUMENT | An incorrect argument was passed to the routine.                                                                                                                                                                                                                                                                                                      |                |                                    |                |               |                |                                                  |              |                               |
| E_NOT_POSTED   | The menu has not been posted.                                                                                                                                                                                                                                                                                                                         |                |                                    |                |               |                |                                                  |              |                               |

| DESCRIPTION     | <p>post_form() writes <i>form</i> into its associated subwindow. The application programmer must use curses library routines to display the form on the physical screen or call update_panels() if the panels library is being used.</p> <p>unpost_form() erases <i>form</i> from its associated subwindow.</p>                                                                                                                                                                                                                                                                                                                                        |                |                                     |                |               |                |                           |          |                     |              |                         |           |                                         |             |                                                                        |                 |                                       |

| DESCRIPTION     | <p>post_menu() writes <i>menu</i> to the subwindow. The application programmer must use curses library routines to display the menu on the physical screen or call update_panels() if the panels library is being used.</p> <p>unpost_menu() erases <i>menu</i> from its associated subwindow.</p>                                                                                                                                                                                                                                                                                                                                                                                           |                |                                    |                |               |                |                                                  |          |                             |             |                                                                        |           |                                             |              |                               |                 |                                     |

| DESCRIPTION | <p>The <code>newpad()</code> routine creates and returns a pointer to a new pad data structure with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (for example, from scrolling or echoing of input) do not occur. It is not legal to call <code>wrefresh(3CURSES)</code> with a <i>pad</i> as an argument; the routines <code>prefresh()</code> or <code>pnoutrefresh()</code> should be called instead. Note that these routines require additional parameters to specify the part of the pad to be displayed and the location on the screen to be used for the display.</p> <p>The <code>subpad()</code> routine creates and returns a pointer to a subwindow within a pad with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. Unlike <code>subwin(3CURSES)</code>, which uses screen coordinates, the window is at position (<i>begin_x</i>, <i>begin_y</i>) on the pad. The window is made in the middle of the window <i>orig</i>, so that changes made to one window affect both windows. During the use of this routine, it will often be necessary to call <code>touchwin(3CURSES)</code> or <code>touchline(3CURSES)</code> on <i>orig</i> before calling <code>prefresh()</code>.</p> <p>The <code>prefresh()</code> and <code>pnoutrefresh()</code> routines are analogous to <code>wrefresh(3CURSES)</code> and <code>wnoutrefresh(3CURSES)</code> except that they relate to pads instead of windows. The additional parameters are needed to indicate what part of the pad and screen are involved. <i>pminrow</i> and <i>pmincol</i> specify the upper left-hand corner of the rectangle to be displayed in the pad. <i>sminrow</i>, <i>smincol</i>, <i>smaxrow</i>, and <i>smaxcol</i> specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of <i>pminrow</i>, <i>pmincol</i>, <i>sminrow</i>, or <i>smincol</i> are treated as if they were zero.</p> |

prefresh(3CURSES)

The `pechochar()` routine is functionally equivalent to a call to `addch(3CURSES)` followed by a call to `refresh(3CURSES)`, a call to `waddch(3CURSES)` followed by a call to `wrefresh(3CURSES)`, or a call to `waddch(3CURSES)` followed by a call to `prefresh()`. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents. In the case of `pechochar()`, the last location of the pad on the screen is reused for the arguments to `prefresh()`.

**RETURN VALUES** Routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

Routines that return pointers return `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `addch(3CURSES)`, `curses(3CURSES)`, `refresh(3CURSES)`, `subwin(3CURSES)`, `touchline(3CURSES)`, `touchwin(3CURSES)`, `waddch(3CURSES)`, `wnoutrefresh(3CURSES)`, `wrefresh(3CURSES)`, `attributes(5)`

**NOTES** The header file `<curses.h>` automatically includes the header files `<stdio.h>`, `<unctrl.h>` and `<widec.h>`.

Note that `pechochar()` may be a macro.

## prefresh(3XCURSES)

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |

| PARAMETERS  | <p><i>nlines</i> Is the number of lines in the pad to be created.</p> <p><i>ncols</i> Is the number of columns in the pad to be created.</p> <p><i>pad</i> Is a pointer to the pad to refresh.</p> <p><i>pminrow</i> Is the row coordinate of the upper left corner of the pad rectangle to be copied</p> <p><i>pmincol</i> Is the column coordinate of the upper left corner of the pad rectangle to be copied.</p> <p><i>sminrow</i> Is the row coordinate of the upper left corner of the rectangle on the physical screen where pad is to be positioned.</p> <p><i>smincol</i> Is the column coordinate of the upper left corner of the rectangle on the physical screen where pad is to be positioned.</p> <p><i>smaxrow</i> Is the row coordinate of the lower right corner of the rectangle on the physical screen where the pad is to be positioned.</p> <p><i>smaxcol</i> Is the column coordinate of the lower right corner of the rectangle on the physical screen where the pad is to be positioned.</p> <p><i>orig</i> Is a pointer to the parent pad within which a sub-pad is created.</p> |  |
| DESCRIPTION | <p>The <code>newpad()</code> function creates a new pad with the specified number of lines and columns. A pointer to the new pad structure is returned. A pad differs from a window in that it is not restricted to the size of the physical screen. It is useful when only part of a large window will be displayed at any one time.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |

## prefresh(3XCURSES)

Automatic refreshes by scrolling or echoing of input do not take place when pads are used. Pads have their own refresh commands, `prefresh()` and `pnoutrefresh()`.

The `prefresh()` function copies the specified portion of the logical pad to the terminal screen. The parameters *pmincol* and *pminrow* specify the upper left corner of the rectangular area of the pad to be displayed. The lower right coordinate of the rectangular area of the pad that is to be displayed is calculated from the screen parameters (*sminrow*, *smincol*, *smaxrow*, *smaxcol*).

This function calls the `pnoutrefresh()` function to copy the specified portion of *pad* to the terminal screen and the `doupdate(3XCURSES)` function to do the actual update. The logical cursor is copied to the same location in the physical window unless `leaveok(3XCURSES)` is enabled (in which case, the cursor is placed in a position that the program finds convenient).

When outputting several pads at once, it is often more efficient to call the `pnoutrefresh()` and `doupdate()` functions directly. A call to `pnoutrefresh()` for each pad first, followed by only one call to `doupdate()` to update the screen, results in one burst of output, fewer characters sent, and less CPU time used.

The `subpad()` function creates a sub-pad within the pad *orig* with the specified number of lines and columns. A pointer to the new pad structure is returned. The sub-pad is positioned in the middle of *orig*. Any changes made to one pad affect the other. `touchwin(3XCURSES)` or `touchline(3XCURSES)` will likely have to be called on pad *orig* to correctly update the window.

### RETURN VALUES

On success, the `newpad()` and `subpad()` functions return a pointer to the new pad data structure. Otherwise, they return a null pointer.

On success, the `pnoutrefresh()` and `prefresh()` functions return OK. Otherwise, they return ERR.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>mvprintw</b>(int y, int x, char *fmt, ...); int <b>mvwprintw</b>(WINDOW *win, int y, int x, char *fmt, ...); int <b>printw</b>(char *fmt, ...); int <b>wprintw</b>(WINDOW *win, char *fmt, ...);</pre> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>y</i> Is the y (row) coordinate position of the string's placement in the window.</p> <p><i>x</i> Is the x (column) coordinate position of the string's placement in the window.</p> <p><i>fmt</i> Is a printf() format string.</p> <p><i>win</i> Is a pointer to the window in which the string is to be written.</p>                                                                            |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | The mvprintw(), mvwprintw(), printw(), and wprintw() functions are analogous to printf(3C). The effect of these functions is as though sprintf() were used to format the string, and then waddstr(3XCURSES) were used to add that multi-byte string to the current or specified window at the current or specified cursor position.                                                                     |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |

| DESCRIPTION | <p>These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, curses routines are more suitable and their use is recommended.</p> <p>Initially, <code>setupterm()</code> should be called. Note that <code>setupterm()</code> is automatically called by <code>initscr()</code> and <code>newterm()</code>. This defines the set of terminal-dependent variables (listed in <code>terminfo(4)</code>). The <i>terminfo</i> variables <code>lines</code> and <code>columns</code> are initialized by <code>setupterm()</code> as follows: If <code>use_env(FALSE)</code> has been called, values for <code>lines</code> and <code>columns</code> specified in <i>terminfo</i> are used. Otherwise, if the environment variables <code>LINES</code> and <code>COLUMNS</code> exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database are used.</p> <p>The headers <code>&lt;curses.h&gt;</code> and <code>&lt;term.h&gt;</code> should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through <code>tparm()</code> to instantiate them. All <i>terminfo</i> strings (including the output</p> |

of `tparm()` should be printed with `tputs()` or `putp()`. Call the `reset_shell_mode()` routine to restore the tty modes before exiting (see `curs_kernel(3CURSES)`). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call `reset_shell_mode` and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call `reset_prog_mode` after returning from the shell.

The `setupterm()` routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fildev* which is initialized for output. If *errret* is not null, then `setupterm()` returns OK or ERR and stores a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo* database could not be found. If *errret* is null, `setupterm()` prints an error message upon finding an error and exits. Thus, the simplest call is:

```
setupterm((char *)0, 1, (int *)0);
```

which uses all the defaults and sends the output to `stdout`.

The `setterm()` routine is being replaced by `setupterm()`. The call:

```
setupterm(term, 1, (int *)0)
```

provides the same functionality as `setterm(term)`. The `setterm()` routine is included here for compatibility and is supported at Level 2.

The `set_curterm()` routine sets the variable `cur_term` to *nterm*, and makes all of the *terminfo* boolean, numeric, and string variables use the values from *nterm*.

The `del_curterm()` routine frees the space pointed to by *oterm* and makes it available for further use. If *oterm* is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another `setupterm()` has been called.

The `restartterm()` routine is similar to `setupterm()` and `initscr()`, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The `tparm()` routine instantiates the string *str* with parameters *pi*. A pointer is returned to the result of *str* with the parameters applied.

The `tputs()` routine applies padding information to the string *str* and outputs it. The *str* must be a *terminfo* string variable or the return value from `tparm()`, `tgetstr()`, or `tgoto()`. *affcnt* is the number of lines affected, or 1 if not applicable. *putc* is a `putchar()`-like routine to which the characters are passed, one at a time.

## putp(3CURSES)

The `putp()` routine calls `tputs(str, 1, putchar)`. Note that the output of `putpA()` always goes to `stdout`, not to the *fil*des specified in `setupterm()`.

The `vidputs()` routine displays the string on the terminal in the video attribute mode *attrs*, which is any combination of the attributes listed in `curses(3CURSES)`. The characters are passed to the `putchar()`-like routine `putc()`.

The `vidattr()` routine is like the `vidputs()` routine, except that it outputs through `putchar()`.

The `mvcur()` routine provides low-level cursor motion.

The `tigetflag()`, `tigetnum()` and `tigetstr()` routines return the value of the capability corresponding to the *terminfo* *capname* passed to them, such as `xenl`.

With the `tigetflag()` routine, the value `-1` is returned if *capname* is not a boolean capability.

With the `tigetnum()` routine, the value `-2` is returned if *capname* is not a numeric capability.

With the `tigetstr()` routine, the value `(char *)-1` is returned if *capname* is not a string capability.

The *capname* for each capability is given in the table column entitled *capname* code in the capabilities section of `terminfo(4)`.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

## RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

## SEE ALSO

`curs_initscr(3CURSES)`, `curs_kernel(3CURSES)`, `curs_termcap(3CURSES)`, `curses(3CURSES)`, `putc(3C)`, `terminfo(4)`, `attributes(5)`

putp(3CURSES)

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

The `setupterm()` routine should be used in place of `setterm()`.

Note that `vidattr()` and `vidputs()` may be macros.

## putp(3XCURSES)

| NAME                                                                                                                                                                   | putp, tputs – apply padding information and output string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                                                                                                                                      |                     |                                                        |                |                         |

| DESCRIPTION                                                                                                                                                            | <p>The putp() and tputs() functions are low-level functions used to deal directly with the terminfo database. The use of appropriate X/Open Curses functions is recommended for most situations.</p> <p>The tputs() function adds padding information and then outputs <i>str</i>. <i>str</i> must be a terminfo string variable or the result value from tgetstr(), tgoto(), tigetstr(), or tparm(). The tputs() function replaces the padding specification (if one exists) with enough characters to produce the specified delay. Characters are output one at a time to <i>putfunc</i>, a user-specified function similar to putchar(3C).</p> <p>The putp() function calls tputs() as follows:</p> <pre>tputs(str, 1, putchar)</pre> |                |                                                                                                                                      |                     |                                                        |                |                         |

| DESCRIPTION | <p>The <code>unctrl()</code> macro expands to a character string which is a printable representation of the character <i>c</i>. Control characters are displayed in the ^X notation. Printing characters are displayed as is.</p> <p>With the <code>keyname()</code> routine, a character string corresponding to the key <i>c</i> is returned.</p> <p>The <code>filter()</code> routine, if used, is called before <code>initscr()</code> or <code>newterm()</code> are called. It makes <code>curses</code> think that there is a one-line screen. <code>curses</code> does not use any terminal capabilities that assume that they know on what line of the screen the cursor is positioned.</p> <p>The <code>use_env()</code> routine, if used, is called before <code>initscr()</code> or <code>newterm()</code> are called. When called with <code>FALSE</code> as an argument, the values of <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database will be used, even if environment variables <code>LINES</code> and <code>COLUMNS</code> (used by default) are set, or if <code>curses</code> is running in a window (in which case default behavior would be to use the window size if <code>LINES</code> and <code>COLUMNS</code> are not set).</p> <p>With the <code>putwin()</code> routine, all data associated with window <i>win</i> is written into the file to which <i>filep</i> points. This information can be later retrieved using the <code>getwin()</code> function.</p> <p>The <code>getwin()</code> routine reads window related data stored in the file by <code>putwin()</code>. The routine then creates and initializes a new window using that data. It returns a pointer to the new window.</p> <p>The <code>delay_output()</code> routine inserts an <i>ms</i> millisecond pause in output. This routine should not be used extensively because padding characters are used rather than a CPU pause.</p> <p>The <code>flushinp()</code> routine throws away any typeahead that has been typed by the user and has not yet been read by the program.</p> |

putwin(3CURSES)

**RETURN VALUES** Except for `flushinp()`, routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`flushinp()` always returns `OK`.

Routines that return pointers return `NULL` on error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_initscr(3CURSES)`, `curs_scr_dump(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `unctrl()` is a macro, which is defined in `<unctrl.h>`.

## putwin(3XCURSES)

| NAME                | getwin, putwin – read a window from, and write a window to, a file                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| SYNOPSIS            | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  WINDOW *getwin(FILE *filep);  int putwin(WINDOW *win, FILE *filep);</pre>                                                                                                                                                                                                                                           |                |                 |                     |          |          |        |
| DESCRIPTION         | <p>The <code>getwin()</code> function reads window-related data (written earlier by <code>putwin()</code>) from the <code>stdio</code> stream pointed to by <code>filep</code>. It then creates and initializes a new window using that data.</p> <p>The <code>putwin()</code> function writes all the data associated with the window pointed to by <code>win</code> to the <code>stdio</code> stream pointed to by <code>filep</code>. The <code>getwin()</code> function can later retrieve this data.</p> |                |                 |                     |          |          |        |
| PARAMETERS          | <p><i>filep</i> Is a pointer to a <code>stdio</code> stream.</p> <p><i>win</i> Is a pointer to a window.</p>                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| RETURN VALUES       | <p>On success, the <code>getwin()</code> function returns a pointer to the new window created. Otherwise, it returns a null pointer.</p> <p>On success, the <code>putwin()</code> function returns OK. Otherwise, it returns ERR.</p>                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |
