| <b>NAME</b>        | is_linetouched, is_wintouched, touchline, touchwin, untouchwin, wtouchln – control window refresh                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |  |
| <b>SYNOPSIS</b>    | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  bool is_linetouched(WINDOW *win, int line); bool is_wintouched(WINDOW *win); int touchline(WINDOW *win, int start, int count); int touchwin(WINDOW *win); int untouchwin(WINDOW *win); int wtouchln(WINDOW *win, int y, int n, int changed);</pre>                                                                                                                                                                                                                                                                                                                                                        |  |
| <b>PARAMETERS</b>  | <p><i>win</i> Is a pointer to the window in which the refresh is to be controlled or monitored.</p> <p><i>line</i> Is the line to be checked for change since refresh.</p> <p><i>start</i> Is the starting line number of the portion of the window to make appear changed.</p> <p><i>count</i> Is the number of lines in the window to mark as changed.</p> <p><i>y</i> Is the starting line number of the portion of the window to make appear changed or not changed.</p> <p><i>n</i> Is the number of lines in the window to mark as changed.</p> <p><i>changed</i> Is a flag indicating whether to make lines look changed (0) or not changed (1).</p>                                                                                                                                         |  |
| <b>DESCRIPTION</b> | <p>The touchwin() function marks the entire window as dirty. This makes it appear to X/Open Curses as if the whole window has been changed, thus causing the entire window to be rewritten with the next call to refresh(3XCURSES). This is sometimes necessary when using overlapping windows; the change to one window will not be reflected in the other and, hence will not be recorded.</p> <p>The touchline() function marks as dirty a portion of the window starting at line <i>start</i> and continuing for <i>count</i> lines instead of the entire window. Consequently, that portion of the window is updated with the next call to refresh().</p> <p>The untouchwin() function marks all lines in the window as unchanged since the last refresh, ensuring that it is not updated.</p> |  |

touchline(3XCURSES)

The `wtouchln()` function marks *n* lines starting at line *y* as either changed (*changed*=1) or unchanged (*changed*=0) since the last refresh.

To find out which lines or windows have been changed since the last refresh, use the `is_linetouched()` and `is_wintouched()` functions, respectively. These return TRUE if the specified line or window have been changed since the last call to `refresh()` or FALSE if no changes have been made.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int touchwin(WINDOW *win); int touchline(WINDOW *win, int start, int count); int untouchwin(WINDOW *win); int wtouchln(WINDOW *win, int y, int n, int changed); int is_linetouched(WINDOW *win, int line); int is_wintouched(WINDOW *win);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>The touchwin() and touchline() routines throw away all optimization information about which parts of the window have been touched, by pretending that the entire window has been drawn on. This is sometimes necessary when using overlapping windows, since a change to one window affects the other window, but the records of which lines have been changed in the other window do not reflect the change. The routine touchline() only pretends that <i>count</i> lines have been changed, beginning with line <i>start</i>.</p> <p>The untouchwin() routine marks all lines in the window as unchanged since the last call to wrefresh().</p> <p>The wtouchln() routine makes <i>n</i> lines in the window, starting at line <i>y</i>, look as if they have (<i>changed</i>=1) or have not (<i>changed</i>=0) been changed since the last call to wrefresh().</p> <p>The is_linetouched() and is_wintouched() routines return TRUE if the specified line/window was modified since the last call to wrefresh(); otherwise they return FALSE. In addition, is_linetouched() returns ERR if line is not valid for the given window.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |

|                    | <i>changed</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Is a flag indicating whether to make lines look changed (0) or not changed (1).                 |
| <b>DESCRIPTION</b> | <p>The <code>touchwin()</code> function marks the entire window as dirty. This makes it appear to X/Open Curses as if the whole window has been changed, thus causing the entire window to be rewritten with the next call to <code>refresh(3XCURSES)</code>. This is sometimes necessary when using overlapping windows; the change to one window will not be reflected in the other and, hence will not be recorded.</p> <p>The <code>touchline()</code> function marks as dirty a portion of the window starting at line <i>start</i> and continuing for <i>count</i> lines instead of the entire window. Consequently, that portion of the window is updated with the next call to <code>refresh()</code>.</p> <p>The <code>untouchwin()</code> function marks all lines in the window as unchanged since the last refresh, ensuring that it is not updated.</p> |                                                                                                 |

touchwin(3XCURSES)

The `wtouchln()` function marks *n* lines starting at line *y* as either changed (*changed*=1) or unchanged (*changed*=0) since the last refresh.

To find out which lines or windows have been changed since the last refresh, use the `is_linetouched()` and `is_wintouched()` functions, respectively. These return TRUE if the specified line or window have been changed since the last call to `refresh()` or FALSE if no changes have been made.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| DESCRIPTION | <p>These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, curses routines are more suitable and their use is recommended.</p> <p>Initially, <code>setupterm()</code> should be called. Note that <code>setupterm()</code> is automatically called by <code>initscr()</code> and <code>newterm()</code>. This defines the set of terminal-dependent variables (listed in <code>terminfo(4)</code>). The <i>terminfo</i> variables <code>lines</code> and <code>columns</code> are initialized by <code>setupterm()</code> as follows: If <code>use_env(FALSE)</code> has been called, values for <code>lines</code> and <code>columns</code> specified in <i>terminfo</i> are used. Otherwise, if the environment variables <code>LINES</code> and <code>COLUMNS</code> exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database are used.</p> <p>The headers <code>&lt;curses.h&gt;</code> and <code>&lt;term.h&gt;</code> should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through <code>tparm()</code> to instantiate them. All <i>terminfo</i> strings (including the output</p> |

## tparm(3CURSES)

of `tparm()` should be printed with `tputs()` or `putp()`. Call the `reset_shell_mode()` routine to restore the tty modes before exiting (see `curs_kernel(3CURSES)`). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call `reset_shell_mode` and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call `reset_prog_mode` after returning from the shell.

The `setupterm()` routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fildef* which is initialized for output. If *errret* is not null, then `setupterm()` returns OK or ERR and stores a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo* database could not be found. If *errret* is null, `setupterm()` prints an error message upon finding an error and exits. Thus, the simplest call is:

`setupterm((char *)0, 1, (int *)0);` which uses all the defaults and sends the output to `stdout`.

The `setterm()` routine is being replaced by `setupterm()`. The call:

`setupterm(term, 1, (int *)0)` provides the same functionality as `setterm(term)`. The `setterm()` routine is included here for compatibility and is supported at Level 2.

The `set_curterm()` routine sets the variable `cur_term` to *nterm*, and makes all of the *terminfo* boolean, numeric, and string variables use the values from *nterm*.

The `del_curterm()` routine frees the space pointed to by *oterm* and makes it available for further use. If *oterm* is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another `setupterm()` has been called.

The `restartterm()` routine is similar to `setupterm()` and `initscr()`, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The `tparm()` routine instantiates the string *str* with parameters *pi*. A pointer is returned to the result of *str* with the parameters applied.

The `tputs()` routine applies padding information to the string *str* and outputs it. The *str* must be a *terminfo* string variable or the return value from `tparm()`, `tgetstr()`, or `tgoto()`. *affcnt* is the number of lines affected, or 1 if not applicable. *putc* is a `putchar()`-like routine to which the characters are passed, one at a time.

tparm(3CURSES)

The `putp()` routine calls `tputs(str, 1, putchar)`. Note that the output of `putpA()` always goes to `stdout`, not to the *fil*des specified in `setupterm()`.

The `vidputs()` routine displays the string on the terminal in the video attribute mode *attrs*, which is any combination of the attributes listed in `curses(3CURSES)`. The characters are passed to the `putchar()`-like routine `putc()`.

The `vidattr()` routine is like the `vidputs()` routine, except that it outputs through `putchar()`.

The `mvcur()` routine provides low-level cursor motion.

The `tigetflag()`, `tigetnum()` and `tigetstr()` routines return the value of the capability corresponding to the *terminfo capname* passed to them, such as `xenl`.

With the `tigetflag()` routine, the value `-1` is returned if *capname* is not a boolean capability.

With the `tigetnum()` routine, the value `-2` is returned if *capname* is not a numeric capability.

With the `tigetstr()` routine, the value `(char *)-1` is returned if *capname* is not a string capability.

The *capname* for each capability is given in the table column entitled *capname* code in the capabilities section of `terminfo(4)`.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

## RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

## ATTRIBUTES

| NAME          | tigetflag, tigetnum, tigetstr, tparm – return the value of a terminfo capability                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| SYNOPSIS      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;term.h&gt;  int <b>tigetflag</b>(char *capname); int <b>tigetnum</b>(char *capname); char *<b>tigetstr</b>(char *capname); char *<b>tparm</b>(char *cap, long p1, long p2, long p3, long p4, long p5,             long p6, long p7, long p8, long p9);</pre>                                                                                                                                                                                                                |
| PARAMETERS    | <p><i>capname</i>                      Is the name of the terminfo capability for which the value is required.</p> <p><i>cap</i>                              Is a pointer to a string capability.</p> <p><i>p1...p9</i>                      Are the parameters to be instantiated.</p>                                                                                                                                                                                                                                                                                                                                                                |
| DESCRIPTION   | <p>The <code>tigetflag()</code>, <code>tigetnum()</code>, and <code>tigetstr()</code> functions return values for terminfo capabilities passed to them.</p> <p>The following null-terminated arrays contain the <i>capnames</i>, the termcap codes and full C names for each of the terminfo variables.</p> <pre>char *boolnames, *boolcodes, *boolfnames char *numnames, *numcodes, *numfnames char *strnames, *strcodes, *strfnames</pre> <p>The <code>tparm()</code> function instantiates a parameterized string using nine arguments. The string is suitable for output processing by <code>tputs()</code>.</p>                                    |
| RETURN VALUES | <p>On success, the <code>tigetflg()</code>, <code>tigetnum()</code>, and <code>tigetstr()</code> functions return the specified terminfo capability.</p> <p><code>tigetflag()</code> returns <code>-1</code> if <i>capname</i> is not a Boolean capability.</p> <p><code>tigetnum()</code> returns <code>-2</code> if <i>capname</i> is not a numeric capability.</p> <p><code>tigetstr()</code> returns <code>(char *)-1</code> if <i>capname</i> is not a string capability.</p> <p>On success, the <code>tparm()</code> function returns <i>cap</i> in a static buffer with the parameterization resolved. Otherwise, it returns a null pointer.</p> |
| ERRORS        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| DESCRIPTION | <p>These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, curses routines are more suitable and their use is recommended.</p> <p>Initially, <code>setupterm()</code> should be called. Note that <code>setupterm()</code> is automatically called by <code>initscr()</code> and <code>newterm()</code>. This defines the set of terminal-dependent variables (listed in <code>terminfo(4)</code>). The <i>terminfo</i> variables <code>lines</code> and <code>columns</code> are initialized by <code>setupterm()</code> as follows: If <code>use_env(FALSE)</code> has been called, values for <code>lines</code> and <code>columns</code> specified in <i>terminfo</i> are used. Otherwise, if the environment variables <code>LINES</code> and <code>COLUMNS</code> exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database are used.</p> <p>The headers <code>&lt;curses.h&gt;</code> and <code>&lt;term.h&gt;</code> should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through <code>tparm()</code> to instantiate them. All <i>terminfo</i> strings (including the output</p> |

## tputs(3CURSES)

of `tparm()` should be printed with `tputs()` or `putp()`. Call the `reset_shell_mode()` routine to restore the tty modes before exiting (see `curs_kernel(3CURSES)`). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call `reset_shell_mode` and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call `reset_prog_mode` after returning from the shell.

The `setupterm()` routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fildef* which is initialized for output. If *errret* is not null, then `setupterm()` returns OK or ERR and stores a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo* database could not be found. If *errret* is null, `setupterm()` prints an error message upon finding an error and exits. Thus, the simplest call is:

`setupterm((char *)0, 1, (int *)0);` which uses all the defaults and sends the output to `stdout`.

The `setterm()` routine is being replaced by `setupterm()`. The call:

`setupterm(term, 1, (int *)0)` provides the same functionality as `setterm(term)`. The `setterm()` routine is included here for compatibility and is supported at Level 2.

The `set_curterm()` routine sets the variable `cur_term` to *nterm*, and makes all of the *terminfo* boolean, numeric, and string variables use the values from *nterm*.

The `del_curterm()` routine frees the space pointed to by *oterm* and makes it available for further use. If *oterm* is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another `setupterm()` has been called.

The `restartterm()` routine is similar to `setupterm()` and `initscr()`, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The `tparm()` routine instantiates the string *str* with parameters *pi*. A pointer is returned to the result of *str* with the parameters applied.

The `tputs()` routine applies padding information to the string *str* and outputs it. The *str* must be a *terminfo* string variable or the return value from `tparm()`, `tgetstr()`, or `tgoto()`. *affcnt* is the number of lines affected, or 1 if not applicable. *putc* is a `putchar()`-like routine to which the characters are passed, one at a time.

`tputs(3CURSES)`

The `putp()` routine calls `tputs(str, 1, putchar)`. Note that the output of `putpA()` always goes to `stdout`, not to the *fil*des specified in `setupterm()`.

The `vidputs()` routine displays the string on the terminal in the video attribute mode *attrs*, which is any combination of the attributes listed in `curses(3CURSES)`. The characters are passed to the `putchar()`-like routine `putc()`.

The `vidattr()` routine is like the `vidputs()` routine, except that it outputs through `putchar()`.

The `mvcur()` routine provides low-level cursor motion.

The `tigetflag()`, `tigetnum()` and `tigetstr()` routines return the value of the capability corresponding to the *terminfo capname* passed to them, such as `xenl`.

With the `tigetflag()` routine, the value `-1` is returned if *capname* is not a boolean capability.

With the `tigetnum()` routine, the value `-2` is returned if *capname* is not a numeric capability.

With the `tigetstr()` routine, the value `(char *)-1` is returned if *capname* is not a string capability.

The *capname* for each capability is given in the table column entitled *capname* code in the capabilities section of `terminfo(4)`.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

## RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

| <b>PARAMETERS</b>    | <pre>#include &lt;curses.h&gt;  int putp(const char *str);  int tputs(const char *str, int affcnt, int (*putfunc) (int));</pre> <p><i>str</i> Is a pointer to a terminfo variable or return value from tgetstr(3XCURSES), tgoto(3XCURSES), tigetstr(3XCURSES), or tparm(3XCURSES).</p> <p><i>affcnt</i> Is the number of lines affected, or 1 if not relevant.</p> <p><i>putfunc</i> Is the output function.</p>                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b>   | <p>The putp() and tputs() functions are low-level functions used to deal directly with the terminfo database. The use of appropriate X/Open Curses functions is recommended for most situations.</p> <p>The tputs() function adds padding information and then outputs <i>str</i>. <i>str</i> must be a terminfo string variable or the result value from tgetstr(), tgoto(), tigetstr(), or tparm(). The tputs() function replaces the padding specification (if one exists) with enough characters to produce the specified delay. Characters are output one at a time to <i>putfunc</i>, a user-specified function similar to putchar(3C).</p> <p>The putp() function calls tputs() as follows:</p> <pre>tputs(str, 1, putchar)</pre> |
| <b>RETURN VALUES</b> | On success, these functions return OK.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>USAGE</b>         | The output of putp() goes to stdout, not to the file descriptor, <i>fildev</i> , specified in setupterm(3XCURSES).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| DESCRIPTION | <p>The <code>cbreak()</code> and <code>nocbreak()</code> routines put the terminal into and out of <code>cbreak()</code> mode, respectively. In this mode, characters typed by the user are immediately available to the program, and erase/kill character-processing is not performed. When out of this mode, the tty driver buffers the typed characters until a newline or carriage return is typed. Interrupt and flow control characters are unaffected by this mode. Initially the terminal may or may not be in <code>cbreak()</code> mode, as the mode is inherited; therefore, a program should call <code>cbreak()</code> or <code>nocbreak()</code> explicitly. Most interactive programs using curses set the <code>cbreak()</code> mode.</p> <p>Note that <code>cbreak()</code> overrides <code>raw()</code>. (See <code>curs_getch(3CURSES)</code> for a discussion of how these routines interact with <code>echo()</code> and <code>noecho()</code>.)</p> <p>The <code>echo()</code> and <code>noecho()</code> routines control whether characters typed by the user are echoed by <code>getch()</code> as they are typed. Echoing by the tty driver is always disabled, but initially <code>getch()</code> is in echo mode, so characters typed are echoed. Authors of</p> |

## typeahead(3CURSES)

most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling `noecho()`. (See `curs_getch(3CURSES)` for a discussion of how these routines interact with `cbreak()` and `nocbreak()`.)

The `halfdelay()` routine is used for half-delay mode, which is similar to `cbreak()` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, `ERR` is returned if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

If the `intrflush()` option is enabled, (*bf* is `TRUE`), when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing `curses` to have the wrong idea of what is on the screen. Disabling (*bf* is `FALSE`), the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.

The `keypad()` option enables the keypad of the user's terminal. If enabled (*bf* is `TRUE`), the user can press a function key (such as an arrow key) and `wgetch()` returns a single value representing the function key, as in `KEY_LEFT`. If disabled (*bf* is `FALSE`), `curses` does not treat function keys specially and the program has to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option causes the terminal keypad to be turned on when `wgetch()` is called. The default value for keypad is false.

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the tty driver (see `termio(7I)`). To force 8 bits to be returned, invoke `meta(win, TRUE)`. To force 7 bits to be returned, invoke `meta(win, FALSE)`. The window argument, *win*, is always ignored. If the terminfo capabilities `smm` (`meta_on`) and `rmm` (`meta_off`) are defined for the terminal, `smm` is sent to the terminal when `meta(win, TRUE)` is called and `rmm` is sent when `meta(win, FALSE)` is called.

The `nodelay()` option causes `getch()` to be a non-blocking call. If no input is ready, `getch()` returns `ERR`. If disabled (*bf* is `FALSE`), `getch()` waits until a key is pressed.

While interpreting an input escape sequence, `wgetch()` sets a timer while waiting for the next character. If `notimeout(win, TRUE)` is called, then `wgetch()` does not set a timer. The purpose of the timeout is to differentiate between sequences received from a function key and those typed by a user.

With the `raw()` and `noraw()` routines, the terminal is placed into or out of raw mode. Raw mode is similar to `cbreak()` mode, in that characters typed are immediately passed through to the user program. The differences are that in raw mode, the interrupt, quit, suspend, and flow control characters are all passed through uninterpreted, instead of generating a signal. The behavior of the `BREAK` key depends on other bits in the tty driver that are not set by `curses`.

typeahead(3CURSES)

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the INTR, QUIT and SUSP characters will not be done (see `termio(7I)`). When `qiflush()` is called, the queues will be flushed when these control characters are read.

The `timeout()` and `wtimeout()` routines set blocking or non-blocking read for a given window. If *delay* is negative, blocking read is used (that is, waits indefinitely for input). If *delay* is zero, then non-blocking read is used (that is, read returns ERR if no input is waiting). If *delay* is positive, then read blocks for *delay* milliseconds, and returns ERR if there is still no input. Hence, these routines provide the same functionality as `nodelay()`, plus the additional capability of being able to block for only *delay* milliseconds (where *delay* is positive).

`curses` does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh()` or `doupdate()` is called again. This allows faster response to commands typed in advance. Normally, the input FILE pointer passed to `newterm()`, or `stdin` in the case that `initscr()` was used, will be used to do this typeahead checking. The `typeahead()` routine specifies that the file descriptor *fildes* is to be used to check for typeahead instead. If *fildes* is `-1`, then no typeahead checking is done.

**RETURN VALUES** All routines that return an integer return ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_getch(3CURSES)`, `curs_initscr(3CURSES)`, `curses(3CURSES)`, `attributes(5)`, `termio(7I)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `echo()`, `noecho()`, `halfdelay()`, `intrflush()`, `meta()`, `nodelay()`, `notimeout()`, `noqiflush()`, `qiflush()`, `timeout()`, and `wtimeout()` may be macros.

## typeahead(3XCURSES)

| NAME                | typeahead – check for type-ahead characters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |

| PARAMETERS          | <i>fd</i> Is the file descriptor that is used to check for type-ahead characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |
| DESCRIPTION         | <p>The <code>typeahead()</code> function specifies the file descriptor (<i>fd</i>) to use to check for type-ahead characters (characters typed by the user but not yet processed by X/Open Curses).</p> <p>X/Open Curses checks for type-ahead characters periodically while updating the screen. If characters are found, the current update is postponed until the next <code>refresh(3XCURSES)</code> or <code>doupdate(3XCURSES)</code>. This speeds up response to commands that have been typed ahead. Normally, the input file pointer passed to <code>newterm(3XCURSES)</code>, or <code>stdin</code> in the case of <code>initscr(3XCURSES)</code>, is used for type-ahead checking.</p> <p>If <i>fd</i> is -1, no type-ahead checking is done.</p> |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, the <code>typeahead()</code> function returns OK. Otherwise, it returns ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |

| SYNOPSIS    | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  char *unctrl(chtype c); char *keyname(int c); int filter(void); void use_env(char bool); int putwin(WINDOW *win, FILE *filep); WINDOW *getwin(FILE *filep); int delay_output(int ms); int flushinp(void);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DESCRIPTION | <p>The <code>unctrl()</code> macro expands to a character string which is a printable representation of the character <code>c</code>. Control characters are displayed in the ^X notation. Printing characters are displayed as is.</p> <p>With the <code>keyname()</code> routine, a character string corresponding to the key <code>c</code> is returned.</p> <p>The <code>filter()</code> routine, if used, is called before <code>initscr()</code> or <code>newterm()</code> are called. It makes <code>curses</code> think that there is a one-line screen. <code>curses</code> does not use any terminal capabilities that assume that they know on what line of the screen the cursor is positioned.</p> <p>The <code>use_env()</code> routine, if used, is called before <code>initscr()</code> or <code>newterm()</code> are called. When called with <code>FALSE</code> as an argument, the values of <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database will be used, even if environment variables <code>LINES</code> and <code>COLUMNS</code> (used by default) are set, or if <code>curses</code> is running in a window (in which case default behavior would be to use the window size if <code>LINES</code> and <code>COLUMNS</code> are not set).</p> <p>With the <code>putwin()</code> routine, all data associated with window <code>win</code> is written into the file to which <code>filep</code> points. This information can be later retrieved using the <code>getwin()</code> function.</p> <p>The <code>getwin()</code> routine reads window related data stored in the file by <code>putwin()</code>. The routine then creates and initializes a new window using that data. It returns a pointer to the new window.</p> <p>The <code>delay_output()</code> routine inserts an <code>ms</code> millisecond pause in output. This routine should not be used extensively because padding characters are used rather than a CPU pause.</p> <p>The <code>flushinp()</code> routine throws away any typeahead that has been typed by the user and has not yet been read by the program.</p> |

unctrl(3CURSES)

**RETURN VALUES**

Except for `flushinp()`, routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`flushinp()` always returns `OK`.

Routines that return pointers return `NULL` on error.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO**

`curs_initscr(3CURSES)`, `curs_scr_dump(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES**

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `unctrl()` is a macro, which is defined in `<unctrl.h>`.

**NAME** unctrl – generate printable representation of a character

**SYNOPSIS**

```
cc [flag...] file... -I /usr/xpg4/include -L /usr/xpg4/lib \
-R /usr/xpg4/lib -lcurses [library...]

c89 [flag...] file... -lcurses [library...]

#include <unctrl.h>

char *unctrl (chtype c);
```

**PARAMETERS** *c* Is a character.

**DESCRIPTION** The unctrl () function generates a character string that is a printable representation of *c*. If *c* is a control character, it is converted to the ^X notation. If *c* contains rendition information, the effect is undefined.

**RETURN VALUES** Upon successful completion, the unctrl () function returns the generated string. Otherwise, it returns a null pointer.

**ERRORS** No errors are defined.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>DESCRIPTION</b>   | <p>With the <code> getch()</code>, <code> wgetch()</code>, <code> mvgetch()</code>, and <code> mvwgetch()</code> routines a character is read from the terminal associated with the window. In no-delay mode, if no input is waiting, the value <code> ERR</code> is returned. In delay mode, the program waits until the system passes text through to the program. Depending on the setting of <code> cbreak()</code>, this is after one character (<code> cbreak</code> mode), or after the first newline (<code> nocbreak</code> mode). In half-delay mode, the program waits until a character is typed or the specified timeout has been reached. Unless <code> noecho()</code> has been set, the character will also be echoed into the designated window.</p> <p>If the window is not a pad, and it has been moved or modified since the last call to <code> wrefresh()</code>, <code> wrefresh()</code> will be called before another character is read.</p> <p>If <code> keypad()</code> is <code> TRUE</code>, and a function key is pressed, the token for that function key is returned instead of the raw characters. Possible function keys are defined in <code> &lt;curses.h&gt;</code> with integers beginning with <code> 0401</code>, whose names begin with <code> KEY_</code>. If a character that could be the beginning of a function key (such as escape) is received, <code> curses</code> sets a timer. If the remainder of the sequence does not come in within the designated time, the character is passed through; otherwise, the function key value is returned. For this reason, many terminals experience a delay between the time a user presses the escape key and the escape is returned to the program. Since tokens returned by these routines are outside the ASCII range, they are not printable.</p> <p>The <code> ungetch()</code> routine places <i>ch</i> back onto the input queue to be returned by the next call to <code> wgetch()</code>.</p> |      |          |           |           |
| <b>Function Keys</b> | <p>The following function keys, defined in <code> &lt;curses.h&gt;</code>, might be returned by <code> getch()</code> if <code> keypad()</code> has been enabled. Note that not all of these may be supported on a particular terminal if the terminal does not transmit a unique code when the key is pressed or if the definition for the key is not present in the <i>terminfo</i> database.</p> <table> <tr> <th>Name</th><th>Key name</th></tr> <tr> <td>KEY_BREAK</td><td>Break key</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Name | Key name | KEY_BREAK | Break key |

|-------------|------------------|
| KEY_SUNDO   | Shifted undo key |
| KEY_SUSPEND | Suspend key      |
| KEY_UNDO    | Undo key         |

**RETURN VALUES** All routines return the integer ERR upon failure. The `ungetch()` routine returns an integer value other than ERR upon successful completion. The other routines return the next input character or function key code upon successful completion.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_inopts(3CURSES)`, `curs_move(3CURSES)`, `curs_refresh(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Use of the escape key for a single character function is discouraged.

When using `getch()`, `wgetch()`, `mvgetch()`, or `mvwgetch()`, `nocbreak` mode (`nocbreak()`) and `echo` mode (`echo()`) should not be used at the same time. Depending on the state of the tty driver when each character is typed, the program may produce undesirable results.

Note that `getch()`, `mvgetch()`, and `mvwgetch()` may be macros.

| <b>NAME</b>          | ungetch, unget_wch – push character back onto the input queue                                                                                                                                                                                                                   |                |                 |                     |          |          |        |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int ungetch(int ch);  int unget_wch(const wchar_t wch);</pre>                         |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>ch</i> Is the single byte character to be put back in the input queue for the next call to <code>getch(3XCURSES)</code>.</p> <p><i>wch</i> Is the wide character to be put back in the input queue for the next call to <code>get_wch(3XCURSES)</code>.</p>               |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>ungetch()</code> function pushes <i>ch</i> back onto the input queue until the next call to <code>getch()</code>.</p> <p>The <code>unget_wch()</code> function is similar to <code>ungetch()</code> except that <i>ch</i> can be of type <code>wchar_t</code>.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                              |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                           |                |                 |                     |          |          |        |
| <b>ATTRIBUTES</b>    | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                    |                |                 |                     |          |          |        |

| DESCRIPTION            | <p>The <code>getwch()</code>, <code>wgetwch()</code>, <code>mvgetwch()</code>, and <code>mvwgetwch()</code> routines read an EUC character from the terminal associated with the window, transform it into a <code>wchar_t</code> character, and return a <code>wchar_t</code> character. In no-delay mode, if no input is waiting, the value <code>ERR</code> is returned. In delay mode, the program waits until the system passes text through to the program. Depending on the setting of <code>cbreak</code>, this is after one character (<code>cbreak</code> mode), or after the first newline (<code>nocbreak</code> mode). In half-delay mode, the program waits until a character is typed or the specified timeout has been reached. Unless <code>noecho</code> has been set, the character will also be echoed into the designated window.</p> <p>If the window is not a pad, and it has been moved or modified since the last call to <code>wrefresh(3CURSES)</code>, <code>wrefresh</code> will be called before another character is read.</p> <p>If <code>keypad</code> is <code>TRUE</code>, and a function key is pressed, the token for that function key is returned instead of the raw characters. Possible function keys are defined in <code>&lt;curses.h&gt;</code> with integers beginning with <code>0401</code>, whose names begin with <code>KEY_</code>. If a character that could be the beginning of a function key (such as escape) is received, <code>curses(3CURSES)</code> sets a timer. If the remainder of the sequence does not come in within the designated time, the character is passed through; otherwise, the function key value is returned. For this reason, many terminals experience a delay between the time a user presses the escape key and the escape is returned to the program.</p> <p>The <code>ungetwch()</code> routine places <code>wch</code> back onto the input queue to be returned by the next call to <code>wgetwch()</code>.</p> |      |          |                        |           |
| Function Keys          | <p>The following function keys, defined in <code>&lt;curses.h&gt;</code>, might be returned by <code>getwch()</code> if <code>keypad</code> has been enabled. Note that not all of these may be supported on a particular terminal if the terminal does not transmit a unique code when the key is pressed or if the definition for the key is not present in the <code>terminfo(4)</code> database.</p> <table><tr><th>Name</th><th>Key name</th></tr><tr><td><code>KEY_BREAK</code></td><td>Break key</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Name | Key name | <code>KEY_BREAK</code> | Break key |

| KEY_CATAB         | Clear all tabs                                                                                    |
| KEY_ENTER         | Enter or send                                                                                     |
| KEY_SRESET        | Soft (partial) reset                                                                              |
| KEY_RESET         | Reset or hard reset                                                                               |
| KEY_PRINT         | Print or copy                                                                                     |
| KEY_LL            | Home down or bottom (lower left). Keypad is arranged like this: A1 up A3 left B2 right C1 down C3 |

ungetwch(3CURSES)

| <i>Name</i>   | <i>Key name</i>       |
|---------------|-----------------------|
| KEY_A1        | Upper left of keypad  |
| KEY_A3        | Upper right of keypad |
| KEY_B2        | Center of keypad      |
| KEY_C1        | Lower left of keypad  |
| KEY_C3        | Lower right of keypad |
| KEY_BTAB      | Back tab key          |
| KEY_BEG       | Beg(inning) key       |
| KEY_CANCEL    | Cancel key            |
| KEY_CLOSE     | Close key             |
| KEY_COMMAND   | Cmd (command) key     |
| KEY_COPY      | Copy key              |
| KEY_CREATE    | Create key            |
| KEY_END       | End key               |
| KEY_EXIT      | Exit key              |
| KEY_FIND      | Find key              |
| KEY_HELP      | Help key              |
| KEY_MARK      | Mark key              |
| KEY_MESSAGE   | Message key           |
| KEY_MOVE      | Move key              |
| KEY_NEXT      | Next object key       |
| KEY_OPEN      | Open key              |
| KEY_OPTIONS   | Options key           |
| KEY_PREVIOUS  | Previous object key   |
| KEY_REDO      | Redo key              |
| KEY_REFERENCE | Reference key         |
| KEY_REFRESH   | Refresh key           |
| KEY_REPLACE   | Replace key           |
| KEY_RESTART   | Restart key           |
| KEY_RESUME    | Resume key            |

| <i>Name</i>   | <i>Key name</i>         |
|---------------|-------------------------|
| KEY_SAVE      | Save key                |
| KEY_SBEG      | Shifted beginning key   |
| KEY_SCANCEL   | Shifted cancel key      |
| KEY_SCOMMAND  | Shifted command key     |
| KEY_SCOPY     | Shifted copy key        |
| KEY_SCREATE   | Shifted create key      |
| KEY_SDC       | Shifted delete char key |
| KEY_SDL       | Shifted delete line key |
| KEY_SELECT    | Select key              |
| KEY_SEND      | Shifted end key         |
| KEY_SEOL      | Shifted clear line key  |
| KEY_SEXIT     | Shifted exit key        |
| KEY_SFIND     | Shifted find key        |
| KEY_SHELP     | Shifted help key        |
| KEY_SHOME     | Shifted home key        |
| KEY_SIC       | Shifted input key       |
| KEY_SLEFT     | Shifted left arrow key  |
| KEY_SMESSAGE  | Shifted message key     |
| KEY_SMOVE     | Shifted move key        |
| KEY_SNEXT     | Shifted next key        |
| KEY_SOPTIONS  | Shifted options key     |
| KEY_SPREVIOUS | Shifted prev key        |
| KEY_SPRINT    | Shifted print key       |
| KEY_SREDO     | Shifted redo key        |
| KEY_SREPLACE  | Shifted replace key     |
| KEY_SRIGHT    | Shifted right arrow     |
| KEY_SRSUME    | Shifted resume key      |
| KEY_SSAVE     | Shifted save key        |
| KEY_SSUSPEND  | Shifted suspend key     |

ungetwch(3CURSES)

| <i>Name</i> | <i>Key name</i>  |
|-------------|------------------|
| KEY_SUNDO   | Shifted undo key |
| KEY_SUSPEND | Suspend key      |
| KEY_UNDO    | Undo key         |

**RETURN VALUE** All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curses(3CURSES), curs\_inopts(3CURSES), curs\_move(3CURSES), wrefresh(3CURSES), terminfo(4), attributes(5)

**NOTES** The header file <curses.h> automatically includes the header files <stdio.h>, <unctrl.h> and <wdec.h>.

Use of the escape key by a programmer for a single character function is discouraged.

When using getwch(), wgetwch(), mvgetwch(), or mvwgetwch(), nocbreak mode and echo mode should not be used at the same time. Depending on the state of the tty driver when each character is typed, the program may produce undesirable results.

Note that getwch(), mvgetwch(), and mvwgetwch() may be macros.

| <b>NAME</b>          | ungetch, unget_wch – push character back onto the input queue                                                                                                                                                                                                                   |                |                 |                     |          |          |        |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int ungetch(int ch);  int unget_wch(const wchar_t wch);</pre>                         |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>ch</i> Is the single byte character to be put back in the input queue for the next call to <code>getch(3XCURSES)</code>.</p> <p><i>wch</i> Is the wide character to be put back in the input queue for the next call to <code>get_wch(3XCURSES)</code>.</p>               |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>ungetch()</code> function pushes <i>ch</i> back onto the input queue until the next call to <code>getch()</code>.</p> <p>The <code>unget_wch()</code> function is similar to <code>ungetch()</code> except that <i>ch</i> can be of type <code>wchar_t</code>.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                              |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                           |                |                 |                     |          |          |        |

| DESCRIPTION     | <p>post_form() writes <i>form</i> into its associated subwindow. The application programmer must use curses library routines to display the form on the physical screen or call update_panels() if the panels library is being used.</p> <p>unpost_form() erases <i>form</i> from its associated subwindow.</p>                                                                                                                                                                                                                                                                                                                                        |                |                                     |                |               |                |                           |          |                     |              |                         |           |                                         |             |                                                                        |                 |                                       |
| RETURN VALUES   | <p>These routines return one of the following:</p> <table><tr><td>E_OK</td><td>The function returned successfully.</td></tr><tr><td>E_SYSTEM_ERROR</td><td>System error.</td></tr><tr><td>E_BAD_ARGUMENT</td><td>An argument is incorrect.</td></tr><tr><td>E_POSTED</td><td>The form is posted.</td></tr><tr><td>E_NOT_POSTED</td><td>The form is not posted.</td></tr><tr><td>E_NO_ROOM</td><td>The form does not fit in the subwindow.</td></tr><tr><td>E_BAD_STATE</td><td>The routine was called from an initialization or termination function.</td></tr><tr><td>E_NOT_CONNECTED</td><td>The field is not connected to a form.</td></tr></table> | E_OK           | The function returned successfully. | E_SYSTEM_ERROR | System error. | E_BAD_ARGUMENT | An argument is incorrect. | E_POSTED | The form is posted. | E_NOT_POSTED | The form is not posted. | E_NO_ROOM | The form does not fit in the subwindow. | E_BAD_STATE | The routine was called from an initialization or termination function. | E_NOT_CONNECTED | The field is not connected to a form. |
| E_OK            | The function returned successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                                     |                |               |                |                           |          |                     |              |                         |           |                                         |             |                                                                        |                 |                                       |

| DESCRIPTION     | <p>post_menu() writes <i>menu</i> to the subwindow. The application programmer must use curses library routines to display the menu on the physical screen or call update_panels() if the panels library is being used.</p> <p>unpost_menu() erases <i>menu</i> from its associated subwindow.</p>                                                                                                                                                                                                                                                                                                                                                                                           |                |                                    |                |               |                |                                                  |          |                             |             |                                                                        |           |                                             |              |                               |                 |                                     |

| <b>DESCRIPTION</b>   | <p>The <code>touchwin()</code> and <code>touchline()</code> routines throw away all optimization information about which parts of the window have been touched, by pretending that the entire window has been drawn on. This is sometimes necessary when using overlapping windows, since a change to one window affects the other window, but the records of which lines have been changed in the other window do not reflect the change. The routine <code>touchline()</code> only pretends that <i>count</i> lines have been changed, beginning with line <i>start</i>.</p> <p>The <code>untouchwin()</code> routine marks all lines in the window as unchanged since the last call to <code>wrefresh()</code>.</p> <p>The <code>wtouchln()</code> routine makes <i>n</i> lines in the window, starting at line <i>y</i>, look as if they have (<i>changed</i>=1) or have not (<i>changed</i>=0) been changed since the last call to <code>wrefresh()</code>.</p> <p>The <code>is_linetouched()</code> and <code>is_wintouched()</code> routines return TRUE if the specified line/window was modified since the last call to <code>wrefresh()</code>; otherwise they return FALSE. In addition, <code>is_linetouched()</code> returns ERR if <i>line</i> is not valid for the given window.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |          |        |

| <b>DESCRIPTION</b> | <p>The <code>touchwin()</code> function marks the entire window as dirty. This makes it appear to X/Open Curses as if the whole window has been changed, thus causing the entire window to be rewritten with the next call to <code>refresh(3XCURSES)</code>. This is sometimes necessary when using overlapping windows; the change to one window will not be reflected in the other and, hence will not be recorded.</p> <p>The <code>touchline()</code> function marks as dirty a portion of the window starting at line <i>start</i> and continuing for <i>count</i> lines instead of the entire window. Consequently, that portion of the window is updated with the next call to <code>refresh()</code>.</p> <p>The <code>untouchwin()</code> function marks all lines in the window as unchanged since the last refresh, ensuring that it is not updated.</p> |            |                                                                                   |             |                                                     |              |                                                                                  |              |                                                          |          |                                                                                                 |          |                                                          |                |                                                                                 |

untouchwin(3XCURSES)

The `wtouchln()` function marks *n* lines starting at line *y* as either changed (*changed*=1) or unchanged (*changed*=0) since the last refresh.

To find out which lines or windows have been changed since the last refresh, use the `is_linetouched()` and `is_wintouched()` functions, respectively. These return TRUE if the specified line or window have been changed since the last call to `refresh()` or FALSE if no changes have been made.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |

## update\_panels(3CURSES)

| <b>NAME</b>        | panel_update, update_panels – panels virtual screen refresh routine                                                                                                                                                              |                |                 |          |        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>    | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lpanel -lcurses [ <i>library</i> .. ]<br/>#include &lt;panel.h&gt;<br/><br/>void <b>update_panels</b>(void);</pre>                                                                  |                |                 |          |        |
| <b>DESCRIPTION</b> | update_panels() refreshes the virtual screen to reflect the depth relationships between the panels in the deck. The user must use the curses library call doupdate() (see curs_refresh(3CURSES)) to refresh the physical screen. |                |                 |          |        |

| DESCRIPTION | <p>The <code>unctrl()</code> macro expands to a character string which is a printable representation of the character <i>c</i>. Control characters are displayed in the ^X notation. Printing characters are displayed as is.</p> <p>With the <code>keyname()</code> routine, a character string corresponding to the key <i>c</i> is returned.</p> <p>The <code>filter()</code> routine, if used, is called before <code>initscr()</code> or <code>newterm()</code> are called. It makes <code>curses</code> think that there is a one-line screen. <code>curses</code> does not use any terminal capabilities that assume that they know on what line of the screen the cursor is positioned.</p> <p>The <code>use_env()</code> routine, if used, is called before <code>initscr()</code> or <code>newterm()</code> are called. When called with <code>FALSE</code> as an argument, the values of <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database will be used, even if environment variables <code>LINES</code> and <code>COLUMNS</code> (used by default) are set, or if <code>curses</code> is running in a window (in which case default behavior would be to use the window size if <code>LINES</code> and <code>COLUMNS</code> are not set).</p> <p>With the <code>putwin()</code> routine, all data associated with window <i>win</i> is written into the file to which <i>filep</i> points. This information can be later retrieved using the <code>getwin()</code> function.</p> <p>The <code>getwin()</code> routine reads window related data stored in the file by <code>putwin()</code>. The routine then creates and initializes a new window using that data. It returns a pointer to the new window.</p> <p>The <code>delay_output()</code> routine inserts an <i>ms</i> millisecond pause in output. This routine should not be used extensively because padding characters are used rather than a CPU pause.</p> <p>The <code>flushinp()</code> routine throws away any typeahead that has been typed by the user and has not yet been read by the program.</p> |

use\_env(3CURSES)

**RETURN VALUES**

Except for `flushinp()`, routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`flushinp()` always returns `OK`.

Routines that return pointers return `NULL` on error.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO**

`curs_initscr(3CURSES)`, `curs_scr_dump(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES**

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `unctrl()` is a macro, which is defined in `<unctrl.h>`.

| <b>NAME</b>          | use_env – specify source of screen size information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |                     |          |          |        |

| <b>PARAMETERS</b>    | <i>boolval</i> Is a Boolean expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>use_env()</code> function specifies the technique by which the implementation determines the size of the screen. If <i>boolval</i> is <code>FALSE</code>, the implementation uses the values of <code>lines</code> and <code>columns</code> specified in the terminfo database. If <i>boolval</i> is <code>TRUE</code>, the implementation uses the <code>LINES</code> and <code>COLUMNS</code> environmental variables. The initial value is <code>TRUE</code>.</p> <p>Any call to <code>use_env()</code> must precede calls to <code>initscr(3XCURSES)</code>, <code>newterm(3XCURSES)</code>, or <code>setupterm(3XCURSES)</code>.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | The <code>use_env()</code> function does not return a value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |                     |          |          |        |
| <b>ATTRIBUTES</b>    | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |                     |          |          |        |

| DESCRIPTION | <p>These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, curses routines are more suitable and their use is recommended.</p> <p>Initially, <code>setupterm()</code> should be called. Note that <code>setupterm()</code> is automatically called by <code>initscr()</code> and <code>newterm()</code>. This defines the set of terminal-dependent variables (listed in <code>terminfo(4)</code>). The <i>terminfo</i> variables <code>lines</code> and <code>columns</code> are initialized by <code>setupterm()</code> as follows: If <code>use_env(FALSE)</code> has been called, values for <code>lines</code> and <code>columns</code> specified in <i>terminfo</i> are used. Otherwise, if the environment variables <code>LINES</code> and <code>COLUMNS</code> exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database are used.</p> <p>The headers <code>&lt;curses.h&gt;</code> and <code>&lt;term.h&gt;</code> should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through <code>tparm()</code> to instantiate them. All <i>terminfo</i> strings (including the output</p> |

of `tparm()` should be printed with `tputs()` or `putp()`. Call the `reset_shell_mode()` routine to restore the tty modes before exiting (see `curs_kernel(3CURSES)`). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call `reset_shell_mode` and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call `reset_prog_mode` after returning from the shell.

The `setupterm()` routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fildev* which is initialized for output. If *errret* is not null, then `setupterm()` returns OK or ERR and stores a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo* database could not be found. If *errret* is null, `setupterm()` prints an error message upon finding an error and exits. Thus, the simplest call is:

```
setupterm((char *)0, 1, (int *)0);
```

which uses all the defaults and sends the output to `stdout`.

The `setterm()` routine is being replaced by `setupterm()`. The call:

```
setupterm(term, 1, (int *)0)
```

provides the same functionality as `setterm(term)`. The `setterm()` routine is included here for compatibility and is supported at Level 2.

The `set_curterm()` routine sets the variable `cur_term` to *nterm*, and makes all of the *terminfo* boolean, numeric, and string variables use the values from *nterm*.

The `del_curterm()` routine frees the space pointed to by *oterm* and makes it available for further use. If *oterm* is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another `setupterm()` has been called.

The `restartterm()` routine is similar to `setupterm()` and `initscr()`, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The `tparm()` routine instantiates the string *str* with parameters *pi*. A pointer is returned to the result of *str* with the parameters applied.

The `tputs()` routine applies padding information to the string *str* and outputs it. The *str* must be a *terminfo* string variable or the return value from `tparm()`, `tgetstr()`, or `tgoto()`. *affcnt* is the number of lines affected, or 1 if not applicable. *putc* is a `putchar()`-like routine to which the characters are passed, one at a time.

## vidattr(3CURSES)

The `putp()` routine calls `tputs(str, 1, putchar)`. Note that the output of `putpA()` always goes to `stdout`, not to the *fildev* specified in `setupterm()`.

The `vidputs()` routine displays the string on the terminal in the video attribute mode *attrs*, which is any combination of the attributes listed in `curses(3CURSES)`. The characters are passed to the `putchar()`-like routine `putc()`.

The `vidattr()` routine is like the `vidputs()` routine, except that it outputs through `putchar()`.

The `mvcur()` routine provides low-level cursor motion.

The `tigetflag()`, `tigetnum()` and `tigetstr()` routines return the value of the capability corresponding to the *terminfo capname* passed to them, such as `xenl`.

With the `tigetflag()` routine, the value `-1` is returned if *capname* is not a boolean capability.

With the `tigetnum()` routine, the value `-2` is returned if *capname* is not a numeric capability.

With the `tigetstr()` routine, the value `(char *)-1` is returned if *capname* is not a string capability.

The *capname* for each capability is given in the table column entitled *capname* code in the capabilities section of `terminfo(4)`.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

## RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

## SEE ALSO

`curs_initscr(3CURSES)`, `curs_kernel(3CURSES)`, `curs_termcap(3CURSES)`, `curses(3CURSES)`, `putc(3C)`, `terminfo(4)`, `attributes(5)`

`vidattr(3CURSES)`

**NOTES** | The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

The `setupterm()` routine should be used in place of `setterm()`.

Note that `vidattr()` and `vidputs()` may be macros.

| <i>putfunc</i>           | Is a user-supplied output function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                            |                          |                  |            |                                                                     |                |                                     |
| <b>DESCRIPTION</b>       | <p>These functions output commands to the terminal that change the terminal's attributes.</p> <p>If the terminfo database indicates that the terminal in use can display characters in the rendition specified by <i>attr</i>, then <code>vidattr()</code> outputs one or more commands to request that the terminal display subsequent characters in that rendition. The function outputs by calling <code>putchar(3C)</code>. The <code>vidattr()</code> function neither relies on your updates the model which Curses maintains of the prior rendition mode.</p> <p>The <code>vidputs()</code> function computes the terminal output string that <code>vidattr()</code> does, based on <i>attr</i>, but <code>vidputs()</code> outputs by calling the user-supplied function <i>putfunc</i>. The <code>vid_attr()</code> and <code>vid_puts()</code> functions correspond to <code>vidattr()</code> and <code>vidputs()</code> respectively, but take a set of arguments, one of type <code>attr_t</code> for the attributes, one of type <code>short</code> for the color pair number, and a <code>void *</code>, and thus support the attribute constants with the <code>WA_</code> prefix.</p> <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, it is implemented as a null pointer.</p> <p>The user-supplied function <i>putfunc</i> (which can be specified as an argument to either <code>vidputs()</code> or <code>vid_puts()</code>) is either <code>putchar()</code> or some other function with the same prototype. Both the <code>vidputs()</code> and <code>vid_puts()</code> functions ignore the return value of <i>putfunc</i>.</p> |             |                                            |                          |                  |            |                                                                     |                |                                     |
| <b>RETURN VALUES</b>     | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |             |                                            |                          |                  |            |                                                                     |                |                                     |
| <b>ERRORS</b>            | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |             |                                            |                          |                  |            |                                                                     |                |                                     |

vid\_attr(3XCURSES)

**USAGE** After use of any of these functions, the model Curses maintains of the state of the terminal might not match the actual state of the terminal. The application should touch and refresh the window before resuming conventional use of Curses.

Of these functions requires that the application contain so much information about a particular class of terminal that it defeats the purpose of using Curses.

On some terminals, a command to change rendition conceptually occupies space in the screen buffer (with or without width). Thus, a command to set the terminal to a new rendition would change the rendition of some characters already displayed.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <i>putfunc</i>           | Is a user-supplied output function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                            |                          |                  |            |                                                                     |                |                                     |
| <b>DESCRIPTION</b>       | <p>These functions output commands to the terminal that change the terminal's attributes.</p> <p>If the terminfo database indicates that the terminal in use can display characters in the rendition specified by <i>attr</i>, then <code>vidattr()</code> outputs one or more commands to request that the terminal display subsequent characters in that rendition. The function outputs by calling <code>putchar(3C)</code>. The <code>vidattr()</code> function neither relies on your updates the model which Curses maintains of the prior rendition mode.</p> <p>The <code>vidputs()</code> function computes the terminal output string that <code>vidattr()</code> does, based on <i>attr</i>, but <code>vidputs()</code> outputs by calling the user-supplied function <i>putfunc</i>. The <code>vid_attr()</code> and <code>vid_puts()</code> functions correspond to <code>vidattr()</code> and <code>vidputs()</code> respectively, but take a set of arguments, one of type <code>attr_t</code> for the attributes, one of type <code>short</code> for the color pair number, and a <code>void *</code>, and thus support the attribute constants with the <code>WA_</code> prefix.</p> <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, it is implemented as a null pointer.</p> <p>The user-supplied function <i>putfunc</i> (which can be specified as an argument to either <code>vidputs()</code> or <code>vid_puts()</code>) is either <code>putchar()</code> or some other function with the same prototype. Both the <code>vidputs()</code> and <code>vid_puts()</code> functions ignore the return value of <i>putfunc</i>.</p> |             |                                            |                          |                  |            |                                                                     |                |                                     |
| <b>RETURN VALUES</b>     | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |             |                                            |                          |                  |            |                                                                     |                |                                     |
| <b>ERRORS</b>            | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |             |                                            |                          |                  |            |                                                                     |                |                                     |

vidattr(3XCURSES)

**USAGE** After use of any of these functions, the model Curses maintains of the state of the terminal might not match the actual state of the terminal. The application should touch and refresh the window before resuming conventional use of Curses.

Of these functions requires that the application contain so much information about a particular class of terminal that it defeats the purpose of using Curses.

On some terminals, a command to change rendition conceptually occupies space in the screen buffer (with or without width). Thus, a command to set the terminal to a new rendition would change the rendition of some characters already displayed.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>DESCRIPTION</b> | <p>These low-level routines must be called by programs that have to deal directly with the <i>terminfo</i> database to handle certain terminal capabilities, such as programming function keys. For all other functionality, curses routines are more suitable and their use is recommended.</p> <p>Initially, <code>setupterm()</code> should be called. Note that <code>setupterm()</code> is automatically called by <code>initscr()</code> and <code>newterm()</code>. This defines the set of terminal-dependent variables (listed in <code>terminfo(4)</code>). The <i>terminfo</i> variables <code>lines</code> and <code>columns</code> are initialized by <code>setupterm()</code> as follows: If <code>use_env(FALSE)</code> has been called, values for <code>lines</code> and <code>columns</code> specified in <i>terminfo</i> are used. Otherwise, if the environment variables <code>LINES</code> and <code>COLUMNS</code> exist, their values are used. If these environment variables do not exist and the program is running in a window, the current window size is used. Otherwise, if the environment variables do not exist, the values for <code>lines</code> and <code>columns</code> specified in the <i>terminfo</i> database are used.</p> <p>The headers <code>&lt;curses.h&gt;</code> and <code>&lt;term.h&gt;</code> should be included (in this order) to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through <code>tparm()</code> to instantiate them. All <i>terminfo</i> strings (including the output</p> |

of `tparm()` should be printed with `tputs()` or `putp()`. Call the `reset_shell_mode()` routine to restore the tty modes before exiting (see `curs_kernel(3CURSES)`). Programs which use cursor addressing should output `enter_ca_mode` upon startup and should output `exit_ca_mode` before exiting. Programs desiring shell escapes should call `reset_shell_mode` and output `exit_ca_mode` before the shell is called and should output `enter_ca_mode` and call `reset_prog_mode` after returning from the shell.

The `setupterm()` routine reads in the *terminfo* database, initializing the *terminfo* structures, but does not set up the output virtualization structures used by *curses*. The terminal type is the character string *term*; if *term* is null, the environment variable `TERM` is used. All output is to file descriptor *fildev* which is initialized for output. If *errret* is not null, then `setupterm()` returns OK or ERR and stores a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo* database could not be found. If *errret* is null, `setupterm()` prints an error message upon finding an error and exits. Thus, the simplest call is:

```
setupterm((char *)0, 1, (int *)0);
```

which uses all the defaults and sends the output to `stdout`.

The `setterm()` routine is being replaced by `setupterm()`. The call:

```
setupterm(term, 1, (int *)0)
```

provides the same functionality as `setterm(term)`. The `setterm()` routine is included here for compatibility and is supported at Level 2.

The `set_curterm()` routine sets the variable `cur_term` to *nterm*, and makes all of the *terminfo* boolean, numeric, and string variables use the values from *nterm*.

The `del_curterm()` routine frees the space pointed to by *oterm* and makes it available for further use. If *oterm* is the same as `cur_term`, references to any of the *terminfo* boolean, numeric, and string variables thereafter may refer to invalid memory locations until another `setupterm()` has been called.

The `restartterm()` routine is similar to `setupterm()` and `initscr()`, except that it is called after restoring memory to a previous state. It assumes that the windows and the input and output options are the same as when memory was saved, but the terminal type and baud rate may be different.

The `tparm()` routine instantiates the string *str* with parameters *pi*. A pointer is returned to the result of *str* with the parameters applied.

The `tputs()` routine applies padding information to the string *str* and outputs it. The *str* must be a *terminfo* string variable or the return value from `tparm()`, `tgetstr()`, or `tgoto()`. *affcnt* is the number of lines affected, or 1 if not applicable. *putc* is a `putchar()`-like routine to which the characters are passed, one at a time.

## vidputs(3CURSES)

The `putp()` routine calls `tputs(str, 1, putchar)`. Note that the output of `putpA()` always goes to `stdout`, not to the *fildev* specified in `setupterm()`.

The `vidputs()` routine displays the string on the terminal in the video attribute mode *attrs*, which is any combination of the attributes listed in `curses(3CURSES)`. The characters are passed to the `putchar()`-like routine `putc()`.

The `vidattr()` routine is like the `vidputs()` routine, except that it outputs through `putchar()`.

The `mvcur()` routine provides low-level cursor motion.

The `tigetflag()`, `tigetnum()` and `tigetstr()` routines return the value of the capability corresponding to the *terminfo capname* passed to them, such as `xenl`.

With the `tigetflag()` routine, the value `-1` is returned if *capname* is not a boolean capability.

With the `tigetnum()` routine, the value `-2` is returned if *capname* is not a numeric capability.

With the `tigetstr()` routine, the value `(char *)-1` is returned if *capname* is not a string capability.

The *capname* for each capability is given in the table column entitled *capname* code in the capabilities section of `terminfo(4)`.

```
char *boolnames, *boolcodes, *boolfnames
char *numnames, *numcodes, *numfnames
char *strnames, *strcodes, *strfnames
```

These null-terminated arrays contain the *capnames*, the *termcap* codes, and the full C names, for each of the *terminfo* variables.

## RETURN VALUES

All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

Routines that return pointers always return `NULL` on error.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

## SEE ALSO

`curs_initscr(3CURSES)`, `curs_kernel(3CURSES)`, `curs_termcap(3CURSES)`, `curses(3CURSES)`, `putc(3C)`, `terminfo(4)`, `attributes(5)`

`vidputs(3CURSES)`

**NOTES** | The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

The `setupterm()` routine should be used in place of `setterm()`.

Note that `vidattr()` and `vidputs()` may be macros.

## vid\_puts(3XCURSES)

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |             |                                            |                          |                  |            |                                                                     |                |                                     |

| <i>putfunc</i>           | Is a user-supplied output function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                            |                          |                  |            |                                                                     |                |                                     |
| <b>DESCRIPTION</b>       | <p>These functions output commands to the terminal that change the terminal's attributes.</p> <p>If the terminfo database indicates that the terminal in use can display characters in the rendition specified by <i>attr</i>, then <code>vidattr()</code> outputs one or more commands to request that the terminal display subsequent characters in that rendition. The function outputs by calling <code>putchar(3C)</code>. The <code>vidattr()</code> function neither relies on your updates the model which Curses maintains of the prior rendition mode.</p> <p>The <code>vidputs()</code> function computes the terminal output string that <code>vidattr()</code> does, based on <i>attr</i>, but <code>vidputs()</code> outputs by calling the user-supplied function <i>putfunc</i>. The <code>vid_attr()</code> and <code>vid_puts()</code> functions correspond to <code>vidattr()</code> and <code>vidputs()</code> respectively, but take a set of arguments, one of type <code>attr_t</code> for the attributes, one of type <code>short</code> for the color pair number, and a <code>void *</code>, and thus support the attribute constants with the <code>WA_</code> prefix.</p> <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, it is implemented as a null pointer.</p> <p>The user-supplied function <i>putfunc</i> (which can be specified as an argument to either <code>vidputs()</code> or <code>vid_puts()</code>) is either <code>putchar()</code> or some other function with the same prototype. Both the <code>vidputs()</code> and <code>vid_puts()</code> functions ignore the return value of <i>putfunc</i>.</p> |             |                                            |                          |                  |            |                                                                     |                |                                     |
| <b>RETURN VALUES</b>     | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |             |                                            |                          |                  |            |                                                                     |                |                                     |
| <b>ERRORS</b>            | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |             |                                            |                          |                  |            |                                                                     |                |                                     |

vid\_puts(3XCURSES)

**USAGE** After use of any of these functions, the model Curses maintains of the state of the terminal might not match the actual state of the terminal. The application should touch and refresh the window before resuming conventional use of Curses.

Of these functions requires that the application contain so much information about a particular class of terminal that it defeats the purpose of using Curses.

On some terminals, a command to change rendition conceptually occupies space in the screen buffer (with or without width). Thus, a command to set the terminal to a new rendition would change the rendition of some characters already displayed.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <i>putfunc</i>           | Is a user-supplied output function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                            |                          |                  |            |                                                                     |                |                                     |
| <b>DESCRIPTION</b>       | <p>These functions output commands to the terminal that change the terminal's attributes.</p> <p>If the terminfo database indicates that the terminal in use can display characters in the rendition specified by <i>attr</i>, then <code>vidattr()</code> outputs one or more commands to request that the terminal display subsequent characters in that rendition. The function outputs by calling <code>putchar(3C)</code>. The <code>vidattr()</code> function neither relies on your updates the model which Curses maintains of the prior rendition mode.</p> <p>The <code>vidputs()</code> function computes the terminal output string that <code>vidattr()</code> does, based on <i>attr</i>, but <code>vidputs()</code> outputs by calling the user-supplied function <i>putfunc</i>. The <code>vid_attr()</code> and <code>vid_puts()</code> functions correspond to <code>vidattr()</code> and <code>vidputs()</code> respectively, but take a set of arguments, one of type <code>attr_t</code> for the attributes, one of type <code>short</code> for the color pair number, and a <code>void *</code>, and thus support the attribute constants with the <code>WA_</code> prefix.</p> <p>The <i>opts</i> argument is reserved for definition in a future release. Currently, it is implemented as a null pointer.</p> <p>The user-supplied function <i>putfunc</i> (which can be specified as an argument to either <code>vidputs()</code> or <code>vid_puts()</code>) is either <code>putchar()</code> or some other function with the same prototype. Both the <code>vidputs()</code> and <code>vid_puts()</code> functions ignore the return value of <i>putfunc</i>.</p> |             |                                            |                          |                  |            |                                                                     |                |                                     |
| <b>RETURN VALUES</b>     | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |             |                                            |                          |                  |            |                                                                     |                |                                     |
| <b>ERRORS</b>            | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |             |                                            |                          |                  |            |                                                                     |                |                                     |

vidputs(3XCURSES)

**USAGE** After use of any of these functions, the model Curses maintains of the state of the terminal might not match the actual state of the terminal. The application should touch and refresh the window before resuming conventional use of Curses.

Of these functions requires that the application contain so much information about a particular class of terminal that it defeats the purpose of using Curses.

On some terminals, a command to change rendition conceptually occupies space in the screen buffer (with or without width). Thus, a command to set the terminal to a new rendition would change the rendition of some characters already displayed.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>DESCRIPTION</b>   | <p>The <code>hline()</code>, <code>vline()</code>, <code>whline()</code>, <code>wvline()</code> functions draw a horizontal or vertical line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>ch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>ch</code> is 0 (zero), the default horizontal or vertical character is used.</p> <p>The <code>mvhline()</code>, <code>mvvline()</code>, <code>mvwhline()</code>, <code>mvwvline()</code> functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code>.</p> <p>The functions with names ending with <code>hline()</code> draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with <code>vline()</code> draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |
| <b>PARAMETERS</b>    | <p><code>ch</code> Is the character used to draw the line.</p> <p><code>n</code> Is the maximum number of characters in the line.</p> <p><code>y</code> Is the y (row) coordinate for the start of the line.</p> <p><code>x</code> Is the x (column) coordinate for the start of the line.</p> <p><code>win</code> Is a pointer to a window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ERRORS</b>        | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>DESCRIPTION</b>   | <p>The <code>hline_set()</code>, <code>vline_set()</code>, <code>whline_set()</code>, <code>wvline_set()</code> functions draw a line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>wch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>wch</code> is a null pointer, the default horizontal or vertical character is used.</p> <p>The <code>mvhline_set()</code>, <code>mvvline_set()</code>, <code>mvwhline_set()</code>, <code>mvwvline_set()</code> functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code>.</p> <p>The functions with names ending with <code>hline_set()</code> draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with <code>vline_set()</code> draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |
| <b>PARAMETERS</b>    | <p><i>wch</i> Is the complex character used to draw the line.</p> <p><i>n</i> Is the maximum number of characters in the line.</p> <p><i>y</i> Is the y (row) coordinate for the start of the line.</p> <p><i>x</i> Is the x (column) coordinate for the start of the line.</p> <p><i>win</i> Is a pointer to a window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## vwprintw(3CURSES)

| <b>NAME</b>          | <code> curs_printw, printw, wprintw, mvprintw, mvwprintw, vwprintw </code> – print formatted output in curses windows                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lcurses [ <i>library</i> ... ] #include &lt;curses.h&gt;  int <b>printw</b>(char *<i>fmt</i>, /* <i>arg</i> */ ... ); int <b>wprintw</b>(WINDOW *<i>win</i>, char *<i>fmt</i>, /* <i>arg</i> */ ... ); int <b>mvprintw</b>(int <i>y</i>, int <i>x</i>, char *<i>fmt</i>, /* <i>arg</i> */ ... ); int <b>mvwprintw</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, char *<i>fmt</i>, /* <i>arg</i> */ ... ); #include &lt;varargs.h&gt; int <b>vwprintw</b>(WINDOW *<i>win</i>, char *<i>fmt</i>, /* <i>varglist</i> */ ... );</pre>                                                                                      |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>printw()</code>, <code>wprintw()</code>, <code>mvprintw()</code>, and <code>mvwprintw()</code> routines are analogous to <code>printf()</code> (see <code>printf(3C)</code>). In effect, the string that would be output by <code>printf()</code> is output instead as though <code>waddstr()</code> were used on the given window.</p> <p>The <code>vwprintw()</code> routine is analogous to <code>vprintf()</code> (see <code>vprintf(3C)</code>) and performs a <code>wprintw()</code> using a variable argument list. The third argument is a <code>va_list</code>, a pointer to a list of arguments, as defined in <code>&lt;varargs.h&gt;</code>.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |

| <b>NOTES</b>         | The header <code>&lt;curses.h&gt;</code> automatically includes the headers <code>&lt;stdio.h&gt;</code> and <code>&lt;unctrl.h&gt;</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |          |        |

| <b>NAME</b>          | vw_printw – print formatted output in window                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;stdarg.h&gt; #include &lt;curses.h&gt;  int vw_printw(WINDOW *win, char *fmt, va_list varlist);</pre> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>fmt</i> Is a printf() format string.</p> <p><i>varlist</i> Is a pointer to a list of parameters.</p> <p><i>win</i> Is a pointer to the window in which the string is to be written.</p>                                                                                     |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | The vw_printw() function achieves the same effect as wprintw(3XCURSES) using a variable argument list. The third argument is a va_list, as defined in <stdarg.h>.                                                                                                                 |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | Upon successful completion, vw_printw() returns OK. Otherwise, it returns ERR.                                                                                                                                                                                                    |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |
| <b>USAGE</b>         | The vw_printw() function is preferred over wprintw(3XCURSES). The use of the wprintw() and vw_printw() in the same file will not work, due to the requirements to include <varargs.h> and <stdarg.h>, which both contain definitions of va_list.                                  |                |                 |                     |          |          |        |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                   |                |                 |                     |          |          |        |

| <i>fmt</i>          | Is a printf() format string.                                                                                                                                                                                                                                                             |                |                              |                     |                                       |            |                                                                  |
| <i>varlist</i>      | Is a pointer to a list of parameters.                                                                                                                                                                                                                                                    |                |                              |                     |                                       |            |                                                                  |
| <i>win</i>          | Is a pointer to the window in which the string is to be written.                                                                                                                                                                                                                         |                |                              |                     |                                       |            |                                                                  |
| DESCRIPTION         | The vwprintw() function achieves the same effect as wprintw(3XCURSES) using a variable argument list. The third argument is a va_list, as defined in <varargs.h>.                                                                                                                        |                |                              |                     |                                       |            |                                                                  |
| RETURN VALUES       | Upon successful completion, vwprintw() returns OK. Otherwise, it returns ERR.                                                                                                                                                                                                            |                |                              |                     |                                       |            |                                                                  |
| ERRORS              | No errors are defined.                                                                                                                                                                                                                                                                   |                |                              |                     |                                       |            |                                                                  |
| USAGE               | The vwprintw() function is deprecated; the vw_printw(3XCURSES) function is preferred. The use of the vwprintw() and vw_printw() in the same file will not work, due to the requirements to include <varargs.h> and <stdarg.h>, which both contain definitions of va_list.                |                |                              |                     |                                       |            |                                                                  |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>scanw</b>(char *fmt, /* arg */ ...); int <b>wscanw</b>(WINDOW *win, char *fmt, /* arg */ ...); int <b>mvscanw</b>(int y, int x, char *fmt, /* arg */ ...); int <b>mvwscanw</b>(WINDOW *win, int y, int x, char *fmt, /* arg */...); int <b>vwscanw</b>(WINDOW *win, char *fmt, va_list varlist);</pre>                                                                                                                                                                                                                                                                               |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>scanw()</code>, <code>wscanw()</code>, and <code>mvscanw()</code> routines correspond to <code>scanf()</code> (see <code>scanf(3C)</code>). The effect of these routines is as though <code>wgetstr()</code> were called on the window, and the resulting line used as input for the scan. Fields which do not map to a variable in the <code>fmt</code> field are lost.</p> <p>The <code>vwscanw()</code> routine is similar to <code>vwprintw()</code> in that it performs a <code>wscanw()</code> using a variable argument list. The third argument is a <i>va_list</i>, a pointer to a list of arguments, as defined in <code>&lt;varargs.h&gt;</code>.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | <p><code>vwscanw()</code> returns <code>ERR</code> on failure and an integer equal to the number of fields scanned on success.</p> <p>Applications may interrogate the return value from the <code>scanw</code>, <code>wscanw()</code>, <code>mvscanw()</code>, and <code>mvwscanw()</code> routines to determine the number of fields which were mapped in the call.</p>                                                                                                                                                                                                                                                                                                     |                |                 |          |        |
| <b>ATTRIBUTES</b>    | <p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>MT-Level</td><td>Unsafe</td></tr> </tbody> </table>                                                                                                                                                                                                                                                                                                                                                                                                                        | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| MT-Level             | Unsafe                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |
| <b>SEE ALSO</b>      | <code>curs_getstr(3CURSES)</code> , <code>curs_printw(3CURSES)</code> , <code>curses(3CURSES)</code> , <code>scanf(3C)</code> , <code>attributes(5)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |
| <b>NOTES</b>         | The header <code>&lt;curses.h&gt;</code> automatically includes the headers <code>&lt;stdio.h&gt;</code> and <code>&lt;unctrl.h&gt;</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |          |        |

## vw\_scanw(3XCURSES)

| <b>NAME</b>          | vw_scanw – convert formatted input from a window                                                                                                                                                                                                                                 |                |                             |                     |                                       |            |                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------------------|---------------------|---------------------------------------|------------|------------------------------------------------------------------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;stdarg.h&gt; #include &lt;curses.h&gt;  int vw_scanw(WINDOW *win, char *fmt, va_list varlist);</pre> |                |                             |                     |                                       |            |                                                                  |
| <b>PARAMETERS</b>    | <table><tr><td><i>fmt</i></td><td>Is a scanf() format string.</td></tr><tr><td><i>varlist</i></td><td>Is a pointer to a list of parameters.</td></tr><tr><td><i>win</i></td><td>Is a pointer to the window in which the character is to be read.</td></tr></table>               | <i>fmt</i>     | Is a scanf() format string. | <i>varlist</i>      | Is a pointer to a list of parameters. | <i>win</i> | Is a pointer to the window in which the character is to be read. |
| <i>fmt</i>           | Is a scanf() format string.                                                                                                                                                                                                                                                      |                |                             |                     |                                       |            |                                                                  |
| <i>varlist</i>       | Is a pointer to a list of parameters.                                                                                                                                                                                                                                            |                |                             |                     |                                       |            |                                                                  |
| <i>win</i>           | Is a pointer to the window in which the character is to be read.                                                                                                                                                                                                                 |                |                             |                     |                                       |            |                                                                  |
| <b>DESCRIPTION</b>   | The vw_scanw() function achieves the same effect as wscanw(3XCURSES) using a variable argument list. The third argument is a va_list, as defined in <stdarg.h>.                                                                                                                  |                |                             |                     |                                       |            |                                                                  |
| <b>RETURN VALUES</b> | Upon successful completion, vw_scanw() returns OK. Otherwise, it returns ERR.                                                                                                                                                                                                    |                |                             |                     |                                       |            |                                                                  |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                           |                |                             |                     |                                       |            |                                                                  |
| <b>USAGE</b>         | The vw_scanw() function is preferred over vwscanw(3XCURSES). The use of the vwscanw() and vw_scanw() in the same file will not work, due to the requirements to include <varargs.h> and <stdarg.h>, which both contain definitions of va_list.                                   |                |                             |                     |                                       |            |                                                                  |

| <b>NAME</b>          | vwscanw – convert formatted input from a window                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;varargs.h&gt; #include &lt;curses.h&gt;  int <b>vwscanw</b>(WINDOW *win, char *fmt, va_list varlist);</pre> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>fmt</i> Is a scanf () format string.</p> <p><i>varlist</i> Is a pointer to a list of parameters.</p> <p><i>win</i> Is a pointer to the window in which the character is to be read.</p>                                                                                           |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | The vwscanw () function achieves the same effect as wscanw(3XCURSES) using a variable argument list. The third argument is a va_list, as defined in <varargs.h>.                                                                                                                        |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | Upon successful completion, vwscanw () returns OK. Otherwise, it returns ERR.                                                                                                                                                                                                           |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>USAGE</b>         | The vwscanw () function is deprecated; the vw_scanw(3XCURSES) function is preferred. The use of the vwscanw () and vw_scanw () in the same file will not work, due to the requirements to include <varargs.h> and <stdarg.h>, which both contain definitions of va_list.                |                |                 |                     |          |          |        |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                         |                |                 |                     |          |          |        |

| NAME          | <code> curs_addch, addch, waddch, mvaddch, mvwaddch, echochar, wechochar </code> – add a character (with attributes) to a curses window and advance cursor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| DESCRIPTION   | <p>With the <code>addch()</code>, <code>waddch()</code>, <code>mvaddch()</code>, and <code>mvwaddch()</code> routines, the character <code>ch</code> is put into the window at the current cursor position of the window and the position of the window cursor is advanced. Its function is similar to that of <code>putchar()</code>. At the right margin, an automatic newline is performed. At the bottom of the scrolling region, if <code>scrollok()</code> is enabled, the scrolling region is scrolled up one line.</p> <p>If <code>ch</code> is a tab, newline, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol()</code> before moving. Tabs are considered to be at every eighth column. If <code>ch</code> is another control character, it is drawn in the <code>^X</code> notation. Calling <code>winch()</code> after adding a control character does not return the control character, but instead returns the representation of the control character. See <code>curs_inch(3CURSES)</code>.</p> <p>Video attributes can be combined with a character by OR-ing them into the parameter. This results in these attributes also being set. (The intent here is that text, including attributes, can be copied from one place to another using <code>inch()</code> and <code>addch()</code>.) (see <code>standout()</code>, predefined video attribute constants, on the <code>curs_attr(3CURSES)</code> page).</p> <p>The <code>echochar()</code> and <code>wechochar()</code> routines are functionally equivalent to a call to <code>addch()</code> followed by a call to <code>refresh()</code>, or a call to <code>waddch</code> followed by a call to <code>wrefresh()</code>. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents.</p> |
| Line Graphics | <p>The following variables may be used to add line drawing characters to the screen with routines of the <code>addch()</code> family. When variables are defined for the terminal, the <code>A_ALTCHARSET</code> bit is turned on (see <code>curs_attr(3CURSES)</code>). Otherwise, the default character listed below is stored in the variable. The names chosen are consistent with the VT100 nomenclature.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## RETURN VALUES

All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.

waddch(3CURSES)

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curs\_attr(3CURSES), curs\_clear(3CURSES), curs\_inch(3CURSES), curs\_outopts(3CURSES), curs\_refresh(3CURSES), curses(3CURSES), putc(3C), attributes(5)

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `addch()`, `mvaddch()`, `mvwaddch()`, and `echochar()` may be macros.

| DESCRIPTION   | <p>The <code>addch()</code> function writes a character to the <code>stdscr</code> window at the current cursor position. The <code>mvaddch()</code> and <code>mvwaddch()</code> functions write the character to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters. The <code>mvaddch()</code> function writes the character to the <code>stdscr</code> window, while <code>mvwaddch()</code> writes the character to the window specified by <i>win</i>. The <code>waddch()</code> function is identical to <code>addch()</code>, but writes the character to the window specified by <i>win</i>.</p> <p>These functions advance the cursor after writing the character. Characters that do not fit on the end of the current line are wrapped to the beginning of the next line unless the current line is the last line of the window and scrolling is disabled. In that situation, characters which extend beyond the end of the line are discarded.</p> <p>When <i>ch</i> is a backspace, carriage return, newline, or tab, X/Open Curses moves the cursor appropriately. Each tab character moves the cursor to the next tab stop. By default, tab stops occur every eight columns. When <i>ch</i> is a control character other than backspace, carriage return, newline, or tab, it is written using <code>^x</code> notation, where <i>x</i> is a printable character. When X/Open Curses writes <i>ch</i> to the last character position on a line, it automatically generates a newline. When <i>ch</i> is written to the last character position of a scrolling region and <code>scrollok()</code> is enabled, X/Open Curses scrolls the scrolling region up one line (see <code>clearok(3XCURSES)</code>).</p> |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |          |                                                                                              |            |                                                                 |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int addchstr(chtype *chstr); int addchnstr(chtype *chstr, int n); int waddchstr(WINDOW *win, chtype *chstr); int waddchnstr(WINDOW *win, chtype *chstr, int n); int mvaddchstr(int y, int x, chtype *chstr); int mvaddchnstr(int y, int x, chtype *chstr, int n); int mvwaddchstr(WINDOW *win, int y, int x, chtype *chstr); int mvwaddchnstr(WINDOW *win, int y, int x, chtype *chstr, int n);</pre>                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>All of these routines copy <i>chstr</i> directly into the window image structure starting at the current cursor position. The four routines with <i>n</i> as the last argument copy at most <i>n</i> elements, but no more than will fit on the line. If <i>n</i>=-1 then the whole string is copied, to the maximum number that fit on the line.</p> <p>The position of the window cursor is not advanced. These routines works faster than <code>waddnstr()</code> (see <code>curs_addstr(3CURSES)</code>) because they merely copy <i>chstr</i> into the window image structure. On the other hand, care must be taken when using these functions because they do not perform any kind of checking (such as for the newline character), they do not advance the current cursor position, and they truncate the string, rather than wrapping it around to the next line.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |

| <b>DESCRIPTION</b>   | <p>The <code>addchstr()</code> function copies the <code>chtype</code> character string to the <code>stdscr</code> window at the current cursor position. The <code>mvaddchstr()</code> and <code>mvwaddchstr()</code> functions copy the character string to the starting position indicated by the <code>x</code> (column) and <code>y</code> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <code>win</code>). The <code>waddchstr()</code> is identical to <code>addchstr()</code>, but writes to the window specified by <code>win</code>.</p> <p>The <code>addchnstr()</code>, <code>waddchnstr()</code>, <code>mvaddchnstr()</code>, and <code>mvwaddchnstr()</code> functions write <code>n</code> characters to the window, or as many as will fit on the line. If <code>n</code> is less than 0, the entire string is written, or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <code>x</code> and <code>y</code> parameters.</p> <p>These functions differ from the <code>addstr(3XCURSES)</code> set of functions in two important respects. First, these functions do <i>not</i> advance the cursor after writing the string to the window. Second, the current window rendition is not combined with the character; only the attributes that are already part of the <code>chtype</code> character are used.</p> |              |                                                                            |          |                                                                                                                                                                     |          |                                                                                          |          |                                                                                             |            |                                                                 |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int  addchstr(chtype *chstr); int  addchnstr(chtype *chstr, int n); int  waddchstr(WINDOW *win, chtype *chstr); int  waddchnstr(WINDOW *win, chtype *chstr, int n); int  mvaddchstr(int y, int x, chtype *chstr); int  mvaddchnstr(int y, int x, chtype *chstr, int n); int  mvwaddchstr(WINDOW *win, int y, int x, chtype *chstr); int  mvwaddchnstr(WINDOW *win, int y, int x, chtype *chstr, int n);</pre>                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |
| DESCRIPTION    | <p>All of these routines copy <i>chstr</i> directly into the window image structure starting at the current cursor position. The four routines with <i>n</i> as the last argument copy at most <i>n</i> elements, but no more than will fit on the line. If <i>n</i>=-1 then the whole string is copied, to the maximum number that fit on the line.</p> <p>The position of the window cursor is not advanced. These routines works faster than <code>waddnstr()</code> (see <code>curs_addstr(3CURSES)</code>) because they merely copy <i>chstr</i> into the window image structure. On the other hand, care must be taken when using these functions because they do not perform any kind of checking (such as for the newline character), they do not advance the current cursor position, and they truncate the string, rather than wrapping it around to the next line.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |

| DESCRIPTION   | <p>The <code>addchstr()</code> function copies the <code>chtype</code> character string to the <code>stdscr</code> window at the current cursor position. The <code>mvaddchstr()</code> and <code>mvwaddchstr()</code> functions copy the character string to the starting position indicated by the <code>x</code> (column) and <code>y</code> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <code>win</code>). The <code>waddchstr()</code> is identical to <code>addchstr()</code>, but writes to the window specified by <code>win</code>.</p> <p>The <code>addchnstr()</code>, <code>waddchnstr()</code>, <code>mvaddchnstr()</code>, and <code>mvwaddchnstr()</code> functions write <code>n</code> characters to the window, or as many as will fit on the line. If <code>n</code> is less than 0, the entire string is written, or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <code>x</code> and <code>y</code> parameters.</p> <p>These functions differ from the <code>addstr(3XCURSES)</code> set of functions in two important respects. First, these functions do <i>not</i> advance the cursor after writing the string to the window. Second, the current window rendition is not combined with the character; only the attributes that are already part of the <code>chtype</code> character are used.</p> |
| PARAMETERS    | <p><i>chstr</i> Is a pointer to the <code>chtype</code> string to be copied to the window.</p> <p><i>n</i> Is the maximum number of characters to be copied from <i>chstr</i>. If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line.</p> <p><i>y</i> Is the <i>y</i> (row) coordinate of the starting position of <i>chstr</i> in the window.</p> <p><i>x</i> Is the <i>x</i> (column) coordinate of the starting position of <i>chstr</i> in the window.</p> <p><i>win</i> Is a pointer to the window to which the string is to be copied.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| RETURN VALUES | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

waddchstr(3XCURSES)

**ERRORS** None.

| <b>SYNOPSIS</b>      | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lcurses [ <i>library</i> ... ] #include &lt;curses.h&gt;  int <b>addstr</b>(char *<i>str</i>); int <b>addnstr</b>(char *<i>str</i>, int <i>n</i>); int <b>waddstr</b>(WINDOW *<i>win</i>, char *<i>str</i>); int <b>waddnstr</b>(WINDOW *<i>win</i>, char *<i>str</i>, int <i>n</i>); int <b>mvaddstr</b>(int <i>y</i>, int <i>x</i>, char *<i>str</i>); int <b>mvaddnstr</b>(int <i>y</i>, int <i>x</i>, char *<i>str</i>, int <i>n</i>); int <b>mvwaddstr</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, char *<i>str</i>); int <b>mvwaddnstr</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, char *<i>str</i>, int <i>n</i>);</pre> |                |                 |          |        |
| <b>DESCRIPTION</b>   | All of these routines write all the characters of the null terminated character string <i>str</i> on the given window. It is similar to calling <code>waddch()</code> once for each character in the string. The four routines with <i>n</i> as the last argument write at most <i>n</i> characters. If <i>n</i> is negative, then the entire string will be added.                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |

| <b>NAME</b>        | addnstr, addstr, mvaddnstr, mvaddstr, mvwaddnstr, mvwaddstr, waddnstr, waddstr – add a multi-byte character string (without rendition) to a window                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>DESCRIPTION</b> | <p>The <code>addstr()</code> function writes a null-terminated string of multi-byte characters to the <code>stdscr</code> window at the current cursor position. The <code>waddstr()</code> function performs an identical action, but writes the character to the window specified by <i>win</i>. The <code>mvaddstr()</code> and <code>mvwaddstr()</code> functions write the string to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The <code>addnstr()</code>, <code>waddnstr()</code>, <code>mvaddnstr()</code>, and <code>mvwaddnstr()</code> functions are similar but write at most <i>n</i> characters to the window. If <i>n</i> is less than 0, the entire string is written.</p> <p>All of these functions advance the cursor after writing the string.</p> <p>These functions are functionally equivalent to calling the corresponding function from the <code>addch(3XCURSES)</code> set of functions once for each character in the string. Refer to the <code>curses(3XCURSES)</code> man page for a complete description of special character handling and of the interaction between the window rendition (or background character and rendition) and the character written.</p> <p>Note that these functions differ from the <code>addchstr()</code> set of functions in that the <code>addchstr(3XCURSES)</code> functions copy the string as is (without combining each character with the window rendition or the background character and rendition).</p> |
| <b>PARAMETERS</b>  | <p><i>str</i> Is a pointer to the character string that is to be written to the window.</p> <p><i>n</i> Is the maximum number of characters to be copied from <i>str</i>. If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line.</p> <p><i>y</i> Is the <i>y</i> (row) coordinate of the starting position of <i>str</i> in the window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

waddnstr(3XCURSES)

*x* Is the x (column) coordinate of the starting position of *str* in the window.

*win* Is a pointer to the window in which the string is to be written.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

## waddnwstr(3CURSES)

| <b>NAME</b>         | <code>curs_addwstr</code> , <code>addwstr</code> , <code>addnwstr</code> , <code>waddwstr</code> , <code>waddnwstr</code> , <code>mvaddwstr</code> , <code>mvaddnwstr</code> , <code>mvwaddwstr</code> , <code>mvwaddnwstr</code> – add a string of <code>wchar_t</code> characters to a curses window and advance cursor                                                                                                                                                        |                |                 |          |        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>     | <pre>cc [flag...] file... -lcurses [library...]  #include&lt;curses.h&gt;  int  addwstr(wchar_t *wstr); int  addnwstr(wchar_t *wstr, int n); int  waddwstr(WINDOW *win, wchar_t *wstr); int  waddnwstr(WINDOW *win, wchar_t *wstr, int n); int  mvaddwstr(int y, int x, wchar_t *wstr); int  mvaddnwstr(int y, int x, wchar_t *wstr, int n); int  mvwaddwstr(WINDOW *win, int y, int x, wchar_t *wstr); int  mvwaddnwstr(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre> |                |                 |          |        |
| <b>DESCRIPTION</b>  | All of these routines write all the characters of the null-terminated <code>wchar_t</code> character string <code>wstr</code> on the given window. The effect is similar to calling <code>waddwch(3CURSES)</code> once for each <code>wchar_t</code> character in the string. The four routines with <code>n</code> as the last argument write at most <code>n</code> <code>wchar_t</code> characters. If <code>n</code> is negative, then the entire string will be added.      |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                       |                |                 |          |        |
| <b>ATTRIBUTES</b>   | See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>MT-Level</td><td>Unsafe</td></tr> </tbody> </table>                                                                                                                                                                                                                                  | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| DESCRIPTION | <p>The <code>addwstr()</code> function writes a null-terminated wide-character string to the <code>stdscr</code> window at the current cursor position. The <code>waddwstr()</code> function performs an identical action, but writes the string to the window specified by <code>win</code>. The <code>mvaddwstr()</code> and <code>mvwaddwstr()</code> functions write the string to the position indicated by the <code>x</code> (column) and <code>y</code> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <code>win</code>).</p> <p>The <code>addnwstr()</code>, <code>waddnwstr()</code>, <code>mvaddnwstr()</code>, and <code>mvwaddnwstr()</code> functions write at most <code>n</code> characters to the window. If <code>n</code> is less than 0, the entire string is written. The former two functions place the characters at the current cursor position; the latter two commands use the position specified by the <code>x</code> and <code>y</code> parameters.</p> <p>All of these functions advance the cursor after writing the string.</p> <p>These functions are functionally equivalent to building a <code>cchar_t</code> from the <code>wchar_t</code> and the window rendition (or background character and rendition) and calling the <code>wadd_wch(3XCURSES)</code> function once for each <code>wchar_t</code> in the string. Refer to the <code>curses(3XCURSES)</code> man page for a complete description of special character handling and of the interaction between the window rendition (or background character and rendition) and the character written.</p> <p>Note that these functions differ from the <code>add_wchnstr(3XCURSES)</code> set of functions in that the latter copy the string as is (without combining each character with the foreground and background attributes of the window).</p> |
| PARAMETERS  | <p><i>wstr</i>        Is a pointer to the wide-character string that is to be written to the window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

waddnwstr(3XCURSES)

|            |                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>   | Is the maximum number of characters to be copied from <i>wstr</i> . If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line. |
| <i>y</i>   | Is the y (row) coordinate of the starting position of <i>wstr</i> in the window.                                                                                   |
| <i>x</i>   | Is the x (column) coordinate of the starting position of <i>wstr</i> in the window.                                                                                |
| <i>win</i> | Is a pointer to the window in which the string is to be written.                                                                                                   |

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>SYNOPSIS</b>      | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lcurses [ <i>library</i> ... ] #include &lt;curses.h&gt;  int <b>addstr</b>(char *<i>str</i>); int <b>addnstr</b>(char *<i>str</i>, int <i>n</i>); int <b>waddstr</b>(WINDOW *<i>win</i>, char *<i>str</i>); int <b>waddnstr</b>(WINDOW *<i>win</i>, char *<i>str</i>, int <i>n</i>); int <b>mvaddstr</b>(int <i>y</i>, int <i>x</i>, char *<i>str</i>); int <b>mvaddnstr</b>(int <i>y</i>, int <i>x</i>, char *<i>str</i>, int <i>n</i>); int <b>mvwaddstr</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, char *<i>str</i>); int <b>mvwaddnstr</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, char *<i>str</i>, int <i>n</i>);</pre> |                |                 |          |        |
| <b>DESCRIPTION</b>   | All of these routines write all the characters of the null terminated character string <i>str</i> on the given window. It is similar to calling <code>waddch()</code> once for each character in the string. The four routines with <i>n</i> as the last argument write at most <i>n</i> characters. If <i>n</i> is negative, then the entire string will be added.                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |

| <b>DESCRIPTION</b> | <p>The <code>addstr()</code> function writes a null-terminated string of multi-byte characters to the <code>stdscr</code> window at the current cursor position. The <code>waddstr()</code> function performs an identical action, but writes the character to the window specified by <i>win</i>. The <code>mvaddstr()</code> and <code>mvwaddstr()</code> functions write the string to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The <code>addnstr()</code>, <code>waddnstr()</code>, <code>mvaddnstr()</code>, and <code>mvwaddnstr()</code> functions are similar but write at most <i>n</i> characters to the window. If <i>n</i> is less than 0, the entire string is written.</p> <p>All of these functions advance the cursor after writing the string.</p> <p>These functions are functionally equivalent to calling the corresponding function from the <code>addch(3XCURSES)</code> set of functions once for each character in the string. Refer to the <code>curses(3XCURSES)</code> man page for a complete description of special character handling and of the interaction between the window rendition (or background character and rendition) and the character written.</p> <p>Note that these functions differ from the <code>addchstr()</code> set of functions in that the <code>addchstr(3XCURSES)</code> functions copy the string as is (without combining each character with the window rendition or the background character and rendition).</p> |
| <b>PARAMETERS</b>  | <p><i>str</i> Is a pointer to the character string that is to be written to the window.</p> <p><i>n</i> Is the maximum number of characters to be copied from <i>str</i>. If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line.</p> <p><i>y</i> Is the <i>y</i> (row) coordinate of the starting position of <i>str</i> in the window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

waddstr(3XCURSES)

*x* Is the x (column) coordinate of the starting position of *str* in the window.

*win* Is a pointer to the window in which the string is to be written.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>DESCRIPTION</b>   | <p>           The <code>addwch()</code>, <code>waddwch()</code>, <code>mvaddwch()</code>, and <code>mvwaddwch()</code> routines put the character <i>wch</i>, holding a <code>wchar_t</code> character, into the window at the current cursor position of the window and advance the position of the window cursor. Their function is similar to that of <code>putwchar(3C)</code> in the C multibyte library. At the right margin, an automatic newline is performed. At the bottom of the scrolling region, if <code>scrollok</code> is enabled, the scrolling region is scrolled up one line.         </p> <p>           If <i>wch</i> is a tab, newline, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol(3CURSES)</code> before moving. Tabs are considered to be at every eighth column. If <i>wch</i> is another control character, it is drawn in the <code>^X</code> notation. Calling <code>winwch(3CURSES)</code> after adding a control character does not return the control character, but instead returns the representation of the control character.         </p> <p>           Video attributes can be combined with a <code>wchar_t</code> character by OR-ing them into the parameter. This results in these attributes also being set. (The intent here is that text, including attributes, can be copied from one place to another using <code>inwch()</code> and <code>addwch()</code>.) See <code>standout(3CURSES)</code>, predefined video attribute constants.         </p> <p>           The <code>echowchar()</code> and <code>wechowchar()</code> routines are functionally equivalent to a call to <code>addwch()</code> followed by a call to <code>refresh(3CURSES)</code>, or a call to <code>waddwch()</code> followed by a call to <code>wrefresh(3CURSES)</code>. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents.         </p> |
| <b>Line Graphics</b> | <p>           The following variables may be used to add line drawing characters to the screen with routines of the <code>addwch()</code> family. When variables are defined for the terminal, the <code>A_ALTCHARSET</code> bit is turned on. (See <code>curl_attr(3CURSES)</code>). Otherwise, the default character listed below is stored in the variable. The names chosen are consistent with the VT100 nomenclature.         </p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## RETURN VALUE

All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.

waddwch(3CURSES)

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** putwchar(3C), clrtoeol(3CURSES), curses(3CURSES), curs\_attr(3CURSES), curs\_inwch(3CURSES), curs\_outopts(3CURSES), refresh(3CURSES), standout(3CURSES), winwch(3CURSES), wrefresh(3CURSES), attributes(5)

**NOTES** The header file <curses.h> automatically includes the header files <stdio.h>, <unctrl.h> and <wdec.h>.

Note that addwch(), mvaddwch(), mvwaddwch(), and echowchar() may be macros.

None of these routines can use the color attribute in chtype.

| <b>DESCRIPTION</b> | <p>The <code>add_wch()</code> function writes a complex character to the <code>stdscr</code> window at the current cursor position. The <code>mvadd_wch()</code> and <code>mvwadd_wch()</code> functions write the character to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters. The <code>mvadd_wch()</code> function writes the character to the <code>stdscr</code> window, while <code>mvwadd_wch()</code> writes the character to the window specified by <i>win</i>. The <code>wadd_wch()</code> function is identical to <code>add_wch()</code>, but writes the character to the window specified by <i>win</i>. These functions advance the cursor after writing the character.</p> <p>If <i>wch</i> is a spacing complex character, X/Open Curses replaces any previous character at the specified location with <i>wch</i> (and its rendition). If <i>wch</i> is a non-spacing complex character, X/Open Curses preserves all existing characters at the specified location and adds the non-spacing characters of <i>wch</i> to the spacing complex character. It ignores the rendition associated with <i>wch</i>.</p> <p>Characters that do not fit on the end of the current line are wrapped to the beginning of the next line unless the current line is the last line of the window and scrolling is disabled. In that situation, X/Open Curses discards characters which extend beyond the end of the line.</p> <p>When <i>wch</i> is a backspace, carriage return, newline, or tab, X/Open Curses moves the cursor appropriately as described in the <code>curses(3XCURSES)</code> man page. Each tab character moves the cursor to the next tab stop. By default, tab stops occur every eight columns. When <i>wch</i> is a control character other than a backspace, carriage return, newline, or tab, it is written using <code>^x</code> notation, where <i>x</i> is a printable character. When X/Open Curses writes <i>wch</i> to the last character position on a line, it automatically generates a newline. When <i>wch</i> is written to the last character position of a scrolling region and <code>scrollok()</code> is enabled, X/Open Curses scrolls the scrolling region up one line (see <code>clearok(3XCURSES)</code>).</p> |
| <b>PARAMETERS</b>  | <p><i>wch</i>        Is the character/attribute pair (rendition) to be written to the window.</p> <p><i>win</i>        Is a pointer to the window in which the character is to be written.</p> <p><i>y</i>           Is the <i>y</i> (row) coordinate of the character's position in the window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

wadd\_wch(3XCURSES)

*x* Is the *x* (column) coordinate of the character's position in the window.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| <b>SYNOPSIS</b>     | <pre>cc [flag...] file... -lcurses [library...]  #include&lt;curses.h&gt;  int  addwchstr(chtype *wchstr); int  addwchnstr(chtype *wchstr, int n); int  waddwchstr(WINDOW *win, chtype *wchstr); int  waddwchnstr(WINDOW *win, chtype *wchstr, int n); int  mvaddwchstr(int y, int x, chtype *wchstr); int  mvaddwchnstr(int y, int x, chtype *wchstr, int n); int  mvwaddwchstr(WINDOW *win, int y, int x, chtype *wchstr); int  mvwaddwchnstr(WINDOW *win, int y, int x, chtype *wchstr, int     n);</pre>                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |
| <b>DESCRIPTION</b>  | <p>All of these routines copy <i>wchstr</i>, which points to a string of <code>wchar_t</code> characters, directly into the window image structure starting at the current cursor position. The four routines with <i>n</i> as the last argument copy at most <i>n</i> elements, but no more than will fit on the line. If <i>n</i>=-1 then the whole string is copied, to the maximum number that fit on the line.</p> <p>The position of the window cursor is not advanced. These routines work faster than <code>waddnwstr(3CURSES)</code> because they merely copy <i>wchstr</i> into the window image structure. On the other hand, care must be taken when using these functions because they don't perform any kind of checking (such as for the newline character), they do not advance the current cursor position, and they truncate the string, rather than wrapping it around to the new line.</p> |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion, unless otherwise noted in the preceding routine descriptions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |          |        |

| DESCRIPTION   | <p>The <code>add_wchstr()</code> function copies the string of <code>cchar_t</code> characters to the <code>stdscr</code> window at the current cursor position. The <code>mvadd_wchstr()</code> and <code>mvwadd_wchstr()</code> functions copy the string to the starting position indicated by the <code>x</code> (column) and <code>y</code> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <code>win</code>). The <code>wadd_wchstr()</code> is identical to <code>add_wchstr()</code>, but writes to the window specified by <code>win</code>.</p> <p>The <code>add_wchnstr()</code>, <code>wadd_wchnstr()</code>, <code>mvadd_wchnstr()</code>, and <code>mvwadd_wchnstr()</code> functions write <code>n</code> characters to the window, or as many as will fit on the line. If <code>n</code> is less than 0, the entire string is written, or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <code>x</code> and <code>y</code> parameters.</p> <p>These functions differ from the <code>addwstr(3XCURSES)</code> set of functions in two important respects. First, these functions do <i>not</i> advance the cursor after writing the string to the window. Second, the current window rendition (that is, the combination of attributes and color pair) is not combined with the character; only those attributes that are already part of the <code>cchar_t</code> character are used.</p> |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |

If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line. | <i>y</i> | Is the <i>y</i> (row) coordinate of the starting position of <i>wchstr</i> in the window. |
| <i>wchstr</i> | Is a pointer to the <code>cchar_t</code> string to be copied to the window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |
| <i>n</i>      | Is the maximum number of characters to be copied from <i>wchstr</i> . If <i>n</i> is less than 0, the entire string is written or as much of it as fits on the line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |
| <i>y</i>      | Is the <i>y</i> (row) coordinate of the starting position of <i>wchstr</i> in the window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |

wadd\_wchnstr(3XCURSES)

*x* Is the x (column) coordinate of the starting position of *wchstr* in the window.

*win* Is a pointer to the window to which the string is to be copied.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>DESCRIPTION</b>  | <p>All of these routines copy <i>wchstr</i>, which points to a string of <code>wchar_t</code> characters, directly into the window image structure starting at the current cursor position. The four routines with <i>n</i> as the last argument copy at most <i>n</i> elements, but no more than will fit on the line. If <i>n</i>==−1 then the whole string is copied, to the maximum number that fit on the line.</p> <p>The position of the window cursor is not advanced. These routines work faster than <code>waddnwstr(3CURSES)</code> because they merely copy <i>wchstr</i> into the window image structure. On the other hand, care must be taken when using these functions because they don't perform any kind of checking (such as for the newline character), they do not advance the current cursor position, and they truncate the string, rather than wrapping it around to the new line.</p> |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion, unless otherwise noted in the preceding routine descriptions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |

| DESCRIPTION   | <p>The <code>add_wchstr()</code> function copies the string of <code>cchar_t</code> characters to the <code>stdscr</code> window at the current cursor position. The <code>mvadd_wchstr()</code> and <code>mvwadd_wchstr()</code> functions copy the string to the starting position indicated by the <code>x</code> (column) and <code>y</code> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <code>win</code>). The <code>wadd_wchstr()</code> is identical to <code>add_wchstr()</code>, but writes to the window specified by <code>win</code>.</p> <p>The <code>add_wchnstr()</code>, <code>wadd_wchnstr()</code>, <code>mvadd_wchnstr()</code>, and <code>mvwadd_wchnstr()</code> functions write <code>n</code> characters to the window, or as many as will fit on the line. If <code>n</code> is less than 0, the entire string is written, or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <code>x</code> and <code>y</code> parameters.</p> <p>These functions differ from the <code>addwstr(3XCURSES)</code> set of functions in two important respects. First, these functions do <i>not</i> advance the cursor after writing the string to the window. Second, the current window rendition (that is, the combination of attributes and color pair) is not combined with the character; only those attributes that are already part of the <code>cchar_t</code> character are used.</p> |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |

| <i>y</i>      | Is the <i>y</i> (row) coordinate of the starting position of <i>wchstr</i> in the window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |               |                                                                             |          |                                                                                                                                                                      |          |                                                                                           |

wadd\_wchstr(3XCURSES)

*x* Is the x (column) coordinate of the starting position of *wchstr* in the window.

*win* Is a pointer to the window to which the string is to be copied.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| SYNOPSIS       | <pre>cc [flag...] file... -lcurses [library...]  #include&lt;curses.h&gt;  int addwstr(wchar_t *wstr);  int addnwstr(wchar_t *wstr, int n);  int waddwstr(WINDOW *win, wchar_t *wstr);  int waddnwstr(WINDOW *win, wchar_t *wstr, int n);  int mvaddwstr(int y, int x, wchar_t *wstr);  int mvaddnwstr(int y, int x, wchar_t *wstr, int n);  int mvwaddwstr(WINDOW *win, int y, int x, wchar_t *wstr);  int mvwaddnwstr(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre> |                |                 |          |        |
| DESCRIPTION    | All of these routines write all the characters of the null-terminated wchar_t character string wstr on the given window. The effect is similar to calling waddwch(3CURSES) once for each wchar_t character in the string. The four routines with n as the last argument write at most n wchar_t characters. If n is negative, then the entire string will be added.                                                                                                             |                |                 |          |        |
| RETURN VALUE   | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |
| ATTRIBUTES     | See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>MT-Level</td><td>Unsafe</td></tr></table>                                                                                                                                                                                                                                                                                                | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| <b>DESCRIPTION</b> | <p>The <code>addwstr()</code> function writes a null-terminated wide-character string to the <code>stdscr</code> window at the current cursor position. The <code>waddwstr()</code> function performs an identical action, but writes the string to the window specified by <i>win</i>. The <code>mvaddwstr()</code> and <code>mvwaddwstr()</code> functions write the string to the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The <code>addnwstr()</code>, <code>waddnwstr()</code>, <code>mvaddnwstr()</code>, and <code>mvwaddnwstr()</code> functions write at most <i>n</i> characters to the window. If <i>n</i> is less than 0, the entire string is written. The former two functions place the characters at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All of these functions advance the cursor after writing the string.</p> <p>These functions are functionally equivalent to building a <code>cchar_t</code> from the <code>wchar_t</code> and the window rendition (or background character and rendition) and calling the <code>wadd_wch(3XCURSES)</code> function once for each <code>wchar_t</code> in the string. Refer to the <code>curses(3XCURSES)</code> man page for a complete description of special character handling and of the interaction between the window rendition (or background character and rendition) and the character written.</p> <p>Note that these functions differ from the <code>add_wchnstr(3XCURSES)</code> set of functions in that the latter copy the string as is (without combining each character with the foreground and background attributes of the window).</p> |
| <b>PARAMETERS</b>  | <p><i>wstr</i>      Is a pointer to the wide-character string that is to be written to the window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

waddwstr(3XCURSES)

- n* Is the maximum number of characters to be copied from *wstr*. If *n* is less than 0, the entire string is written or as much of it as fits on the line.
- y* Is the y (row) coordinate of the starting position of *wstr* in the window.
- x* Is the x (column) coordinate of the starting position of *wstr* in the window.
- win* Is a pointer to the window in which the string is to be written.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

## wadjcurpos(3CURSES)

| NAME           | <code> curs_alecompat, movenextch, wmovenextch, moveprevch, wmoveprevch, adjcurpos, wadjcurpos </code> – these functions are added to ALE curses library for moving the cursor by character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |

| DESCRIPTION    | <p><code>movenextch()</code> and <code>wmovenextch()</code> move the cursor to the next character to the right. If the next character is a multicolumn character, the cursor is positioned on the first (left-most) column of that character. The new cursor position will be on the next character, even if the cursor was originally positioned on the left-most column of a multicolumn character. Note that the simple cursor increment (<code>++x</code>) does not guarantee movement to the next character, if the cursor was originally positioned on a multicolumn character. <code>getyx(3CURSES)</code> can be used to find the new position.</p> <p><code>moveprevch()</code> and <code>wmoveprevch()</code> routines are the opposite of <code>movenextch()</code> and <code>wmovenextch()</code>, moving the cursor to the left-most column of the previous character.</p> <p><code>adjcurpos()</code> and <code>wadjcurpos()</code> move the cursor to the first(left-most) column of the multicolumn character that the cursor is presently on. If the cursor is already on the first column, or if the cursor is on a single-column character, these routines will have no effect.</p> |                |                 |          |        |
| RETURN VALUE   | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |          |        |

| DESCRIPTION | <p>The attr_get() function retrieves the current rendition of <i>stdscr</i>. The wattr_get() function retrieves the current rendition of window <i>win</i>. If <i>attrs</i> or <i>color</i> is a null pointer, no information is retrieved.</p> <p>The attr_off() and attr_on() functions unset and set, respectively, the specified window attributes of <i>stdscr</i>. These functions only affect the attributes specified; attributes that existed before the call are retained.</p> <p>The wattr_off() and wattr_on() functions unset or set the specified attributes for window <i>win</i>.</p> <p>The attr_set() and wattr_set() functions change the rendition of <i>stdscr</i> and <i>win</i>; the old values are not retained.</p> <p>The color_set() and wcolor_set() functions set the window color of <i>stdscr</i> and <i>win</i> to <i>color</i>.</p> <p>The attributes and color pairs that can be used are specified in the Attributes, Color Pairs, and Renditions section of the curses(3XCURSES) man page.</p> |
| PARAMETERS  | <p><i>attrs</i> Is a pointer to the foreground window attributes to be set or unset.</p> <p><i>color</i> Is a pointer to a color pair number .</p> <p><i>opts</i> Is reserved for future use.</p> <p><i>win</i> Is a pointer to the window in which attribute changes are to be made.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

wattr\_get(3XCURSES)

**RETURN VALUES** These functions always return OK.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>DESCRIPTION</b>        | <p>All of these routines manipulate the current attributes of the named window. The current attributes of a window are applied to all characters that are written into the window with <code>waddch()</code>, <code>waddstr()</code>, and <code>wprintw()</code>. Attributes are a property of the character, and move with the character through any scrolling and insert/delete line/character operations. To the extent possible on the particular terminal, they are displayed as the graphic rendition of characters put on the screen.</p> <p>The routine <code>attrset()</code> sets the current attributes of the given window to <i>attrs</i>. The routine <code>attroff()</code> turns off the named attributes without turning any other attributes on or off. The routine <code>attron()</code> turns on the named attributes without affecting any others. The routine <code>standout()</code> is the same as <code>attron(A_STANDOUT)</code>. The routine <code>standend()</code> is the same as <code>attrset()</code>, that is, it turns off all attributes.</p> |                         |                                        |                          |             |                        |               |                      |          |                    |             |                     |                      |                           |                         |

wattroff(3CURSES)

A\_CHARTEXT                      Bit-mask to extract a character

COLOR\_PAIR(*n*)                      Color-pair number *n*

The following macro is the reverse of COLOR\_PAIR(*n*) :

PAIR\_NUMBER(*attrs*)                      Returns the pair number associated with the  
COLOR\_PAIR(*n*) attribute

**RETURN VALUES**                      These routines always return 1.

**ATTRIBUTES**                      See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO**                      curs\_addch(3CURSES), curs\_addstr(3CURSES), curs\_printw(3CURSES),  
curses(3CURSES), attributes(5)

**NOTES**                      The header <curses.h> automatically includes the headers <stdio.h> and  
<unctrl.h>.

Note that attroff(), wattroff(), attron(), wattron(), wattrset(),  
standend(), and standout() may be macros.

| DESCRIPTION | <p>The attr_get() function retrieves the current rendition of <i>stdscr</i>. The wattr_get() function retrieves the current rendition of window <i>win</i>. If <i>attrs</i> or <i>color</i> is a null pointer, no information is retrieved.</p> <p>The attr_off() and attr_on() functions unset and set, respectively, the specified window attributes of <i>stdscr</i>. These functions only affect the attributes specified; attributes that existed before the call are retained.</p> <p>The wattr_off() and wattr_on() functions unset or set the specified attributes for window <i>win</i>.</p> <p>The attr_set() and wattr_set() functions change the rendition of <i>stdscr</i> and <i>win</i>; the old values are not retained.</p> <p>The color_set() and wcolor_set() functions set the window color of <i>stdscr</i> and <i>win</i> to <i>color</i>.</p> <p>The attributes and color pairs that can be used are specified in the Attributes, Color Pairs, and Renditions section of the curses(3XCURSES) man page.</p> |
| PARAMETERS  | <p><i>attrs</i> Is a pointer to the foreground window attributes to be set or unset.</p> <p><i>color</i> Is a pointer to a color pair number .</p> <p><i>opts</i> Is reserved for future use.</p> <p><i>win</i> Is a pointer to the window in which attribute changes are to be made.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

wattr\_off(3XCURSES)

**RETURN VALUES** These functions always return OK.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>NAME</b>          | attroff, attron, attrset, wattroff, wattron, wattrset – change foreground window attributes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>attroff</b>(int <i>attrs</i>); int <b>attron</b>(int <i>attrs</i>); int <b>attrset</b>(int <i>attrs</i>); int <b>wattroff</b>(WINDOW *<i>win</i>, int <i>attrs</i>); int <b>wattron</b>(WINDOW *<i>win</i>, int <i>attrs</i>); int <b>wattrset</b>(WINDOW *<i>win</i>, int <i>attrs</i>);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b>   | <p>The <code>attroff()</code> and <code>attron()</code> functions unset and set, respectively, the specified window attributes of <code>stdscr</code>. These functions only affect the attributes specified; attributes that existed before the call are retained. The <code>wattroff()</code> and <code>wattron()</code> functions unset or set the specified attributes for window <i>win</i>.</p> <p>The <code>attrset()</code> and <code>wattrset()</code> functions change the specified window renditions of <code>stdscr</code> and <i>win</i> to new values; the old values are not retained.</p> <p>The attributes that can be used are specified in the Attributes, Color Pairs, and Renditions section of the <code>curses(3XCURSES)</code> man page.</p> <p>Here is an example that prints some text using the current window rendition, adds underlining, changes the attributes, prints more text, then changes the attributes back.</p> <pre>printw("This word is"); attron(A_UNDERLINE); printw("underlined."); attroff(A_NORMAL); printw("This is back to normal text.\n"); refresh();</pre> |
| <b>PARAMETERS</b>    | <p><i>attrs</i> are the foreground window attributes to be set or unset.</p> <p><i>win</i> Is a pointer to the window in which attribute changes are to be made.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>RETURN VALUES</b> | These functions always return OK or 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>DESCRIPTION</b>        | <p>All of these routines manipulate the current attributes of the named window. The current attributes of a window are applied to all characters that are written into the window with <code>waddch()</code>, <code>waddstr()</code>, and <code>wprintw()</code>. Attributes are a property of the character, and move with the character through any scrolling and insert/delete line/character operations. To the extent possible on the particular terminal, they are displayed as the graphic rendition of characters put on the screen.</p> <p>The routine <code>attrset()</code> sets the current attributes of the given window to <i>attrs</i>. The routine <code>attroff()</code> turns off the named attributes without turning any other attributes on or off. The routine <code>attron()</code> turns on the named attributes without affecting any others. The routine <code>standout()</code> is the same as <code>attron(A_STANDOUT)</code>. The routine <code>standend()</code> is the same as <code>attrset()</code>, that is, it turns off all attributes.</p> |                         |                                        |                          |             |                        |               |                      |          |                    |             |                     |                      |                           |                         |
| <b>Attributes</b>         | <p>The following video attributes, defined in <code>&lt;curses.h&gt;</code>, can be passed to the routines <code>attron()</code>, <code>attroff()</code>, and <code>attrset()</code>, or OR-ed with the characters passed to <code>addch()</code>.</p> <table> <tr> <td><code>A_STANDOUT</code></td><td>Best highlighting mode of the terminal</td></tr> <tr> <td><code>A_UNDERLINE</code></td><td>Underlining</td></tr> <tr> <td><code>A_REVERSE</code></td><td>Reverse video</td></tr> <tr> <td><code>A_BLINK</code></td><td>Blinking</td></tr> <tr> <td><code>A_DIM</code></td><td>Half bright</td></tr> <tr> <td><code>A_BOLD</code></td><td>Extra bright or bold</td></tr> <tr> <td><code>A_ALTCHARSET</code></td><td>Alternate character set</td></tr> </table>                                                                                                                                                                                                                                                                                                            | <code>A_STANDOUT</code> | Best highlighting mode of the terminal | <code>A_UNDERLINE</code> | Underlining | <code>A_REVERSE</code> | Reverse video | <code>A_BLINK</code> | Blinking | <code>A_DIM</code> | Half bright | <code>A_BOLD</code> | Extra bright or bold | <code>A_ALTCHARSET</code> | Alternate character set |

wattron(3CURSES)

A\_CHARTEXT                      Bit-mask to extract a character

COLOR\_PAIR(*n*)                      Color-pair number *n*

The following macro is the reverse of COLOR\_PAIR(*n*) :

PAIR\_NUMBER(*attrs*)                      Returns the pair number associated with the  
COLOR\_PAIR(*n*) attribute

**RETURN VALUES**                      These routines always return 1.

**ATTRIBUTES**                      See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO**                      curs\_addch(3CURSES), curs\_addstr(3CURSES), curs\_printw(3CURSES),  
curses(3CURSES), attributes(5)

**NOTES**                      The header <curses.h> automatically includes the headers <stdio.h> and  
<unctrl.h>.

Note that attroff(), wattroff(), attron(), wattron(), wattrset(),  
standend(), and standout() may be macros.

| DESCRIPTION | <p>The attr_get() function retrieves the current rendition of <i>stdscr</i>. The wattr_get() function retrieves the current rendition of window <i>win</i>. If <i>attrs</i> or <i>color</i> is a null pointer, no information is retrieved.</p> <p>The attr_off() and attr_on() functions unset and set, respectively, the specified window attributes of <i>stdscr</i>. These functions only affect the attributes specified; attributes that existed before the call are retained.</p> <p>The wattr_off() and wattr_on() functions unset or set the specified attributes for window <i>win</i>.</p> <p>The attr_set() and wattr_set() functions change the rendition of <i>stdscr</i> and <i>win</i>; the old values are not retained.</p> <p>The color_set() and wcolor_set() functions set the window color of <i>stdscr</i> and <i>win</i> to <i>color</i>.</p> <p>The attributes and color pairs that can be used are specified in the Attributes, Color Pairs, and Renditions section of the curses(3XCURSES) man page.</p> |
| PARAMETERS  | <p><i>attrs</i> Is a pointer to the foreground window attributes to be set or unset.</p> <p><i>color</i> Is a pointer to a color pair number .</p> <p><i>opts</i> Is reserved for future use.</p> <p><i>win</i> Is a pointer to the window in which attribute changes are to be made.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

wattr\_on(3XCURSES)

**RETURN VALUES** These functions always return OK.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>NAME</b>          | attroff, attron, attrset, wattroff, wattron, wattrset – change foreground window attributes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>attroff</b>(int <i>attrs</i>); int <b>attron</b>(int <i>attrs</i>); int <b>attrset</b>(int <i>attrs</i>); int <b>wattroff</b>(WINDOW *<i>win</i>, int <i>attrs</i>); int <b>wattron</b>(WINDOW *<i>win</i>, int <i>attrs</i>); int <b>wattrset</b>(WINDOW *<i>win</i>, int <i>attrs</i>);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b>   | <p>The <code>attroff()</code> and <code>attron()</code> functions unset and set, respectively, the specified window attributes of <code>stdscr</code>. These functions only affect the attributes specified; attributes that existed before the call are retained. The <code>wattroff()</code> and <code>wattron()</code> functions unset or set the specified attributes for window <i>win</i>.</p> <p>The <code>attrset()</code> and <code>wattrset()</code> functions change the specified window renditions of <code>stdscr</code> and <i>win</i> to new values; the old values are not retained.</p> <p>The attributes that can be used are specified in the Attributes, Color Pairs, and Renditions section of the <code>curses(3XCURSES)</code> man page.</p> <p>Here is an example that prints some text using the current window rendition, adds underlining, changes the attributes, prints more text, then changes the attributes back.</p> <pre>printw("This word is"); attron(A_UNDERLINE); printw("underlined."); attroff(A_NORMAL); printw("This is back to normal text.\n"); refresh();</pre> |
| <b>PARAMETERS</b>    | <p><i>attrs</i> are the foreground window attributes to be set or unset.</p> <p><i>win</i> Is a pointer to the window in which attribute changes are to be made.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>RETURN VALUES</b> | These functions always return OK or 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>DESCRIPTION</b>        | <p>All of these routines manipulate the current attributes of the named window. The current attributes of a window are applied to all characters that are written into the window with <code>waddch()</code>, <code>waddstr()</code>, and <code>wprintw()</code>. Attributes are a property of the character, and move with the character through any scrolling and insert/delete line/character operations. To the extent possible on the particular terminal, they are displayed as the graphic rendition of characters put on the screen.</p> <p>The routine <code>attrset()</code> sets the current attributes of the given window to <i>attrs</i>. The routine <code>attroff()</code> turns off the named attributes without turning any other attributes on or off. The routine <code>attron()</code> turns on the named attributes without affecting any others. The routine <code>standout()</code> is the same as <code>attron(A_STANDOUT)</code>. The routine <code>standend()</code> is the same as <code>attrset()</code>, that is, it turns off all attributes.</p> |                         |                                        |                          |             |                        |               |                      |          |                    |             |                     |                      |                           |                         |
| <b>Attributes</b>         | <p>The following video attributes, defined in <code>&lt;curses.h&gt;</code>, can be passed to the routines <code>attron()</code>, <code>attroff()</code>, and <code>attrset()</code>, or OR-ed with the characters passed to <code>addch()</code>.</p> <table> <tr> <td><code>A_STANDOUT</code></td><td>Best highlighting mode of the terminal</td></tr> <tr> <td><code>A_UNDERLINE</code></td><td>Underlining</td></tr> <tr> <td><code>A_REVERSE</code></td><td>Reverse video</td></tr> <tr> <td><code>A_BLINK</code></td><td>Blinking</td></tr> <tr> <td><code>A_DIM</code></td><td>Half bright</td></tr> <tr> <td><code>A_BOLD</code></td><td>Extra bright or bold</td></tr> <tr> <td><code>A_ALTCHARSET</code></td><td>Alternate character set</td></tr> </table>                                                                                                                                                                                                                                                                                                            | <code>A_STANDOUT</code> | Best highlighting mode of the terminal | <code>A_UNDERLINE</code> | Underlining | <code>A_REVERSE</code> | Reverse video | <code>A_BLINK</code> | Blinking | <code>A_DIM</code> | Half bright | <code>A_BOLD</code> | Extra bright or bold | <code>A_ALTCHARSET</code> | Alternate character set |

wattrset(3CURSES)

A\_CHARTEXT                      Bit-mask to extract a character

COLOR\_PAIR(*n*)                      Color-pair number *n*

The following macro is the reverse of COLOR\_PAIR(*n*) :

PAIR\_NUMBER(*attrs*)                      Returns the pair number associated with the  
COLOR\_PAIR(*n*) attribute

**RETURN VALUES**                      These routines always return 1.

**ATTRIBUTES**                      See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO**                      curs\_addch(3CURSES), curs\_addstr(3CURSES), curs\_printw(3CURSES),  
curses(3CURSES), attributes(5)

**NOTES**                      The header <curses.h> automatically includes the headers <stdio.h> and  
<unctrl.h>.

Note that attroff(), wattroff(), attron(), wattron(), wattrset(),  
standend(), and standout() may be macros.

| DESCRIPTION | <p>The attr_get() function retrieves the current rendition of <i>stdscr</i>. The wattr_get() function retrieves the current rendition of window <i>win</i>. If <i>attrs</i> or <i>color</i> is a null pointer, no information is retrieved.</p> <p>The attr_off() and attr_on() functions unset and set, respectively, the specified window attributes of <i>stdscr</i>. These functions only affect the attributes specified; attributes that existed before the call are retained.</p> <p>The wattr_off() and wattr_on() functions unset or set the specified attributes for window <i>win</i>.</p> <p>The attr_set() and wattr_set() functions change the rendition of <i>stdscr</i> and <i>win</i>; the old values are not retained.</p> <p>The color_set() and wcolor_set() functions set the window color of <i>stdscr</i> and <i>win</i> to <i>color</i>.</p> <p>The attributes and color pairs that can be used are specified in the Attributes, Color Pairs, and Renditions section of the curses(3XCURSES) man page.</p> |
| PARAMETERS  | <p><i>attrs</i> Is a pointer to the foreground window attributes to be set or unset.</p> <p><i>color</i> Is a pointer to a color pair number .</p> <p><i>opts</i> Is reserved for future use.</p> <p><i>win</i> Is a pointer to the window in which attribute changes are to be made.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

wattr\_set(3XCURSES)

**RETURN VALUES** These functions always return OK.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>DESCRIPTION</b>   | <p>The <code>attroff()</code> and <code>attron()</code> functions unset and set, respectively, the specified window attributes of <code>stdscr</code>. These functions only affect the attributes specified; attributes that existed before the call are retained. The <code>wattroff()</code> and <code>wattron()</code> functions unset or set the specified attributes for window <i>win</i>.</p> <p>The <code>attrset()</code> and <code>wattrset()</code> functions change the specified window renditions of <code>stdscr</code> and <i>win</i> to new values; the old values are not retained.</p> <p>The attributes that can be used are specified in the Attributes, Color Pairs, and Renditions section of the <code>curses(3XCURSES)</code> man page.</p> <p>Here is an example that prints some text using the current window rendition, adds underlining, changes the attributes, prints more text, then changes the attributes back.</p> <pre>printw("This word is"); attron(A_UNDERLINE); printw("underlined."); attroff(A_NORMAL); printw("This is back to normal text.\n"); refresh( );</pre> |
| <b>PARAMETERS</b>    | <p><i>attrs</i> are the foreground window attributes to be set or unset.</p> <p><i>win</i> Is a pointer to the window in which attribute changes are to be made.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>RETURN VALUES</b> | These functions always return OK or 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>USAGE</b>         | All of these functions may be macros.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>DESCRIPTION</b>   | <p>The <code>bkgdsets()</code> and <code>wbkgdset()</code> routines manipulate the background of the named window. Background is a <code>chtype</code> consisting of any combination of attributes and a character. The attribute part of the background is combined (ORed) with all non-blank characters that are written into the window with <code>waddch()</code>. Both the character and attribute parts of the background are combined with the blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations. To the extent possible on a particular terminal, the attribute part of the background is displayed as the graphic rendition of the character put on the screen.</p> <p>The <code>bkgd()</code> and <code>wbkgd()</code> routines combine the new background with every position in the window. Background is any combination of attributes and a character. Only the attribute part is used to set the background of non-blank characters, while both character and attributes are used for blank positions. To the extent possible on a particular terminal, the attribute part of the background is displayed as the graphic rendition of the character put on the screen.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | <code>bkgd()</code> and <code>wbkgd()</code> return the integer <code>OK</code> , or a non-negative integer, if <code>immedok()</code> is set. See <code>curs_ouptops(3CURSES)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| <b>DESCRIPTION</b>   | <p>The bkgdset () and wbkgdset () functions turn off the previous background attributes, logical OR the requested attributes into the window rendition, and set the background property of the current or specified window based on the information in <i>ch</i>. If <i>ch</i> refers to a multi-column character, the results are undefined.</p> <p>The bkgd () and wbkgd () functions turn off the previous background attributes, logical OR the requested attributes into the window rendition, and set the background property of the current or specified window and then apply this setting to every character position in that window:</p> <ul style="list-style-type: none"> <li>■ The rendition of every character on the screen is changed to the new window rendition.</li> <li>■ Wherever the former background character appears, it is changed to the new background character.</li> </ul> <p>The getbkgd () function extracts the specified window's background character and rendition.</p> |
| <b>PARAMETERS</b>    | <p><i>ch</i>            Is the background character to be set.</p> <p><i>win</i>           Is a pointer to the window in which the background character is to be set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>RETURN VALUES</b> | <p>Upon successful completion, the bkgd () and wbkgd () functions return OK. Otherwise, they return ERR.</p> <p>The bkgdset () and wbkgdset () functions do not return a value.</p> <p>Upon successful completion, the getbkgd () function returns the specified window's background character and rendition. Otherwise, it returns (chtype) ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

wbkgd(3XCURSES)

**USAGE** These functions are only guaranteed to operate reliably on character sets in which each character fits into a single byte, whose attributes can be expressed using only constants with the A\_ prefix.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| DESCRIPTION    | <p>The bkgdsets() and wbkgdset() routines manipulate the background of the named window. Background is a chtype consisting of any combination of attributes and a character. The attribute part of the background is combined (ORed) with all non-blank characters that are written into the window with waddch(). Both the character and attribute parts of the background are combined with the blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations. To the extent possible on a particular terminal, the attribute part of the background is displayed as the graphic rendition of the character put on the screen.</p> <p>The bkgd() and wbkgd() routines combine the new background with every position in the window. Background is any combination of attributes and a character. Only the attribute part is used to set the background of non-blank characters, while both character and attributes are used for blank positions. To the extent possible on a particular terminal, the attribute part of the background is displayed as the graphic rendition of the character put on the screen.</p> |                |                 |          |        |
| RETURN VALUES  | bkgd() and wbkgd() return the integer OK, or a non-negative integer, if immedok() is set. See curs_ouptops(3CURSES).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int bkgd(chtype ch);  void bkgdset(chtype ch);  chtype getbkgd(WINDOW *win);  int wbkgd(WINDOW *win, chtype ch);  void wbkgdset(WINDOW *win, chtype ch);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b>   | <p>The bkgdset() and wbkgdset() functions turn off the previous background attributes, logical OR the requested attributes into the window rendition, and set the background property of the current or specified window based on the information in <i>ch</i>. If <i>ch</i> refers to a multi-column character, the results are undefined.</p> <p>The bkgd() and wbkgd() functions turn off the previous background attributes, logical OR the requested attributes into the window rendition, and set the background property of the current or specified window and then apply this setting to every character position in that window:</p> <ul style="list-style-type: none"> <li>■ The rendition of every character on the screen is changed to the new window rendition.</li> <li>■ Wherever the former background character appears, it is changed to the new background character.</li> </ul> <p>The getbkgd() function extracts the specified window's background character and rendition.</p> |
| <b>PARAMETERS</b>    | <p><i>ch</i> Is the background character to be set.</p> <p><i>win</i> Is a pointer to the window in which the background character is to be set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>RETURN VALUES</b> | <p>Upon successful completion, the bkgd() and wbkgd() functions return OK. Otherwise, they return ERR.</p> <p>The bkgdset() and wbkgdset() functions do not return a value.</p> <p>Upon successful completion, the getbkgd() function returns the specified window's background character and rendition. Otherwise, it returns (chtype) ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

wbkgdset(3XCURSES)

**USAGE** These functions are only guaranteed to operate reliably on character sets in which each character fits into a single byte, whose attributes can be expressed using only constants with the A\_ prefix.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO** addch(3XCURSES), addchstr(3XCURSES), attroff(3XCURSES), bkgrnd(3XCURSES), clear(3XCURSES), clrtoeol(3XCURSES), clrtobot(3XCURSES), erase(3XCURSES), inch(3XCURSES), libcurses(3XCURSES), mvprintw(3XCURSES), attributes(5), standards(5)

| DESCRIPTION   | <p>The <code>bkgrndset()</code> and <code>wbkgrndset()</code> functions turn off the previous background attributes, logical OR the requested attributes into the window rendition, and set the background property of the current or specified window based on the information in <i>wch</i>.</p> <p>The <code>bkgrnd()</code> and <code>wbkgrnd()</code> functions turn off the previous background attributes, logical OR the requested attributes into the window rendition, and set the background property of the current or specified window and then apply this setting to every character position in that window:</p> <ul style="list-style-type: none"> <li>■ The rendition of every character on the screen is changed to the new window rendition.</li> <li>■ Wherever the former background character appears, it is changed to the new background character.</li> </ul> <p>If <i>wch</i> refers to a non-spacing complex character for <code>bkgrnd()</code>, <code>bkgrndset()</code>, <code>wbkgrnd()</code>, and <code>wbkgrndset()</code>, then <i>wch</i> is added to the existing spacing complex character that is the background character. If <i>wch</i> refers to a multi-column character, the results are unspecified.</p> <p>The <code>getbkgrnd()</code> and <code>wgetbkgrnd()</code> functions store, into the area pointed to by <i>wch</i>, the window's background character and rendition.</p> |
| PARAMETERS    | <p><i>wch</i> Is a pointer to the complex background character to be set.</p> <p><i>win</i> Is a pointer to the window in which the complex background character is to be set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| RETURN VALUES | <p>The <code>bkgrndset()</code> and <code>wbkgrndset()</code> functions do not return a value.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| DESCRIPTION   | <p>The <code>bkgrndset()</code> and <code>wbkgrndset()</code> functions turn off the previous background attributes, logical OR the requested attributes into the window rendition, and set the background property of the current or specified window based on the information in <i>wch</i>.</p> <p>The <code>bkgrnd()</code> and <code>wbkgrnd()</code> functions turn off the previous background attributes, logical OR the requested attributes into the window rendition, and set the background property of the current or specified window and then apply this setting to every character position in that window:</p> <ul style="list-style-type: none"> <li>■ The rendition of every character on the screen is changed to the new window rendition.</li> <li>■ Wherever the former background character appears, it is changed to the new background character.</li> </ul> <p>If <i>wch</i> refers to a non-spacing complex character for <code>bkgrnd()</code>, <code>bkgrndset()</code>, <code>wbkgrnd()</code>, and <code>wbkgrndset()</code>, then <i>wch</i> is added to the existing spacing complex character that is the background character. If <i>wch</i> refers to a multi-column character, the results are unspecified.</p> <p>The <code>getbkgrnd()</code> and <code>wgetbkgrnd()</code> functions store, into the area pointed to by <i>wch</i>, the window's background character and rendition.</p> |
| PARAMETERS    | <p><i>wch</i> Is a pointer to the complex background character to be set.</p> <p><i>win</i> Is a pointer to the window in which the complex background character is to be set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| RETURN VALUES | <p>The <code>bkgrndset()</code> and <code>wbkgrndset()</code> functions do not return a value.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| DESCRIPTION | <p>With the <code>border()</code>, <code>wborder()</code>, and <code>box()</code> routines, a border is drawn around the edges of the window. The arguments and attributes are:</p> <table border="1"> <tbody> <tr><td><i>ls</i></td><td>left side of the border</td></tr> <tr><td><i>rs</i></td><td>right side of the border</td></tr> <tr><td><i>ts</i></td><td>top side of the border</td></tr> <tr><td><i>bs</i></td><td>bottom side of the border</td></tr> <tr><td><i>tl</i></td><td>top left-hand corner</td></tr> <tr><td><i>tr</i></td><td>top right-hand corner</td></tr> <tr><td><i>bl</i></td><td>bottom left-hand corner</td></tr> <tr><td><i>br</i></td><td>bottom right-hand corner</td></tr> </tbody> </table> <p>If any of these arguments is zero, then the following default values (defined in <code>&lt;curses.h&gt;</code>) are used respectively instead: <code>ACS_VLINE</code>, <code>ACS_VLINE</code>, <code>ACS_HLINE</code>, <code>ACS_HLINE</code>, <code>ACS_ULCORNER</code>, <code>ACS_URCORNER</code>, <code>ACS_BLCORNER</code>, <code>ACS_BRCORNER</code>.</p> <p><code>box(<i>win</i>, <i>verch</i>, <i>horch</i>)</code> is a shorthand for the following call:</p> <pre>wborder(<i>win</i>, <i>verch</i>, <i>verch</i>, <i>horch</i>, <i>horch</i>, 0, 0, 0, 0)</pre> <p><code>hline()</code> and <code>whline()</code> draw a horizontal (left to right) line using <i>ch</i> starting at the current cursor position in the window. The current cursor position is not changed. The line is at most <i>n</i> characters long, or as many as fit into the window.</p> | <i>ls</i> | left side of the border | <i>rs</i> | right side of the border | <i>ts</i> | top side of the border | <i>bs</i> | bottom side of the border | <i>tl</i> | top left-hand corner | <i>tr</i> | top right-hand corner | <i>bl</i> | bottom left-hand corner | <i>br</i> | bottom right-hand corner |
| <i>ls</i>   | left side of the border                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |           |                         |           |                          |           |                        |           |                           |           |                      |           |                       |           |                         |           |                          |

wborder(3CURSES)

`vline()` and `wvline()` draw a vertical (top to bottom) line using *ch* starting at the current cursor position in the window. The current cursor position is not changed. The line is at most *n* characters long, or as many as fit into the window.

**RETURN VALUES** All routines return the integer `OK`, or a non-negative integer if `immedok()` is set. See `curl_outopts(3CURSES)`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curl_outopts(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `border()` and `box()` may be macros.

**NAME** border, box, wborder – add a single-byte border to a window

**SYNOPSIS** `cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \`  
`-R /usr/xpg4/lib -lcurses [ library... ]`

```
c89 [flag...] file... -lcurses [library...]

#include <curses.h>

int border(chtype ls, chtype rs, chtype ts, chtype bs, chtype tl,
 chtype tr, chtype bl, chtype br);

int wborder(WINDOW *win, chtype ls, chtype rs, chtype ts, chtype bs,
 chtype tl, chtype tr, chtype bl, chtype br);

int box(WINDOW *win, chtype verch, chtype horch);
```

**DESCRIPTION** The `border()` and `wborder()` functions draw a border around the specified window. All parameters must be single-byte characters whose rendition can be expressed using only constants beginning with `ACS_`. A parameter with the value of 0 is replaced by the default value.

| Constant Values for Borders |                  |                   |
|-----------------------------|------------------|-------------------|
| Parameter                   | Default Constant | Default Character |
| <i>verch</i>                | ACS_VLINE        |                   |
| <i>horch</i>                | ACS_HLINE        | -                 |
| <i>ls</i>                   | ACS_VLINE        |                   |
| <i>rs</i>                   | ACS_VLINE        |                   |
| <i>ts</i>                   | ACS_HLINE        | -                 |
| <i>bs</i>                   | ACS_HLINE        | -                 |

| <i>br</i>                   | ACS_BRCORNER     | +                 |
| <i>tl</i>                   | ACS_ULCORNER     | +                 |
| <i>tr</i>                   | ACS_URCORNER     | +                 |

The call

```
box(win,
verch, horch)
```

is a short form for

```
wborder(win,
verch, verch,
horch, horch, 0, 0, 0,
```

## wborder(3XCURSES)

o) When the window is boxed, the bottom and top rows and right and left columns overwrite existing text.

### PARAMETERS

|              |                                                                                |
|--------------|--------------------------------------------------------------------------------|
| <i>ls</i>    | Is the character and rendition used for the left side of the border.           |
| <i>rs</i>    | Is the character and rendition used for the right side of the border.          |
| <i>ts</i>    | Is the character and rendition used for the top of the border.                 |
| <i>bs</i>    | Is the character and rendition used for the bottom of the border.              |
| <i>tl</i>    | Is the character and rendition used for the top-left corner of the border.     |
| <i>tr</i>    | Is the character and rendition used for the top-right corner of the border.    |
| <i>bl</i>    | Is the character and rendition used for the bottom-left corner of the border.  |
| <i>br</i>    | Is the character and rendition used for the bottom-right corner of the border. |
| <i>win</i>   | Is the pointer to the window in which the border or box is to be drawn.        |
| <i>verch</i> | Is the character and rendition used for the left and right columns of the box. |
| <i>horch</i> | Is the character and rendition used for the top and bottom rows of the box.    |

### RETURN VALUES

On success, these functions return OK. Otherwise, they return ERR.

### ERRORS

None.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

### SEE ALSO

NAME

SYNOPSIS

DESCRIPTION

border\_set, box\_set, wborder\_set – use complex characters (and renditions) to draw borders

```
cc [flag...] file... -I /usr/xpg4/include -L /usr/xpg4/lib \
-R /usr/xpg4/lib -lcurses [library...]

c89 [flag...] file... -lcurses [library...]

#include <curses.h>

int border_set(const cchar_t *ls, const cchar_t *rs, const cchar_t
 *ts, const cchar_t *bs, const cchar_t *tl, const cchar_t *tr,
 const cchar_t *bl, const cchar_t *br);

int wborder_set(WINDOW *win, const cchar_t *ls, const cchar_t *rs,
 const cchar_t *ts, const cchar_t *bs, const cchar_t *tl, const
 cchar_t *tr, const cchar_t *bl, const cchar_t *br);

int box_set(WINDOW *win, const cchar_t *verch, const cchar_t
 *horch);
```

The `border_set()` and `wborder_set()` functions draw a border around the specified window. All parameters must be spacing complex characters with renditions. A parameter which is a null pointer is replaced by the default character.

Constant Values for Borders

| Constant Values for Borders |                  |                   |
|-----------------------------|------------------|-------------------|
| Parameter                   | Default Constant | Default Character |
| <i>verch</i>                | WACS_VLINE       |                   |
| <i>horch</i>                | WACS_HLINE       | -                 |
| <i>ls</i>                   | WACS_VLINE       |                   |
| <i>rs</i>                   | WACS_VLINE       |                   |
| <i>ts</i>                   | WACS_HLINE       | -                 |
| <i>bs</i>                   | WACS_HLINE       | -                 |
| <i>bl</i>                   | WACS_BLCORNER    | +                 |
| <i>br</i>                   | WACS_BRCORNER    | +                 |
| <i>tl</i>                   | WACS_ULCORNER    | +                 |
| <i>tr</i>                   | WACS_URCORNER    | +                 |

The call

## wborder\_set(3XCURSES)

`box_set(win, verch, horch)` is a short form for

```
wborder(win,
verch, verch,
horch, horch, NULL,
NULL, NULL, NULL)
```

When the window is boxed, the bottom and top rows and right and left columns are unavailable for text.

### PARAMETERS

|              |                                                                                |
|--------------|--------------------------------------------------------------------------------|
| <i>ls</i>    | Is the character and rendition used for the left side of the border.           |
| <i>rs</i>    | Is the character and rendition used for the right side of the border.          |
| <i>ts</i>    | Is the character and rendition used for the top of the border.                 |
| <i>bs</i>    | Is the character and rendition used for the bottom of the border.              |
| <i>tl</i>    | Is the character and rendition used for the top-left corner of the border.     |
| <i>tr</i>    | Is the character and rendition used for the top-right corner of the border.    |
| <i>bl</i>    | Is the character and rendition used for the bottom-left corner of the border.  |
| <i>br</i>    | Is the character and rendition used for the bottom-right corner of the border. |
| <i>win</i>   | Is the pointer to the window in which the border or box is to be drawn.        |
| <i>verch</i> | Is the character and rendition used for the left and right columns of the box. |
| <i>horch</i> | Is the character and rendition used for the top and bottom rows of the box.    |

### RETURN VALUES

On success, these functions return OK. Otherwise, they return ERR.

### ERRORS

None.

| NAME           | curs_clear, erase, werase, clear, wclear, clrtoebot, wclrtoebot, clrtoeol, wclrtoeol – clear all or part of a curses window                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |          |        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int  erase(void); int  werase(WINDOW *win); int  clear(void); int  wclear(WINDOW *win); int  clrtoebot(void); int  wclrtoebot(WINDOW *win); int  clrtoeol(void); int  wclrtoeol(WINDOW *win);</pre>                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |
| DESCRIPTION    | <p>The erase() and werase() routines copy blanks to every position in the window.</p> <p>The clear() and wclear() routines are like erase() and werase(), but they also call clearok(), so that the screen is cleared completely on the next call to wrefresh() for that window and repainted from scratch.</p> <p>The clrtoebot() and wclrtoebot() routines erase all lines below the cursor in the window. Also, the current line to the right of the cursor, inclusive, is erased.</p> <p>The clrtoeol() and wclrtoeol() routines erase the current line to the right of the cursor, inclusive.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer OK, or a non-negative integer if immedok() is set. See curs_ouptops(3CURSES).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |

| <b>DESCRIPTION</b>  | <p>The <code>clear()</code> and <code>erase()</code> functions clear <code>stdscr</code>, destroying its previous contents. The <code>wclear()</code> and <code>werase()</code> functions perform the same action, but clear the window specified by <i>win</i> instead of <code>stdscr</code>.</p> <p>The <code>clear()</code> and <code>wclear()</code> functions also call the <code>clearok()</code> function. This function clears and redraws the entire screen on the next call to <code>refresh(3XCURSES)</code> or <code>wrefresh(3XCURSES)</code> for the window.</p> <p>The current background character (and attributes) is used to clear the screen.</p> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>   | <p><i>win</i> Is a pointer to the window that is to be cleared.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |                     |          |          |        |
| <b>ERRORS</b>       | <p>OK Successful completion.</p> <p>ERR An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |

wclrbot(3CURSES)

| NAME           | curs_clear, erase, werase, clear, wclear, clrbot, wclrbot, clrtoeol, wclrtoeol – clear all or part of a curses window                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |          |        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int  erase(void); int  werase(WINDOW *win); int  clear(void); int  wclear(WINDOW *win); int  clrbot(void); int  wclrbot(WINDOW *win); int  clrtoeol(void); int  wclrtoeol(WINDOW *win);</pre>                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |
| DESCRIPTION    | <p>The erase() and werase() routines copy blanks to every position in the window.</p> <p>The clear() and wclear() routines are like erase() and werase(), but they also call clearok(), so that the screen is cleared completely on the next call to wrefresh() for that window and repainted from scratch.</p> <p>The clrbot() and wclrbot() routines erase all lines below the cursor in the window. Also, the current line to the right of the cursor, inclusive, is erased.</p> <p>The clrtoeol() and wclrtoeol() routines erase the current line to the right of the cursor, inclusive.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer OK, or a non-negative integer if immedok() is set. See curs_ouptos(3CURSES).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>clrbot</b>(void);  int <b>wclrbot</b>(WINDOW *win);</pre>                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>clrbot()</code> function clears all characters in the <code>stdscr</code> window from the cursor to the end of the window. The <code>wclrbot()</code> function performs the same action in the window specified by <i>win</i> instead of in <code>stdscr</code>. The current background character (and rendition) is used to clear the screen.</p> <p>If the clearing action results in clearing only a portion of a multicolumn character, background characters are displayed in place of the remaining portion.</p> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>win</i>                      Is a pointer to the window that is to be cleared.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |

| <b>SYNOPSIS</b>      | <pre> cc [ flag... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int  erase(void);  int  werase(WINDOW *win);  int  clear(void);  int  wclear(WINDOW *win);  int  clrtoobot(void);  int  wclrtoobot(WINDOW *win);  int  clrtoeol(void);  int  wclrtoeol(WINDOW *win); </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>erase()</code> and <code>werase()</code> routines copy blanks to every position in the window.</p> <p>The <code>clear()</code> and <code>wclear()</code> routines are like <code>erase()</code> and <code>werase()</code>, but they also call <code>clearok()</code>, so that the screen is cleared completely on the next call to <code>wrefresh()</code> for that window and repainted from scratch.</p> <p>The <code>clrtoobot()</code> and <code>wclrtoobot()</code> routines erase all lines below the cursor in the window. Also, the current line to the right of the cursor, inclusive, is erased.</p> <p>The <code>clrtoeol()</code> and <code>wclrtoeol()</code> routines erase the current line to the right of the cursor, inclusive.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>OK</code> , or a non-negative integer if <code>immedok()</code> is set. See <code>curs_outopts(3CURSES)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |          |        |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>clrtoeol</b>(void);  int <b>wclrtoeol</b>(WINDOW *win);</pre>                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>clrtoeol()</code> function clears the current line from the cursor to the right margin in the <code>stdscr</code> window. The <code>wclrtoeol()</code> function performs the same action, but in the window specified by <i>win</i> instead of <code>stdscr</code>. The current background character (and rendition) is used to clear the screen.</p> <p>If the clearing action results in clearing only a portion of a multicolumn character, background characters are displayed in place of the remaining portion.</p> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>win</i>                      Is a pointer to the window in which to clear to the end of the line.</p>                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b> | <p>The <code>attr_get()</code> function retrieves the current rendition of <code>stdscr</code>. The <code>wattr_get()</code> function retrieves the current rendition of window <code>win</code>. If <code>attrs</code> or <code>color</code> is a null pointer, no information is retrieved.</p> <p>The <code>attr_off()</code> and <code>attr_on()</code> functions unset and set, respectively, the specified window attributes of <code>stdscr</code>. These functions only affect the attributes specified; attributes that existed before the call are retained.</p> <p>The <code>wattr_off()</code> and <code>wattr_on()</code> functions unset or set the specified attributes for window <code>win</code>.</p> <p>The <code>attr_set()</code> and <code>wattr_set()</code> functions change the rendition of <code>stdscr</code> and <code>win</code>; the old values are not retained.</p> <p>The <code>color_set()</code> and <code>wcolor_set()</code> functions set the window color of <code>stdscr</code> and <code>win</code> to <code>color</code>.</p> <p>The attributes and color pairs that can be used are specified in the <code>Attributes</code>, <code>Color Pairs</code>, and <code>Renditions</code> section of the <code>curses(3XCURSES)</code> man page.</p> |              |                                                                      |              |                                       |             |                             |            |                                                                       |

| DESCRIPTION | <p>The <code>newwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The upper left-hand corner of the window is at line <i>begin_y</i>, column <i>begin_x</i>. If either <i>nlines</i> or <i>ncols</i> is zero, they default to <code>LINES</code> — <i>begin_y</i> and <code>COLS</code> — <i>begin_x</i>. A new full-screen window is created by calling <code>newwin(0, 0, 0, 0)</code>.</p> <p>The <code>delwin()</code> routine deletes the named window, freeing all memory associated with it. Subwindows must be deleted before the main window can be deleted.</p> <p>The <code>mvwin()</code> routine moves the window so that the upper left-hand corner is at position (<i>x</i>, <i>y</i>). If the move would cause the window to be off the screen, it is an error and the window is not moved. Moving subwindows is allowed, but should be avoided.</p> <p>The <code>subwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The window is at position (<i>begin_y</i>, <i>begin_x</i>) on the screen. (This position is relative to the screen, and not to the window <i>orig</i>.) The window is made in the middle of the window <i>orig</i>, so that changes made to one window will affect both windows. The subwindow shares memory with the window <i>orig</i>. When using this routine, it is necessary to call <code>touchwin()</code> or <code>touchline()</code> on <i>orig</i> before calling <code>wrefresh()</code> on the subwindow.</p> <p>The <code>derwin()</code> routine is the same as <code>subwin()</code>, except that <i>begin_y</i> and <i>begin_x</i> are relative to the origin of the window <i>orig</i> rather than the screen. There is no difference between the subwindows and the derived windows.</p> |

The `mvderwin()` routine moves a derived window (or subwindow) inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

The `dupwin()` routine creates an exact duplicate of the window *win*.

Each `curses` window maintains two data structures: the character image structure and the status structure. The character image structure is shared among all windows in the window hierarchy (that is, the window with all subwindows). The status structure, which contains information about individual line changes in the window, is private to each window. The routine `wrefresh()` uses the status data structure when performing screen updating. Since status structures are not shared, changes made to one window in the hierarchy may not be properly reflected on the screen.

The routine `wsyncup()` causes the changes in the status structure of a window to be reflected in the status structures of its ancestors. If `syncok()` is called with second argument `TRUE` then `wsyncup()` is called automatically whenever there is a change in the window.

The routine `wcursyncup()` updates the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

The routine `wsyncdown()` updates the status structure of the window to reflect the changes in the status structures of its ancestors. Applications seldom call this routine because it is called automatically by `wrefresh()`.

## RETURN VALUES

Routines that return an integer return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`delwin()` returns the integer `ERR` upon failure and `OK` upon successful completion.

Routines that return pointers return `NULL` on error.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

## SEE ALSO

`curs_refresh(3CURSES)`, `curs_touch(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

## NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

If many small changes are made to the window, the `wsyncup()` option could degrade performance.

`wcursyncup(3CURSES)`

Note that `syncok()` may be a macro.

| <b>NAME</b>          | syncok, wcursyncup, wsyncdown, wsyncup – synchronize window with its parents or children                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |

| <b>PARAMETERS</b>    | <p><i>win</i> Is a pointer to a window.</p> <p><i>bf</i> Is a Boolean expression.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>syncok()</code> function uses the value of <i>bf</i> to determine whether or not the window <i>win</i>'s ancestors are implicitly touched whenever there is a change to <i>win</i>. If <i>bf</i> is TRUE, this touching occurs. If <i>bf</i> is FALSE, it does not occur. The initial value for <i>bf</i> is FALSE.</p> <p>The <code>wcursyncup()</code> function moves the cursor in <i>win</i>'s ancestors to match its position in <i>win</i>.</p> <p>The <code>wsyncdown()</code> function touches <i>win</i> if any of its ancestors have been touched.</p> <p>The <code>wsyncup()</code> function touches all ancestors of <i>win</i>.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | <p>On success, the <code>syncok()</code> function returns OK. Otherwise, it returns ERR.</p> <p>The other functions do not return a value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |

## wdelch(3CURSES)

| NAME           | curs_delch, delch, wdelch, mvdelch, mvwdelch – delete character under cursor in a curses window                                                                                                                                                                                                                                                                                           |                |                 |          |        |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int delch(void); int wdelch(WINDOW *win); int mvdelch(int y, int x); int mvwdelch(WINDOW *win, int y, int x);</pre>                                                                                                                                                                                     |                |                 |          |        |
| DESCRIPTION    | With these routines the character under the cursor in the window is deleted; all characters to the right of the cursor on the same line are moved to the left one position and the last character on the line is filled with a blank. The cursor position does not change (after moving to <i>y, x</i> , if specified). This does not imply use of the hardware delete character feature. |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                          |                |                 |          |        |

| DESCRIPTION         | <p>The <code>delch()</code> and <code>wdelch()</code> functions delete the character at the current cursor position from <code>stdscr</code> and <code>win</code>, respectively. All remaining characters after cursor through to the end of the line are shifted one character towards the start of the line. The last character on the line becomes a space; characters on other lines are not affected.</p> <p>The <code>mvdelch()</code> and <code>mvwdelch()</code> functions delete the character at the position specified by the <code>x</code> and <code>y</code> parameters; the former deletes the character from <code>stdscr</code>; the latter from <code>win</code>.</p> |                |                 |                     |          |          |        |
| PARAMETERS          | <p><code>y</code> Is the <code>y</code> (row) coordinate of the position of the character to be removed.</p> <p><code>x</code> Is the <code>x</code> (column) coordinate of the position of the character to be removed.</p> <p><code>win</code> Is a pointer to the window containing the character to be removed.</p>                                                                                                                                                                                                                                                                                                                                                                 |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return <code>OK</code> . Otherwise, they return <code>ERR</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |                     |          |          |        |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int deleteln(void); int wdeleteln(WINDOW *win); int insdelln(int n); int winsdelln(WINDOW *win, int n); int insertln(void); int winsertln(WINDOW *win);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |          |        |
| DESCRIPTION    | <p>With the <code>deleteln()</code> and <code>wdeleteln()</code> routines, the line under the cursor in the window is deleted; all lines below the current line are moved up one line. The bottom line of the window is cleared. The cursor position does not change. This does not imply use of a hardware delete line feature.</p> <p>With the <code>insdelln()</code> and <code>winsdelln()</code> routines, for positive <i>n</i>, insert <i>n</i> lines into the specified window above the current line. The <i>n</i> bottom lines are lost. For negative <i>n</i>, delete <i>n</i> lines (starting with the one under the cursor), and move the remaining lines up. The bottom <i>n</i> lines are cleared. The current cursor position remains the same.</p> <p>With the <code>insertln()</code> and <code>winsertln()</code> routines, a blank line is inserted above the current line and the bottom line is lost. This does not imply use of a hardware insert line feature.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |          |        |

|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | deleteln, wdeleteln – remove a line                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>deleteln</b>(void);  int <b>wdeleteln</b>(WINDOW *win);</pre> |
| <b>DESCRIPTION</b>   | The deleteln() and wdeleteln() functions delete the line containing the cursor from stdscr and win, respectively. All lines below the one deleted are moved up one line. The last line of the window becomes blank. The position of the cursor is unchanged.   |
| <b>PARAMETERS</b>    | <i>win</i> Is a pointer to the window from which the line is removed.                                                                                                                                                                                          |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                             |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                          |

| <b>NAME</b>          | <code> curs_addch, addch, waddch, mvaddch, mvwaddch, echochar, wechochar </code> – add a character (with attributes) to a curses window and advance cursor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>DESCRIPTION</b>   | <p>With the <code>addch()</code>, <code>waddch()</code>, <code>mvaddch()</code>, and <code>mvwaddch()</code> routines, the character <i>ch</i> is put into the window at the current cursor position of the window and the position of the window cursor is advanced. Its function is similar to that of <code>putchar()</code>. At the right margin, an automatic newline is performed. At the bottom of the scrolling region, if <code>scrollok()</code> is enabled, the scrolling region is scrolled up one line.</p> <p>If <i>ch</i> is a tab, newline, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol()</code> before moving. Tabs are considered to be at every eighth column. If <i>ch</i> is another control character, it is drawn in the ^X notation. Calling <code>winch()</code> after adding a control character does not return the control character, but instead returns the representation of the control character. See <code>curs_inch(3CURSES)</code>.</p> <p>Video attributes can be combined with a character by OR-ing them into the parameter. This results in these attributes also being set. (The intent here is that text, including attributes, can be copied from one place to another using <code>inch()</code> and <code>addch()</code>.) (see <code>standout()</code>, predefined video attribute constants, on the <code>curs_attr(3CURSES)</code> page).</p> <p>The <code>echochar()</code> and <code>wechochar()</code> routines are functionally equivalent to a call to <code>addch()</code> followed by a call to <code>refresh()</code>, or a call to <code>waddch</code> followed by a call to <code>wrefresh()</code>. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents.</p> |
| <b>Line Graphics</b> | <p>The following variables may be used to add line drawing characters to the screen with routines of the <code>addch()</code> family. When variables are defined for the terminal, the <code>A_ALTCHARSET</code> bit is turned on (see <code>curs_attr(3CURSES)</code>). Otherwise, the default character listed below is stored in the variable. The names chosen are consistent with the VT100 nomenclature.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## RETURN VALUES

All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.

wechochar(3CURSES)

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curs\_attr(3CURSES), curs\_clear(3CURSES), curs\_inch(3CURSES), curs\_outopts(3CURSES), curs\_refresh(3CURSES), curses(3CURSES), putc(3C), attributes(5)

**NOTES** The header <curses.h> automatically includes the headers <stdio.h> and <unctrl.h>.

Note that addch(), mvaddch(), mvwaddch(), and echochar() may be macros.

| <b>NAME</b>          | echochar, wechochar – add a single-byte character and refresh window                                                                                                                                                                                                                                              |                |                 |                     |          |          |        |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>echochar</b>(const chtype <i>ch</i>) ;  int <b>wechochar</b>(WINDOW *<i>win</i>, const chtype <i>ch</i>) ;</pre> |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | The echochar() function produces the same effect as calling addch(3XCURSES) and then refresh(3XCURSES). The wechochar() function produces the same effect as calling waddch(3XCURSES) and then wrefresh(3XCURSES).                                                                                                |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>ch</i>            Is a pointer to the character to be written to the window.</p> <p><i>win</i>           Is a pointer to the window in which the character is to be added.</p>                                                                                                                              |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                             |                |                 |                     |          |          |        |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                   |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>   | <p>           The <code>addwch()</code>, <code>waddwch()</code>, <code>mvaddwch()</code>, and <code>mvwaddwch()</code> routines put the character <i>wch</i>, holding a <code>wchar_t</code> character, into the window at the current cursor position of the window and advance the position of the window cursor. Their function is similar to that of <code>putwchar(3C)</code> in the C multibyte library. At the right margin, an automatic newline is performed. At the bottom of the scrolling region, if <code>scrollok</code> is enabled, the scrolling region is scrolled up one line.         </p> <p>           If <i>wch</i> is a tab, newline, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol(3CURSES)</code> before moving. Tabs are considered to be at every eighth column. If <i>wch</i> is another control character, it is drawn in the <code>^X</code> notation. Calling <code>winwch(3CURSES)</code> after adding a control character does not return the control character, but instead returns the representation of the control character.         </p> <p>           Video attributes can be combined with a <code>wchar_t</code> character by OR-ing them into the parameter. This results in these attributes also being set. (The intent here is that text, including attributes, can be copied from one place to another using <code>inwch()</code> and <code>addwch()</code>.) See <code>standout(3CURSES)</code>, predefined video attribute constants.         </p> <p>           The <code>echowchar()</code> and <code>wechownchar()</code> routines are functionally equivalent to a call to <code>addwch()</code> followed by a call to <code>refresh(3CURSES)</code>, or a call to <code>waddwch()</code> followed by a call to <code>wrefresh(3CURSES)</code>. The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain might be seen by using these routines instead of their equivalents.         </p> |
| <b>Line Graphics</b> | <p>           The following variables may be used to add line drawing characters to the screen with routines of the <code>addwch()</code> family. When variables are defined for the terminal, the <code>A_ALTCHARSET</code> bit is turned on. (See <code>curl_attr(3CURSES)</code>). Otherwise, the default character listed below is stored in the variable. The names chosen are consistent with the VT100 nomenclature.         </p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| ACS_LANTERN  | #       | lantern symbol          |
| ACS_BLOCK    | #       | solid square block      |

## RETURN VALUE

All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.

wechownchar(3CURSES)

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** putwchar(3C), clrtoeol(3CURSES), curses(3CURSES), curs\_attr(3CURSES), curs\_inwch(3CURSES), curs\_outopts(3CURSES), refresh(3CURSES), standout(3CURSES), winwch(3CURSES), wrefresh(3CURSES), attributes(5)

**NOTES** The header file <curses.h> automatically includes the header files <stdio.h>, <unctrl.h> and <wdec.h>.

Note that addwch(), mvaddwch(), mvwaddwch(), and echowchar() may be macros.

None of these routines can use the color attribute in chtype.

| <b>NAME</b>          | echo_wchar, wecho_wchar – add a complex character and refresh window                                                                                                                                                                                                                                 |                |                 |                     |          |          |        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>echo_wchar</b>(const cchar_t *wch);  int <b>wecho_wchar</b>(WINDOW *win, const cchar_t *wch);</pre> |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | The echo_wchar() function produces the same effect as calling add_wch(3XCURSES) and then refresh(3XCURSES). The wecho_wchar() function produces the same effect as calling wadd_wch(3XCURSES) and then wrefresh(3XCURSES).                                                                           |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>wch</i> Is a pointer to the complex character to be written to the window.</p> <p><i>win</i> Is a pointer to the window in which the character is to be added.</p>                                                                                                                             |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                   |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |

werase(3CURSES)

| NAME           | curs_clear, erase, werase, clear, wclear, clrtoobot, wclrtoobot, clrtoeol, wclrtoeol – clear all or part of a curses window                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |          |        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int  erase(void); int  werase(WINDOW *win); int  clear(void); int  wclear(WINDOW *win); int  clrtoobot(void); int  wclrtoobot(WINDOW *win); int  clrtoeol(void); int  wclrtoeol(WINDOW *win);</pre>                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |
| DESCRIPTION    | <p>The erase() and werase() routines copy blanks to every position in the window.</p> <p>The clear() and wclear() routines are like erase() and werase(), but they also call clearok(), so that the screen is cleared completely on the next call to wrefresh() for that window and repainted from scratch.</p> <p>The clrtoobot() and wclrtoobot() routines erase all lines below the cursor in the window. Also, the current line to the right of the cursor, inclusive, is erased.</p> <p>The clrtoeol() and wclrtoeol() routines erase the current line to the right of the cursor, inclusive.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer OK, or a non-negative integer if immedok() is set. See curs_ouptops(3CURSES).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |

| <b>DESCRIPTION</b>  | <p>The <code>clear()</code> and <code>erase()</code> functions clear <code>stdscr</code>, destroying its previous contents. The <code>wclear()</code> and <code>werase()</code> functions perform the same action, but clear the window specified by <i>win</i> instead of <code>stdscr</code>.</p> <p>The <code>clear()</code> and <code>wclear()</code> functions also call the <code>clearok()</code> function. This function clears and redraws the entire screen on the next call to <code>refresh(3XCURSES)</code> or <code>wrefresh(3XCURSES)</code> for the window.</p> <p>The current background character (and attributes) is used to clear the screen.</p> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>   | <p><i>win</i> Is a pointer to the window that is to be cleared.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |                     |          |          |        |
| <b>ERRORS</b>       | <p>OK Successful completion.</p> <p>ERR An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>   | <p>The <b>bkgrndset()</b> and <b>wbkgrndset()</b> functions turn off the previous background attributes, logical OR the requested attributes into the window rendition, and set the background property of the current or specified window based on the information in <i>wch</i>.</p> <p>The <b>bkgrnd()</b> and <b>wbkgrnd()</b> functions turn off the previous background attributes, logical OR the requested attributes into the window rendition, and set the background property of the current or specified window and then apply this setting to every character position in that window:</p> <ul style="list-style-type: none"> <li>■ The rendition of every character on the screen is changed to the new window rendition.</li> <li>■ Wherever the former background character appears, it is changed to the new background character.</li> </ul> <p>If <i>wch</i> refers to a non-spacing complex character for <b>bkgrnd()</b>, <b>bkgrndset()</b>, <b>wbkgrnd()</b>, and <b>wbkgrndset()</b>, then <i>wch</i> is added to the existing spacing complex character that is the background character. If <i>wch</i> refers to a multi-column character, the results are unspecified.</p> <p>The <b>getbkgrnd()</b> and <b>wgetbkgrnd()</b> functions store, into the area pointed to by <i>wch</i>, the window's background character and rendition.</p> |
| <b>PARAMETERS</b>    | <p><i>wch</i> Is a pointer to the complex background character to be set.</p> <p><i>win</i> Is a pointer to the window in which the complex background character is to be set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>RETURN VALUES</b> | <p>The <b>bkgrndset()</b> and <b>wbkgrndset()</b> functions do not return a value.</p> <p>Upon successful completion, the other functions return OK. Otherwise, they return ERR.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int  <b>getch</b>(void); int  <b>wgetch</b>(WINDOW *win); int  <b>mvwgetch</b>(int y, int x); int  <b>mvwgetch</b>(WINDOW *win, int y, int x); int  <b>ungetch</b>(int ch);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |      |          |           |           |
| <b>DESCRIPTION</b>   | <p>With the <code>getch()</code>, <code>wgetch()</code>, <code>mvwgetch()</code>, and <code>mvwgetch()</code> routines a character is read from the terminal associated with the window. In no-delay mode, if no input is waiting, the value <code>ERR</code> is returned. In delay mode, the program waits until the system passes text through to the program. Depending on the setting of <code>cbreak()</code>, this is after one character (<code>cbreak</code> mode), or after the first newline (<code>nocbreak</code> mode). In half-delay mode, the program waits until a character is typed or the specified timeout has been reached. Unless <code>noecho()</code> has been set, the character will also be echoed into the designated window.</p> <p>If the window is not a pad, and it has been moved or modified since the last call to <code>wrefresh()</code>, <code>wrefresh()</code> will be called before another character is read.</p> <p>If <code>keypad()</code> is <code>TRUE</code>, and a function key is pressed, the token for that function key is returned instead of the raw characters. Possible function keys are defined in <code>&lt;curses.h&gt;</code> with integers beginning with <code>0401</code>, whose names begin with <code>KEY_</code>. If a character that could be the beginning of a function key (such as escape) is received, <code>curses</code> sets a timer. If the remainder of the sequence does not come in within the designated time, the character is passed through; otherwise, the function key value is returned. For this reason, many terminals experience a delay between the time a user presses the escape key and the escape is returned to the program. Since tokens returned by these routines are outside the ASCII range, they are not printable.</p> <p>The <code>ungetch()</code> routine places <code>ch</code> back onto the input queue to be returned by the next call to <code>wgetch()</code>.</p> |      |          |           |           |
| <b>Function Keys</b> | <p>The following function keys, defined in <code>&lt;curses.h&gt;</code>, might be returned by <code>getch()</code> if <code>keypad()</code> has been enabled. Note that not all of these may be supported on a particular terminal if the terminal does not transmit a unique code when the key is pressed or if the definition for the key is not present in the <i>terminfo</i> database.</p> <table> <tr> <th>Name</th><th>Key name</th></tr> <tr> <td>KEY_BREAK</td><td>Break key</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Name | Key name | KEY_BREAK | Break key |

| KEY_SOPTIONS  | Shifted options key     |
| KEY_SPREVIOUS | Shifted prev key        |
| KEY_SPRINT    | Shifted print key       |
| KEY_SREDO     | Shifted redo key        |
| KEY_SREPLACE  | Shifted replace key     |
| KEY_SRIGHT    | Shifted right arrow     |
| KEY_SRSUME    | Shifted resume key      |
| KEY_SSAVE     | Shifted save key        |
| KEY_SSUSPEND  | Shifted suspend key     |

wgetch(3CURSES)

| <i>Name</i> | <i>Key name</i>  |
|-------------|------------------|
| KEY_SUNDO   | Shifted undo key |
| KEY_SUSPEND | Suspend key      |
| KEY_UNDO    | Undo key         |

**RETURN VALUES** All routines return the integer ERR upon failure. The wgetch() routine returns an integer value other than ERR upon successful completion. The other routines return the next input character or function key code upon successful completion.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curs\_inopts(3CURSES), curs\_move(3CURSES), curs\_refresh(3CURSES), curses(3CURSES), attributes(5)

**NOTES** The header <curses.h> automatically includes the headers <stdio.h> and <unctrl.h>.

Use of the escape key for a single character function is discouraged.

When using getch(), wgetch(), mvgetch(), or mvwgetch(), nocbreak mode (nocbreak()) and echo mode (echo()) should not be used at the same time. Depending on the state of the tty driver when each character is typed, the program may produce undesirable results.

Note that getch(), mvgetch(), and mvwgetch() may be macros.

| <b>NAME</b>                              | getch, wgetch, mvgetch, mvwgetch – get a single-byte character from the terminal                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>                          | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;urses.h&gt;  int <b>getch</b>(void);  int <b>wgetch</b>(WINDOW *win);  int <b>mvgetch</b>(int y, int x);  int <b>mvwgetch</b>(WINDOW *win, int y, int x);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>PARAMETERS</b>                        | <p><i>win</i> Is a pointer to the window associated with the terminal from which the character is to be read.</p> <p><i>y</i> Is the y (row) coordinate for the position of the character to be read.</p> <p><i>x</i> Is the x (column) coordinate for the position of the character to be read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b>                       | <p>These functions read a single-byte character from the terminal associated with the current or specified window. The results are unspecified if the input is not a single-byte character. If keypad(3XCURSES) is enabled, these functions respond to the pressing of a function key by returning the corresponding <code>KEY_</code> value defined in <code>&lt;urses.h&gt;</code></p> <p>Processing of terminal input is subject to the general rules described on the keypad(3XCURSES) manual page.</p> <p>If echoing is enabled, then the character is echoed as though it were provided as an input argument to <code>addch(3XCURSES)</code>, except for the following characters:</p> <p><code>&lt;backspace&gt;</code> The input is interpreted as follows: unless the cursor already was in column 0, <code>&lt;backspace&gt;</code> moves the cursor one column toward the start of the current line and any characters after the <code>&lt;backspace&gt;</code> are added or inserted starting there. The character at the resulting cursor position is then deleted as though <code>delch(3XCURSES)</code> were called, except that if the cursor was originally in the first column of the line, the user is alerted as though <code>beep(3XCURSES)</code> were called.</p> <p>Function keys The user is alerted as though <code>beep()</code> were called. Information concerning the function keys is not returned to the caller.</p> <p>If the current or specified window is not a pad, and it has been moved modified since the last refresh operation, then it will be refreshed before another character is read.</p> |
| <b>Constant Values for Function Keys</b> | The following is a list of tokens for function keys that are returned by the <code>getch()</code> set of functions if keypad handling is enabled (some terminals may not support all tokens).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

# wgetch(3XCURSES)

| Constant          | Description                                   |
|-------------------|-----------------------------------------------|
| KEY_BREAK         | Break key                                     |
| KEY_DOWN          | The down arrow key                            |
| KEY_UP            | The up arrow key                              |
| KEY_LEFT          | The left arrow key                            |
| KEY_RIGHT         | The right arrow key                           |
| KEY_HOME          | Home key                                      |
| KEY_BACKSPACE     | Backspace                                     |
| KEY_F0            | Function keys. Space for 64 keys is reserved. |
| KEY_F( <i>n</i> ) | For $0 \leq n \leq 63$                        |
| KEY_DL            | Delete line                                   |
| KEY_IL            | Insert line                                   |
| KEY_DC            | Delete character                              |
| KEY_IC            | Insert char or enter insert mode              |
| KEY_EIC           | Exit insert char mode                         |
| KEY_CLEAR         | Clear screen                                  |
| KEY_EOS           | Clear to end of screen                        |
| KEY_EOL           | Clear to end of line                          |
| KEY_SF            | Scroll 1 line forward                         |
| KEY_SR            | Scroll 1 line backwards                       |
| KEY_NPAGE         | Next page                                     |
| KEY_PPAGE         | Previous page                                 |
| KEY_STAB          | Set tab                                       |
| KEY_CTAB          | Clear tab                                     |
| KEY_CATAB         | Clear all tabs                                |
| KEY_ENTER         | Enter or send                                 |
| KEY_SRESET        | Soft (partial) reset                          |
| KEY_RESET         | Reset or hard reset                           |
| KEY_PRINT         | Print or copy                                 |
| KEY_LL            | Home down or bottom (lower left)              |

| Constant      | Description           |
|---------------|-----------------------|
| KEY_A1        | Upper left of keypad  |
| KEY_A3        | Upper right of keypad |
| KEY_B2        | Center of keypad      |
| KEY_C1        | Lower left of keypad  |
| KEY_C3        | Lower right of keypad |
| KEY_BTAB      | Back tab              |
| KEY_BEG       | Beginning key         |
| KEY_CANCEL    | Cancel key            |
| KEY_CLOSE     | Close key             |
| KEY_COMMAND   | Cmd (command) key     |
| KEY_COPY      | Copy key              |
| KEY_CREATE    | Create key            |
| KEY_END       | End key               |
| KEY_EXIT      | Exit key              |
| KEY_FIND      | Find key              |
| KEY_HELP      | Help key              |
| KEY_MARK      | Mark key              |
| KEY_MESSAGE   | Message key           |
| KEY_MOVE      | Move key              |
| KEY_NEXT      | Next object key       |
| KEY_OPEN      | Open key              |
| KEY_OPTIONS   | Options key           |

wgetch(3XCURSES)

| Constant    | Description      |
|-------------|------------------|
| KEY_SUNDO   | Shifted undo key |
| KEY_SUSPEND | Suspend key      |
| KEY_UNDO    | Undo key         |

**RETURN VALUES** Upon successful completion, these functions return the single-byte character, `KEY_` value, or `ERR`. When in the nodelay mode and no data is available, `ERR` is returned.

**ERRORS** No errors are defined.

**USAGE** Applications should not define the escape key by itself as a single-character function.

When using these functions, nocbreak mode (`cbreak(3XCURSES)`) and echo mode (`echo(3XCURSES)`) should not be used at the same time. Depending on the state of the terminal when each character is typed, the application may produce undesirable results.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

## wgetnstr(3CURSES)

| <b>NAME</b>          | <code>curs_getstr</code> , <code>getstr</code> , <code>wgetstr</code> , <code>mvgetstr</code> , <code>mvwgetstr</code> , <code>wgetnstr</code> – get character strings from curses terminal keyboard                                                                                                                                                                                                                                                                                                     |                |                 |          |        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lcurses [ <i>library</i> ... ] #include &lt;curses.h&gt;  int <b>getstr</b>(char *<i>str</i>) ; int <b>wgetstr</b>(WINDOW *<i>win</i>, char *<i>str</i>) ; int <b>mvgetstr</b>(int <i>y</i>, int <i>x</i>, char *<i>str</i>) ; int <b>mvwgetstr</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, char *<i>str</i>) ; int <b>wgetnstr</b>(WINDOW *<i>win</i>, char *<i>str</i>, int <i>n</i>) ;</pre>                                                     |                |                 |          |        |
| <b>DESCRIPTION</b>   | The effect of <code>getstr()</code> is as though a series of calls to <code>getch()</code> were made, until a newline or carriage return is received. The resulting value is placed in the area pointed to by the character pointer <i>str</i> . <code>wgetnstr()</code> reads at most <i>n</i> characters, thus preventing a possible overflow of the input buffer. The user's erase and kill characters are interpreted, as well as any special keys (such as function keys, HOME key, and CLEAR key.) |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |          |        |

| DESCRIPTION | <p>The <code>getstr()</code> and <code>wgetstr()</code> functions get a character string from the terminal associated with the window <code>stdscr</code> or window <i>win</i>, respectively. The <code>mvgetstr()</code> and <code>mvwgetstr()</code> functions move the cursor to the position specified in <code>stdscr</code> or <i>win</i>, respectively, then get a character string.</p> <p>These functions call <code>wgetch(3XCURSES)</code> and place each received character in <i>str</i> until a newline is received, which is also placed in <i>str</i>. The erase and kill characters set by the user are processed.</p> <p>The <code>getnstr()</code>, <code>mvgetnstr()</code>, <code>mvwgetnstr()</code> and <code>wgetnstr()</code> functions read at most <i>n</i> characters. These functions are used to prevent overflowing the input buffer.</p> <p>The <code>getnstr()</code>, <code>wgetnstr()</code>, <code>mvgetnstr()</code>, and <code>mvwgetnstr()</code> functions only return complete multibyte characters. If the area pointed to by <i>str</i> is not large enough to hold at least one character, these functions fail.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>SYNOPSIS</b>     | <pre>cc [ flag ... ] file ... -lcurses [ library .. ] #include &lt;curses.h&gt;  int <b>getwstr</b>(wchar_t *wstr); int <b>getnwstr</b>(wchar_t *wstr, int n); int <b>wgetwstr</b>(WINDOW *win, wchar_t *wstr); int <b>wgetnwstr</b>(WINDOW *win, wchar_t *wstr, int n); int <b>mvgetwstr</b>(int y, int x, wchar_t *wstr); int <b>mvgetnwstr</b>(int y, int x, wchar_t *wstr, int n); int <b>mvwgetwstr</b>(WINDOW *win, int y, int x, wchar_t *wstr); int <b>mvwgetnwstr</b>(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre> |                |                 |          |        |
| <b>DESCRIPTION</b>  | The effect of getwstr() is as though a series of calls to getwch(3CURSES) were made, until a newline and carriage return is received. The resulting value is placed in the area pointed to by the wchar_t pointer wstr. getnwstr() reads at most n wchar_t characters, thus preventing a possible overflow of the input buffer. The user's erase and kill characters are interpreted, as well as any special keys (such as function keys, HOME key, CLEAR key, etc.).                                                                  |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |          |        |

| <b>DESCRIPTION</b>   | <p>The <code>get_wstr()</code> and <code>wget_wstr()</code> functions get a wide character string from the terminal associated with the window <code>stdscr</code> or window <i>win</i>, respectively. The <code>mvget_wstr()</code> and <code>mvwget_wstr()</code> functions move the cursor to the position specified in <code>stdscr</code> or <i>win</i>, respectively, then get a wide character string.</p> <p>These functions call <code>wget_wch(3XCURSES)</code> and place each received character in <i>wstr</i> until a newline character, end-of-line character, or end-of-file character is received, which is also placed in <i>wstr</i>. The erase and kill characters set by the user are processed.</p> <p>The <code>getn_wstr()</code>, <code>mvgetn_wstr()</code>, <code>mvwgetn_wstr()</code> and <code>wgetn_wstr()</code> functions read at most <i>n</i> characters. These functions are used to prevent overflowing the input buffer.</p> |
| <b>PARAMETERS</b>    | <p><i>wstr</i> Is a pointer to the area where the character string is to be placed.</p> <p><i>n</i> Is the maximum number of characters to read from input.</p> <p><i>y</i> Is the y (row) coordinate of starting position of character string to be read.</p> <p><i>x</i> Is the x (column) coordinate of starting position of character string to be read.</p> <p><i>win</i> points to the window associated with the terminal from which the character is to be read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>getstr</b>(char *str); int <b>wgetstr</b>(WINDOW *win, char *str); int <b>mvgetstr</b>(int y, int x, char *str); int <b>mvwgetstr</b>(WINDOW *win, int y, int x, char *str); int <b>wgetnstr</b>(WINDOW *win, char *str, int n);</pre>                                                                                                                                                                                      |                |                 |          |        |
| DESCRIPTION    | The effect of <code>getstr()</code> is as though a series of calls to <code>getch()</code> were made, until a newline or carriage return is received. The resulting value is placed in the area pointed to by the character pointer <code>str</code> . <code>wgetnstr()</code> reads at most <code>n</code> characters, thus preventing a possible overflow of the input buffer. The user's erase and kill characters are interpreted, as well as any special keys (such as function keys, HOME key, and CLEAR key.) |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| DESCRIPTION | <p>The <code>getstr()</code> and <code>wgetstr()</code> functions get a character string from the terminal associated with the window <code>stdscr</code> or window <i>win</i>, respectively. The <code>mvgetstr()</code> and <code>mvwgetstr()</code> functions move the cursor to the position specified in <code>stdscr</code> or <i>win</i>, respectively, then get a character string.</p> <p>These functions call <code>wgetch(3XCURSES)</code> and place each received character in <i>str</i> until a newline is received, which is also placed in <i>str</i>. The erase and kill characters set by the user are processed.</p> <p>The <code>getnstr()</code>, <code>mvgetnstr()</code>, <code>mvwgetnstr()</code> and <code>wgetnstr()</code> functions read at most <i>n</i> characters. These functions are used to prevent overflowing the input buffer.</p> <p>The <code>getnstr()</code>, <code>wgetnstr()</code>, <code>mvgetnstr()</code>, and <code>mvwgetnstr()</code> functions only return complete multibyte characters. If the area pointed to by <i>str</i> is not large enough to hold at least one character, these functions fail.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PARAMETERS  | <p><i>str</i></p> <p><i>n</i></p> <p><i>y</i></p> <p><i>x</i></p> <p><i>win</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <p>Is a pointer to the area where the character string is to be placed.</p> <p>Is the maximum number of characters to read from input.</p> <p>Is the y (row) coordinate of starting position of character string to be read.</p> <p>Is the x (column) coordinate of starting position of character string to be read.</p> <p>Points to the window associated with the terminal from which the character is to be read.</p> |

wgetstr(3XCURSES)

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| DESCRIPTION   | <p>The <code>getwch()</code>, <code>wgetwch()</code>, <code>mvgetwch()</code>, and <code>mvwgetwch()</code> routines read an EUC character from the terminal associated with the window, transform it into a <code>wchar_t</code> character, and return a <code>wchar_t</code> character. In no-delay mode, if no input is waiting, the value <code>ERR</code> is returned. In delay mode, the program waits until the system passes text through to the program. Depending on the setting of <code>cbreak</code>, this is after one character ( <code>cbreak</code> mode ), or after the first newline ( <code>nocbreak</code> mode ). In half-delay mode, the program waits until a character is typed or the specified timeout has been reached. Unless <code>noecho</code> has been set, the character will also be echoed into the designated window.</p> <p>If the window is not a pad, and it has been moved or modified since the last call to <code>wrefresh(3CURSES)</code>, <code>wrefresh</code> will be called before another character is read.</p> <p>If <code>keypad</code> is <code>TRUE</code>, and a function key is pressed, the token for that function key is returned instead of the raw characters. Possible function keys are defined in <code>&lt;curses.h&gt;</code> with integers beginning with <code>0401</code>, whose names begin with <code>KEY_</code>. If a character that could be the beginning of a function key (such as escape) is received, <code>curses(3CURSES)</code> sets a timer. If the remainder of the sequence does not come in within the designated time, the character is passed through; otherwise, the function key value is returned. For this reason, many terminals experience a delay between the time a user presses the escape key and the escape is returned to the program.</p> <p>The <code>ungetwch()</code> routine places <code>wch</code> back onto the input queue to be returned by the next call to <code>wgetwch()</code>.</p> |      |          |           |           |
| Function Keys | <p>The following function keys, defined in <code>&lt;curses.h&gt;</code>, might be returned by <code>getwch()</code> if <code>keypad</code> has been enabled. Note that not all of these may be supported on a particular terminal if the terminal does not transmit a unique code when the key is pressed or if the definition for the key is not present in the <code>terminfo(4)</code> database.</p> <table><tr><th>Name</th><th>Key name</th></tr><tr><td>KEY_BREAK</td><td>Break key</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Name | Key name | KEY_BREAK | Break key |

| KEY_ENTER         | Enter or send                                                                                     |
| KEY_SRESET        | Soft (partial) reset                                                                              |
| KEY_RESET         | Reset or hard reset                                                                               |
| KEY_PRINT         | Print or copy                                                                                     |
| KEY_LL            | Home down or bottom (lower left). Keypad is arranged like this: A1 up A3 left B2 right C1 down C3 |

| <i>Name</i>   | <i>Key name</i>       |
|---------------|-----------------------|
| KEY_A1        | Upper left of keypad  |
| KEY_A3        | Upper right of keypad |
| KEY_B2        | Center of keypad      |
| KEY_C1        | Lower left of keypad  |
| KEY_C3        | Lower right of keypad |
| KEY_BTAB      | Back tab key          |
| KEY_BEG       | Beg(inning) key       |
| KEY_CANCEL    | Cancel key            |
| KEY_CLOSE     | Close key             |
| KEY_COMMAND   | Cmd (command) key     |
| KEY_COPY      | Copy key              |
| KEY_CREATE    | Create key            |
| KEY_END       | End key               |
| KEY_EXIT      | Exit key              |
| KEY_FIND      | Find key              |
| KEY_HELP      | Help key              |
| KEY_MARK      | Mark key              |
| KEY_MESSAGE   | Message key           |
| KEY_MOVE      | Move key              |
| KEY_NEXT      | Next object key       |
| KEY_OPEN      | Open key              |
| KEY_OPTIONS   | Options key           |
| KEY_PREVIOUS  | Previous object key   |
| KEY_REDO      | Redo key              |
| KEY_REFERENCE | Reference key         |
| KEY_REFRESH   | Refresh key           |
| KEY_REPLACE   | Replace key           |
| KEY_RESTART   | Restart key           |
| KEY_RESUME    | Resume key            |

wgetwch(3CURSES)

| <i>Name</i>   | <i>Key name</i>         |
|---------------|-------------------------|
| KEY_SAVE      | Save key                |
| KEY_SBEG      | Shifted beginning key   |
| KEY_SCANCEL   | Shifted cancel key      |
| KEY_SCOMMAND  | Shifted command key     |
| KEY_SCOPY     | Shifted copy key        |
| KEY_SCREATE   | Shifted create key      |
| KEY_SDC       | Shifted delete char key |
| KEY_SDL       | Shifted delete line key |
| KEY_SELECT    | Select key              |
| KEY_SEND      | Shifted end key         |
| KEY_SEOL      | Shifted clear line key  |
| KEY_SEXIT     | Shifted exit key        |
| KEY_SFIND     | Shifted find key        |
| KEY_SHELP     | Shifted help key        |
| KEY_SHOME     | Shifted home key        |
| KEY_SIC       | Shifted input key       |
| KEY_SLEFT     | Shifted left arrow key  |
| KEY_SMESSAGE  | Shifted message key     |
| KEY_SMOVE     | Shifted move key        |
| KEY_SNEXT     | Shifted next key        |
| KEY_SOPTIONS  | Shifted options key     |
| KEY_SPREVIOUS | Shifted prev key        |
| KEY_SPRINT    | Shifted print key       |
| KEY_SREDO     | Shifted redo key        |
| KEY_SREPLACE  | Shifted replace key     |
| KEY_SRIGHT    | Shifted right arrow     |
| KEY_SRSUME    | Shifted resume key      |
| KEY_SSAVE     | Shifted save key        |
| KEY_SSUSPEND  | Shifted suspend key     |

wgetwch(3CURSES)

| <i>Name</i> | <i>Key name</i>  |
|-------------|------------------|
| KEY_SUNDO   | Shifted undo key |
| KEY_SUSPEND | Suspend key      |
| KEY_UNDO    | Undo key         |

**RETURN VALUE** All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curses(3CURSES), curs\_inopts(3CURSES), curs\_move(3CURSES), wrefresh(3CURSES), terminfo(4), attributes(5)

**NOTES** The header file <curses.h> automatically includes the header files <stdio.h>, <unctrl.h> and <wider.h>.

Use of the escape key by a programmer for a single character function is discouraged.

When using getch(), wgetwch(), mvgetwch(), or mvwgetwch(), nocbreak mode and echo mode should not be used at the same time. Depending on the state of the tty driver when each character is typed, the program may produce undesirable results.

Note that getch(), mvgetwch(), and mvwgetwch() may be macros.

| <b>NAME</b>        | get_wch, wget_wch, mvget_wch, mvwget_wch – get a wide character from terminal                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>DESCRIPTION</b> | <p>The <code>get_wch()</code> and <code>wget_wch()</code> functions get a wide character from the terminal associated with the window <code>stdscr</code> or window <code>win</code>, respectively. The <code>mvget_wch()</code> and <code>mvwget_wch()</code> functions move the cursor to the position specified in <code>stdscr</code> or <code>win</code>, respectively, then get a character.</p> <p>If the window is not a pad and has been changed since the last call to <code>refresh(3XCURSES)</code>, <code>get_wch()</code> calls <code>refresh()</code> to update the window before the next character is read.</p> <p>The setting of certain functions affects the behavior of the <code>get_wch()</code> set of functions. For example, if <code>cbreak(3XCURSES)</code> is set, characters typed by the user are immediately processed. If <code>halfdelay(3XCURSES)</code> is set, <code>get_wch()</code> waits until a character is typed or returns <code>ERR</code> if no character is typed within the specified timeout period. This timeout can also be specified for individual windows with the <i>delay</i> parameter of <code>timeout(3XCURSES)</code>. A negative value waits for input; a value of 0 returns <code>ERR</code> if no input is ready; a positive value blocks until input arrives or the time specified expires (in which case <code>ERR</code> is returned). If <code>nodelay(3XCURSES)</code> is set, <code>ERR</code> is returned if no input is waiting; if not set, <code>get_wch()</code> waits until input arrives. Each character will be echoed to the window unless <code>noecho(3XCURSES)</code> has been set.</p> <p>If keypad handling is enabled ( <code>keypad(3XCURSES)</code> is <code>TRUE</code>), the token for the function key (a <code>KEY_</code> value) is stored in the object pointed to by <code>ch</code> and <code>KEY_CODE_YES</code> is returned. If a character is received that could be the beginning of a function key (for example, <code>ESC</code>), an inter-byte timer is set. If the remainder of the sequence is not received before the time expires, the character is passed through; otherwise, the value of the function key is returned. If <code>notimeout()</code> is set, the inter-byte timer is not used.</p> <p>The <code>ESC</code> key is typically a prefix key used with function keys and should not be used as a single character.</p> <p>See the <code>getch(3XCURSES)</code> manual page for a list of tokens for function keys that are returned by the <code>get_wch()</code> set of functions if keypad handling is enabled (Some terminals may not support all tokens).</p> |

wget\_wch(3XCURSES)

|                      |                                                                                                                                                                                                                                          |                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| <b>PARAMETERS</b>    | <i>ch</i>                                                                                                                                                                                                                                | Is a pointer to a wide integer where the returned wide character or <code>KEY_</code> value can be stored. |
|                      | <i>win</i>                                                                                                                                                                                                                               | Is a pointer to the window associated with the terminal from which the character is to be read.            |
|                      | <i>y</i>                                                                                                                                                                                                                                 | Is the y (row) coordinate for the position of the character to be read.                                    |
|                      | <i>x</i>                                                                                                                                                                                                                                 | Is the x (column) coordinate for the position of the character to be read.                                 |
| <b>RETURN VALUES</b> | When these functions successfully report the pressing of a function key, they return <code>KEY_CODE_YES</code> . When they successfully report a wide character, they return <code>OK</code> . Otherwise, they return <code>ERR</code> . |                                                                                                            |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                    |                                                                                                            |

## wgetwstr(3CURSES)

| <b>NAME</b>         | <code>curs_getwstr</code> , <code>getwstr</code> , <code>getnwstr</code> , <code>wgetwstr</code> , <code>wgetnwstr</code> , <code>mvgetwstr</code> , <code>mvgetnwstr</code> , <code>mvwgetwstr</code> , <code>mvwgetnwstr</code> – get <code>wchar_t</code> character strings from curses terminal keyboard                                                                                                                                                                                                                                                      |                |                 |          |        |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>     | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lcurses [ <i>library</i> .. ] #include &lt;curses.h&gt;  int <b>getwstr</b>(wchar_t *wstr); int <b>getnwstr</b>(wchar_t *wstr, int n); int <b>wgetwstr</b>(WINDOW *win, wchar_t *wstr); int <b>wgetnwstr</b>(WINDOW *win, wchar_t *wstr, int n); int <b>mvgetwstr</b>(int y, int x, wchar_t *wstr); int <b>mvgetnwstr</b>(int y, int x, wchar_t *wstr, int n); int <b>mvwgetwstr</b>(WINDOW *win, int y, int x, wchar_t *wstr); int <b>mvwgetnwstr</b>(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre>       |                |                 |          |        |
| <b>DESCRIPTION</b>  | The effect of <code>getwstr()</code> is as though a series of calls to <code>getwch(3CURSES)</code> were made, until a newline and carriage return is received. The resulting value is placed in the area pointed to by the <code>wchar_t</code> pointer <code>wstr</code> . <code>getnwstr()</code> reads at most <code>n</code> <code>wchar_t</code> characters, thus preventing a possible overflow of the input buffer. The user's erase and kill characters are interpreted, as well as any special keys (such as function keys, HOME key, CLEAR key, etc.). |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |        |

| DESCRIPTION   | <p>The <code>get_wstr()</code> and <code>wget_wstr()</code> functions get a wide character string from the terminal associated with the window <code>stdscr</code> or window <code>win</code>, respectively. The <code>mvget_wstr()</code> and <code>mvwget_wstr()</code> functions move the cursor to the position specified in <code>stdscr</code> or <code>win</code>, respectively, then get a wide character string.</p> <p>These functions call <code>wget_wch(3XCURSES)</code> and place each received character in <code>wstr</code> until a newline character, end-of-line character, or end-of-file character is received, which is also placed in <code>wstr</code>. The erase and kill characters set by the user are processed.</p> <p>The <code>getn_wstr()</code>, <code>mvgetn_wstr()</code>, <code>mvwgetn_wstr()</code> and <code>wgetn_wstr()</code> functions read at most <code>n</code> characters. These functions are used to prevent overflowing the input buffer.</p> |
| PARAMETERS    | <p><i>wstr</i> Is a pointer to the area where the character string is to be placed.</p> <p><i>n</i> Is the maximum number of characters to read from input.</p> <p><i>y</i> Is the y (row) coordinate of starting position of character string to be read.</p> <p><i>x</i> Is the x (column) coordinate of starting position of character string to be read.</p> <p><i>win</i> points to the window associated with the terminal from which the character is to be read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| RETURN VALUES | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| DESCRIPTION | <p>With the <code>border()</code>, <code>wborder()</code>, and <code>box()</code> routines, a border is drawn around the edges of the window. The arguments and attributes are:</p> <table><tr><td><i>ls</i></td><td>left side of the border</td></tr><tr><td><i>rs</i></td><td>right side of the border</td></tr><tr><td><i>ts</i></td><td>top side of the border</td></tr><tr><td><i>bs</i></td><td>bottom side of the border</td></tr><tr><td><i>tl</i></td><td>top left-hand corner</td></tr><tr><td><i>tr</i></td><td>top right-hand corner</td></tr><tr><td><i>bl</i></td><td>bottom left-hand corner</td></tr><tr><td><i>br</i></td><td>bottom right-hand corner</td></tr></table> <p>If any of these arguments is zero, then the following default values (defined in <code>&lt;curses.h&gt;</code>) are used respectively instead: <code>ACS_VLINE</code>, <code>ACS_VLINE</code>, <code>ACS_HLINE</code>, <code>ACS_HLINE</code>, <code>ACS_ULCORNER</code>, <code>ACS_URCORNER</code>, <code>ACS_BLCORNER</code>, <code>ACS_BRCORNER</code>.</p> <p><code>box(<i>win</i>, <i>verch</i>, <i>horch</i>)</code> is a shorthand for the following call:</p> <pre>wborder(<i>win</i>, <i>verch</i>, <i>verch</i>, <i>horch</i>, <i>horch</i>, 0, 0, 0, 0)</pre> <p><code>hline()</code> and <code>whline()</code> draw a horizontal (left to right) line using <i>ch</i> starting at the current cursor position in the window. The current cursor position is not changed. whline(3CURSES)

`vline()` and `wvline()` draw a vertical (top to bottom) line using *ch* starting at the current cursor position in the window. The current cursor position is not changed. The line is at most *n* characters long, or as many as fit into the window.

**RETURN VALUES** All routines return the integer `OK`, or a non-negative integer if `immedok()` is set. See `curl_outopts(3CURSES)`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curl_outopts(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `border()` and `box()` may be macros.

| DESCRIPTION   | <p>The <code>hline()</code>, <code>vline()</code>, <code>whline()</code>, <code>wvline()</code> functions draw a horizontal or vertical line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>ch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>ch</code> is 0 (zero), the default horizontal or vertical character is used.</p> <p>The <code>mvhline()</code>, <code>mvvline()</code>, <code>mvwhline()</code>, <code>mvwvline()</code> functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code>.</p> <p>The functions with names ending with <code>hline()</code> draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with <code>vline()</code> draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |
| PARAMETERS    | <p><i>ch</i> Is the character used to draw the line.</p> <p><i>n</i> Is the maximum number of characters in the line.</p> <p><i>y</i> Is the y (row) coordinate for the start of the line.</p> <p><i>x</i> Is the x (column) coordinate for the start of the line.</p> <p><i>win</i> Is a pointer to a window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| RETURN VALUES | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ERRORS        | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>DESCRIPTION</b>   | <p>The <code>hline_set()</code>, <code>vline_set()</code>, <code>whline_set()</code>, <code>wvline_set()</code> functions draw a line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>wch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>wch</code> is a null pointer, the default horizontal or vertical character is used.</p> <p>The <code>mvhline_set()</code>, <code>mvvline_set()</code>, <code>mvwhline_set()</code>, <code>mvwvline_set()</code> functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code>.</p> <p>The functions with names ending with <code>hline_set()</code> draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with <code>vline_set()</code> draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |
| <b>PARAMETERS</b>    | <p><i>wch</i> Is the complex character used to draw the line.</p> <p><i>n</i> Is the maximum number of characters in the line.</p> <p><i>y</i> Is the y (row) coordinate for the start of the line.</p> <p><i>x</i> Is the x (column) coordinate for the start of the line.</p> <p><i>win</i> Is a pointer to a window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| NAME           | curs_inch, inch, winch, mvinch, mvwinch – get a character and its attributes from a curses window                                                                                                                                                                                                                                     |                |                               |              |                                |         |                                                  |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-------------------------------|--------------|--------------------------------|---------|--------------------------------------------------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  chtype <b>inch</b>(void); chtype <b>winch</b>(WINDOW *win); chtype <b>mvinch</b>(int y, int x); chtype <b>mvwinch</b>(WINDOW *win, int y, int x);</pre>                                                                                             |                |                               |              |                                |         |                                                  |
| DESCRIPTION    | With these routines, the character, of type chtype, at the current position in the named window is returned. If any attributes are set for that position, their values are OR-ed into the value returned. Constants defined in <curses.h> can be used with the logical AND (&) operator to extract the character or attributes alone. |                |                               |              |                                |         |                                                  |
| Attributes     | <p>The following bit-masks can be AND-ed with characters returned by winch().</p> <table><tr><td>A_CHARTEXT</td><td>Bit-mask to extract character</td></tr><tr><td>A_ATTRIBUTES</td><td>Bit-mask to extract attributes</td></tr><tr><td>A_COLOR</td><td>Bit-mask to extract color-pair field information</td></tr></table>            | A_CHARTEXT     | Bit-mask to extract character | A_ATTRIBUTES | Bit-mask to extract attributes | A_COLOR | Bit-mask to extract color-pair field information |
| A_CHARTEXT     | Bit-mask to extract character                                                                                                                                                                                                                                                                                                         |                |                               |              |                                |         |                                                  |
| A_ATTRIBUTES   | Bit-mask to extract attributes                                                                                                                                                                                                                                                                                                        |                |                               |              |                                |         |                                                  |

| SYNOPSIS            | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  ctype <b>inch</b>(void);  ctype <b>mvinch</b>(int <i>y</i>, int <i>x</i>);  ctype <b>mvwinch</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>);  ctype <b>winch</b>(WINDOW *<i>win</i>);</pre>                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| DESCRIPTION         | <p>The <code>inch()</code> and <code>winch()</code> functions return the <code>ctype</code> character located at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively. The <code>mvinch()</code> and <code>mvwinch()</code> functions return the <code>ctype</code> character located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The complete character/attribute pair will be returned. The character or attributes can be extracted by performing a bitwise AND on the returned value, using the constants <code>A_CHARTEXT</code>, <code>A_ATTRIBUTES</code>, and <code>A_COLOR</code>.</p> |                |                 |                     |          |          |        |
| PARAMETERS          | <p><i>y</i>            Is the <i>y</i> (row) coordinate of the position of the character to be returned.</p> <p><i>x</i>            Is the <i>x</i> (column) coordinate of the position of the character to be returned.</p> <p><i>win</i>          Is a pointer to the window that contains the character to be returned.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return the specified character and rendition. Otherwise, they return <code>ERR</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>   | With these routines, a string of type <code>chtype</code> , starting at the current cursor position in the named window and ending at the right margin of the window, is returned. The four functions with <i>n</i> as the last argument, return the string at most <i>n</i> characters long. Constants defined in <code>&lt;curses.h&gt;</code> can be used with the <code>&amp;</code> (logical AND) operator to extract the character or the attribute alone from any position in the <i>chstr</i> (see <code>curs_inch(3CURSES)</code> ).                                                                                                                                                                                                |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |

| <b>DESCRIPTION</b> | <p>The <code>inchstr()</code> and <code>winchstr()</code> functions retrieve the character string (with rendition) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinchstr()</code> and <code>mvwinchstr()</code> functions retrieve the character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>inchnstr()</code>, <code>winchnstr()</code>, <code>mvinchnstr()</code>, and <code>mvwinchnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All these functions store the retrieved character string in the object pointed to by <i>chstr</i>.</p> <p>The complete character/attribute pair is retrieved. The character or attributes can be extracted by performing a bitwise AND on the retrieved value, using the constants <code>A_CHARTEXT</code>, <code>A_ATTRIBUTES</code>, and <code>A_COLOR</code>. The character string can also be retrieved without attributes by using <code>instr(3XCURSES)</code> set of functions.</p> |
| <b>PARAMETERS</b>  | <p><i>chstr</i>      Is a pointer to an object that can hold the retrieved character string.</p> <p><i>n</i>            Is the number of characters not to exceed when retrieving <i>chstr</i>.</p> <p><i>y</i>            Is the <i>y</i> (row) coordinate of the starting position of the string to be retrieved.</p> <p><i>x</i>            Is the <i>x</i> (column) coordinate of the starting position of the string to be retrieved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

`winchnstr(3XCURSES)`

*win* Is a pointer to the window in which the string is to be retrieved.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO** `inch(3XCURSES)`, `innstr(3XCURSES)`, `libcurses(3XCURSES)`, `attributes(5)`, `standards(5)`

## winchstr(3CURSES)

| <b>NAME</b>          | <code>curs_inchstr</code> , <code>inchstr</code> , <code>inchnstr</code> , <code>winchstr</code> , <code>winchnstr</code> , <code>mvinchstr</code> , <code>mvinchnstr</code> , <code>mvwinchstr</code> , <code>mvwinchnstr</code> – get a string of characters (and attributes) from a curses window                                                                                                                                                                                                                                          |                |                 |          |        |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>inchstr</b>(chtype *chstr); int <b>inchnstr</b>(chtype *chstr, int n); int <b>winchstr</b>(WINDOW *win, chtype *chstr); int <b>winchnstr</b>(WINDOW *win, chtype *chstr, int n); int <b>mvinchstr</b>(int y, int x, chtype *chstr); int <b>mvinchnstr</b>(int y, int x, chtype *chstr, int n); int <b>mvwinchstr</b>(WINDOW *win, int y, int x, chtype *chstr); int <b>mvwinchnstr</b>(WINDOW *win, int y, int x, chtype *chstr, int n);</pre>       |                |                 |          |        |
| <b>DESCRIPTION</b>   | With these routines, a string of type <code>chtype</code> , starting at the current cursor position in the named window and ending at the right margin of the window, is returned. The four functions with <i>n</i> as the last argument, return the string at most <i>n</i> characters long. Constants defined in <code>&lt;curses.h&gt;</code> can be used with the <code>&amp;</code> (logical AND) operator to extract the character or the attribute alone from any position in the <i>chstr</i> (see <code>curs_inch(3CURSES)</code> ). |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |
| <b>ATTRIBUTES</b>    | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |          |        |

| DESCRIPTION  | <p>The <b>inchstr()</b> and <b>winchstr()</b> functions retrieve the character string (with rendition) starting at the current cursor position of the <b>stdscr</b> window and window <i>win</i>, respectively, and ending at the right margin. The <b>mvinchstr()</b> and <b>mvwinchstr()</b> functions retrieve the character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <b>stdscr</b> window; the latter in window <i>win</i>).</p> <p>The <b>inchnstr()</b>, <b>winchnstr()</b>, <b>mvinchnstr()</b>, and <b>mvwinchnstr()</b> functions retrieve at most <i>n</i> characters from the window <b>stdscr</b> and <i>win</i>, respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All these functions store the retrieved character string in the object pointed to by <i>chstr</i>.</p> <p>The complete character/attribute pair is retrieved. The character or attributes can be extracted by performing a bitwise AND on the retrieved value, using the constants <b>A_CHARTEXT</b>, <b>A_ATTRIBUTES</b>, and <b>A_COLOR</b>. The character string can also be retrieved without attributes by using <b>instr(3XCURSES)</b> set of functions.</p> |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |

| <i>chstr</i> | Is a pointer to an object that can hold the retrieved character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |
| <i>n</i>     | Is the number of characters not to exceed when retrieving <i>chstr</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |
| <i>y</i>     | Is the <i>y</i> (row) coordinate of the starting position of the string to be retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |
| <i>x</i>     | Is the <i>x</i> (column) coordinate of the starting position of the string to be retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |              |                                                                         |          |                                                                          |          |                                                                                          |          |                                                                                             |

winchstr(3XCURSES)

*win* Is a pointer to the window in which the string is to be retrieved.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int instr(char *str); int innstr(char *str, int n); int winstr(WINDOW *win, char *str); int winnstr(WINDOW *win, char *str, int n); int mvinstr(int y, int x, char *str); int mvinnstr(int y, int x, char *str, int n); int mvwinstr(WINDOW *win, int y, int x, char *str); int mvwinnstr(WINDOW *win, int y, int x, char *str, int n);</pre> |                |                 |          |        |
| DESCRIPTION    | These routines return a string of characters in <i>str</i> , starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with <i>n</i> as the last argument return the string at most <i>n</i> characters long.                                                                                                   |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                |                |                 |          |        |
| ATTRIBUTES     | See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>MT-Level</td><td>Unsafe</td></tr></table>                                                                                                                                                                                                                                                | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| <b>DESCRIPTION</b> | <p>The <code>instr()</code> and <code>winstr()</code> functions retrieve a multibyte character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinstr()</code> and <code>mvwinstr()</code> functions retrieve a multibyte character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>innstr()</code>, <code>winnstr()</code>, <code>mvinnstr()</code>, and <code>mvwinnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> |                                                                                      |

winnstr(3XCURSES)

All these functions store the retrieved string in the object pointed to by *str*. They only store complete multibyte characters. If the area pointed to by *str* is not large enough to hold at least one character, these functions fail.

Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use `winchstr()`.

**ERRORS** OK Successful completion.  
ERR An error occurred.

**USAGE** All functions except `winnstr()` may be macros.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [library .. ] #include &lt;curses.h&gt;  int inwstr(wchar_t *wstr); int innwstr(wchar_t *wstr, int n); int winwstr(WINDOW *win, wchar_t *wstr); int winnwstr(WINDOW *win, wchar_t *wstr, int n); int mvinwstr(int y, int x, wchar_t *wstr); int mvinnwstr(int y, int x, wchar_t *wstr, int n); int mvwinwstr(WINDOW *win, int y, int x, wchar_t *wstr); int mvwinnwstr(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre> |                |                 |          |        |
| DESCRIPTION    | These routines return the string of wchar_t characters in <i>wstr</i> starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with <i>n</i> as the last argument return the string at most <i>n</i> wchar_t characters long.                                                                                                                        |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                      |                |                 |          |        |

| <b>PARAMETERS</b>  | <p><i>wstr</i>        Is a pointer to an object that can hold the retrieved multibyte character string.</p> <p><i>n</i>            Is the number of characters not to exceed when retrieving <i>wstr</i>.</p> <p><i>y</i>            Is the y (row) coordinate of the starting position of the string to be retrieved.</p> <p><i>x</i>            Is the x (column) coordinate of the starting position of the string to be retrieved.</p> <p><i>win</i>          Is a pointer to the window in which the string is to be retrieved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The <code>inwstr()</code> and <code>winwstr()</code> functions retrieve a wide character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinwstr()</code> and <code>mvwinwstr()</code> functions retrieve a wide character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>innwstr()</code>, <code>winnwstr()</code>, <code>mvinnwstr()</code>, and <code>mvwinnwstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All these functions store the retrieved string in the object pointed to by <i>wstr</i>. They only store complete wide characters. If the area pointed to by <i>wstr</i> is not large enough to hold at least one character, these functions fail.</p> |

winnwstr(3XCURSES)

|                      | Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use <code>win_wchstr(3XCURSES)</code> .                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>RETURN VALUES</b> | <p>On success, the <code>inwstr()</code>, <code>mvinwstr()</code>, <code>mvwinwstr()</code>, and <code>winnwstr()</code> functions return OK. Otherwise, they return ERR.</p> <p>On success, the <code>innwstr()</code>, <code>mvinnwstr()</code>, <code>mvwinnwstr()</code>, and <code>winnwstr()</code> functions return the number of characters read into the string. Otherwise, they return ERR.</p> |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |                     |          |          |        |

| NAME           | curs_insch, insch, winsch, mvinsch, mvwinsch – insert a character before the character under the cursor in a curses window                                                                                                                                                                                                                                                                                        |                |                 |          |        |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file... -lcurses [ library ... ] #include &lt;curses.h&gt;  int <b>insch</b>(chtype <i>ch</i>) ; int <b>winsch</b>(WINDOW *<i>win</i>, chtype <i>ch</i>) ; int <b>mvinsch</b>(int <i>y</i>, int <i>x</i>, chtype <i>ch</i>) ; int <b>mvwinsch</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, chtype <i>ch</i>) ;</pre>                                                                  |                |                 |          |        |
| DESCRIPTION    | With these routines, the character <i>ch</i> is inserted before the character under the cursor. All characters to the right of the cursor are moved one space to the right, with the possibility of the rightmost character on the line being lost. The cursor position does not change (after moving to <i>y</i> , <i>x</i> , if specified). (This does not imply use of the hardware insert character feature.) |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                  |                |                 |          |        |

| <i>ch</i>           | Is the character to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| <i>y</i>            | Is the y (row) coordinate of the position of the character.                                                                                                                                                                                                                                                                                                                                                                                                  |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| <i>x</i>            | Is the x (column) coordinate of the position of the character.                                                                                                                                                                                                                                                                                                                                                                                               |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| <i>win</i>          | Is a pointer to the window in which the character is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                         |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| DESCRIPTION         | <p>These functions insert the character and rendition from <i>ch</i> into the current or specified window at the current or specified position.</p> <p>These functions do not perform wrapping and do not advance the cursor position. These functions perform special-character processing, with the exception that if a newline is inserted into the last line of a window and scrolling is not enabled, the behavior is unspecified.</p>                  |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| RETURN VALUES       | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                           |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| ERRORS              | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |
| USAGE               | These functions are only guaranteed to operate reliably on character sets in which each character fits into a single byte, whose attributes can be expressed using only constants with the A_ prefix.                                                                                                                                                                                                                                                        |                |                                  |                     |                                                             |          |                                                                |            |                                                                      |

| <b>SYNOPSIS</b>      | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lcurses [ <i>library</i> ... ] #include &lt;curses.h&gt;  int <b>deleteln</b>(void); int <b>wdeleteln</b>(WINDOW *<i>win</i>); int <b>insdelln</b>(int <i>n</i>); int <b>winsdelln</b>(WINDOW *<i>win</i>, int <i>n</i>); int <b>insertln</b>(void); int <b>wininsertln</b>(WINDOW *<i>win</i>);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>With the <code>deleteln()</code> and <code>wdeleteln()</code> routines, the line under the cursor in the window is deleted; all lines below the current line are moved up one line. The bottom line of the window is cleared. The cursor position does not change. This does not imply use of a hardware delete line feature.</p> <p>With the <code>insdelln()</code> and <code>winsdelln()</code> routines, for positive <i>n</i>, insert <i>n</i> lines into the specified window above the current line. The <i>n</i> bottom lines are lost. For negative <i>n</i>, delete <i>n</i> lines (starting with the one under the cursor), and move the remaining lines up. The bottom <i>n</i> lines are cleared. The current cursor position remains the same.</p> <p>With the <code>insertln()</code> and <code>wininsertln()</code> routines, a blank line is inserted above the current line and the bottom line is lost. This does not imply use of a hardware insert line feature.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |

## winsdelln(3XCURSES)

| <b>NAME</b>          | insdelln, winsdelln – insert/delete lines to/from the window                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |                     |          |          |        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>insdelln</b>(int <i>n</i>);  int <b>winsdelln</b>(WINDOW *<i>win</i>, int <i>n</i>);</pre>                                                                                                                                                      |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>n</i> Is the number of lines to insert or delete (positive <i>n</i> inserts; negative <i>n</i> deletes).</p> <p><i>win</i> Is a pointer to the window in which to insert or delete a line.</p>                                                                                                                                                                                                                                             |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | The insdelln() and winsdelln() functions insert or delete blank lines in stdscr or <i>win</i> , respectively. When <i>n</i> is positive, <i>n</i> lines are added before the current line and the bottom <i>n</i> lines are lost; when <i>n</i> is negative, <i>n</i> lines are deleted starting with the current line, the remaining lines are moved up, and the bottom <i>n</i> lines are cleared. The position of the cursor does not change. |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int deleteln(void); int wdeleteln(WINDOW *win); int insdelln(int n); int winsdelln(WINDOW *win, int n); int insertln(void); int winsertln(WINDOW *win);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>With the <code>deleteln()</code> and <code>wdeleteln()</code> routines, the line under the cursor in the window is deleted; all lines below the current line are moved up one line. The bottom line of the window is cleared. The cursor position does not change. This does not imply use of a hardware delete line feature.</p> <p>With the <code>insdelln()</code> and <code>winsdelln()</code> routines, for positive <i>n</i>, insert <i>n</i> lines into the specified window above the current line. The <i>n</i> bottom lines are lost. For negative <i>n</i>, delete <i>n</i> lines (starting with the one under the cursor), and move the remaining lines up. The bottom <i>n</i> lines are cleared. The current cursor position remains the same.</p> <p>With the <code>insertln()</code> and <code>winsertln()</code> routines, a blank line is inserted above the current line and the bottom line is lost. This does not imply use of a hardware insert line feature.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |          |        |

## winsertrln(3XCURSES)

| NAME                | insertln, winsertrln – insert a line in a window                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| SYNOPSIS            | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int insertln(void);  int winsertrln(WINDOW *win);</pre>                                               |                |                 |                     |          |          |        |
| PARAMETERS          | <i>win</i> Is a pointer to the window in which to insert the line.                                                                                                                                                                                                                              |                |                 |                     |          |          |        |
| DESCRIPTION         | The insertln() and winsertrln() functions insert a blank line before the current line in stdscr or <i>win</i> , respectively. The new line becomes the current line. The current line and all lines after it in the window are moved down one line. The bottom line in the window is discarded. |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                              |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                                           |                |                 |                     |          |          |        |

| DESCRIPTION    | <p>With these routines, a character string (as many characters as will fit on the line) is inserted before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <i>y</i>, <i>x</i>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <i>n</i> as the last argument insert at most <i>n</i> characters. If <i>n</i> ≤ 0, then the entire string is inserted.</p> <p>If a character in <i>str</i> is a tab, newline, carriage return or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol()</code> before moving. Tabs are considered to be at every eighth column. If a character in <i>str</i> is another control character, it is drawn in the ^X notation. Calling <code>winch()</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |          |        |
| ATTRIBUTES     | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |

If <i>n</i> is less than 1, the entire string is inserted. | <i>y</i> | Is the y (row) coordinate of the starting position of the string. | <i>x</i> | Is the x (column) coordinate of the starting position of the string. | <i>win</i> | Is a pointer to the window in which the string is to be inserted. |
| <i>str</i>  | Is a pointer to the string to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>n</i>    | Is the number of characters not to exceed when inserting <i>str</i> . If <i>n</i> is less than 1, the entire string is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>y</i>    | Is the y (row) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>x</i>    | Is the x (column) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>win</i>  | Is a pointer to the window in which the string is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| DESCRIPTION | <p>The <code>insstr()</code> function inserts <i>str</i> at the current cursor position of the <code>stdscr</code> window. The <code>winsstr()</code> function performs the identical action, but in window <i>win</i>. The <code>mvinsstr()</code> and <code>mvwinsstr()</code> functions insert the character string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The <code>insnstr()</code>, <code>winsnstr()</code>, <code>mvinsnstr()</code>, and <code>mvwinsnstr()</code> functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.</p> |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |

winsnstr(3XCURSES)

If a character in *str* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using  $\wedge x$  notation, where  $x$  is a printable character. `clrtoeol(3XCURSES)` is automatically done before a newline.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| <b>DESCRIPTION</b>  | <p>These routines insert a <code>wchar_t</code> character string (as many <code>wchar_t</code> characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <code>y, x</code>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <code>n</code> as the last argument insert at most <code>n</code> <code>wchar_t</code> characters. If <code>n</code> ≤ 0, then the entire string is inserted.</p> <p>If a character in <code>wstr</code> is a tab, newline, carriage return, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol(3CURSES)</code> before moving. Tabs are considered to be at every eighth column. If a character in <code>wstr</code> is another control character, it is drawn in the <code>^X</code> notation. Calling <code>winch(3CURSES)</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |

If <i>n</i> is less than 1, the entire string is inserted. | <i>y</i> | Is the y (row) coordinate of the starting position of the string. | <i>x</i> | Is the x (column) coordinate of the starting position of the string. | <i>win</i> | Is a pointer to the window in which the string is to be inserted. |
| <i>wstr</i> | Is a pointer to the string to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>n</i>    | Is the number of characters not to exceed when inserting <i>wstr</i> . If <i>n</i> is less than 1, the entire string is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>y</i>    | Is the y (row) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>x</i>    | Is the x (column) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>win</i>  | Is a pointer to the window in which the string is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| DESCRIPTION | <p>The <code>ins_wstr()</code> function inserts <i>wstr</i> at the current cursor position of the <code>stdscr</code> window. The <code>wins_wstr()</code> function performs the identical action, but in window <i>win</i>. The <code>mvins_wstr()</code> and <code>mvwins_wstr()</code> functions insert <i>wstr</i> string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>ins_nwstr()</code>, <code>wins_nwstr()</code>, <code>mvins_nwstr()</code>, and <code>mvwins_nwstr()</code> functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |

wins\_nwstr(3XCURSES)

All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.

If a character in *wstr* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using *^x* notation, where *x* is a printable character. `clrtoeol(3XCURSES)` is automatically done before a newline.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>DESCRIPTION</b>   | <p>With these routines, a character string (as many characters as will fit on the line) is inserted before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <i>y</i>, <i>x</i>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <i>n</i> as the last argument insert at most <i>n</i> characters. If <i>n</i> ≤ 0, then the entire string is inserted.</p> <p>If a character in <i>str</i> is a tab, newline, carriage return or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol()</code> before moving. Tabs are considered to be at every eighth column. If a character in <i>str</i> is another control character, it is drawn in the ^X notation. Calling <code>winch()</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

If <i>n</i> is less than 1, the entire string is inserted. | <i>y</i> | Is the y (row) coordinate of the starting position of the string. | <i>x</i> | Is the x (column) coordinate of the starting position of the string. | <i>win</i> | Is a pointer to the window in which the string is to be inserted. |
| <i>str</i>  | Is a pointer to the string to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>n</i>    | Is the number of characters not to exceed when inserting <i>str</i> . If <i>n</i> is less than 1, the entire string is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>y</i>    | Is the y (row) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>x</i>    | Is the x (column) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>win</i>  | Is a pointer to the window in which the string is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |
| DESCRIPTION | <p>The <code>insstr()</code> function inserts <i>str</i> at the current cursor position of the <code>stdscr</code> window. The <code>winsstr()</code> function performs the identical action, but in window <i>win</i>. The <code>mvinsstr()</code> and <code>mvwinsstr()</code> functions insert the character string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former to the <code>stdscr</code> window; the latter to window <i>win</i>).</p> <p>The <code>insnstr()</code>, <code>winsnstr()</code>, <code>mvinsnstr()</code>, and <code>mvwinsnstr()</code> functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.</p> |            |                                            |          |                                                                                                                                  |          |                                                                   |          |                                                                      |            |                                                                   |

winsstr(3XCURSES)

If a character in *str* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using  $\wedge x$  notation, where *x* is a printable character. `clrtoeol(3XCURSES)` is automatically done before a newline.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int instr(char *str); int innstr(char *str, int n); int winstr(WINDOW *win, char *str); int winnstr(WINDOW *win, char *str, int n); int mvinstr(int y, int x, char *str); int mvinnstr(int y, int x, char *str, int n); int mvwinstr(WINDOW *win, int y, int x, char *str); int mvwinnstr(WINDOW *win, int y, int x, char *str, int n);</pre> |                |                 |          |        |
| DESCRIPTION    | These routines return a string of characters in <i>str</i> , starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with <i>n</i> as the last argument return the string at most <i>n</i> characters long.                                                                                                   |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                |                |                 |          |        |

| <i>str</i>  | Is a pointer to an object that can hold the retrieved multibyte character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |            |                                                                                   |          |                                                                        |          |                                                                                   |          |                                                                                      |            |                                                                    |
| <i>n</i>    | Is the number of characters not to exceed when retrieving <i>str</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |            |                                                                                   |          |                                                                        |          |                                                                                   |          |                                                                                      |            |                                                                    |
| <i>y</i>    | Is the y (row) coordinate of the starting position of the string to be retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |            |                                                                                   |          |                                                                        |          |                                                                                   |          |                                                                                      |            |                                                                    |
| <i>x</i>    | Is the x (column) coordinate of the starting position of the string to be retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |            |                                                                                   |          |                                                                        |          |                                                                                   |          |                                                                                      |            |                                                                    |
| <i>win</i>  | Is a pointer to the window in which the string is to be retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |            |                                                                                   |          |                                                                        |          |                                                                                   |          |                                                                                      |            |                                                                    |
| DESCRIPTION | <p>The <code>instr()</code> and <code>winstr()</code> functions retrieve a multibyte character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinstr()</code> and <code>mvwinstr()</code> functions retrieve a multibyte character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>innstr()</code>, <code>winnstr()</code>, <code>mvinnstr()</code>, and <code>mvwinnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> |            |                                                                                   |          |                                                                        |          |                                                                                   |          |                                                                                      |            |                                                                    |

`winstr(3XCURSES)`

All these functions store the retrieved string in the object pointed to by *str*. They only store complete multibyte characters. If the area pointed to by *str* is not large enough to hold at least one character, these functions fail.

Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use `winchstr()`.

**ERRORS**    `OK`                      Successful completion.  
              `ERR`                     An error occurred.

**USAGE**     All functions except `winnstr()` may be macros.

**ATTRIBUTES**   See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

## winswch(3CURSES)

| <b>NAME</b>         | <p> <b> curs_inswch, inswch, winswch, mvinswch, mvwinswch</b> – insert a <code>wchar_t</code> character before the character under the cursor in a curses window </p>                                                                                                                                                                                                                                                                                     |                |                 |          |        |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>     | <pre> cc [ flag ... ] file ... -lcurses [ library .. ] #include &lt;curses.h&gt;  int <b>inswch</b>(chtype <i>wch</i>) ; int <b>winswch</b>(WINDOW *<i>win</i>, chtype <i>wch</i>) ; int <b>mvinswch</b>(int <i>y</i>, int <i>x</i>, chtype <i>wch</i>) ; int <b>mvwinswch</b>(WINDOW *<i>win</i>, int <i>y</i>, int <i>x</i>, chtype <i>wch</i>) ; </pre>                                                                                                |                |                 |          |        |
| <b>DESCRIPTION</b>  | <p> These routines insert the character <i>wch</i>, holding a <code>wchar_t</code> character, before the character under the cursor. All characters to the right of the cursor are moved one space to the right, with the possibility of the rightmost character on the line being lost. The cursor position does not change (after moving to <i>y</i>, <i>x</i>, if specified). (This does not imply use of the hardware insert character feature.) </p> |                |                 |          |        |
| <b>RETURN VALUE</b> | <p> All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion. </p>                                                                                                                                                                                                                                                                                                       |                |                 |          |        |

| <b>PARAMETERS</b>    | <pre>#include &lt;curses.h&gt;  int ins_wch(const cchar_t *wch); int mvins_wch(int y, int x, const cchar_t *wch); int mvwins_wch(WINDOW *win, int y, int x, const cchar_t *wch); int wins_wch(WINDOW *win, const cchar_t *wch);</pre> <p><i>wch</i> Is the complex character to be inserted.</p> <p><i>y</i> Is the y (row) coordinate of the position of the character.</p> <p><i>x</i> Is the x (column) coordinate of the position of the character.</p> <p><i>win</i> Is a pointer to the window in which the character is to be inserted.</p>                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b>   | <p>The <code>ins_wch()</code> function inserts the complex character <i>wch</i> at the current cursor position of the <code>stdscr</code> window. The <code>wins_wch()</code> function performs the identical action but in window <i>win</i>. The <code>mvins_wch()</code> and <code>mvwins_wch()</code> functions insert the character at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>). The cursor position does not change.</p> <p>All characters to the right of the inserted character are moved right one character. The last character on the line is deleted.</p> <p>Insertions and deletions occur at the character level. The cursor is adjusted to the first column of the character prior to the operation.</p> |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>DESCRIPTION</b>  | <p>These routines insert a <code>wchar_t</code> character string (as many <code>wchar_t</code> characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are moved to the right, with the possibility of the rightmost characters on the line being lost. The cursor position does not change (after moving to <code>y, x</code>, if specified). (This does not imply use of the hardware insert character feature.) The four routines with <code>n</code> as the last argument insert at most <code>n</code> <code>wchar_t</code> characters. If <code>n</code> ≤ 0, then the entire string is inserted.</p> <p>If a character in <code>wstr</code> is a tab, newline, carriage return, or backspace, the cursor is moved appropriately within the window. A newline also does a <code>clrtoeol(3CURSES)</code> before moving. Tabs are considered to be at every eighth column. If a character in <code>wstr</code> is another control character, it is drawn in the <code>^X</code> notation. Calling <code>winch(3CURSES)</code> after adding a control character (and moving to it, if necessary) does not return the control character, but instead returns the representation of the control character.</p> |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |
| <b>ATTRIBUTES</b>   | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |          |        |

| <i>wstr</i>        | Is a pointer to the string to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>n</i>           | Is the number of characters not to exceed when inserting <i>wstr</i> . If <i>n</i> is less than 1, the entire string is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>y</i>           | Is the y (row) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>x</i>           | Is the x (column) coordinate of the starting position of the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <i>win</i>         | Is a pointer to the window in which the string is to be inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |
| <b>DESCRIPTION</b> | <p>The <code>ins_wstr()</code> function inserts <i>wstr</i> at the current cursor position of the <code>stdscr</code> window. The <code>wins_wstr()</code> function performs the identical action, but in window <i>win</i>. The <code>mvins_wstr()</code> and <code>mvwins_wstr()</code> functions insert <i>wstr</i> string at the starting position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>ins_nwstr()</code>, <code>wins_nwstr()</code>, <code>mvins_nwstr()</code>, and <code>mvwins_nwstr()</code> functions insert <i>n</i> characters to the window or as many as will fit on the line. If <i>n</i> is less than 1, the entire string is inserted or as much of it as fits on the line. The former two functions place the string at the current cursor position; the latter two commands use the position specified by the <i>x</i> and <i>y</i> parameters.</p> |             |                                            |          |                                                                                                                                   |          |                                                                   |          |                                                                      |            |                                                                   |

wins\_wstr(3XCURSES)

All characters to the right of inserted characters are moved to the right. Characters that don't fit on the current line are discarded. The cursor is left at the point of insertion.

If a character in *wstr* is a newline, carriage return, backspace, or tab, the cursor is moved appropriately. The cursor is moved to the next tab stop for each tab character (by default, tabs are eight characters apart). If the character is a control character other than those previously mentioned, the character is inserted using *^x* notation, where *x* is a printable character. `clrtoeol(3XCURSES)` is automatically done before a newline.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| <b>SYNOPSIS</b>    | <pre>cc [ flag ... ] file ... -lcurses [ library .. ] #include &lt;curses.h&gt;  chtype inwch(void); chtype winwch(WINDOW *win); chtype mvwinch(int y, int x); chtype mvwinwch(WINDOW *win, int y, int x);</pre>                                                                                                                   |                |                 |          |        |
| <b>DESCRIPTION</b> | These routines return the wchar_t character, of type chtype, at the current position in the named window. If any attributes are set for that position, their values are OR-ed into the value returned. Constants defined in <curses.h> can be used with the logical AND (&) operator to extract the character or attributes alone. |                |                 |          |        |
| <b>Attributes</b>  | <p>The following bit-masks may be AND-ed with characters returned by winwch().</p> <pre>A_WCHARTEXT      Bit-mask to extract character A_WATTRIBUTES    Bit-mask to extract attributes</pre>                                                                                                                                       |                |                 |          |        |

| <b>DESCRIPTION</b>   | <p>The in_wch() and win_wch() functions retrieve the complex character and its rendition located at the current cursor position of the stdscr window and window win, respectively. The mvin_wch() and mvwin_wch() functions retrieve the complex character and its rendition located at the position indicated by the x (column) and y (row) parameters (the former in the stdscr window; the latter in window win).</p> <p>All these functions store the retrieved character and its rendition in the object pointed to by wcv.</p> |                |                                                                                 |                     |                                                                            |          |                                                                               |     |                                                                        |

|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>     | <pre>cc [ flag ... ] file ... -lcurses [ library .. ] #include &lt;curses.h&gt;  int inwchstr(chtype *wchstr); int inwchnstr(chtype *wchstr, int n); int winwchstr(WINDOW *win, chtype *wchstr); int winwchnstr(WINDOW *win, chtype *wchstr, int n); int mvinwchstr(int y, int x, chtype *wchstr); int mvinwchnstr(int y, int x, chtype *wchstr, int n); int mvwinwchstr(WINDOW *win, int y, int x, chtype *wchstr); int mvwinwchnstr(WINDOW *win, int y, int x, chtype *wchstr, int n);</pre>                  |                |                 |          |        |
| <b>DESCRIPTION</b>  | These routines return a string of type chtype, holding wchar_t characters, starting at the current cursor position in the named window and ending at the right margin of the window. The four functions with <i>n</i> as the last argument, return the string at most <i>n</i> wchar_t characters long. Constants defined in <curses.h> can be used with the logical AND (&) operator to extract the wchar_t character or the attribute alone from any position in the <i>wchstr</i> (see curs_inwch(3CURSES)). |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |

| <b>DESCRIPTION</b> | <p>The in_wchstr() and win_wchstr() functions retrieve a complex character string (with rendition) starting at the current cursor position of the stdscr window and window win, respectively, and ending at the right margin. The mvin_wchstr() and mvwin_wchstr() functions retrieve a complex character string located at the position indicated by the x (column) and y (row) parameters (the former in the stdscr window; the latter in window win).</p> <p>The in_wchnstr(), win_wchnstr(), mvin_wchnstr(), and mvwin_wchnstr() functions retrieve at most n characters from the window stdscr and win, respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the x and y parameters.</p> <p>The retrieved character string (with renditions) is stored in the object pointed to by wcvval.</p> |                                                                                       |

| <b>SYNOPSIS</b>     | <pre>cc [ flag ... ] file ... -lcurses [ library .. ] #include &lt;curses.h&gt;  int inwchstr(chtype *wchstr); int inwchnstr(chtype *wchstr, int n); int winwchstr(WINDOW *win, chtype *wchstr); int winwchnstr(WINDOW *win, chtype *wchstr, int n); int mvinwchstr(int y, int x, chtype *wchstr); int mvinwchnstr(int y, int x, chtype *wchstr, int n); int mvwinwchstr(WINDOW *win, int y, int x, chtype *wchstr); int mvwinwchnstr(WINDOW *win, int y, int x, chtype *wchstr, int n);</pre>                                                                                                        |                |                 |          |        |
| <b>DESCRIPTION</b>  | These routines return a string of type <code>chtype</code> , holding <code>wchar_t</code> characters, starting at the current cursor position in the named window and ending at the right margin of the window. The four functions with <i>n</i> as the last argument, return the string at most <i>n</i> <code>wchar_t</code> characters long. Constants defined in <code>&lt;curses.h&gt;</code> can be used with the logical AND (&) operator to extract the <code>wchar_t</code> character or the attribute alone from any position in the <i>wchstr</i> (see <code>curs_inwch(3CURSES)</code> ). |                |                 |          |        |
| <b>RETURN VALUE</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |          |        |

| <b>DESCRIPTION</b> | <p>The <code>in_wchstr()</code> and <code>win_wchstr()</code> functions retrieve a complex character string (with rendition) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvin_wchstr()</code> and <code>mvwin_wchstr()</code> functions retrieve a complex character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>in_wchnstr()</code>, <code>win_wchnstr()</code>, <code>mvin_wchnstr()</code>, and <code>mvwin_wchnstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string, starting at the current cursor position; the latter two commands retrieve the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>The retrieved character string (with renditions) is stored in the object pointed to by <i>wcval</i>.</p> |                                                                                             |
| <b>PARAMETERS</b>  | <i>wchstr</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Is a pointer to an object where the retrieved complex character string can be stored.       |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lcurses[library .. ] #include &lt;curses.h&gt;  int inwstr(wchar_t *wstr); int innwstr(wchar_t *wstr, int n); int winwstr(WINDOW *win, wchar_t *wstr); int winnwstr(WINDOW *win, wchar_t *wstr, int n); int mvinwstr(int y, int x, wchar_t *wstr); int mvinnwstr(int y, int x, wchar_t *wstr, int n); int mvwinwstr(WINDOW *win, int y, int x, wchar_t *wstr); int mvwinnwstr(WINDOW *win, int y, int x, wchar_t *wstr, int n);</pre> |                |                 |          |        |
| <b>DESCRIPTION</b>   | These routines return the string of <code>wchar_t</code> characters in <code>wstr</code> starting at the current cursor position in the named window and ending at the right margin of the window. Attributes are stripped from the characters. The four functions with <code>n</code> as the last argument return the string at most <code>n</code> <code>wchar_t</code> characters long.                                                                           |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |

| <b>DESCRIPTION</b> | <p>The <code>inwstr()</code> and <code>winwstr()</code> functions retrieve a wide character string (without attributes) starting at the current cursor position of the <code>stdscr</code> window and window <i>win</i>, respectively, and ending at the right margin. The <code>mvinwstr()</code> and <code>mvwinwstr()</code> functions retrieve a wide character string located at the position indicated by the <i>x</i> (column) and <i>y</i> (row) parameters (the former in the <code>stdscr</code> window; the latter in window <i>win</i>).</p> <p>The <code>innwstr()</code>, <code>winnwstr()</code>, <code>mvinnwstr()</code>, and <code>mvwinnwstr()</code> functions retrieve at most <i>n</i> characters from the window <code>stdscr</code> and <i>win</i>, respectively. The former two functions retrieve the string starting at the current cursor position; the latter two commands return the string, starting at the position specified by the <i>x</i> and <i>y</i> parameters.</p> <p>All these functions store the retrieved string in the object pointed to by <i>wstr</i>. They only store complete wide characters. If the area pointed to by <i>wstr</i> is not large enough to hold at least one character, these functions fail.</p> |

winwstr(3XCURSES)

**RETURN VALUES** Only the character portion of the character/rendition pair is returned. To return the complete character/rendition pair, use `win_wchstr(3XCURSES)`.

On success, the `inwstr()`, `mvinwstr()`, `mvwinwstr()`, and `winwstr()` functions return OK. Otherwise, they return ERR.

On success, the `innwstr()`, `mvinnwstr()`, `mvwinnwstr()`, and `winnwstr()` functions return the number of characters read into the string. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

**SEE ALSO** `in_wch(3XCURSES)`, `in_wchnstr(3XCURSES)`, `libcurses(3XCURSES)`, `attributes(5)`, `standards(5)`

wmove(3CURSES)

| NAME           | curs_move, move, wmove – move curses window cursor                                                                                                                                                                                                                                                                |                |                 |          |        |

| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int move(int y, int x); int wmove(WINDOW *win, int y, int x);</pre>                                                                                                                                                             |                |                 |          |        |
| DESCRIPTION    | With these routines, the cursor associated with the window is moved to line <i>y</i> and column <i>x</i> . This routine does not move the physical cursor of the terminal until <code>refresh()</code> is called. The position specified is relative to the upper left-hand corner of the window, which is (0,0). |                |                 |          |        |
| RETURN VALUES  | These routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                |                |                 |          |        |
| ATTRIBUTES     | See <code>attributes(5)</code> for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>MT-Level</td><td>Unsafe</td></tr></table>                                                                                                                     | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

| <i>y</i>            | Is the y (row) coordinate of the position of the cursor in the window.                                                                                                                                                                                                                                                                                                                                                                                                     |                |                                                                        |                     |                                                                           |            |                                                                  |
| <i>x</i>            | Is the x (column) coordinate of the position of the cursor in the window.                                                                                                                                                                                                                                                                                                                                                                                                  |                |                                                                        |                     |                                                                           |            |                                                                  |
| <i>win</i>          | Is a pointer to the window in which the cursor is to be written.                                                                                                                                                                                                                                                                                                                                                                                                           |                |                                                                        |                     |                                                                           |            |                                                                  |
| DESCRIPTION         | The <code>move()</code> function moves the logical cursor (for <code>stdscr</code> ) to the position specified by <i>y</i> (row) and <i>x</i> (column), where the upper left corner of the window is row 0, column 0. The <code>wmove()</code> function performs the same action, but moves the cursor in the window specified by <i>win</i> . The physical cursor will not move until after a call to <code>refresh(3XCURSES)</code> or <code>doupdate(3XCURSES)</code> . |                |                                                                        |                     |                                                                           |            |                                                                  |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                         |                |                                                                        |                     |                                                                           |            |                                                                  |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                                                                        |                     |                                                                           |            |                                                                  |

## wmovenextch(3CURSES)

| NAME           | <code> curs_alecompat, movenextch, wmovenextch, moveprevch, wmoveprevch, adjcurspos, wadjcurspos </code> – these functions are added to ALE curses library for moving the cursor by character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |          |        |

| DESCRIPTION    | <p><code>movenextch()</code> and <code>wmovenextch()</code> move the cursor to the next character to the right. If the next character is a multicolumn character, the cursor is positioned on the first (left-most) column of that character. The new cursor position will be on the next character, even if the cursor was originally positioned on the left-most column of a multicolumn character. Note that the simple cursor increment (<code>++x</code>) does not guarantee movement to the next character, if the cursor was originally positioned on a multicolumn character. <code>getyx(3CURSES)</code> can be used to find the new position.</p> <p><code>moveprevch()</code> and <code>wmoveprevch()</code> routines are the opposite of <code>movenextch()</code> and <code>wmovenextch()</code>, moving the cursor to the left-most column of the previous character.</p> <p><code>adjcurspos()</code> and <code>wadjcurspos()</code> move the cursor to the first(left-most) column of the multicolumn character that the cursor is presently on. If the cursor is already on the first column, or if the cursor is on a single-column character, these routines will have no effect.</p> |                |                 |          |        |
| RETURN VALUE   | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |          |        |

| <b>DESCRIPTION</b>  | <p> <b>movenextch()</b> and <b>wmovenextch()</b> move the cursor to the next character to the right. If the next character is a multicolumn character, the cursor is positioned on the first (left-most) column of that character. The new cursor position will be on the next character, even if the cursor was originally positioned on the left-most column of a multicolumn character. Note that the simple cursor increment (++x) does not guarantee movement to the next character, if the cursor was originally positioned on a multicolumn character. <b>getyx(3CURSES)</b> can be used to find the new position. </p> <p> <b>moveprevch()</b> and <b>wmoveprevch()</b> routines are the opposite of <b>movenextch()</b> and <b>wmovenextch()</b>, moving the cursor to the left-most column of the previous character. </p> <p> <b>adjcurspos()</b> and <b>wadjcurspos()</b> move the cursor to the first(left-most) column of the multicolumn character that the cursor is presently on. If the cursor is already on the first column, or if the cursor is on a single-column character, these routines will have no effect. </p> |                |                 |          |        |
| <b>RETURN VALUE</b> | <p> All routines return the integer <b>ERR</b> upon failure and an integer value other than <b>ERR</b> upon successful completion. </p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |

| NAME        | <code>curs_refresh</code> , <code>refresh</code> , <code>wrefresh</code> , <code>wnoutrefresh</code> , <code>doupdate</code> , <code>redrawwin</code> , <code>wredrawln</code> – refresh curses windows and lines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| SYNOPSIS    | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lcurses [ <i>library</i> ... ] #include &lt;curses.h&gt;  int <b>refresh</b>(void); int <b>wrefresh</b>(WINDOW *<i>win</i>); int <b>wnoutrefresh</b>(WINDOW *<i>win</i>); int <b>doupdate</b>(void); int <b>redrawwin</b>(WINDOW *<i>win</i>); int <b>wredrawln</b>(WINDOW *<i>win</i>, int <i>beg_line</i>, int <i>num_lines</i>);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DESCRIPTION | <p>The <code>refresh()</code> and <code>wrefresh()</code> routines (or <code>wnoutrefresh()</code> and <code>doupdate()</code>) must be called to get any output on the terminal, as other routines merely manipulate data structures. The routine <code>wrefresh()</code> copies the named window to the physical terminal screen, taking into account what is already there in order to do optimizations. The <code>refresh()</code> routine is the same, using <code>stdscr</code> as the default window. Unless <code>leaveok()</code> has been enabled, the physical cursor of the terminal is left at the location of the cursor for that window.</p> <p>The <code>wnoutrefresh()</code> and <code>doupdate()</code> routines allow multiple updates with more efficiency than <code>wrefresh()</code> alone. In addition to all the window structures, <code>curses</code> keeps two data structures representing the terminal screen: a physical screen, describing what is actually on the screen, and a virtual screen, describing what the programmer wants to have on the screen.</p> <p>The routine <code>wrefresh()</code> works by first calling <code>wnoutrefresh()</code>, which copies the named window to the virtual screen, and then calling <code>doupdate()</code>, which compares the virtual screen to the physical screen and does the actual update. If the programmer wishes to output several windows at once, a series of calls to <code>wrefresh()</code> results in alternating calls to <code>wnoutrefresh()</code> and <code>doupdate()</code>, causing several bursts of output to the screen. By first calling <code>wnoutrefresh()</code> for each window, it is then possible to call <code>doupdate()</code> once, resulting in only one burst of output, with fewer total characters transmitted and less CPU time used. If the <i>win</i> argument to <code>wrefresh()</code> is the global variable <code>curscr</code>, the screen is immediately cleared and repainted from scratch.</p> <p>The <code>redrawwin()</code> routine indicates to <code>curses</code> that some screen lines are corrupted and should be thrown away before anything is written over them. These routines could be used for programs such as editors, which want a command to redraw some part of the screen or the entire screen. The routine <code>redrawln()</code> is preferred over <code>redrawwin()</code> where a noisy communication line exists and redrawing the entire window could be subject to even more communication noise. Just redrawing several lines offers the possibility that they would show up unblemished.</p> |

`wnoutrefresh(3CURSES)`

**RETURN VALUES** All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_outopts(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `refresh()` and `redrawwin()` may be macros.

## wnoutrefresh(3XCURSES)

| NAME                | douupdate, refresh, wnoutrefresh, wrefresh – refresh windows and lines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |

| DESCRIPTION         | <p>The <code>refresh()</code> and <code>wrefresh()</code> functions copy <code>stdscr</code> and <code>win</code>, respectively, to the terminal screen. These functions call the <code>wnoutrefresh()</code> function to copy the specified window to <code>curscr</code> and the <code>douupdate()</code> function to do the actual update. The physical cursor is mapped to the same position as the logical cursor of the last window to update <code>curscr</code> unless <code>leaveok(3XCURSES)</code> is enabled (in which case, the cursor is placed in a position that X/Open Curses finds convenient).</p> <p>When outputting several windows at once, it is often more efficient to call the <code>wnoutrefresh()</code> and <code>douupdate()</code> functions directly. A call to <code>wnoutrefresh()</code> for each window, followed by only one call to <code>douupdate()</code> to update the screen, results in one burst of output, fewer characters sent, and less CPU time used.</p> <p>If the <code>win</code> parameter to <code>wrefresh()</code> is the global variable <code>curscr</code>, the screen is immediately cleared and repainted from scratch.</p> <p>For details on how the <code>wnoutrefresh()</code> function handles overlapping windows with broad glyphs, see the Overlapping Windows section of the <code>curses(3XCURSES)</code> reference manual page.</p> |                |                 |                     |          |          |        |
| PARAMETERS          | <p><i>win</i>            Is a pointer to the window in which to refresh.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |

| NAME           | curs_printw, printw, wprintw, mvprintw, mvwprintw, vwprintw – print formatted output in curses windows                                                                                                                                                                                                                                                                                                                                                                              |                |                 |          |        |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| SYNOPSIS       | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int printw(char *fmt, /* arg */ ... ); int wprintw(WINDOW *win, char *fmt, /* arg */ ... ); int mvprintw(int y, int x, char *fmt, /* arg */ ... ); int mvwprintw(WINDOW *win, int y, int x, char *fmt, /* arg */ ... ); #include &lt;varargs.h&gt; int vwprintw(WINDOW *win, char *fmt, /* varglist */ ... );</pre>                                                                               |                |                 |          |        |
| DESCRIPTION    | <p>The printw(), wprintw(), mvprintw(), and mvwprintw() routines are analogous to printf() (see printf(3C)). In effect, the string that would be output by printf() is output instead as though waddstr() were used on the given window.</p> <p>The vwprintw() routine is analogous to vprintf() (see vprintf(3C)) and performs a wprintw() using a variable argument list. The third argument is a va_list, a pointer to a list of arguments, as defined in &lt;varargs.h&gt;.</p> |                |                 |          |        |
| RETURN VALUES  | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion.                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |

## wprintw(3XCURSES)

| <b>NAME</b>          | mvprintw, mvwprintw, printw, wprintw – print formatted output window                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  int <b>mvprintw</b>(int <i>y</i>, int <i>x</i>, char <i>*fmt</i>, ...); int <b>mvwprintw</b>(WINDOW <i>*win</i>, int <i>y</i>, int <i>x</i>, char <i>*fmt</i>, ...); int <b>printw</b>(char <i>*fmt</i>, ...); int <b>wprintw</b>(WINDOW <i>*win</i>, char <i>*fmt</i>, ...);</pre> |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <p><i>y</i> Is the y (row) coordinate position of the string's placement in the window.</p> <p><i>x</i> Is the x (column) coordinate position of the string's placement in the window.</p> <p><i>fmt</i> Is a printf() format string.</p> <p><i>win</i> Is a pointer to the window in which the string is to be written.</p>                                                                                                                                                  |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | The mvprintw(), mvwprintw(), printw(), and wprintw() functions are analogous to printf(3C). The effect of these functions is as though sprintf() were used to format the string, and then waddstr(3XCURSES) were used to add that multi-byte string to the current or specified window at the current or specified cursor position.                                                                                                                                           |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |                     |          |          |        |

| NAME        | curs_refresh, refresh, wrefresh, wnoutrefresh, doupdate, redrawwin, wredrawln – refresh curses windows and lines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| SYNOPSIS    | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int refresh(void); int wrefresh(WINDOW *win); int wnoutrefresh(WINDOW *win); int doupdate(void); int redrawwin(WINDOW *win); int wredrawln(WINDOW *win, int beg_line, int num_lines);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| DESCRIPTION | <p>The <code>refresh()</code> and <code>wrefresh()</code> routines (or <code>wnoutrefresh()</code> and <code>doupdate()</code>) must be called to get any output on the terminal, as other routines merely manipulate data structures. The routine <code>wrefresh()</code> copies the named window to the physical terminal screen, taking into account what is already there in order to do optimizations. The <code>refresh()</code> routine is the same, using <code>stdscr</code> as the default window. Unless <code>leaveok()</code> has been enabled, the physical cursor of the terminal is left at the location of the cursor for that window.</p> <p>The <code>wnoutrefresh()</code> and <code>doupdate()</code> routines allow multiple updates with more efficiency than <code>wrefresh()</code> alone. In addition to all the window structures, <code>curses</code> keeps two data structures representing the terminal screen: a physical screen, describing what is actually on the screen, and a virtual screen, describing what the programmer wants to have on the screen.</p> <p>The routine <code>wrefresh()</code> works by first calling <code>wnoutrefresh()</code>, which copies the named window to the virtual screen, and then calling <code>doupdate()</code>, which compares the virtual screen to the physical screen and does the actual update. If the programmer wishes to output several windows at once, a series of calls to <code>wrefresh()</code> results in alternating calls to <code>wnoutrefresh()</code> and <code>doupdate()</code>, causing several bursts of output to the screen. By first calling <code>wnoutrefresh()</code> for each window, it is then possible to call <code>doupdate()</code> once, resulting in only one burst of output, with fewer total characters transmitted and less CPU time used. If the <code>win</code> argument to <code>wrefresh()</code> is the global variable <code>curscr</code>, the screen is immediately cleared and repainted from scratch.</p> <p>The <code>redrawwin()</code> routine indicates to <code>curses</code> that some screen lines are corrupted and should be thrown away before anything is written over them. These routines could be used for programs such as editors, which want a command to redraw some part of the screen or the entire screen. The routine <code>redrawln()</code> is preferred over <code>redrawwin()</code> where a noisy communication line exists and redrawing the entire window could be subject to even more communication noise. Just redrawing several lines offers the possibility that they would show up unblemished.</p> |

wredrawln(3CURSES)

**RETURN VALUES** All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_outopts(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `refresh()` and `redrawwin()` may be macros.

| <b>NAME</b>          | redrawwin, wredrawln – redraw screen or portion of screen                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |

| <b>PARAMETERS</b>    | <p><i>win</i> Is a pointer to the window in which to redraw.</p> <p><i>beg_line</i> Is the first line to redraw.</p> <p><i>num_lines</i> Is the number of lines to redraw.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>redrawwin()</code> and <code>wredrawln()</code> functions force portions of a window to be redrawn to the terminal when the next refresh operation is performed.</p> <p>The <code>redrawwin()</code> function forces the entire window <i>win</i> to be redrawn, while the <code>wredrawln()</code> function forces only <i>num_lines</i> lines starting with <i>beg_line</i> to be redrawn. Normally, refresh operations use optimization methods to reduce the actual amount of the screen to redraw based on the current screen contents. These functions tell the refresh operations not to attempt any optimization when redrawing the indicated areas.</p> <p>These functions are useful when the data that exists on the screen is believed to be corrupt and for applications such as screen editors that redraw portions of the screen.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |                     |          |          |        |

| NAME        | <code> curs_refresh, refresh, wrefresh, wnoutrefresh, doupdate, redrawwin, wredrawln </code> – refresh curses windows and lines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| SYNOPSIS    | <pre>cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int refresh(void); int wrefresh(WINDOW *win); int wnoutrefresh(WINDOW *win); int doupdate(void); int redrawwin(WINDOW *win); int wredrawln(WINDOW *win, int beg_line, int num_lines);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DESCRIPTION | <p>The <code>refresh()</code> and <code>wrefresh()</code> routines (or <code>wnoutrefresh()</code> and <code>doupdate()</code>) must be called to get any output on the terminal, as other routines merely manipulate data structures. The routine <code>wrefresh()</code> copies the named window to the physical terminal screen, taking into account what is already there in order to do optimizations. The <code>refresh()</code> routine is the same, using <code>stdscr</code> as the default window. Unless <code>leaveok()</code> has been enabled, the physical cursor of the terminal is left at the location of the cursor for that window.</p> <p>The <code>wnoutrefresh()</code> and <code>doupdate()</code> routines allow multiple updates with more efficiency than <code>wrefresh()</code> alone. In addition to all the window structures, <code>curses</code> keeps two data structures representing the terminal screen: a physical screen, describing what is actually on the screen, and a virtual screen, describing what the programmer wants to have on the screen.</p> <p>The routine <code>wrefresh()</code> works by first calling <code>wnoutrefresh()</code>, which copies the named window to the virtual screen, and then calling <code>doupdate()</code>, which compares the virtual screen to the physical screen and does the actual update. If the programmer wishes to output several windows at once, a series of calls to <code>wrefresh()</code> results in alternating calls to <code>wnoutrefresh()</code> and <code>doupdate()</code>, causing several bursts of output to the screen. By first calling <code>wnoutrefresh()</code> for each window, it is then possible to call <code>doupdate()</code> once, resulting in only one burst of output, with fewer total characters transmitted and less CPU time used. If the <code>win</code> argument to <code>wrefresh()</code> is the global variable <code>curscr</code>, the screen is immediately cleared and repainted from scratch.</p> <p>The <code>redrawwin()</code> routine indicates to <code>curses</code> that some screen lines are corrupted and should be thrown away before anything is written over them. These routines could be used for programs such as editors, which want a command to redraw some part of the screen or the entire screen. The routine <code>wredrawln()</code> is preferred over <code>redrawwin()</code> where a noisy communication line exists and redrawing the entire window could be subject to even more communication noise. Just redrawing several lines offers the possibility that they would show up unblemished.</p> |

wrefresh(3CURSES)

**RETURN VALUES** All routines return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_outopts(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `refresh()` and `redrawwin()` may be macros.

## wrefresh(3XCURSES)

| NAME                | douupdate, refresh, wnoutrefresh, wrefresh – refresh windows and lines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |

| DESCRIPTION         | <p>The <code>refresh()</code> and <code>wrefresh()</code> functions copy <code>stdscr</code> and <code>win</code>, respectively, to the terminal screen. These functions call the <code>wnoutrefresh()</code> function to copy the specified window to <code>curscr</code> and the <code>douupdate()</code> function to do the actual update. The physical cursor is mapped to the same position as the logical cursor of the last window to update <code>curscr</code> unless <code>leaveok(3XCURSES)</code> is enabled (in which case, the cursor is placed in a position that X/Open Curses finds convenient).</p> <p>When outputting several windows at once, it is often more efficient to call the <code>wnoutrefresh()</code> and <code>douupdate()</code> functions directly. A call to <code>wnoutrefresh()</code> for each window, followed by only one call to <code>douupdate()</code> to update the screen, results in one burst of output, fewer characters sent, and less CPU time used.</p> <p>If the <code>win</code> parameter to <code>wrefresh()</code> is the global variable <code>curscr</code>, the screen is immediately cleared and repainted from scratch.</p> <p>For details on how the <code>wnoutrefresh()</code> function handles overlapping windows with broad glyphs, see the Overlapping Windows section of the <code>curses(3XCURSES)</code> reference manual page.</p> |                |                 |                     |          |          |        |
| PARAMETERS          | <p><i>win</i>            Is a pointer to the window in which to refresh.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>   | <p>The <code>scanw()</code>, <code>wscanw()</code>, and <code>mvscanw()</code> routines correspond to <code>scanf()</code> (see <code>scanf(3C)</code>). The effect of these routines is as though <code>wgetstr()</code> were called on the window, and the resulting line used as input for the scan. Fields which do not map to a variable in the <code>fmt</code> field are lost.</p> <p>The <code>vwscanw()</code> routine is similar to <code>vwprintw()</code> in that it performs a <code>wscanw()</code> using a variable argument list. The third argument is a <i>va_list</i>, a pointer to a list of arguments, as defined in <code>&lt;varargs.h&gt;</code>.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | <p><code>vwscanw()</code> returns <code>ERR</code> on failure and an integer equal to the number of fields scanned on success.</p> <p>Applications may interrogate the return value from the <code>scanw</code>, <code>wscanw()</code>, <code>mvscanw()</code>, and <code>mvwscanw()</code> routines to determine the number of fields which were mapped in the call.</p>                                                                                                                                                                                                                                                                                                     |                |                 |          |        |
| <b>ATTRIBUTES</b>    | <p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>MT-Level</td><td>Unsafe</td></tr> </tbody> </table>                                                                                                                                                                                                                                                                                                                                                                                                                        | ATTRIBUTE TYPE | ATTRIBUTE VALUE | MT-Level | Unsafe |

|                     | fmt                                                                                                                                                                                                                                                                                                                                                                        | Is a scanf ( ) format string.                                             |                |                 |                     |          |          |        |
|                     | win                                                                                                                                                                                                                                                                                                                                                                        | Is a pointer to the window in which the character is to be read.          |                |                 |                     |          |          |        |
| DESCRIPTION         | These functions are similar to scanf(3C). Their effect is as though mvwgetstr(3XCURSES) were called to get a multi-byte character string from the current or specified window at the current or specified cursor position, and then sscanf ( ) were used to interpret and convert that string.                                                                             |                                                                           |                |                 |                     |          |          |        |
| RETURN VALUES       | Upon successful completion, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                         |                                                                           |                |                 |                     |          |          |        |
| ERRORS              | No errors are defined.                                                                                                                                                                                                                                                                                                                                                     |                                                                           |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b>   | <p>With the <code>scroll()</code> routine, the window is scrolled up one line. This involves moving the lines in the window data structure. As an optimization, if the scrolling region of the window is the entire screen, the physical screen is scrolled at the same time.</p> <p>With the <code>scl()</code> and <code>wscrl()</code> routines, for positive <math>n</math> scroll the window up <math>n</math> lines (line <math>i+n</math> becomes <math>i</math>); otherwise scroll the window down <math>n</math> lines. This involves moving the lines in the window character image structure. The current cursor position is not changed.</p> <p>For these functions to work, scrolling must be enabled via <code>scrollok()</code>.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer <code>ERR</code> upon failure and an integer value other than <code>ERR</code> upon successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |

| PARAMETERS          | <i>n</i> number and direction of lines to scroll<br><i>win</i> pointer to the window in which to scroll                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |        |
| DESCRIPTION         | <p>The <code>scroll()</code> function scrolls the window <i>win</i> up one line. The current cursor position is not changed.</p> <p>The <code>sclr()</code> and <code>wscrl()</code> functions scroll the window <code>stdscr</code> or <i>win</i> up or down <i>n</i> lines, where <i>n</i> is a positive (scroll up) or negative (scroll down) integer.</p> <p>The <code>scrollok(3XCURSES)</code> function must be enabled for these functions to work.</p> |                |                 |                     |          |          |        |
| RETURN VALUES       | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |                     |          |          |        |

| DESCRIPTION | <p>These routines set options that deal with output within curses. All options are initially FALSE, unless otherwise stated. It is not necessary to turn these options off before calling <code>endwin()</code>.</p> <p>With the <code>clearok()</code> routine, if enabled (<i>bf</i> is TRUE), the next call to <code>wrefresh()</code> with this window will clear the screen completely and redraw the entire screen from scratch. This is useful when the contents of the screen are uncertain, or in some cases for a more pleasing visual effect. If the <i>win</i> argument to <code>clearok()</code> is the global variable <code>curscr()</code>, the next call to <code>wrefresh()</code> with any window causes the screen to be cleared and repainted from scratch.</p> <p>With the <code>idlok()</code> routine, if enabled (<i>bf</i> is TRUE), curses considers using the hardware insert/delete line feature of terminals so equipped. If disabled (<i>bf</i> is FALSE), curses very seldom uses this feature. (The insert/delete character feature is always considered.) This option should be enabled only if the application needs insert/delete line, for example, for a screen editor. It is disabled by default because insert/delete line tends to be visually annoying when used in applications where it isn't really needed. If insert/delete line cannot be used, curses redraws the changed portions of all lines.</p> <p>With the <code>idcok()</code> routine, if enabled (<i>bf</i> is TRUE), curses considers using the hardware insert/delete character feature of terminals so equipped. This is enabled by default.</p> <p>With the <code>immedok()</code> routine, if enabled (<i>bf</i> is TRUE), any change in the window image, such as the ones caused by <code>waddch()</code>, <code>wclrtoeol()</code>, <code>wscrl()</code>, etc., automatically cause a call to <code>wrefresh()</code>. However, it may degrade the performance considerably, due to repeated calls to <code>wrefresh()</code>. It is disabled by default.</p> |

## wsetscrreg(3CURSES)

Normally, the hardware cursor is left at the location of the window cursor being refreshed. The `leaveok()` option allows the cursor to be left wherever the update happens to leave it. It is useful for applications where the cursor is not used, since it reduces the need for cursor motions. If possible, the cursor is made invisible when this option is enabled.

The `setscrreg()` and `wsetscrreg()` routines allow the application programmer to set a software scrolling region in a window. *top* and *bot* are the line numbers of the top and bottom margin of the scrolling region. (Line 0 is the top line of the window.) If this option and `scrollok()` are enabled, an attempt to move off the bottom margin line causes all lines in the scrolling region to scroll up one line. Only the text of the window is scrolled. (Note that this has nothing to do with the use of a physical scrolling region capability in the terminal, like that in the VT100. If `idlok()` is enabled and the terminal has either a scrolling region or insert/delete line capability, they will probably be used by the output routines.)

The `scrollok()` option controls what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If disabled, (*bf* is FALSE), the cursor is left on the bottom line. If enabled, (*bf* is TRUE), `wrefresh()` is called on the window, and the physical terminal and window are scrolled up one line. (Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call `idlok()`.)

The `nl()` and `nonl()` routines control whether newline is translated into carriage return and linefeed on output, and whether return is translated into newline on input. Initially, the translations do occur. By disabling these translations using `nonl()`, `curses` is able to make better use of the linefeed capability, resulting in faster cursor motion.

**RETURN VALUES** `setscrreg()` and `wsetscrreg()` return OK upon success and ERR upon failure. All other routines that return an integer always return OK.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `curs_addch(3CURSES)`, `curs_clear(3CURSES)`, `curs_initscr(3CURSES)`, `curs_refresh(3CURSES)`, `curs_scroll(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

**NOTES** The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `clearok()`, `leaveok()`, `scrollok()`, `idcok()`, `nl()`, `nonl()`, and `setscrreg()` may be macros.

`wsetscrreg(3CURSES)`

The `immedok()` routine is useful for windows that are used as terminal emulators.

| DESCRIPTION | <p>These functions set options that deal with the output within Curses functions.</p> <p>The <code>clearok()</code> function assigns the value of <i>bf</i> to an internal flag in the specified window that governs clearing of the screen during a refresh. If, during a refresh operation on the specified window, the flag in <i>curscr</i> is TRUE or the flag in the specified window is TRUE, <code>clearok()</code> clears the screen, redraws it in its entirety, and sets the flag to FALSE in <i>curscr</i> and in the specified window. The initial state is unspecified</p> <p>The <code>idlok()</code> function specifies whether the implementation may use the hardware insert-line, delete-line, and scroll features of terminals so equipped. If <i>bf</i> is TRUE, use of these features is enabled. If <i>bf</i> is FALSE, use of these features is disabled and lines are instead redrawn as required. The initial state is FALSE.</p> <p>The <code>leaveok()</code> function controls the cursor position after a refresh operation. If <i>bf</i> is TRUE, refresh operations on the specified window may leave the terminal's cursor at an arbitrary position. If <i>bf</i> is FALSE, then at the end of any refresh operation, the terminal's cursor is positioned at the cursor position contained in the specified window. The initial state is FALSE.</p> <p>The <code>scrollok()</code> function controls the use of scrolling. If <i>bf</i> is TRUE, then scrolling is enabled for the specified window. If <i>bf</i> is FALSE, scrolling is disabled for the specified window. The initial state is FALSE.</p> <p>The <code>setscrreg()</code> and <code>wsetscrreg()</code> functions define a software scrolling region in the current or specified window. The <i>top</i> and <i>bottom</i> arguments are the line numbers of the first and last line defining the scrolling region. (Line 0 is the top line of the window.) If this option and <code>scrollok()</code> are enabled, an attempt to move off the last line of the margin causes all lines in the scrolling region to scroll one line in the</p> |

wsetscrreg(3XCURSES)

direction of the first line. Only characters in the window are scrolled. If a software scrolling region is set and `scrollok()` is not enabled, an attempt to move off the last line of the margin does not reposition any lines in the scrolling region.

**PARAMETERS**

*win* Is a pointer to a window.  
*bf* Is a Boolean expression.  
*top* Is the top line of the scrolling region (top of the window is line 0).  
*bot* Is the bottom line of the scrolling region (top of the window is line 0).

**RETURN VALUES**

Upon successful completion, the `setscrreg()` and `wsetscrreg()` functions return OK. Otherwise, they return ERR.

The other functions always return OK.

**ERRORS**

No errors are defined.

**USAGE**

The only reason to enable the `idlok()` feature is to use scrolling to achieve the visual effect of motion of a partial window, such as for a screen editor. In other cases, the feature can be visually annoying.

The `leaveok()` option provides greater efficiency for applications that do not use the cursor.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>NAME</b>               | <p> <code> curs_attr, attroff, wattroff, attron, wattron, attrset, wattrset, standend, wstandend, standout, wstandout</code> – curses character and window attribute control routines </p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                         |                                        |                          |             |                        |               |                      |          |                    |             |                     |                      |                           |                         |
| <b>SYNOPSIS</b>           | <pre> cc [ flag ... ] file ... -lcurses [ library ... ] #include &lt;curses.h&gt;  int  attroff(int  attrs);  int  wattroff(WINDOW *win, int  attrs);  int  attron(int  attrs);  int  wattron(WINDOW *win, int  attrs);  int  attrset(int  attrs);  int  wattrset(WINDOW *win, int  attrs);  int  standend(void);  int  wstandend(WINDOW *win);  int  standout(void);  int  wstandout(WINDOW *win); </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                         |                                        |                          |             |                        |               |                      |          |                    |             |                     |                      |                           |                         |
| <b>DESCRIPTION</b>        | <p> All of these routines manipulate the current attributes of the named window. The current attributes of a window are applied to all characters that are written into the window with <code>waddch()</code>, <code>waddstr()</code>, and <code>wprintw()</code>. Attributes are a property of the character, and move with the character through any scrolling and insert/delete line/character operations. To the extent possible on the particular terminal, they are displayed as the graphic rendition of characters put on the screen. </p> <p> The routine <code>attrset()</code> sets the current attributes of the given window to <i>attrs</i>. The routine <code>attroff()</code> turns off the named attributes without turning any other attributes on or off. The routine <code>attron()</code> turns on the named attributes without affecting any others. The routine <code>standout()</code> is the same as <code>attron(A_STANDOUT)</code>. The routine <code>standend()</code> is the same as <code>attrset()</code>, that is, it turns off all attributes. </p> |                         |                                        |                          |             |                        |               |                      |          |                    |             |                     |                      |                           |                         |
| <b>Attributes</b>         | <p> The following video attributes, defined in <code>&lt;curses.h&gt;</code>, can be passed to the routines <code>attron()</code>, <code>attroff()</code>, and <code>attrset()</code>, or OR-ed with the characters passed to <code>addch()</code>. </p> <table> <tbody> <tr> <td><code>A_STANDOUT</code></td><td>Best highlighting mode of the terminal</td></tr> <tr> <td><code>A_UNDERLINE</code></td><td>Underlining</td></tr> <tr> <td><code>A_REVERSE</code></td><td>Reverse video</td></tr> <tr> <td><code>A_BLINK</code></td><td>Blinking</td></tr> <tr> <td><code>A_DIM</code></td><td>Half bright</td></tr> <tr> <td><code>A_BOLD</code></td><td>Extra bright or bold</td></tr> <tr> <td><code>A_ALTCHARSET</code></td><td>Alternate character set</td></tr> </tbody> </table>                                                                                                                                                                                                                                                                                             | <code>A_STANDOUT</code> | Best highlighting mode of the terminal | <code>A_UNDERLINE</code> | Underlining | <code>A_REVERSE</code> | Reverse video | <code>A_BLINK</code> | Blinking | <code>A_DIM</code> | Half bright | <code>A_BOLD</code> | Extra bright or bold | <code>A_ALTCHARSET</code> | Alternate character set |

wstandend(3CURSES)

A\_CHARTEXT Bit-mask to extract a character

COLOR\_PAIR(*n*) Color-pair number *n*

The following macro is the reverse of COLOR\_PAIR(*n*) :

PAIR\_NUMBER(*attrs*) Returns the pair number associated with the  
COLOR\_PAIR(*n*) attribute

**RETURN VALUES** These routines always return 1.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curs\_addch(3CURSES), curs\_addstr(3CURSES), curs\_printw(3CURSES),  
curses(3CURSES), attributes(5)

**NOTES** The header <curses.h> automatically includes the headers <stdio.h> and  
<unctrl.h>.

Note that attroff(), wattroff(), attron(), wattroff(), wattrset(),  
standend(), and standout() may be macros.

## wstandend(3XCURSES)

| NAME                | standend, standout, wstandend, wstandout – set/clear window attributes                                                                                                                                                                                                                           |                |                 |                     |          |          |        |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|--------|
| SYNOPSIS            | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt; curses.h&gt;  int standend(void); int standout(void); int wstandend(WINDOW *win); int wstandout(WINDOW *win);</pre> |                |                 |                     |          |          |        |
| PARAMETERS          | <i>win</i> Is a pointer to the window in which attribute changes are to be made.                                                                                                                                                                                                                 |                |                 |                     |          |          |        |
| DESCRIPTION         | <p>The standend() and wstandend() functions turn off all attributes associated with stdscr and <i>win</i> respectively.</p> <p>The standout() and wstandout() functions turn on the A_STANDOUT attribute of stdscr and <i>win</i> respectively.</p>                                              |                |                 |                     |          |          |        |
| RETURN VALUES       | These functions always return 1.                                                                                                                                                                                                                                                                 |                |                 |                     |          |          |        |
| ERRORS              | None.                                                                                                                                                                                                                                                                                            |                |                 |                     |          |          |        |

| <b>DESCRIPTION</b> | <p>All of these routines manipulate the current attributes of the named window. The current attributes of a window are applied to all characters that are written into the window with <code>waddch()</code>, <code>waddstr()</code>, and <code>wprintw()</code>. Attributes are a property of the character, and move with the character through any scrolling and insert/delete line/character operations. To the extent possible on the particular terminal, they are displayed as the graphic rendition of characters put on the screen.</p> <p>The routine <code>attrset()</code> sets the current attributes of the given window to <i>attrs</i>. The routine <code>attroff()</code> turns off the named attributes without turning any other attributes on or off. The routine <code>attron()</code> turns on the named attributes without affecting any others. The routine <code>standout()</code> is the same as <code>attron(A_STANDOUT)</code>. The routine <code>standend()</code> is the same as <code>attrset()</code>, that is, it turns off all attributes.</p> |            |                                        |             |             |           |               |         |          |       |             |        |                      |              |                         |
| <b>Attributes</b>  | <p>The following video attributes, defined in <code>&lt;curses.h&gt;</code>, can be passed to the routines <code>attron()</code>, <code>attroff()</code>, and <code>attrset()</code>, or OR-ed with the characters passed to <code>addch()</code>.</p> <table> <tbody> <tr> <td>A_STANDOUT</td><td>Best highlighting mode of the terminal</td></tr> <tr> <td>A_UNDERLINE</td><td>Underlining</td></tr> <tr> <td>A_REVERSE</td><td>Reverse video</td></tr> <tr> <td>A_BLINK</td><td>Blinking</td></tr> <tr> <td>A_DIM</td><td>Half bright</td></tr> <tr> <td>A_BOLD</td><td>Extra bright or bold</td></tr> <tr> <td>A_ALTCHARSET</td><td>Alternate character set</td></tr> </tbody> </table>                                                                                                                                                                                                                                                                                                                                                                                      | A_STANDOUT | Best highlighting mode of the terminal | A_UNDERLINE | Underlining | A_REVERSE | Reverse video | A_BLINK | Blinking | A_DIM | Half bright | A_BOLD | Extra bright or bold | A_ALTCHARSET | Alternate character set |

wstandout(3CURSES)

A\_CHARTEXT                      Bit-mask to extract a character

COLOR\_PAIR(*n*)                      Color-pair number *n*

The following macro is the reverse of COLOR\_PAIR(*n*) :

PAIR\_NUMBER(*attrs*)                      Returns the pair number associated with the  
COLOR\_PAIR(*n*) attribute

**RETURN VALUES**                      These routines always return 1.

**ATTRIBUTES**                      See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO**                      curs\_addch(3CURSES), curs\_addstr(3CURSES), curs\_printw(3CURSES),  
curses(3CURSES), attributes(5)

**NOTES**                      The header <curses.h> automatically includes the headers <stdio.h> and  
<unctrl.h>.

Note that attroff(), wattroff(), attron(), wattron(), wattrset(),  
standend(), and standout() may be macros.

| DESCRIPTION | <p>The <code>newwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The upper left-hand corner of the window is at line <i>begin_y</i>, column <i>begin_x</i>. If either <i>nlines</i> or <i>ncols</i> is zero, they default to <code>LINES</code> — <i>begin_y</i> and <code>COLS</code> — <i>begin_x</i>. A new full-screen window is created by calling <code>newwin(0,0,0,0)</code>.</p> <p>The <code>delwin()</code> routine deletes the named window, freeing all memory associated with it. Subwindows must be deleted before the main window can be deleted.</p> <p>The <code>mvwin()</code> routine moves the window so that the upper left-hand corner is at position (<i>x</i>, <i>y</i>). If the move would cause the window to be off the screen, it is an error and the window is not moved. Moving subwindows is allowed, but should be avoided.</p> <p>The <code>subwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The window is at position (<i>begin_y</i>, <i>begin_x</i>) on the screen. (This position is relative to the screen, and not to the window <i>orig</i>.) The window is made in the middle of the window <i>orig</i>, so that changes made to one window will affect both windows. The subwindow shares memory with the window <i>orig</i>. When using this routine, it is necessary to call <code>touchwin()</code> or <code>touchline()</code> on <i>orig</i> before calling <code>wrefresh()</code> on the subwindow.</p> <p>The <code>derwin()</code> routine is the same as <code>subwin()</code>, except that <i>begin_y</i> and <i>begin_x</i> are relative to the origin of the window <i>orig</i> rather than the screen. There is no difference between the subwindows and the derived windows.</p> |

wsyncdown(3CURSES)

The `mvderwin()` routine moves a derived window (or subwindow) inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

The `dupwin()` routine creates an exact duplicate of the window *win*.

Each curses window maintains two data structures: the character image structure and the status structure. The character image structure is shared among all windows in the window hierarchy (that is, the window with all subwindows). The status structure, which contains information about individual line changes in the window, is private to each window. The routine `wrefresh()` uses the status data structure when performing screen updating. Since status structures are not shared, changes made to one window in the hierarchy may not be properly reflected on the screen.

The routine `wsyncup()` causes the changes in the status structure of a window to be reflected in the status structures of its ancestors. If `syncok()` is called with second argument `TRUE` then `wsyncup()` is called automatically whenever there is a change in the window.

The routine `wcursyncup()` updates the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

The routine `wsyncdown()` updates the status structure of the window to reflect the changes in the status structures of its ancestors. Applications seldom call this routine because it is called automatically by `wrefresh()`.

#### RETURN VALUES

Routines that return an integer return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`delwin()` returns the integer `ERR` upon failure and `OK` upon successful completion.

Routines that return pointers return `NULL` on error.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

#### SEE ALSO

`curs_refresh(3CURSES)`, `curs_touch(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

#### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

If many small changes are made to the window, the `wsyncup()` option could degrade performance.

`wsyncdown(3CURSES)`

Note that `syncok()` may be a macro.

| <b>NAME</b>          | syncok, wcursyncup, wsyncdown, wsyncup – synchronize window with its parents or children                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |

| <b>PARAMETERS</b>    | <p><i>win</i> Is a pointer to a window.</p> <p><i>bf</i> Is a Boolean expression.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>syncok()</code> function uses the value of <i>bf</i> to determine whether or not the window <i>win</i>'s ancestors are implicitly touched whenever there is a change to <i>win</i>. If <i>bf</i> is TRUE, this touching occurs. If <i>bf</i> is FALSE, it does not occur. The initial value for <i>bf</i> is FALSE.</p> <p>The <code>wcursyncup()</code> function moves the cursor in <i>win</i>'s ancestors to match its position in <i>win</i>.</p> <p>The <code>wsyncdown()</code> function touches <i>win</i> if any of its ancestors have been touched.</p> <p>The <code>wsyncup()</code> function touches all ancestors of <i>win</i>.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | <p>On success, the <code>syncok()</code> function returns OK. Otherwise, it returns ERR.</p> <p>The other functions do not return a value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The <code>newwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The upper left-hand corner of the window is at line <i>begin_y</i>, column <i>begin_x</i>. If either <i>nlines</i> or <i>ncols</i> is zero, they default to <code>LINES</code> — <i>begin_y</i> and <code>COLS</code> — <i>begin_x</i>. A new full-screen window is created by calling <code>newwin(0,0,0,0)</code>.</p> <p>The <code>delwin()</code> routine deletes the named window, freeing all memory associated with it. Subwindows must be deleted before the main window can be deleted.</p> <p>The <code>mvwin()</code> routine moves the window so that the upper left-hand corner is at position (<i>x</i>, <i>y</i>). If the move would cause the window to be off the screen, it is an error and the window is not moved. Moving subwindows is allowed, but should be avoided.</p> <p>The <code>subwin()</code> routine creates and returns a pointer to a new window with the given number of lines, <i>nlines</i>, and columns, <i>ncols</i>. The window is at position (<i>begin_y</i>, <i>begin_x</i>) on the screen. (This position is relative to the screen, and not to the window <i>orig</i>.) The window is made in the middle of the window <i>orig</i>, so that changes made to one window will affect both windows. The subwindow shares memory with the window <i>orig</i>. When using this routine, it is necessary to call <code>touchwin()</code> or <code>touchline()</code> on <i>orig</i> before calling <code>wrefresh()</code> on the subwindow.</p> <p>The <code>derwin()</code> routine is the same as <code>subwin()</code>, except that <i>begin_y</i> and <i>begin_x</i> are relative to the origin of the window <i>orig</i> rather than the screen. There is no difference between the subwindows and the derived windows.</p> |

wsyncup(3CURSES)

The `mvderwin()` routine moves a derived window (or subwindow) inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

The `dupwin()` routine creates an exact duplicate of the window *win*.

Each curses window maintains two data structures: the character image structure and the status structure. The character image structure is shared among all windows in the window hierarchy (that is, the window with all subwindows). The status structure, which contains information about individual line changes in the window, is private to each window. The routine `wrefresh()` uses the status data structure when performing screen updating. Since status structures are not shared, changes made to one window in the hierarchy may not be properly reflected on the screen.

The routine `wsyncup()` causes the changes in the status structure of a window to be reflected in the status structures of its ancestors. If `syncok()` is called with second argument `TRUE` then `wsyncup()` is called automatically whenever there is a change in the window.

The routine `wcursyncup()` updates the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

The routine `wsyncdown()` updates the status structure of the window to reflect the changes in the status structures of its ancestors. Applications seldom call this routine because it is called automatically by `wrefresh()`.

#### RETURN VALUES

Routines that return an integer return the integer `ERR` upon failure and an integer value other than `ERR` upon successful completion.

`delwin()` returns the integer `ERR` upon failure and `OK` upon successful completion.

Routines that return pointers return `NULL` on error.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

#### SEE ALSO

`curs_refresh(3CURSES)`, `curs_touch(3CURSES)`, `curses(3CURSES)`, `attributes(5)`

#### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

If many small changes are made to the window, the `wsyncup()` option could degrade performance.

`wsyncup(3CURSES)`

Note that `syncok()` may be a macro.

| <b>NAME</b>          | syncok, wcursyncup, wsyncdown, wsyncup – synchronize window with its parents or children                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |

| <b>PARAMETERS</b>    | <p><i>win</i> Is a pointer to a window.</p> <p><i>bf</i> Is a Boolean expression.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The <code>syncok()</code> function uses the value of <i>bf</i> to determine whether or not the window <i>win</i>'s ancestors are implicitly touched whenever there is a change to <i>win</i>. If <i>bf</i> is TRUE, this touching occurs. If <i>bf</i> is FALSE, it does not occur. The initial value for <i>bf</i> is FALSE.</p> <p>The <code>wcursyncup()</code> function moves the cursor in <i>win</i>'s ancestors to match its position in <i>win</i>.</p> <p>The <code>wsyncdown()</code> function touches <i>win</i> if any of its ancestors have been touched.</p> <p>The <code>wsyncup()</code> function touches all ancestors of <i>win</i>.</p> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | <p>On success, the <code>syncok()</code> function returns OK. Otherwise, it returns ERR.</p> <p>The other functions do not return a value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |        |

| DESCRIPTION | <p>The <code>cbreak()</code> and <code>nocbreak()</code> routines put the terminal into and out of <code>cbreak()</code> mode, respectively. In this mode, characters typed by the user are immediately available to the program, and erase/kill character-processing is not performed. When out of this mode, the tty driver buffers the typed characters until a newline or carriage return is typed. Interrupt and flow control characters are unaffected by this mode. Initially the terminal may or may not be in <code>cbreak()</code> mode, as the mode is inherited; therefore, a program should call <code>cbreak()</code> or <code>nocbreak()</code> explicitly. Most interactive programs using curses set the <code>cbreak()</code> mode.</p> <p>Note that <code>cbreak()</code> overrides <code>raw()</code>. (See <code>curs_getch(3CURSES)</code> for a discussion of how these routines interact with <code>echo()</code> and <code>noecho()</code>.)</p> <p>The <code>echo()</code> and <code>noecho()</code> routines control whether characters typed by the user are echoed by <code>getch()</code> as they are typed. Echoing by the tty driver is always disabled, but initially <code>getch()</code> is in echo mode, so characters typed are echoed. Authors of</p> |

most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling `noecho()`. (See `curs_getch(3CURSES)` for a discussion of how these routines interact with `cbreak()` and `nocbreak()`.)

The `halfdelay()` routine is used for half-delay mode, which is similar to `cbreak()` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, `ERR` is returned if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

If the `intrflush()` option is enabled, (*bf* is `TRUE`), when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing `curses` to have the wrong idea of what is on the screen. Disabling (*bf* is `FALSE`), the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.

The `keypad()` option enables the keypad of the user's terminal. If enabled (*bf* is `TRUE`), the user can press a function key (such as an arrow key) and `wgetch()` returns a single value representing the function key, as in `KEY_LEFT`. If disabled (*bf* is `FALSE`), `curses` does not treat function keys specially and the program has to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option causes the terminal keypad to be turned on when `wgetch()` is called. The default value for keypad is false.

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the tty driver (see `termio(7I)`). To force 8 bits to be returned, invoke `meta(win, TRUE)`. To force 7 bits to be returned, invoke `meta(win, FALSE)`. The window argument, *win*, is always ignored. If the terminfo capabilities `smm` (`meta_on`) and `rmm` (`meta_off`) are defined for the terminal, `smm` is sent to the terminal when `meta(win, TRUE)` is called and `rmm` is sent when `meta(win, FALSE)` is called.

The `nodelay()` option causes `getch()` to be a non-blocking call. If no input is ready, `getch()` returns `ERR`. If disabled (*bf* is `FALSE`), `getch()` waits until a key is pressed.

While interpreting an input escape sequence, `wgetch()` sets a timer while waiting for the next character. If `notimeout(win, TRUE)` is called, then `wgetch()` does not set a timer. The purpose of the timeout is to differentiate between sequences received from a function key and those typed by a user.

With the `raw()` and `noraw()` routines, the terminal is placed into or out of raw mode. Raw mode is similar to `cbreak()` mode, in that characters typed are immediately passed through to the user program. The differences are that in raw mode, the interrupt, quit, suspend, and flow control characters are all passed through uninterpreted, instead of generating a signal. The behavior of the `BREAK` key depends on other bits in the tty driver that are not set by `curses`.

## wtimeout(3CURSES)

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done (see `termio(7I)`). When `qiflush()` is called, the queues will be flushed when these control characters are read.

The `timeout()` and `wtimeout()` routines set blocking or non-blocking read for a given window. If *delay* is negative, blocking read is used (that is, waits indefinitely for input). If *delay* is zero, then non-blocking read is used (that is, read returns `ERR` if no input is waiting). If *delay* is positive, then read blocks for *delay* milliseconds, and returns `ERR` if there is still no input. Hence, these routines provide the same functionality as `nodelay()`, plus the additional capability of being able to block for only *delay* milliseconds (where *delay* is positive).

`curses` does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh()` or `doupdate()` is called again. This allows faster response to commands typed in advance. Normally, the input FILE pointer passed to `newterm()`, or `stdin` in the case that `initscr()` was used, will be used to do this typeahead checking. The `typeahead()` routine specifies that the file descriptor *fildev* is to be used to check for typeahead instead. If *fildev* is `-1`, then no typeahead checking is done.

### RETURN VALUES

All routines that return an integer return `ERR` upon failure and an integer value other than `ERR` upon successful completion, unless otherwise noted in the preceding routine descriptions.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

### SEE ALSO

`curs_getch(3CURSES)`, `curs_initscr(3CURSES)`, `curses(3CURSES)`, `attributes(5)`, `termio(7I)`

### NOTES

The header `<curses.h>` automatically includes the headers `<stdio.h>` and `<unctrl.h>`.

Note that `echo()`, `noecho()`, `halfdelay()`, `intrflush()`, `meta()`, `nodelay()`, `notimeout()`, `noqiflush()`, `qiflush()`, `timeout()`, and `wtimeout()` may be macros.

| <b>PARAMETERS</b>    | <p><i>win</i> Is a pointer to the window in which to set the timed blocking.</p> <p><i>bf</i> Is a Boolean expression.</p> <p><i>delay</i> Is the number of milliseconds to block or wait for input.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b>   | <p>If <i>bool</i> is TRUE, the notimeout() function disables a timer used by getch(3XCURSES) when handling multibyte function key sequences.</p> <p>When <i>bool</i> is FALSE and keypad handling is enabled, a timer is set by getch() to handle bytes received that could be the beginning of a function key (for example, ESC). If the remainder of the sequence is not received before the time expires, the first byte is returned; otherwise, the value of the function key is returned. Subsequent calls to the getch() function will return the other bytes received for the incomplete key sequence.</p> <p>The timeout() and wtimeout() functions set the length of time getch() waits for input for windows stdscr and <i>win</i>, respectively. These functions are similar to nodelay(3XCURSES) except the time to block or wait for input can be specified.</p> <p>A negative <i>delay</i> causes the program to wait indefinitely for input; a <i>delay</i> of 0 returns ERR if no input is ready; and a positive <i>delay</i> blocks until input arrives or the time specified expires, (in which case, ERR is returned).</p> |
| <b>RETURN VALUES</b> | <p>On success, the notimeout() function returns OK. Otherwise, it returns ERR.</p> <p>The timeout() and wtimeout() functions do not return a value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ERRORS</b>        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>DESCRIPTION</b>   | <p>The touchwin() and touchline() routines throw away all optimization information about which parts of the window have been touched, by pretending that the entire window has been drawn on. This is sometimes necessary when using overlapping windows, since a change to one window affects the other window, but the records of which lines have been changed in the other window do not reflect the change. The routine touchline() only pretends that <i>count</i> lines have been changed, beginning with line <i>start</i>.</p> <p>The untouchwin() routine marks all lines in the window as unchanged since the last call to wrefresh().</p> <p>The wtouchln() routine makes <i>n</i> lines in the window, starting at line <i>y</i>, look as if they have (<i>changed</i>=1) or have not (<i>changed</i>=0) been changed since the last call to wrefresh().</p> <p>The is_linetouched() and is_wintouched() routines return TRUE if the specified line/window was modified since the last call to wrefresh(); otherwise they return FALSE. In addition, is_linetouched() returns ERR if line is not valid for the given window.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | All routines return the integer ERR upon failure and an integer value other than ERR upon successful completion, unless otherwise noted in the preceding routine descriptions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |          |        |

| <b>DESCRIPTION</b> | <p>The <code>touchwin()</code> function marks the entire window as dirty. This makes it appear to X/Open Curses as if the whole window has been changed, thus causing the entire window to be rewritten with the next call to <code>refresh(3XCURSES)</code>. This is sometimes necessary when using overlapping windows; the change to one window will not be reflected in the other and, hence will not be recorded.</p> <p>The <code>touchline()</code> function marks as dirty a portion of the window starting at line <i>start</i> and continuing for <i>count</i> lines instead of the entire window. Consequently, that portion of the window is updated with the next call to <code>refresh()</code>.</p> <p>The <code>untouchwin()</code> function marks all lines in the window as unchanged since the last refresh, ensuring that it is not updated.</p> |                                                                                                 |

`wtouchln(3XCURSES)`

The `wtouchln()` function marks *n* lines starting at line *y* as either changed (*changed*=1) or unchanged (*changed*=0) since the last refresh.

To find out which lines or windows have been changed since the last refresh, use the `is_linetouched()` and `is_wintouched()` functions, respectively. These return TRUE if the specified line or window have been changed since the last call to `refresh()` or FALSE if no changes have been made.

**RETURN VALUES** On success, these functions return OK. Otherwise, they return ERR.

**ERRORS** None.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | Unsafe          |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -I /usr/xpg4/include -L /usr/xpg4/lib \ -R /usr/xpg4/lib -lcurses [ library... ]  c89 [ flag... ] file... -lcurses [ library... ]  #include &lt;curses.h&gt;  wchar_t *wunctrl (cchar_t *wc);</pre>                                                                                                                                                    |                |                 |                     |          |          |        |
| <b>PARAMETERS</b>    | <i>wc</i> Is a pointer to the wide character.                                                                                                                                                                                                                                                                                                                                      |                |                 |                     |          |          |        |
| <b>DESCRIPTION</b>   | <p>The wunctrl() function converts the a wide character string that is a printable representation of the wide character <i>wc</i>.</p> <p>This function also performs the following processing on the input argument:</p> <ul style="list-style-type: none"> <li>■ Control characters are converted to the ^X notation</li> <li>■ Any rendition information is removed.</li> </ul> |                |                 |                     |          |          |        |
| <b>RETURN VALUES</b> | Upon successful completion, the wunctrl() function returns the generated string. Otherwise, it returns a null pointer.                                                                                                                                                                                                                                                             |                |                 |                     |          |          |        |
| <b>ERRORS</b>        | No errors are defined.                                                                                                                                                                                                                                                                                                                                                             |                |                 |                     |          |          |        |

| DESCRIPTION | <p>With the <code>border()</code>, <code>wborder()</code>, and <code>box()</code> routines, a border is drawn around the edges of the window. The arguments and attributes are:</p> <table><tr><td><i>ls</i></td><td>left side of the border</td></tr><tr><td><i>rs</i></td><td>right side of the border</td></tr><tr><td><i>ts</i></td><td>top side of the border</td></tr><tr><td><i>bs</i></td><td>bottom side of the border</td></tr><tr><td><i>tl</i></td><td>top left-hand corner</td></tr><tr><td><i>tr</i></td><td>top right-hand corner</td></tr><tr><td><i>bl</i></td><td>bottom left-hand corner</td></tr><tr><td><i>br</i></td><td>bottom right-hand corner</td></tr></table> <p>If any of these arguments is zero, then the following default values (defined in <code>&lt;curses.h&gt;</code>) are used respectively instead: <code>ACS_VLINE</code>, <code>ACS_VLINE</code>, <code>ACS_HLINE</code>, <code>ACS_HLINE</code>, <code>ACS_ULCORNER</code>, <code>ACS_URCORNER</code>, <code>ACS_BLCORNER</code>, <code>ACS_BRCORNER</code>.</p> <p><code>box(<i>win</i>, <i>verch</i>, <i>horch</i>)</code> is a shorthand for the following call:</p> <pre>wborder(<i>win</i>, <i>verch</i>, <i>verch</i>, <i>horch</i>, <i>horch</i>, 0, 0, 0, 0)</pre> <p><code>hline()</code> and <code>whline()</code> draw a horizontal (left to right) line using <i>ch</i> starting at the current cursor position in the window. The current cursor position is not changed. The line is at most <i>n</i> characters long, or as many as fit into the window.</p> | <i>ls</i> | left side of the border | <i>rs</i> | right side of the border | <i>ts</i> | top side of the border | <i>bs</i> | bottom side of the border | <i>tl</i> | top left-hand corner | <i>tr</i> | top right-hand corner | <i>bl</i> | bottom left-hand corner | <i>br</i> | bottom right-hand corner |
| <i>ls</i>   | left side of the border                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |           |                         |           |                          |           |                        |           |                           |           |                      |           |                       |           |                         |           |                          |

wvline(3CURSES)

vline() and wvline() draw a vertical (top to bottom) line using *ch* starting at the current cursor position in the window. The current cursor position is not changed. The line is at most *n* characters long, or as many as fit into the window.

**RETURN VALUES** All routines return the integer OK, or a non-negative integer if immedok() is set. See curs\_outopts(3CURSES).

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** curs\_outopts(3CURSES), curses(3CURSES), attributes(5)

**NOTES** The header <curses.h> automatically includes the headers <stdio.h> and <unctrl.h>.

Note that border() and box() may be macros.

| DESCRIPTION   | <p>The <code>hline()</code>, <code>vline()</code>, <code>whline()</code>, <code>wvline()</code> functions draw a horizontal or vertical line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>ch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>ch</code> is 0 (zero), the default horizontal or vertical character is used.</p> <p>The <code>mvhline()</code>, <code>mvvline()</code>, <code>mvwhline()</code>, <code>mvwvline()</code> functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code>.</p> <p>The functions with names ending with <code>hline()</code> draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with <code>vline()</code> draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |           |                                         |          |                                                  |          |                                                      |          |                                                         |            |                           |

| <b>DESCRIPTION</b>   | <p>The <code>hline_set()</code>, <code>vline_set()</code>, <code>whline_set()</code>, <code>wvline_set()</code> functions draw a line, in either the window <code>stdscr</code> or <code>win</code> starting at the current cursor position. The line is drawn using the character <code>wch</code> and is a maximum of <code>n</code> positions long, or as many as will fit into the window. If <code>wch</code> is a null pointer, the default horizontal or vertical character is used.</p> <p>The <code>mvhline_set()</code>, <code>mvvline_set()</code>, <code>mvwhline_set()</code>, <code>mvwvline_set()</code> functions are similar to the previous group of functions but the line begins at cursor position specified by <code>x</code> and <code>y</code>.</p> <p>The functions with names ending with <code>hline_set()</code> draw horizontal lines proceeding towards the last column of the same line. The functions with names ending with <code>vline_set()</code> draw vertical lines proceeding towards the last column of the same line.</p> <p>These functions do not change the position of the cursor.</p> |
| <b>PARAMETERS</b>    | <p><i>wch</i> Is the complex character used to draw the line.</p> <p><i>n</i> Is the maximum number of characters in the line.</p> <p><i>y</i> Is the y (row) coordinate for the start of the line.</p> <p><i>x</i> Is the x (column) coordinate for the start of the line.</p> <p><i>win</i> Is a pointer to a window.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>RETURN VALUES</b> | On success, these functions return OK. Otherwise, they return ERR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## A

activate audio-visual alarm

— beep, 100

— flash, 100

add a string of `wchar_t` characters to a curses window and advance cursor —

`curs_addwstr`, 199

add a `wchar_t` character (with attributes) to a curses window and advance cursor —

`curs_addwch`, 194

add string of `wchar_t` characters (and attributes) to a curses window — `curs_addwchstr`, 197

add a string of `wchar_t` characters to a curses window and advance cursor —

`curs_addwstr`

`addnwstr`, 199

add a `wchar_t` character (with attributes) to a curses window and advance cursor —

`curs_addwch`

`addwch`, 194

add string of `wchar_t` characters (and attributes) to a curses window — `curs_addwchstr`

`addwchnstr`, 197

`addwchstr`, 197

add a string of `wchar_t` characters to a curses window and advance cursor —

`curs_addwstr`

`addwstr`, 199

add a `wchar_t` character (with attributes) to a curses window and advance cursor —

`curs_addwch`

`echowchar`, 194

add a string of `wchar_t` characters to a curses window and advance cursor —

`curs_addwstr`

`mvaddnwstr`, 199

add a `wchar_t` character (with attributes) to a curses window and advance cursor —

`curs_addwch`

`mvaddwch`, 194

add string of `wchar_t` characters (and attributes) to a curses window — `curs_addwchstr`

`mvaddwchnstr`, 197

`mvaddwchstr`, 197

add a string of `wchar_t` characters to a curses window and advance cursor —

`curs_addwstr`

`mvaddwstr`, 199

`mvwaddnwstr`, 199

add a `wchar_t` character (with attributes) to a curses window and advance cursor —

`curs_addwch`

`mvwaddwch`, 194

add string of `wchar_t` characters (and attributes) to a curses window — `curs_addwchstr`

`mvwaddwchnstr`, 197

`mvwaddwchstr`, 197

add a string of `wchar_t` characters to a curses window and advance cursor —

`curs_addwstr`

`mvwaddwstr`, 199

`waddnwstr`, 199

add a `wchar_t` character (with attributes) to a curses window and advance cursor —

`curs_addwch`

add a `wchar_t` character (with attributes) to a curses window and advance cursor —  
`curs_addwch` (Continued)  
     `waddwch`, 194  
 add string of `wchar_t` characters (and attributes) to a curses window — `curs_addwchstr`  
     `waddwchnstr`, 197  
     `waddwchstr`, 197  
 add a string of `wchar_t` characters to a curses window and advance cursor —  
     `curs_addwstr`  
     `waddwstr`, 199  
 add a `wchar_t` character (with attributes) to a curses window and advance cursor —  
     `curs_addwch`  
     `wechowchar`, 194  
 add a character (with rendition) to a window  
     — `addch`, 39  
     — `mvaddch`, 39  
     — `mvwaddch`, 39  
     — `waddch`, 39  
 add a complex character (with rendition) to a window  
     — `add_wch`, 59  
     — `mvadd_wch`, 59  
     — `mvwadd_wch`, 59  
     — `wadd_wch`, 59  
 add a complex character and refresh window  
     — `echo_wchar`, 361  
     — `wecho_wchar`, 361  
 add a multi-byte character string (without rendition) to a window  
     — `addnstr`, 48  
     — `addstr`, 48  
     — `mvaddnstr`, 48  
     — `mvaddstr`, 48  
     — `mvwaddstr`, 48  
     — `mwwaddnstr`, 48  
     — `waddnstr`, 48  
     — `waddstr`, 48  
 add a single-byte border to a window  
     — `border`, 113  
     — `box`, 113  
     — `wborder`, 113  
 add a single-byte character and refresh window  
     — `echochar`, 357  
     — `wechochar`, 357  
 add a wide-character string to a window  
     — `addnwstr`, 51  
     — `addwstr`, 51  
     — `mvaddnwstr`, 51  
     — `mvaddwstr`, 51  
     — `mvwaddnwstr`, 51  
     — `mvwaddwstr`, 51  
     — `waddnwstr`, 51  
     — `waddwstr`, 51  
 add character and refresh window  
     — `pecho_wchar`, 1098  
     — `pechochar`, 1098  
`add_wch` — add a complex character (with rendition) to a window, 59  
`add_wchnstr` — copy a string of complex characters (with renditions) to a window, 63  
`add_wchstr` — copy a string of complex characters (with renditions) to a window, 63  
`addch` — add a character (with rendition) to a window, 39  
`addchnstr` — copy a character string (with renditions) to a window, 45  
`addchstr` — copy a character string (with renditions) to a window, 45  
`addnstr` — add a multi-byte character string (without rendition) to a window, 48  
`addnwstr` — add a string of `wchar_t` characters to a curses window and advance cursor, 199  
`addnwstr` — add a wide-character string to a window, 51  
`addstr` — add a multi-byte character string (without rendition) to a window, 48  
`addwch` — add a `wchar_t` character (with attributes) to a curses window and advance cursor, 194  
`addwchnstr` — add string of `wchar_t` characters (and attributes) to a curses window, 197  
`addwchstr` — add string of `wchar_t` characters (and attributes) to a curses window, 197  
`addwstr` — add a string of `wchar_t` characters to a curses window and advance cursor, 199  
`addwstr` — add a wide-character string to a window, 51  
`adjcurspos` — moving the cursor by character, 200

ALE curses library  
*See* curses library  
 apply padding information and output string  
   — `putp`, 1126  
   — `tputs`, 1126  
 arc — graphics interface, 1102  
 attr\_get — control window attributes, 76  
 attr\_off — control window attributes, 76  
 attr\_on — control window attributes, 76  
 attr\_set — control window attributes, 76  
 attroff — change foreground window attributes, 82  
 attroff — curses character and window attribute control routines, 201  
 attron — change foreground window attributes, 82  
 attron — curses character and window attribute control routines, 201  
 attrset — change foreground window attributes, 82  
 attrset — curses character and window attribute control routines, 201

## B

baudrate — return terminal baud rate, 98  
 beep — activate audio-visual alarm, 100  
 bkgd — set or get the background character (and rendition) of window, 102  
 bkgdset — set or get the background character (and rendition) of window, 102  
 bkgrnd — set or get the background character (and rendition) of window using a complex character, 107  
 bkgrndset — set or get the background character (and rendition) of window using a complex character, 107  
 border — add a single-byte border to a window, 113  
 border\_set — use complex characters (and renditions) to draw borders, 115  
 box — add a single-byte border to a window, 113  
 box — graphics interface, 1102  
 box\_set — use complex characters (and renditions) to draw borders, 115

## C

call refresh on changes to window — `immedok`, 529  
 can\_change\_color — manipulate color information, 132  
 cbreak — set input mode controls, 138  
 change foreground window attributes  
   — `attroff`, 82  
   — `attron`, 82  
   — `attrset`, 82  
   — `wattroff`, 82  
   — `wattron`, 82  
   — `wattrset`, 82  
 change the rendition of characters in a window  
   — `chgat`, 139  
   — `mvchgat`, 139  
   — `mvwchgat`, 139  
   — `wchgat`, 139  
 character based forms package, — forms, 435  
 character based menus package, — menus, 709  
 character based panels package, — panels, 1089  
 check for type-ahead characters — `typeahead`, 1460  
 chgat — change the rendition of characters in a window, 139  
 circle — graphics interface, 1102  
 clear — clear a window, 145  
 clear a window  
   — `clear`, 145  
   — `erase`, 145  
   — `wclear`, 145  
   — `werase`, 145  
 clear to the end of a line  
   — `clrtoeol`, 160  
   — `wclrtoeol`, 160  
 clear to the end of a window  
   — `clrbot`, 158  
   — `wclrbot`, 158  
 clearok — set terminal output controls, 149  
 closepl — graphics interface, 1102  
 closevt — graphics interface, 1102  
 clrbot — clear to the end of a window, 158  
 clrtoeol — clear to the end of a line, 160  
 color\_content — manipulate color information, 132  
 COLOR\_PAIR — manipulate color information, 132

COLOR\_PAIRS — manipulate color information, 132  
 color\_set — control window attributes, 76  
 COLORS — manipulate color information, 132  
 COLS — number of columns on terminal screen, 178  
 cont — graphics interface, 1102  
 control flush of input and output on interrupt  
   — noqiflush, 1049  
   — qiflush, 1049  
 control window attributes  
   — attr\_get, 76  
   — attr\_off, 76  
   — attr\_on, 76  
   — attr\_set, 76  
   — color\_set, 76  
   — wattr\_get, 76  
   — wattr\_off, 76  
   — wattr\_on, 76  
   — wattr\_set, 76  
   — wcolor\_set, 76  
 control window refresh  
   — is\_linetouched, 608  
   — is\_wintouched, 608  
   — touchline, 608  
   — touchwin, 608  
   — untouchwin, 608  
   — wtouchln, 608  
 convert formatted input from a window — mvscanw, 864  
 convert formatted input from a window — mvwscanw, 864  
 convert formatted input from a window — scanw, 864  
 convert formatted input from a window — wscanw, 864  
 convert formatted input from a window — vwscanw, 1511  
 copy overlapped windows — overlay, 1066  
 copy overlapped windows — overwrite, 1066  
 copy a character string (with renditions) to a window  
   — addchnstr, 45  
   — addchstr, 45  
   — mvaddchnstr, 45  
   — mvaddchstr, 45  
   — mvwaddchnstr, 45  
   — mvwaddchstr, 45  
 copy a character string (with renditions) to a window (Continued)  
   — waddchnstr, 45  
   — waddchstr, 45  
 copy a string of complex characters (with renditions) to a window  
   — add\_wchnstr, 63  
   — add\_wchstr, 63  
   — mvadd\_wchnstr, 63  
   — mvadd\_wchstr, 63  
   — mvwadd\_wchnstr, 63  
   — mvwadd\_wchstr, 63  
   — wadd\_wchnstr, 63  
   — wadd\_wchstr, 63  
 copywin — overlay or overwrite any portion of window, 183  
 create a new window or subwindow  
   — derwin, 339  
   — newwin, 339  
   — subwin, 339  
 create or refresh a pad or subpad  
   — newpad, 1013  
   — pnoutrefresh, 1013  
   — prefresh, 1013  
   — subpad, 1013  
 CRT handling and optimization package, — curses, 214  
 cur\_term — current terminal information, 306  
 current terminal information — cur\_term, 306  
 current window — curscr, 211  
 curs\_addwch — add a wchar\_t character (with attributes) to a curses window and advance cursor, 194  
 curs\_addwchstr — add string of wchar\_t characters (and attributes) to a curses window, 197  
 curs\_addwstr — add a string of wchar\_t characters to a curses window and advance cursor, 199  
 curs\_alecompat — moving the cursor by character, 200  
 curs\_attr — curses character and window attribute control routines, 201  
   Attributes, 201  
 curs\_getwch — get (or push back) wchar\_t characters from curses terminal keyboard, 246  
   Function Keys, 246

- `curs_getwstr` — get `wchar_t` character strings from curses terminal keyboard, 251
- `curs_inswch` — insert a `wchar_t` character before the character under the cursor in a curses window, 264
- `curs_inswstr` — insert `wchar_t` string before character under the cursor in a curses window, 265
- `curs_inwch` — get a `wchar_t` character and its attributes from a curses window, 267
- `curs_inwchstr` — get a string of `wchar_t` characters (and attributes) from a curses window, 268
- `curs_inwstr` — get a string of `wchar_t` characters from a curses window, 269
- `curs_pad` — create and display curses pads, 277

- `mvwinsstr`, 261
- `winsnstr`, 261
- `winsstr`, 261

curses window, scroll

- `curs_scroll`, 285
- `sclrl`, 285
- `scroll`, 285
- `wscroll`, 285

curses window background manipulation routines

- `bkgd`, 204
- `bkgdset`, 204
- `curs_bkgd`, 204
- `wbkgd`, 204
- `wbkgdset`, 204

curses window cursor

- `curs_move`, 272
- `move`, 272
- `wmove`, 272

curses windows, create

- `curs_window`, 303
- `delwin`, 303
- `derwin`, 303
- `dupwin`, 303
- `mvderwin`, 303
- `mvwin`, 303
- `newwin`, 303
- `subwin`, 303
- `syncok`, 303
- `wcursyncup`, 303
- `wsyncdown`, 303
- `wsyncup`, 303

curses windows, overlap and manipulate

- `copywin`, 276
- `curs_overlay`, 276
- `overlay`, 276
- `overwrite`, 276

curses windows, print formatted output

- `curs_printw`, 279
- `mvprintw`, 279

curses windows, print formatted output  
(Continued)

- mvwprintw, 279
- printw, 279
- vwprintw, 279
- wprintw, 279

curses windows and lines, refresh

- curs\_refresh, 280
- doupdate, 280
- redrawwin, 280
- refresh, 280
- wnoutrefresh, 280
- wredrawln, 280
- wrefresh, 280

## D

def\_prog\_mode — save/restore terminal  
modes, 311

def\_shell\_mode — save/restore terminal  
modes, 311

default window — stdscr, 1370

del\_curterm — interfaces to the terminfo  
database, 324

delay\_output — delays output, 317

delays output — delay\_output, 317

delch — remove a character, 319

delete a window — delwin, 335

deleteln — remove a line, 327

delwin — delete a window, 335

derwin — create a new window or  
subwindow, 339

determine insert/delete character/line  
capability

- has\_ic, 508
- has\_il, 508

disable use of certain terminal capabilities —  
filter, 399

discard type-ahead characters — flushinp, 404

doupdate — refresh windows and lines, 343

duplicate a window — dupwin, 348

dupwin — duplicate a window, 348

## E

echo — enable/disable terminal echo, 353

echo\_wchar — add a complex character and  
refresh window, 361

echochar — add a single-byte character and  
refresh window, 357

echowchar — add a wchar\_t character (with  
attributes) to a curses window and advance  
cursor, 194

emulate the termcap database

- tgetent, 1393
- tgetflag, 1393
- tgetnum, 1393
- tgetstr, 1393
- tgoto, 1393

enable/disable half-delay mode —  
halfdelay, 499

enable/disable hardware insert-character and  
delete-character features — idcok, 520

enable/disable keypad handling —  
keypad, 638

enable/disable meta keys — meta, 721

enable/disable newline control  
— nl, 1029  
— nonl, 1029

enable/disable terminal echo  
— echo, 353  
— noecho, 353

endwin — restore initial terminal  
environment, 364

erase — clear a window, 145

erase — graphics interface, 1102

erasechar — return current ERASE or KILL  
characters, 372

erasewchar — return current ERASE or KILL  
characters, 372

## F

filter — disable use of certain terminal  
capabilities, 399

flash — activate audio-visual alarm, 100

enable or disable flush on interrupt —  
intrflush, 591

flushinp — discard type-ahead characters, 404

form library

*See also* curses library

forms — character based forms package, 435

- forms, application-specific routines
  - field\_init, 423
  - field\_term, 423
  - form\_hook, 423
  - form\_init, 423
  - form\_term, 423
  - set\_field\_init, 423
  - set\_field\_term, 423
  - set\_form\_init, 423
  - set\_form\_term, 423
- forms, associate application data
  - field\_userptr, 421
  - form\_field\_userptr, 421
  - form\_userptr, 442
  - set\_field\_userptr, 421
  - set\_form\_userptr, 442
- forms, command processor, — form\_driver, 407
- forms, connect fields
  - field\_count, 410
  - form\_field, 410
  - form\_fields, 410
  - move\_field, 410
  - set\_form\_fields, 410
- forms, create and destroy
  - form\_new, 427
  - free\_form, 427
  - new\_form, 427
- forms, format general appearance
  - field\_just, 414
  - form\_field\_just, 414
  - set\_field\_just, 414
- forms, format general display attributes
  - field\_back, 411
  - field\_fore, 411
  - field\_pad, 411
  - form\_field\_attributes, 411
  - set\_field\_back, 411
  - set\_field\_fore, 411
  - set\_field\_pad, 411
- forms, set current page and field
  - current\_field, 432
  - field\_index, 432
  - form\_page, 432
  - set\_current\_field, 432
  - set\_form\_page, 432
- forms, write/erase from associated subwindows
  - form\_post, 434
- forms, write/erase from associated subwindows (Continued)
  - post\_form, 434
  - unpost\_form, 434
- forms field, off-screen data ahead or behind
  - data\_ahead, 406
  - data\_behind, 406
  - form\_data, 406
- forms field attributes, set and get
  - field\_buffer, 412
  - field\_status, 412
  - form\_field\_buffer, 412
  - set\_field\_buffer, 412
  - set\_field\_status, 412
  - set\_max\_field, 412
- forms field characteristics
  - dynamic\_field\_info, 413
  - field\_info, 413
  - form\_field\_info, 413
- forms field data type validation
  - field\_arg, 422
  - field\_type, 422
  - form\_field\_validation, 422
  - set\_field\_type, 422
- forms field option routines
  - field\_opts, 416
  - field\_opts\_off, 416
  - field\_opts\_on, 416
  - form\_field\_opts, 416
  - set\_field\_opts, 416
- forms fields, create and destroy
  - dup\_field, 415
  - form\_field\_new, 415
  - free\_field, 415
  - link\_field, 415
  - new\_field, 415
- forms fieldtype routines
  - form\_fieldtype, 419
  - free\_fieldtype, 419
  - link\_fieldtype, 419
  - new\_fieldtype, 419
  - set\_fieldtype\_arg, 419
  - set\_fieldtype\_choice, 419
- forms option routines
  - form\_opts, 429
  - form\_opts\_off, 429
  - form\_opts\_on, 429
  - set\_form\_opts, 429

- forms pagination
  - `form_new_page`, 428
  - `new_page`, 428
  - `set_new_page`, 428
- forms window and subwindow association routines
  - `form_sub`, 443
  - `form_win`, 443
  - `scale_form`, 443
  - `set_form_sub`, 443
  - `set_form_win`, 443
- forms window cursor, position
  - `form_cursor`, 405
  - `pos_form_cursor`, 405

## G

- generate printable representation of a character
  - `unctrl`, 1463
- generate printable representation of a wide character — `wunctrl`, 1751
- get a string of `wchar_t` characters (and attributes) from a curses window — `curs_inwchstr`, 268
- get a string of `wchar_t` characters from a curses window — `curs_inwstr`, 269
- get a `wchar_t` character and its attributes from a curses window — `curs_inwch`, 267
- get supported terminal video attributes — `termattrs`, 1387
- get supported terminal video attributes — `term_attrs`, 1387
- get `wchar_t` character strings from curses terminal keyboard — `curs_getwstr`, 251
- `getnwstr`, 251
- get `wchar_t` character strings from curses terminal keyboard — `curs_getwstr`, `getwstr`, 251
- get a string of `wchar_t` characters from a curses window — `curs_inwstr`
- `innwstr`, 269
- get a `wchar_t` character and its attributes from a curses window — `curs_inwch`
- `inwch`, 267
- get a string of `wchar_t` characters (and attributes) from a curses window — `curs_inwchstr`

- get a string of `wchar_t` characters (and attributes) from a curses window — `curs_inwchstr` (Continued)
- `inwchnstr`, 268
- `inwchstr`, 268
- get a string of `wchar_t` characters from a curses window — `curs_inwstr`
- `inwstr`, 269
- get `wchar_t` character strings from curses terminal keyboard — `curs_getwstr`
- `mvgetnwstr`, 251
- `mvgetwstr`, 251
- get a string of `wchar_t` characters from a curses window — `curs_inwstr`
- `mvinnwstr`, 269
- get a `wchar_t` character and its attributes from a curses window — `curs_inwch`
- `mvinnwch`, 267
- get a string of `wchar_t` characters (and attributes) from a curses window — `curs_inwchstr`
- `mvinnwchnstr`, 268
- `mvinnwchstr`, 268
- get a string of `wchar_t` characters from a curses window — `curs_inwstr`
- `mvinnwstr`, 269
- get `wchar_t` character strings from curses terminal keyboard — `curs_getwstr`
- `mvwgetnwstr`, 251
- `mvwgetwstr`, 251
- get a string of `wchar_t` characters from a curses window — `curs_inwstr`
- `mvwinnwstr`, 269
- get a `wchar_t` character and its attributes from a curses window — `curs_inwch`
- `mvwinwch`, 267
- get a string of `wchar_t` characters (and attributes) from a curses window — `curs_inwchstr`
- `mvwinwchnstr`, 268
- `mvwinwchstr`, 268
- get a string of `wchar_t` characters from a curses window — `curs_inwstr`
- `mvwinwstr`, 269
- get `wchar_t` character strings from curses terminal keyboard — `curs_getwstr`
- `wgetnwstr`, 251
- `wgetwstr`, 251

get a string of `wchar_t` characters from a curses window — `curs_inwstr`  
`winnwstr`, 269

get a `wchar_t` character and its attributes from a curses window — `curs_inwch`  
`winwch`, 267

get a string of `wchar_t` characters (and attributes) from a curses window — `curs_inwchstr`  
`winwchnstr`, 268  
`winwchstr`, 268

get a string of `wchar_t` characters from a curses window — `curs_inwstr`  
`winwstr`, 269

get (or push back) `wchar_t` characters from curses terminal keyboard  
— `curs_getwch`, 246  
— `getwch`, 246  
— `mvgetwch`, 246  
— `mvwgetwch`, 246  
— `ungetwch`, 246  
— `wgetwch`, 246

get a multibyte character string from terminal  
— `getnstr`, 469  
— `getstr`, 469  
— `mvgetnstr`, 469  
— `mvgetstr`, 469  
— `mvwgetnstr`, 469  
— `mvwgetstr`, 469  
— `wgetnstr`, 469  
— `wgetstr`, 469

get a single-byte character from terminal  
— `getch`, 462  
— `mvgetch`, 462  
— `mvwgetch`, 462  
— `wgetch`, 462

get a wide character from terminal  
— `get_wch`, 486  
— `mvget_wch`, 486  
— `mvwget_wch`, 486  
— `wget_wch`, 486

get a wide character string (with rendition) from a `cchar_t` — `getcchar`, 456

get a wide character string from terminal  
— `get_wstr`, 472  
— `getn_wstr`, 472  
— `mvget_wstr`, 472  
— `mvgetn_wstr`, 472

get a wide character string from terminal (Continued)  
— `mvwget_wstr`, 472  
— `mvwgetn_wstr`, 472  
— `wget_wstr`, 472  
— `wgetn_wstr`, 472

get cursor or window coordinates  
— `getbegyx`, 451  
— `getmaxyx`, 451  
— `getparyx`, 451  
— `getyx`, 451

`get_wch` — get a wide character from terminal, 486

`get_wstr` — get a wide character string from terminal, 472

`getbegyx` — get cursor or window coordinates, 451

`getbkgd` — set or get the background character (and rendition) of window, 102

`getbkgrnd` — set or get the background character (and rendition) of window using a complex character, 107

`getcchar` — get a wide character string (with rendition) from a `cchar_t`, 456

`getch` — get a single-byte character from terminal, 462

`getmaxyx` — get cursor or window coordinates, 451

`getn_wstr` — get a wide character string from terminal, 472

`getnstr` — get a multibyte character string from terminal, 469

`getnwstr` — get `wchar_t` character strings from curses terminal keyboard, 251

`getparyx` — get cursor or window coordinates, 451

`getstr` — get a multibyte character string from terminal, 469

`getwch` — get (or push back) `wchar_t` characters from curses terminal keyboard, 246

`getwin` — read a window from, and write a window to, a file, 490

`getwstr` — get `wchar_t` character strings from curses terminal keyboard, 251

`getyx` — get cursor or window coordinates, 451

graphics interface  
— `arc`, 1102  
— `box`, 1102

#### graphics interface (Continued)

- circle, 1102
- closepl, 1102
- closevt, 1102
- cont, 1102
- erase, 1102
- label, 1102
- line, 1102
- linemod, 1102
- move, 1102
- openpl, 1102
- openvt, 1102
- plot, 1102
- point, 1102
- space, 1102

#### H

- halfdelay — enable/disable half-delay mode, 499
- has\_colors — manipulate color information, 132
- has\_ic — determine insert/delete character/line capability, 508
- has\_il — determine insert/delete character/line capability, 508
- hline — use single-byte characters (and renditions) to draw lines, 513
- hline\_set — use complex characters (and renditions) to draw lines, 515

#### I

- idcok — enable/disable hardware insert-character and delete-character features, 520
- idlok — set terminal output controls, 149
- immedok — call refresh on changes to window, 529
- in\_wch — retrieve a complex character (with rendition), 593
- in\_wchnstr — retrieve complex character string (with rendition), 595
- in\_wchstr — retrieve complex character string (with rendition), 595

- inch — return a single-byte character (with rendition), 531
- inchnstr — retrieve a single-byte character string (with rendition), 533
- inchstr — retrieve a single-byte character string (with rendition), 533
- init\_color — manipulate color information, 132
- init\_pair — manipulate color information, 132
- initscr — screen initialization functions, 552
- innstr — retrieve a multibyte character string (without rendition), 555
- innwstr — get a string of wchar\_t characters from a curses window, 269
- innwstr — retrieve a wide character string (without rendition), 558
- ins\_nwstr — insert a wide character string, 572
- ins\_wch — insert a complex character, 582
- ins\_wstr — insert a wide character string, 572
- insch — insert a character, 561
- insdelln — insert/delete lines to/from the window, 563
- insert a wchar\_t character before the character under the cursor in a curses window — curs\_inswch, 264
- insert wchar\_t string before character under the cursor in a curses window — curs\_inswstr, 265
- insnwstr, 265
- insert a wchar\_t character before the character under the cursor in a curses window — curs\_inswch
- inswch, 264
- insert wchar\_t string before character under the cursor in a curses window — curs\_inswstr
- inswstr, 265
- mvinsnwstr, 265
- insert a wchar\_t character before the character under the cursor in a curses window — curs\_inswch
- mvinswch, 264
- insert wchar\_t string before character under the cursor in a curses window — curs\_inswstr
- mvinswstr, 265
- mvwinsnwstr, 265
- insert a wchar\_t character before the character under the cursor in a curses window — curs\_inswch
- mvwinswch, 264

insert `wchar_t` string before character under the cursor in a curses window — `curs_inswstr` `mvwinswstr`, 265  
     `winsnwstr`, 265  
 insert a `wchar_t` character before the character under the cursor in a curses window — `curs_inswch` `winswch`, 264  
 insert `wchar_t` string before character under the cursor in a curses window — `curs_inswstr` `winswstr`, 265  
 insert a character  
     — `insch`, 561  
     — `mvinsch`, 561  
     — `mvwinsch`, 561  
     — `winsch`, 561  
 insert a complex character  
     — `ins_wch`, 582  
     — `mvins_wch`, 582  
     — `mvwins_wch`, 582  
     — `wins_wch`, 582  
 insert a line in a window  
     — `insertln`, 565  
     — `winsertln`, 565  
 insert a multibyte character string  
     — `insnstr`, 568  
     — `insstr`, 568  
     — `mvinsnstr`, 568  
     — `mvinsstr`, 568  
     — `mvwinsnstr`, 568  
     — `mvwinsstr`, 568  
     — `winsnstr`, 568  
     — `winsstr`, 568  
 insert a wide character string  
     — `ins_nwstr`, 572  
     — `ins_wstr`, 572  
     — `mvins_nwstr`, 572  
     — `mvins_wstr`, 572  
     — `mvwins_nwstr`, 572  
     — `mvwins_wstr`, 572  
     — `wins_nwstr`, 572  
     — `wins_wstr`, 572  
 insert/delete lines to/from the window  
     — `insdelln`, 563  
     — `winsdelln`, 563  
 insertln — insert a line in a window, 565  
 insnstr — insert a multibyte character string, 568

insnwstr — insert `wchar_t` string before character under the cursor in a curses window, 265  
 insstr — insert a multibyte character string, 568  
 instr — retrieve a multibyte character string (without rendition), 555  
 inswch — insert a `wchar_t` character before the character under the cursor in a curses window, 264  
 inswstr — insert `wchar_t` string before character under the cursor in a curses window, 265  
 interfaces to the terminfo database — `del_curterm`, 324  
 interfaces to the terminfo database — `restartterm`, 324  
 interfaces to the terminfo database — `setupterm`, 324  
 interfaces to the terminfo database — `set_curterm`, 324  
 intrflush — enable or disable flush on interrupt, 591  
 introduction and overview of X/Open Curses — `curses`, 229  
 inwch — get a `wchar_t` character and its attributes from a curses window, 267  
 inwchnstr — get a string of `wchar_t` characters (and attributes) from a curses window, 268  
 inwchstr — get a string of `wchar_t` characters (and attributes) from a curses window, 268  
 inwstr — get a string of `wchar_t` characters from a curses window, 269  
 inwstr — retrieve a wide character string (without rendition), 558  
 is\_linetouched — control window refresh, 608  
 is\_wintouched — control window refresh, 608  
 isendwin — restore initial terminal environment, 364

## K

key\_name — return character string used as key name, 633  
 keyname — return character string used as key name, 633  
 keypad — enable/disable keypad handling, 638

killchar — return current ERASE or KILL characters, 372  
killwchar — return current ERASE or KILL characters, 372

## L

label — graphics interface, 1102  
leaveok — set terminal output controls, 149  
line — graphics interface, 1102  
linemod — graphics interface, 1102  
LINES — number of lines on terminal screen, 668  
longname — return full terminal type name, 674

## M

manipulate color information —  
    can\_change\_color, 132  
manipulate color information — COLORS, 132  
manipulate color information —  
    color\_content, 132  
manipulate color information —  
    COLOR\_PAIR, 132  
manipulate color information —  
    COLOR\_PAIRS, 132  
manipulate color information —  
    has\_colors, 132  
manipulate color information — init\_color, 132  
manipulate color information — init\_pair, 132  
manipulate color information —  
    pair\_content, 132  
manipulate color information —  
    PAIR\_NUMBER, 132  
manipulate color information —  
    start\_color, 132  
map area of parent window to subwindow —  
    mvderwin, 779  
menu library  
    *See also* curses library  
menus — character based menus package, 709  
menus, application-specific routines  
    — item\_init, 687  
    — item\_term, 687  
    — menu\_hook, 687

 menus pattern match buffer  
   — menu\_pattern, 707  
   — set\_menu\_pattern, 707  
 menus subsystem, command processor, —  
   menu\_driver, 680  
 menus window and subwindow association  
   routines  
     — menu\_sub, 717  
     — menu\_win, 717  
     — scale\_menu, 717  
     — set\_menu\_sub, 717  
     — set\_menu\_win, 717  
 meta — enable/disable meta keys, 721  
 move — graphics interface, 1102  
 move — move cursor in window, 726  
 move cursor in window  
   — move, 726  
   — wmove, 726  
 move the cursor — mvcur, 773  
 move window — mvwin, 944  
 movenextch — moving the cursor by  
   character, 200  
 moveprevch — moving the cursor by  
   character, 200  
 mvadd\_wch — add a complex character (with  
   rendition) to a window, 59  
 mvadd\_wchnstr — copy a string of complex  
   characters (with renditions) to a window, 63  
 mvadd\_wchstr — copy a string of complex  
   characters (with renditions) to a window, 63  
 mvaddch — add a character (with rendition) to  
   a window, 39  
 mvaddchnstr — copy a character string (with  
   renditions) to a window, 45  
 mvaddchstr — copy a character string (with  
   renditions) to a window, 45  
 mvaddnstr — add a multi-byte character string  
   (without rendition) to a window, 48  
 mvaddnwstr — add a string of wchar\_t  
   characters to a curses window and advance  
   cursor, 199  
 mvaddnwstr — add a wide-character string to a  
   window, 51  
 mvaddstr — add a multi-byte character string  
   (without rendition) to a window, 48  
 mvaddwch — add a wchar\_t character (with  
   attributes) to a curses window and advance  
   cursor, 194  
 mvaddwchnstr — add string of wchar\_t  
   characters (and attributes) to a curses  
   window, 197  
 mvaddwchstr — add string of wchar\_t  
   characters (and attributes) to a curses  
   window, 197  
 mvaddwstr — add a string of wchar\_t  
   characters to a curses window and advance  
   cursor, 199  
 mvaddwstr — add a wide-character string to a  
   window, 51  
 mvchgat — change the rendition of characters  
   in a window, 139  
 mvcur — move the cursor, 773  
 mvdelch — remove a character, 319

mvderwin — map area of parent window to subwindow, 779  
 mvget\_wch — get a wide character from terminal, 486  
 mvget\_wstr — get a wide character string from terminal, 472  
 mvgetch — get a single-byte character from terminal, 462  
 mvgetn\_wstr — get a wide character string from terminal, 472  
 mvgetnstr — get a multibyte character string from terminal, 469  
 mvgetnwstr — get wchar\_t character strings from curses terminal keyboard, 251  
 mvgetstr — get a multibyte character string from terminal, 469  
 mvgetwch — get (or push back) wchar\_t characters from curses terminal keyboard, 246  
 mvgetwstr — get wchar\_t character strings from curses terminal keyboard, 251  
 mvhline — use single-byte characters (and renditions) to draw lines, 513  
 mvhline\_set — use complex characters (and renditions) to draw lines, 515  
 mvin\_wch — retrieve a complex character (with rendition), 593  
 mvin\_wchnstr — retrieve complex character string (with rendition), 595  
 mvin\_wchstr — retrieve complex character string (with rendition), 595  
 mvinch — return a single-byte character (with rendition), 531  
 mvinchnstr — retrieve a single-byte character string (with rendition), 533  
 mvinchstr — retrieve a single-byte character string (with rendition), 533  
 mvinnstr — retrieve a multibyte character string (without rendition), 555  
 mvinnwstr — get a string of wchar\_t characters from a curses window, 269  
 mvinnwstr — retrieve a wide character string (without rendition), 558  
 mvins\_nwstr — insert a wide character string, 572  
 mvins\_wch — insert a complex character, 582  
 mvins\_wstr — insert a wide character string, 572  
 mvinsch — insert a character, 561  
 mvinsnstr — insert a multibyte character string, 568  
 mvinsnstr — insert wchar\_t string before character under the cursor in a curses window, 265  
 mvinsstr — insert a multibyte character string, 568  
 mvinstr — retrieve a multibyte character string (without rendition), 555  
 mvinswch — insert a wchar\_t character before the character under the cursor in a curses window, 264  
 mvinswstr — insert wchar\_t string before character under the cursor in a curses window, 265  
 mvinwch — get a wchar\_t character and its attributes from a curses window, 267  
 mvinwchnstr — get a string of wchar\_t characters (and attributes) from a curses window, 268  
 mvinwchstr — get a string of wchar\_t characters (and attributes) from a curses window, 268  
 mvinwstr — get a string of wchar\_t characters from a curses window, 269  
 mvnwstr — retrieve a wide character string (without rendition), 558  
 mvprintw — print formatted output window, 862  
 mvscanw — convert formatted input from a window, 864  
 mvvline — use single-byte characters (and renditions) to draw lines, 513  
 mvvline\_set — use complex characters (and renditions) to draw lines, 515  
 mvwadd\_wch — add a complex character (with rendition) to a window, 59  
 mvwadd\_wchnstr — copy a string of complex characters (with renditions) to a window, 63  
 mvwadd\_wchstr — copy a string of complex characters (with renditions) to a window, 63  
 mvwaddch — add a character (with rendition) to a window, 39  
 mvwaddchnstr — copy a character string (with renditions) to a window, 45  
 mvwaddchstr — copy a character string (with renditions) to a window, 45

mvwaddnwstr — add a string of wchar\_t characters to a curses window and advance cursor, 199  
 mvwaddnwstr — add a wide-character string to a window, 51  
 mvwaddstr — add a multi-byte character string (without rendition) to a window, 48  
 mvwaddwch — add a wchar\_t character (with attributes) to a curses window and advance cursor, 194  
 mvwaddwchnstr — add string of wchar\_t characters (and attributes) to a curses window, 197  
 mvwaddwchstr — add string of wchar\_t characters (and attributes) to a curses window, 197  
 mvwaddwstr — add a string of wchar\_t characters to a curses window and advance cursor, 199  
 mvwaddwstr — add a wide-character string to a window, 51  
 mvwchgat — change the rendition of characters in a window, 139  
 mvwdelch — remove a character, 319  
 mvwget\_wch — get a wide character from terminal, 486  
 mvwget\_wstr — get a wide character string from terminal, 472  
 mvwgetch — get a single-byte character from terminal, 462  
 mvwgetn\_wstr — get a wide character string from terminal, 472  
 mvwgetnstr — get a multibyte character string from terminal, 469  
 mvwgetnwstr — get wchar\_t character strings from curses terminal keyboard, 251  
 mvwgetstr — get a multibyte character string from terminal, 469  
 mvwgetwch — get (or push back) wchar\_t characters from curses terminal keyboard, 246  
 mvwgetwstr — get wchar\_t character strings from curses terminal keyboard, 251  
 mvwhline — use single-byte characters (and renditions) to draw lines, 513  
 mvwhline\_set — use complex characters (and renditions) to draw lines, 515  
 mvwin — move window, 944  
 mvwin\_wch — retrieve a complex character (with rendition), 593  
 mvwin\_wchnstr — retrieve complex character string (with rendition), 595  
 mvwin\_wchstr — retrieve complex character string (with rendition), 595  
 mvwinch — return a single-byte character (with rendition), 531  
 mvwinchnstr — retrieve a single-byte character string (with rendition), 533  
 mvwinchstr — retrieve a single-byte character string (with rendition), 533  
 mvwinnstr — retrieve a multibyte character string (without rendition), 555  
 mvwinnwstr — get a string of wchar\_t characters from a curses window, 269  
 mvwinnwstr — retrieve a wide character string (without rendition), 558  
 mvwins\_nwstr — insert a wide character string, 572  
 mvwins\_wch — insert a complex character, 582  
 mvwins\_wstr — insert a wide character string, 572  
 mvwinsch — insert a character, 561  
 mvwinsnstr — insert a multibyte character string, 568  
 mvwinsnwstr — insert wchar\_t string before character under the cursor in a curses window, 265  
 mvwinsstr — insert a multibyte character string, 568  
 mvwinstr — retrieve a multibyte character string (without rendition), 555  
 mvwinswch — insert a wchar\_t character before the character under the cursor in a curses window, 264  
 mvwinswstr — insert wchar\_t string before character under the cursor in a curses window, 265  
 mvwinwch — get a wchar\_t character and its attributes from a curses window, 267  
 mvwinwchnstr — get a string of wchar\_t characters (and attributes) from a curses window, 268  
 mvwinwchstr — get a string of wchar\_t characters (and attributes) from a curses window, 268

mvwinwstr — get a string of `wchar_t` characters from a curses window, 269  
 mvwinwstr — retrieve a wide character string (without rendition), 558  
 mvwprintw — print formatted output window, 862  
 mvwscanw — convert formatted input from a window, 864  
 mvwvline — use single-byte characters (and renditions) to draw lines, 513  
 mvwvline\_set — use complex characters (and renditions) to draw lines, 515  
 mwwaddnstr — add a multi-byte character string (without rendition) to a window, 48

## N

napms — sleep process for a specified length of time, 1004  
 newpad — create and display curses pads, 277  
 newpad — create or refresh a pad or subpad, 1013  
 newterm — screen initialization functions, 552  
 newwin — create a new window or subwindow, 339  
 nl — enable/disable newline control, 1029  
 nocbreak — set input mode controls, 138  
 nodelay — set blocking or non-blocking read, 1037  
 noecho — enable/disable terminal echo, 353  
 nonl — enable/disable newline control, 1029  
 noqiflush — control flush of input and output on interrupt, 1049  
 noraw — set input mode controls, 138  
 notimeout — set timed blocking or non-blocking read, 1057  
 number of columns on terminal screen — COLS, 178  
 number of lines on terminal screen — LINES, 668

## O

openpl — graphics interface, 1102  
 openvt — graphics interface, 1102

output attributes to the terminal — vidattr, 1492  
 output attributes to the terminal — vidputs, 1492  
 output attributes to the terminal — vid\_attr, 1492  
 output attributes to the terminal — vid\_puts, 1492  
 overlay — copy overlapped windows, 1066  
 overlay or overwrite any portion of window — copywin, 183  
 overwrite — copy overlapped windows, 1066

## P

pair\_content — manipulate color information, 132  
 PAIR\_NUMBER — manipulate color information, 132  
 panel library  
   *See also* curses library  
 panels — character based panels package, 1089  
 panels, create and destroy  
   — del\_panel, 1088  
   — new\_panel, 1088  
   — panel\_new, 1088  
 panels deck manipulation routines  
   — bottom\_panel, 1092  
   — hide\_panel, 1091  
   — panel\_hidden, 1091  
   — panel\_show, 1091  
   — panel\_top, 1092  
   — show\_panel, 1091  
   — top\_panel, 1092  
 panels deck traversal primitives  
   — panel\_above, 1084  
   — panel\_below, 1084  
 panels panel, associate application data  
   — panel\_userptr, 1094  
   — set\_panel\_userptr, 1094  
 panels panel, get or set current window  
   — panel\_window, 1095  
   — replace\_panel, 1095  
 panels virtual screen refresh routine  
   — panel\_update, 1093  
   — update\_panel, 1093

panels window on virtual screen, move  
   — `move_panel`, 1087  
   — `panel_move`, 1087  
`pecho_wchar` — add character and refresh  
   window, 1098  
`pechochar` — add character and refresh  
   window, 1098  
`pechochar` — create and display curses  
   pads, 277  
`pechowchar` — create and display curses  
   pads, 277  
`plot` — graphics interface, 1102  
   Link Editor, 1103  
`pnoutrefresh` — create and display curses  
   pads, 277  
`pnoutrefresh` — create or refresh a pad or  
   subpad, 1013  
`point` — graphics interface, 1102  
`prefresh` — create and display curses pads, 277  
`prefresh` — create or refresh a pad or  
   subpad, 1013  
`print formatted output window` —  
   `mvprintw`, 862  
`print formatted output window` —  
   `mvwprintw`, 862  
`print formatted output window` — `printw`, 862  
`print formatted output window` —  
   `wprintw`, 862  
`print formatted output in window` —  
   `vwprintw`, 1508  
`print formatted output in window` —  
   `vw_printw`, 1507  
`print formatted output in window` —  
   `vw_scanw`, 1510  
`printw` — print formatted output window, 862  
`push character back onto the input queue`  
   — `unget_wch`, 1469  
   — `ungetch`, 1469  
`putp` — apply padding information and output  
   string, 1126  
`putwin` — read a window from, and write a  
   window to, a file, 490

## Q

`qiflush` — control flush of input and output on  
   interrupt, 1049

## R

`raw` — set input mode controls, 138  
`read a window from, and write a window to, a  
   file`  
   — `getwin`, 490  
   — `putwin`, 490  
`redraw screen or portion of screen`  
   — `redrawwin`, 1141  
   — `wredrawln`, 1141  
`redrawwin` — redraw screen or portion of  
   screen, 1141  
`refresh` — refresh windows and lines, 343  
`refresh windows and lines`  
   — `doupdate`, 343  
   — `refresh`, 343  
   — `wnoutrefresh`, 343  
   — `wrefresh`, 343  
`remove a character`  
   — `delch`, 319  
   — `mvdelch`, 319  
   — `mvwdelch`, 319  
   — `wdelch`, 319  
`remove a line`  
   — `deleteln`, 327  
   — `wdeleteln`, 327  
`reserve screen line for dedicated purpose` —  
   `ripoffline`, 1163  
`reset_prog_mode` — save/restore terminal  
   modes, 311  
`reset_shell_mode` — save/restore terminal  
   modes, 311  
`resetty` — restore/save terminal modes, 1154  
`restartterm` — interfaces to the terminfo  
   database, 324  
`restore initial terminal environment`  
   — `endwin`, 364  
   — `isendwin`, 364  
`restore/save terminal modes`  
   — `resetty`, 1154  
   — `savetty`, 1154  
`retrieve a complex character (with rendition)`  
   — `in_wch`, 593  
   — `mvin_wch`, 593  
   — `mvwin_wch`, 593  
   — `win_wch`, 593  
`retrieve a multibyte character string (without  
   rendition)`  
   — `innstr`, 555

retrieve a multibyte character string (without rendition) (Continued)

- instr, 555
- mvinnstr, 555
- mvinstr, 555
- mvwinstr, 555
- winnstr, 555
- winstr, 555

retrieve a single-byte character string (with rendition)

- inchnstr, 533
- inchstr, 533
- mvinchnstr, 533
- mvinchstr, 533
- mvwinchnstr, 533
- mvwinchstr, 533
- winchnstr, 533
- winchstr, 533

retrieve a wide character string (without rendition)

- innwstr, 558
- inwstr, 558
- mvinnwstr, 558
- mvinnwstr, 558
- mvwinwstr, 558
- winnwstr, 558
- winwstr, 558

retrieve complex character string (with rendition)

- in\_wchnstr, 595
- in\_wchstr, 595
- mvin\_wchnstr, 595
- mvin\_wchstr, 595
- mvwin\_wchnstr, 595
- mvwin\_wchstr, 595
- win\_wchnstr, 595
- win\_wchstr, 595

return a single-byte character (with rendition)

- inch, 531
- mvinch, 531
- mvwinch, 531
- winch, 531

return character string used as key name

- key\_name, 633
- keyname, 633

return current ERASE or KILL characters

- erasechar, 372
- erasewchar, 372
- killchar, 372
- killwchar, 372

return full terminal type name —

- longname, 674

return terminal baud rate — baudrate, 98

return the value of a terminfo capability

- tigetflag, 1415
- tigetnum, 1415
- tigetstr, 1415
- tparm, 1415

return the value of the environmental variable

- TERM — termname, 1390

ripcoll — reserve screen line for dedicated purpose, 1163

## S

save/restore terminal modes

- def\_prog\_mode, 311
- def\_shell\_mode, 311
- reset\_prog\_mode, 311
- reset\_shell\_mode, 311

savetty — restore/save terminal modes, 1154

scanw — convert formatted input from a window, 864

scr\_dump — write screen contents to/from a file, 1173

scr\_init — write screen contents to/from a file, 1173

scr\_restore — write screen contents to/from a file, 1173

scr\_set — write screen contents to/from a file, 1173

screen initialization functions

- initscr, 552
- newterm, 552

sclr — scroll a window, 1178

scroll — scroll a window, 1178

scroll a window

- sclr, 1178
- scroll, 1178
- wsclr, 1178

scrollok — set terminal output controls, 149

set or get the background character (and rendition) of window — `bkgd`, 102  
 set or get the background character (and rendition) of window — `bkgdset`, 102  
 set or get the background character (and rendition) of window — `getbkgd`, 102  
 set or get the background character (and rendition) of window — `wbkgd`, 102  
 set or get the background character (and rendition) of window — `wbkgdset`, 102  
 set a `cchar_t` type character from a wide character and rendition — `setcchar`, 1192  
 set blocking or non-blocking read — `nodelay`, 1037  
 set/clear window attributes  
   — `standend`, 1360  
   — `standout`, 1360  
   — `wstandend`, 1360  
   — `wstandout`, 1360  
 set `curterm` — interfaces to the terminfo database, 324  
 set input mode controls  
   — `cbreak`, 138  
   — `nocbreak`, 138  
   — `noraw`, 138  
   — `raw`, 138  
 set or get the background character (and rendition) of window using a complex character  
   — `bkgrnd`, 107  
   — `bkgrndset`, 107  
   — `getbkgrnd`, 107  
   — `wbkgrnd`, 107  
   — `wbkgrndset`, 107  
   — `wgetbkgrnd`, 107  
 set `term` — switch between terminals, 1275  
 set terminal output controls  
   — `clearok`, 149  
   — `idlok`, 149  
   — `leaveok`, 149  
   — `scrollok`, 149  
   — `setscrreg`, 149  
   — `wsetscrreg`, 149  
 set timed blocking or non-blocking read  
   — `notimeout`, 1057  
   — `timeout`, 1057  
   — `wtimeout`, 1057  
 set visibility of cursor — `curs_set`, 288  
 setcchar — set a `cchar_t` type character from a wide character and rendition, 1192  
 setscrreg — set terminal output controls, 149  
 setupterm — interfaces to the terminfo database, 324  
 sleep process for a specified length of time — `napms`, 1004  
 slk\_attr\_off — soft label functions, 1291  
 slk\_attr\_on — soft label functions, 1291  
 slk\_attr\_set — soft label functions, 1291  
 slk\_attroff — soft label functions, 1291  
 slk\_attron — soft label functions, 1291  
 slk\_attrset — soft label functions, 1291  
 slk\_clear — soft label functions, 1291  
 slk\_color — soft label functions, 1291  
 slk\_init — soft label functions, 1291  
 slk\_label — soft label functions, 1291  
 slk\_noutrefresh — soft label functions, 1291  
 slk\_refresh — soft label functions, 1291  
 slk\_restore — soft label functions, 1291  
 slk\_set — soft label functions, 1291  
 slk\_touch — soft label functions, 1291  
 slk\_wset — soft label functions, 1291  
 soft label functions — `slk_attroff`, 1291  
 soft label functions — `slk_attron`, 1291  
 soft label functions — `slk_attrset`, 1291  
 soft label functions — `slk_attr_off`, 1291  
 soft label functions — `slk_attr_on`, 1291  
 soft label functions — `slk_attr_set`, 1291  
 soft label functions — `slk_clear`, 1291  
 soft label functions — `slk_color`, 1291  
 soft label functions — `slk_init`, 1291  
 soft label functions — `slk_label`, 1291  
 soft label functions — `slk_noutrefresh`, 1291  
 soft label functions — `slk_refresh`, 1291  
 soft label functions — `slk_restore`, 1291  
 soft label functions — `slk_set`, 1291  
 soft label functions — `slk_touch`, 1291  
 soft label functions — `slk_wset`, 1291  
 space — graphics interface, 1102  
 specify source of screen size information — `use_env`, 1485  
 standend — curses character and window attribute control routines, 201  
 standout — set/clear window attributes, 1360  
 standout — curses character and window attribute control routines, 201  
 standout — set/clear window attributes, 1360

start\_color — manipulate color information, 132  
 stdscr — default window, 1370  
 subpad — create and display curses pads, 277  
 subpad — create or refresh a pad or subpad, 1013  
 subwin — create a new window or subwindow, 339  
 switch between terminals — set\_term, 1275  
 synchronize window with its parents or children  
   — syncok, 1383  
   — wcursyncup, 1383  
   — wsyncdown, 1383  
   — wsyncup, 1383  
 syncok — synchronize window with its parents or children, 1383

## T

term\_attrs — get supported terminal video attributes, 1387  
 termattrs — get supported terminal video attributes, 1387  
 termname — return the value of the environmental variable TERM, 1390  
 tgetent — emulate the termcap database, 1393  
 tgetflag — emulate the termcap database, 1393  
 tgetnum — emulate the termcap database, 1393  
 tgetstr — emulate the termcap database, 1393  
 tgoto — emulate the termcap database, 1393  
 tigetflag — return the value of a terminfo capability, 1415  
 tigetnum — return the value of a terminfo capability, 1415  
 tigetstr — return the value of a terminfo capability, 1415  
 timeout — set timed blocking or non-blocking read, 1057  
 touchline — control window refresh, 608  
 touchwin — control window refresh, 608  
 tparm — return the value of a terminfo capability, 1415  
 tputs — apply padding information and output string, 1126  
 typeahead — check for type-ahead characters, 1460

## U

unctrl — generate printable representation of a character, 1463  
 unget\_wch — push character back onto the input queue, 1469  
 ungetch — push character back onto the input queue, 1469  
 ungetwch — get (or push back) wchar\_t characters from curses terminal keyboard, 246  
 untouchwin — control window refresh, 608  
 use complex characters (and renditions) to draw borders  
   — border\_set, 115  
   — box\_set, 115  
   — wborder\_set, 115  
 use complex characters (and renditions) to draw lines  
   — hline\_set, 515  
   — mvhline\_set, 515  
   — mvvline\_set, 515  
   — mvwhline\_set, 515  
   — mvwvline\_set, 515  
   — vline\_set, 515  
   — whline\_set, 515  
   — wvline\_set, 515  
 use\_env — specify source of screen size information, 1485  
 use single-byte characters (and renditions) to draw lines  
   — hline, 513  
   — mvhline, 513  
   — mvvline, 513  
   — mvwhline, 513  
   — mvwvline, 513  
   — vline, 513  
   — whline, 513  
   — wvline, 513

## V

vid\_attr — output attributes to the terminal, 1492  
 vid\_puts — output attributes to the terminal, 1492  
 vidattr — output attributes to the terminal, 1492

vidputs — output attributes to the terminal, 1492  
 vline — use single-byte characters (and renditions) to draw lines, 513  
 vline\_set — use complex characters (and renditions) to draw lines, 515  
 vwprintw — print formatted output in window, 1508  
 vw\_printw — print formatted output in window, 1507  
 vw\_scanw — print formatted output in window, 1510  
 vwscanw — convert formatted input from a window, 1511

## W

wadd\_wch — add a complex character (with rendition) to a window, 59  
 wadd\_wchnstr — copy a string of complex characters (with renditions) to a window, 63  
 wadd\_wchstr — copy a string of complex characters (with renditions) to a window, 63  
 waddch — add a character (with rendition) to a window, 39  
 waddchnstr — copy a character string (with renditions) to a window, 45  
 waddchstr — copy a character string (with renditions) to a window, 45  
 waddnstr — add a multi-byte character string (without rendition) to a window, 48  
 waddnwstr — add a string of wchar\_t characters to a curses window and advance cursor, 199  
 waddnwstr — add a wide-character string to a window, 51  
 waddstr — add a multi-byte character string (without rendition) to a window, 48  
 waddwch — add a wchar\_t character (with attributes) to a curses window and advance cursor, 194  
 waddwchnstr — add string of wchar\_t characters (and attributes) to a curses window, 197  
 waddwchstr — add string of wchar\_t characters (and attributes) to a curses window, 197

waddwstr — add a string of wchar\_t characters to a curses window and advance cursor, 199  
 waddwstr — add a wide-character string to a window, 51  
 wadjcurspos — moving the cursor by character, 200  
 wattr\_get — control window attributes, 76  
 wattr\_off — control window attributes, 76  
 wattr\_on — control window attributes, 76  
 wattr\_set — control window attributes, 76  
 wattroff — change foreground window attributes, 82  
 wattroff — curses character and window attribute control routines, 201  
 wattron — change foreground window attributes, 82  
 wattron — curses character and window attribute control routines, 201  
 wattrset — change foreground window attributes, 82  
 wattrset — curses character and window attribute control routines, 201  
 wbkgd — set or get the background character (and rendition) of window, 102  
 wbkgdset — set or get the background character (and rendition) of window, 102  
 wbkgnd — set or get the background character (and rendition) of window using a complex character, 107  
 wbkgndset — set or get the background character (and rendition) of window using a complex character, 107  
 wborder — add a single-byte border to a window, 113  
 wborder\_set — use complex characters (and renditions) to draw borders, 115  
 wchgat — change the rendition of characters in a window, 139  
 wclear — clear a window, 145  
 wclrtoebot — clear to the end of a window, 158  
 wclrtoeol — clear to the end of a line, 160  
 wcolor\_set — control window attributes, 76  
 wcursyncup — synchronize window with its parents or children, 1383  
 wdelch — remove a character, 319  
 wdeleteln — remove a line, 327  
 wecho\_wchar — add a complex character and refresh window, 361

wechochar — add a single-byte character and refresh window, 357  
 wechowchar — add a `wchar_t` character (with attributes) to a curses window and advance cursor, 194  
 werase — clear a window, 145  
 wget\_wch — get a wide character from terminal, 486  
 wget\_wstr — get a wide character string from terminal, 472  
 wgetbkgrnd — set or get the background character (and rendition) of window using a complex character, 107  
 wgetch — get a single-byte character from terminal, 462  
 wgetn\_wstr — get a wide character string from terminal, 472  
 wgetnstr — get a multibyte character string from terminal, 469  
 wgetnwstr — get `wchar_t` character strings from curses terminal keyboard, 251  
 wgetstr — get a multibyte character string from terminal, 469  
 wgetwch — get (or push back) `wchar_t` characters from curses terminal keyboard, 246  
 wgetwstr — get `wchar_t` character strings from curses terminal keyboard, 251  
 whline — use single-byte characters (and renditions) to draw lines, 513  
 whline\_set — use complex characters (and renditions) to draw lines, 515  
 win\_wch — retrieve a complex character (with rendition), 593  
 win\_wchnstr — retrieve complex character string (with rendition), 595  
 win\_wchstr — retrieve complex character string (with rendition), 595  
 winch — return a single-byte character (with rendition), 531  
 winchnstr — retrieve a single-byte character string (with rendition), 533  
 winchstr — retrieve a single-byte character string (with rendition), 533  
 winnstr — retrieve a multibyte character string (without rendition), 555  
 winnwstr — get a string of `wchar_t` characters from a curses window, 269  
 winnwstr — retrieve a wide character string (without rendition), 558  
 wins\_nwstr — insert a wide character string, 572  
 wins\_wch — insert a complex character, 582  
 wins\_wstr — insert a wide character string, 572  
 winsch — insert a character, 561  
 winsdelln — insert/delete lines to/from the window, 563  
 winsertln — insert a line in a window, 565  
 winsnstr — insert a multibyte character string, 568  
 winsnwstr — insert `wchar_t` string before character under the cursor in a curses window, 265  
 winsstr — insert a multibyte character string, 568  
 winstr — retrieve a multibyte character string (without rendition), 555  
 winswch — insert a `wchar_t` character before the character under the cursor in a curses window, 264  
 winswstr — insert `wchar_t` string before character under the cursor in a curses window, 265  
 winwch — get a `wchar_t` character and its attributes from a curses window, 267  
 winwchnstr — get a string of `wchar_t` characters (and attributes) from a curses window, 268  
 winwchstr — get a string of `wchar_t` characters (and attributes) from a curses window, 268  
 winwstr — get a string of `wchar_t` characters from a curses window, 269  
 winwstr — retrieve a wide character string (without rendition), 558  
 wmove — move cursor in window, 726  
 wmovenextch — moving the cursor by character, 200  
 wmoveprevch — moving the cursor by character, 200  
 wnoutrefresh — refresh windows and lines, 343  
 wprintw — print formatted output window, 862  
 wredrawln — redraw screen or portion of screen, 1141  
 wrefresh — refresh windows and lines, 343

write screen contents to/from a file  
     — `scr_dump`, 1173  
     — `scr_init`, 1173  
     — `scr_restore`, 1173  
     — `scr_set`, 1173  
`wscanw` — convert formatted input from a  
     window, 864  
`wscrl` — scroll a window, 1178  
`wsetscrreg` — set terminal output controls, 149  
`wstandend` — curses character and window  
     attribute control routines, 201  
`wstandend` — set/clear window  
     attributes, 1360  
`wstandout` — curses character and window  
     attribute control routines, 201  
`wstandout` — set/clear window  
     attributes, 1360  
`wsyncdown` — synchronize window with its  
     parents or children, 1383  
`wsyncup` — synchronize window with its  
     parents or children, 1383  
`wtimeout` — set timed blocking or non-blocking  
     read, 1057  
`wtouchln` — control window refresh, 608  
`wunctrl` — generate printable representation of  
     a wide character, 1751  
`wvline` — use single-byte characters (and  
     renditions) to draw lines, 513  
`wvline_set` — use complex characters (and  
     renditions) to draw lines, 515
