Reconfigure the cluster tag, or disk group name, of a Remote Mirror set’s local volumes, in those cases where this is not indicated by the pathname. This does not affect the remote volumes. This parameter cannot be used on a system that is not clustered.
-R m {sync | async}
Reconfigure the replication mode of a Remote Mirror set. The sets belonging to a consistency group must be either all synchronous or all asynchronous. It is not possible to mix modes within a group.

-R g group
Reconfigure the consistency group of a Remote Mirror set. This command should be entered with the same group name on both primary and secondary servers.

To remove a set from a consistency group, specify the null string (""”) when reconfiguring the consistency group.

The following parameters can be issued only from the primary server:

- m
Starts a full volume copy from the primary volume to the secondary volume, and concurrently enables Remote Mirror replication of new updates from the primary volume to the secondary volume. Use this parameter when the primary and secondary volumes might be different and no logging information exists to incrementally resynchronize the volumes. See EXIT STATUS.

- r
Reverses the direction of the synchronization so the primary volume is synchronized from the secondary volume. Use this parameter with the -m or -u parameter. -m -r starts a full volume copy from the secondary (source) volume to the primary (target) volume but concurrently enables Remote Mirror replication of new updates from the primary (source) volume to the secondary (target) volume, ensuring the volume sets remain synchronized. Use -m -r when the primary and secondary volume content might differ and the secondary has the desired contents, yet no logging information exists to incrementally resynchronize the volumes (using -u). -u -r resynchronizes the primary (target) volume from the secondary (source) volume, using the Remote Mirror scoreboard logs maintained while replication was suspended. It then resumes Remote Mirror replication of new updates from the primary volume to the secondary volume so that the volume sets remain synchronized. Quiesce the workload to the volume sets during the restore/refresh operation. This action ensures that the primary and secondary volumes match before replication of new updates resumes.

- u
Updates a Remote Mirror volume set. This parameter resynchronizes a Remote Mirror volume set. Only the blocks logged as changed in the Remote Mirror scoreboards are updated. Enables Remote Mirror replication for the primary volume and also uses the Remote Mirror scoreboard logs to start the resynchronization process so that the corresponding secondary volume matches the primary volume.

The following are the states that can be returned from sndadm -P.
volume failed
An I/O operation to the local data volume has failed
bitmap failed
   An I/O operation to the local bitmap volume has failed

disk queue failed
   An I/O operation to disk queue volume has failed

need sync
   A sync to this volume has been interrupted. It needs to be completed (or restored via
   Point-in-Time Copy). The direction of the data flow must not be changed until one or the
   other is done.

need reverse sync
   A reverse sync to this volume has been interrupted. It needs to be completed (or restored
   via Point-in-Time Copy). The direction of the data flow must not be changed until one or
   the other is done.

logging
   Incoming writes are logged in the bitmap only. Data is not replicated to the remote site.
   need sync, need reverse sync, and queuing are all substates of logging such that writes
   are logged in the bitmap, but not replicated. Queuing mode (described below) logs the
   writes to the bitmap, and queues the request for later replication by the async flushers.

reverse syncing
   A secondary to primary copy is in progress.

csyncing
   A primary to secondary copy is in progress.

queuing
   During normal async replication using disk queues, i/o is placed on the disk queue to be
   replicated by the async flusher threads. In the event of a temporary link failure, the set
   transitions to queuing mode. The queue is not discarded, as it would be with memory based
   queues. Instead, data is logged in the bitmap and placed on the queue. When the link comes
   up, and sndradm -u is issued, (automated by turning autosync on for the set) the flushers
   restarts. This preserves write ordering through a temporary link outage. If write ordering is
   not necessary, and only the latest data is needed, the set can be put into logging manually
   (sndradm -l) and an update sync issued (sndradm -u). This action discards the data on the
   queue, and fast resyncs using the bitmap. If the queue fills before the link comes back and
   the update sync is issued, the queue is discarded and the set put into logging mode to avoid
   application hangs.

Examples

EXAMPLE 1   Enabling a Remote Mirror Set

   The following command enables a Remote Mirror asynchronous set on host example, where
   example is the primary host and example-remote is the secondary host.

   example% sndradm -e example /dev/rdsk/c1t0d0s1 /dev/rdsk/c1t1d0s3 \
   example-remote /dev/rdsk/c2t3d0s5 /dev/rdsk/c2t4d0s5 ip async
Example 2  Adding a Disk Queue to an Asynchronous Set
The following command adds a disk queue volume to an asynchronous set.

```
example% sndradm -q a /dev/rdsk/c1t2d0s3 \ 
example-remote:/dev/rdsk/c2t3d0s5
```

Example 3  Removing a Disk Queue from an Asynchronous Set
The following command removes the disk queue volume from a set with a disk queue volume attached to it.

```
example% sndradm -q d example-remote:/dev/rdsk/c2t3d0s5
```

Example 4  Disabling a Remote Mirror Set
The following command disables a Remote Mirror set enabled on host example.

```
example% sndradm -d example-remote:/dev/rdsk/c2t3d0s5
```

Exit Status

- **0** Command completed successfully.
- **>0** An error occurred.

When the -m or -u option is executed in a script, the exit status following one of these options always returns success, regardless of the current status of the Remote Mirror set.

Attributes

The `sndrd` daemon processes client Remote Mirror requests. Only the root user or a user with equivalent privileges can run this daemon. The daemon is automatically invoked in run level 2. `sndrd` restarts the TCP transport layers.

Administrators wanting to change startup parameters for `sndrd` should, as root or equivalent, make changes in the `/etc/default/sndr` file rather than editing the `/lib/svc/method/svc-rdcsyncd` file. See `sndr(4)`.

The `sndrd` daemon supports the following options:

- `-c max_connections`
  Sets the maximum number of connections allowed to the server over connection-oriented transports. By default, the number of connections is 16.

- `-l listen_backlog`
  Sets connection queue length for the RDC TCP over a connection-oriented transport. The default value is 10 entries.

**Exit Status**

`svcadm(1M), syslogd(1M), ds.log(4), attributes(5)`

**Notes**

Do not manually stop the `sndrd` daemon. If you need to manually stop `sndrd` perform these steps. This stops both the `sndrd` and `snmdsyncd` daemons.

```
# svcadm disable svc:/system/nws_rdc
# svcadm disable svc:/system/nws_rdcsyncd
```
Do not manually start or restart the sndrd daemon. If you need to manually start sndrd perform these steps. This starts both the sndrd and sndrsyncd daemons.

```
# svcadm enable svc:/system/nws_rdc
# svcadm enable svc:/system/nws_rdcsyncd
```

See `svcadm(1M)` for additional information.
The sndrsyncd daemon automates update resynchronization after a network or machine failure and invokes Point-in-Time Copy copies when needed to protect the data volumes being updated during a resynchronization.

The daemon is notified by the kernel when a network link being used by Remote Mirror goes down and invokes the `sndradm(1M)` command with the `-u` option to resynchronize all Remote Mirror sets which have autosync switched on and are using the network link. See `sndradm(1M)` for details on how to configure autosync for a Remote Mirror set.

The daemon is also notified when any Remote Mirror resynchronization starts or completes. The daemon takes Point-in-Time Copy snapshots, if configured in the Availability Suite configuration file. On a secondary server, the daemon checks if a file system is currently mounted on the secondary volume and informs the kernel not to allow the synchronization to start if the file system is currently mounted.

**Exit Status**

- **0** Daemon started successfully.
- **>0** Daemon failed to start.

**Files**

- `/lib/svc/method/svc-rdc` Shell script for starting sndrsyncd.
- `/lib/svc/method/svc-rdsyncd` Shell script for stopping sndrsyncd.

**Notes**

Do not manually stop the sndrsyncd daemon. If you need to manually stop sndrsyncd perform these steps. This stops both the sndrd and sndrsyncd daemons.

```
# svcadm disable svc:/system/nws_rdc
# svcadm disable svc:/system/nws_rdsyncd
```

Do not manually start or restart the sndrsyncd daemon. If you need to manually start sndrsyncd perform these steps. This starts both the sndrd and sndrsyncd daemons.

```
# svcadm enable svc:/system/nws_rdc
# svcadm enable svc:/system/nws_rdsyncd
```
See `svcadm(1M)` for additional information.
The Master Agent, `snmpdx`, is the main component of Solstice Enterprise Agent (SEA) technology. It runs as a daemon process and listens to User Datagram Protocol (UDP) port 161 for SNMP requests. The Master Agent also opens another port to receive SNMP trap notifications from various subagents. These traps are forwarded to various managers, as determined by the configuration file.

Upon invocation, `snmpdx` reads its various configuration files and takes appropriate actions by activating subagents, determining the subtree Object Identifier (OID) for various subagents, populating its own Management Information Bases (MIBs), and so forth. The Master Agent invokes subagents, registers subagents, sends requests to subagents, receives responses from subagents, and traps notifications from subagents.

The Master Agent is invoked by the service management facility `smf(5)` at boot time if `svc:/application/management/snmpdx` is enabled (see NOTES) and contents of the resource configuration file `/etc/snmp/conf/snmpdx.rsrc` are non-trivial.

**Note** – The SMA (Systems Management Agent) is the default SNMP agent in the Solaris operating system. `snmpdx` is Obsolete and may not be supported in a future release of Solaris.

**Options**

The following options are supported:

- `-a filename` Specify the full path of the access control file used by the Master Agent. The default access control file is `/etc/snmp/conf/snmpdx.acl`.

- `-c config-dir` Specify the full path of the directory containing the Master Agent configuration files. The default directory is `/etc/snmp/conf`.

- `-d debug-level` Debug. Levels from 0 to 4 are supported, giving various levels of debug information. The default is 0 which means no debug information is given.

- `-h` Help. Print the command line usage.

- `-i filename` Specify the full path of the enterprise-name OID map. This file contains the PID used by the Master Agent for recovery after a crash. It contains tuples of the UNIX process ID, port number, resource name, and agent name. The default file is `/var/snmp/snmpdx.st`.

- `-m GROUP | -m SPLIT` Specify the mode to use for forwarding of SNMP requests.

GROUP Multiple variables can be included in each request from the Master Agent to the subagents. This results in, at most, one send-request per agent.
SPLIT  Each variable in the incoming request results in one send-request to each subagent.

The default is GROUP.

- ofilename
  Specify the full path of the file containing the tuple (enterprise-name, OID). For example, (Sun Microsystems, 1.3.1.6.1.4.32). The Master Agent uses this file as a base for look-up in the trap-filtering and forwarding process. The default file is /etc/snmp/conf/enterprises.oid.

- pport
  Specify the port number. The default port number is 161.

- rfilename
  Specify the full path of the resource file to be used by the Master Agent. This file stores information about the subagents that the Master Agent invokes and manages. The default resource file is /etc/snmp/conf/snmpdx.rsrc.

- y
  Set a recovery indicator to invoke the recovery module. The recovery process discovers which subagents in the previous session are still active; those subagents not active are re-spawned by the Master Agent.

The `snmpdx` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/application/management/snmpdx
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
**Name**

snmp-notify – SNMP notification daemon for software events

**Synopsis**

/usr/lib/fm/notify/snmp-notify

**Description**

`snmp-notify` is a daemon that subscribes to software events and FMA diagnosis and repair events and generates SNMP trap notifications based on a set of notification preferences that are stored in the SMF service configuration repository.

SNMP notification preferences are set using `svccfg(1M)`.

`snmp-notify` is managed by the service management facility, `smf(5)`, under the service FMRI:

svc:/system/fm/snmp-notify:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

**Properties**

The following service properties can be set:

- `config/rootdir`
  - This is a string property that defaults to `/`. When set, the specified root directory will be used for all pathnames evaluated by `snmp-notify`.

**Examples**

**EXAMPLE 1** Configuring Notification Preferences

The following command configures notification preferences for SMF service state transition events.

```
# svccfg setnotify -g from-online,to-maintenance snmp:active
```

**EXAMPLE 2** Enabling SNMP Notifications

The following command enables notifications for Fault Management diagnosis events.

```
# svccfg setnotify problem-diagnosed snmp:active
```

**EXAMPLE 3** Listing Notification Settings

The following command lists all notification settings for Fault Management diagnosis events.

```
# svccfg listnotify fma-diagnosis
```

Refer to `svccfg(1M)` for more information on configuring SNMP notification preferences.

See Also  `svcs(1), svcadm(1M), svccfg(1M), syslogd(1M), attributes(5), smf(5)`
The `snmpXwbemd` daemon is a subagent in the Web-Based Enterprise Management (WBEM) services package.

This daemon maps the Simple Network Management Protocol (SNMP) requests forwarded by the Solstice Enterprise Agents (SEA) Master Agent `snmpdx(1M)` into one or more equivalent WBEM Common Information Model (CIM) properties and instances. Further, it remaps the response from the CIM Object Manager into a SNMP response, which it passes back to `snmpdx(1M)`,

A mapping file contains the corresponding Object Identifier (OID), class name, property name, and Abstract Syntax Notation 1 (ASN.1) type for each object. You can also create your own mapping file.

### Options

The following options are supported:

- `-d` Displays all debug information.
- `-h` Displays help by printing the correct command line usage.
- `-p` Specifies the port number to use.

### Operands

The following operand is supported:

- `port` Specifies the port number you want to use.

### Examples

**EXAMPLE 1**  An Example of a `050SUNwbcou.map` File

This mapping file that Sun Microsystems provides contains definitions of objects, in this format:

```plaintext
# #pragma ident "@(#)050SUNwbcou.map 1.0 01/04/03 SMI"
# # Copyright (c) 2001 by Sun Microsystems, Inc.
# All rights reserved.
# # *** Description of contents ***
# # First non-commented non-blank line contains required Version label.
# # Remaining non-commented non-blank lines are considered map entries
# # used as described below:
# # Column 1 - SNMP OID - Uniquely describes an SNMP variable
# Column 2 - CIM Class Name - CIM class associated with this variable
# Column 3 - CIM Property Name - CIM property that maps to SNMP OID variable
# Column 4 - ASN.1 type - SNMP datatype that dictates how data is mapped
to/from SNMP requests. Supported types are: SnmpString, SnmpOid,
```
EXAMPLE 1  An Example of a 050SUNWwbcou.map File  (Continued)

# SnmpTimeTicks, SnmpCounter, SnmpInt, SnmpGauge, SnmpIpAddress, SnmpOpaque
# Column 5 and greater are ignored
# Version 1.0

1.3.6.1.2.1.1.1.0 Solaris_ComputerSystem Description SnmpString
1.3.6.1.2.1.1.3.0 Solaris_OperatingSystem LastBootUpTime SnmpTimeTicks
1.3.6.1.2.1.1.4.0 Solaris_ComputerSystem PrimaryOwnerContact SnmpString
1.3.6.1.2.1.1.5.0 Solaris_ComputerSystem Name SnmpString

1.3.6.1.2.1.25.1.5.0 Solaris_OperatingSystem NumberOfUsers SnmpGauge
1.3.6.1.2.1.25.1.6.0 Solaris_OperatingSystem NumberOfProcesses SnmpGauge
1.3.6.1.2.1.25.1.7.0 Solaris_OperatingSystem MaxNumberOfProcesses SnmpGauge
1.3.6.1.2.1.25.1.2.0 Solaris_OperatingSystem LocalDateTime SnmpString

Each definition of an object in this file contains an OID, its corresponding CIM class name, its corresponding CIM property name, and its corresponding ASN.1 type. Each of these elements is separated by a space character.

Files  /var/sadm/wbem/snmp/map/050SUNWwbcou.map

The SNMP Adapter Subagent for WBEM MIB–2 mapping file that Sun Microsystems provides contains SNMP Management Information Base (MIB) definitions for the CIM instrumentation that SNMP manages.

Exit Status  The following exit values are returned:

0  Successful completion.
1  An error occurred.

**Name**  
snoop – capture and inspect network packets

**Synopsis**  
snoop [-aqrCDINPSvV] [-t [r | a | d]] [-c maxcount]  
[-d device] [-I IP_interface] [-i filename] [-n filename]  
[-o filename] [-p first [, last]] [-s snaplen]  
[-x offset [, length]] [expression]

**Description**  
From a datalink or IP interface, snoop captures packets and displays their contents. If the datalink or IP interface is not specified, snoop will pick a datalink to use, giving priority to datalinks that have been plumbed for IP traffic. snoop uses the `pfmod(7M)` and `bufmod(7M)` STREAMS modules to provide efficient capture of packets from the network. Captured packets can be displayed as they are received or saved to a file (which is RFC 1761-compliant) for later inspection.

snoop can display packets in a single-line summary form or in verbose multi-line forms. In summary form, with the exception of certain VLAN packets, only the data pertaining to the highest level protocol is displayed. If a packet has a VLAN header and its VLAN ID is non-zero, then snoop will show that the packet is VLAN tagged. For example, an NFS packet will have only NFS information displayed. Except for VLAN information under the condition just described, the underlying RPC, UDP, IP, and Ethernet frame information is suppressed, but can be displayed if either of the verbose options are chosen.

In the absence of a name service, such as LDAP or NIS, snoop displays host names as numeric IP addresses.

snoop requires an interactive interface.

**Note**  
The snoop command is Obsolete. It is recommended that you use Wireshark or its non-GUI version, Tshark instead. These programs are available in the following packages:

- `pkg://solaris/diagnostic/wireshark`
- `pkg://solaris/diagnostic/wireshark/tshark`

These packages are available in the Solaris package repository.

**Options**  
- **-C**  
  List the code generated from the filter expression for either the kernel packet filter, or snoop's own filter.

- **-D**  
  Display number of packets dropped during capture on the summary line.

- **-N**  
  Create an IP address-to-name file from a capture file. This must be set together with the `-i filename` option that names a capture file. The address-to-name file has the same name as the capture file with `.names` appended. This file records the IP address to hostname mapping at the capture site and increases the portability of the capture file. Generate a `.names` file if the capture file is to be analyzed elsewhere. Packets are not displayed when this flag is used.
-I **IP_interface**
  Capture IP packets from the network using the IP interface specified by **IP_interface**, for example, lo0. The `ipadm(1M)` command can be used to list available IP interfaces. The -I and -d options are mutually exclusive.

-P
  Capture packets in non-promiscuous mode. Only broadcast, multicast, or packets addressed to the host machine will be seen.

-S
  Display size of the entire link layer frame in bytes on the summary line.

-V
  Verbose summary mode. This is halfway between summary mode and verbose mode in degree of verbosity. Instead of displaying just the summary line for the highest level protocol in a packet, it displays a summary line for each protocol layer in the packet. For instance, for an NFS packet it will display a line each for the ETHER, IP, UDP, RPC and NFS layers. Verbose summary mode output may be easily piped through `grep` to extract packets of interest. For example, to view only RPC summary lines, enter the following: `example# snoop -i rpc.cap -V | grep RPC`

-a
  Listen to packets on `/dev/audio` (warning: can be noisy).

-c **maxcount**
  Quit after capturing **maxcount** packets. Otherwise keep capturing until there is no disk space left or until interrupted with Control-C.

-d **datalink**
  Capture link-layer packets from the network using the DLPI datalink specified by **datalink**, for example, bge0 or net0. The `dladm(1M) show-link` subcommand can be used to list available datalinks. The -d and -I options are mutually exclusive.

-I **filename**
  Display packets previously captured in **filename**. Without this option, `snoop` reads packets from the first network interface. If a **filename**.names file is present, it is automatically loaded into the `snoop` IP address-to-name mapping table (See -N flag).

-n **filename**
  Use **filename** as an IP address-to-name mapping table. This file must have the same format as the `/etc/hosts` file (IP address followed by the hostname).

-o **filename**
  Save captured packets in **filename** as they are captured. (This **filename** is referred to as the "capture file".) The format of the capture file is RFC 1761–compliant. During packet capture, a count of the number of packets saved in the file is displayed. If you wish just to count packets without saving to a file, name the file `/dev/null`.
-p first [ , last ]
Select one or more packets to be displayed from a capture file. The first packet in the file is packet number 1.

-q
When capturing network packets into a file, do not display the packet count. This can improve packet capturing performance.

-r
Do not resolve the IP address to the symbolic name. This prevents snoop from generating network traffic while capturing and displaying packets. However, if the -n option is used, and an address is found in the mapping file, its corresponding name will be used.

-s snaplen
Truncate each packet after snaplen bytes. Usually the whole packet is captured. This option is useful if only certain packet header information is required. The packet truncation is done within the kernel giving better utilization of the streams packet buffer. This means less chance of dropped packets due to buffer overflow during periods of high traffic. It also saves disk space when capturing large traces to a capture file. To capture only IP headers (no options) use a snaplen of 34. For UDP use 42, and for TCP use 54. You can capture RPC headers with a snaplen of 80 bytes. NFS headers can be captured in 120 bytes.

-t [ r | a | d ]
Time-stamp presentation. Time-stamps are accurate to within 4 microseconds. The default is for times to be presented in d (delta) format (the time since receiving the previous packet). Option a (absolute) gives wall-clock time. Option r (relative) gives time relative to the first packet displayed. This can be used with the -p option to display time relative to any selected packet.

-v
Verbose mode. Print packet headers in lots of detail. This display consumes many lines per packet and should be used only on selected packets.

-x offset [ , length]
Display packet data in hexadecimal and ASCII format. The offset and length values select a portion of the packet to be displayed. To display the whole packet, use an offset of 0. If a length value is not provided, the rest of the packet is displayed.

Operands
expression
Select packets either from the network or from a capture file. Only packets for which the expression is true will be selected. If no expression is provided it is assumed to be true.

Given a filter expression, snoop generates code for either the kernel packet filter or for its own internal filter. If capturing packets with the network interface, code for the kernel packet filter is generated. This filter is implemented as a streams module, upstream of the buffer module. The buffer module accumulates packets until it becomes full and passes the packets on to snoop. The kernel packet filter is very efficient, since it rejects unwanted packets in the kernel before they reach the packet buffer or snoop. The kernel packet filter
has some limitations in its implementation; it is possible to construct filter expressions that it cannot handle. In this event, snoop tries to split the filter and do as much filtering in the kernel as possible. The remaining filtering is done by the packet filter for snoop. The -c flag can be used to view generated code for either the packet filter for the kernel or the packet filter for snoop. If packets are read from a capture file using the -i filename option, only the packet filter for snoop is used.

A filter expression consists of a series of one or more boolean primitives that may be combined with boolean operators (AND, OR, and NOT). Normal precedence rules for boolean operators apply. Order of evaluation of these operators may be controlled with parentheses. Since parentheses and other filter expression characters are known to the shell, it is often necessary to enclose the filter expression in quotes. Refer to Example 2 for information about setting up more efficient filters.

The primitives are:

host hostname
True if the source or destination address is that of hostname. The hostname argument may be a literal address. The keyword host may be omitted if the name does not conflict with the name of another expression primitive. For example, pinky selects packets transmitted to or received from the host pinky, whereas pinky and dinky selects packets exchanged between hosts pinky AND dinky.

The type of address used depends on the primitive which precedes the host primitive. The possible qualifiers are inet, inet6, ether, or none. These three primitives are discussed below. Having none of the primitives present is equivalent to "inet host hostname or inet6 host hostname". In other words, snoop tries to filter on all IP addresses associated with hostname.

inet or inet6
A qualifier that modifies the host primitive that follows. If it is inet, then snoop tries to filter on all IPv4 addresses returned from a name lookup. If it is inet6, snoop tries to filter on all IPv6 addresses returned from a name lookup.

ipaddr, atalkaddr, or etheraddr
Literal addresses, IP dotted, AppleTalk dotted, and Ethernet colon are recognized. For example,

- "172.16.40.13" matches all packets with that IP
- "2:9255:a00:20ff:fe73:6e35" matches all packets with that IPv6 address as source or destination;
- "65281.13" matches all packets with that AppleTalk address;
- "8:0:20:f:b1:51" matches all packets with the Ethernet address as source or destination.
An Ethernet address beginning with a letter is interpreted as a hostname. To avoid this, prepend a zero when specifying the address. For example, if the Ethernet address is aa:0:45:23:52:44, then specify it by add a leading zero to make it 0aa:0:45:23:52:44.

from or src
A qualifier that modifies the following host, net, ipaddr, atalkaddr, etheraddr, port or rpc primitive to match just the source address, port, or RPC reply.

to or dst
A qualifier that modifies the following host, net, ipaddr, atalkaddr, etheraddr, port or rpc primitive to match just the destination address, port, or RPC call.

ether
A qualifier that modifies the following host primitive to resolve a name to an Ethernet address. Normally, IP address matching is performed. This option is not supported on media such as IPoIB (IP over InfiniBand).

ethertype number
True if the Ethernet type field has value number. If number is not 0x8100 (VLAN) and the packet is VLAN tagged, then the expression will match the encapsulated Ethernet type.

ip, ip6, arp, rarp, pppoe, pppoes
True if the packet is of the appropriate ethertype.

vlan
True if the packet has ethertype VLAN and the VLAN ID is not zero.

vlan-id id
True for packets of ethertype VLAN with the id id.

pppoe
True if the ethertype of the packet is either pppoe or pppoes.

broadcast
True if the packet is a broadcast packet. Equivalent to ether[2:4] = 0xffffffff for Ethernet. This option is not supported on media such as IPoIB (IP over InfiniBand).

multicast
True if the packet is a multicast packet. Equivalent to "ether[0] & 1 = 1" on Ethernet. This option is not supported on media such as IPoIB (IP over InfiniBand).

bootp, dhcp
True if the packet is an unfragmented IPv4 UDP packet with either a source port of BOOTPS (67) and a destination port of BOOTPC (68), or a source port of BOOTPC (68) and a destination of BOOTPS (67).

dhcp6
True if the packet is an unfragmented IPv6 UDP packet with either a source port of DHCPV6- SERVER (547) and a destination port of DHCPV6- CLIENT (546), or a source port of DHCPV6- CLIENT (546) and a destination of DHCPV6- SERVER (547).
apple
   True if the packet is an Apple Ethertalk packet. Equivalent to "ethertype 0x809b or ethertype 0x80f3".

decnet
   True if the packet is a DECNET packet.

greater length
   True if the packet is longer than length.

less length
   True if the packet is shorter than length.

udp, tcp, icmp, icmp6, ah, esp
   True if the IP or IPv6 protocol is of the appropriate type.

net net
   True if either the IP source or destination address has a network number of net. The from or to qualifier may be used to select packets for which the network number occurs only in the source or destination address.

port port
   True if either the source or destination port is port. The port may be either a port number or name from /etc/services. The tcp or udp primitives may be used to select TCP or UDP ports only. The from or to qualifier may be used to select packets for which the port occurs only as the source or destination.

rpc prog[, vers[, proc]]
   True if the packet is an RPC call or reply packet for the protocol identified by prog. The prog may be either the name of an RPC protocol from /etc/rpc or a program number. The vers and proc may be used to further qualify the program version and procedure number, for example, rpc nfs,2,0 selects all calls and replies for the NFS null procedure. The to or from qualifier may be used to select either call or reply packets only.

zone zoneid
   True if zoneid matches either the source or destination zoneid of a packet received on an ipnet device.

ldap
   True if the packet is an LDAP packet on port 389.

gateway host
   True if the packet used host as a gateway, that is, the Ethernet source or destination address was for host but not the IP address. Equivalent to "ether host host and not host host".

nofrag
   True if the packet is unfragmented or is the first in a series of IP fragments. Equivalent to ip[6:2] & 0x1fff = 0.
expr relop expr
True if the relation holds, where relop is one of >, >=, <, <=, !=, and expr is an arithmetic expression composed of numbers, packet field selectors, the length primitive, and arithmetic operators +, −, *, /, |, &, ^, and %. The arithmetic operators within expr are evaluated before the relational operator and normal precedence rules apply between the arithmetic operators, such as multiplication before addition. Parentheses may be used to control the order of evaluation. To use the value of a field in the packet use the following syntax:

base[expr [: size ] ]

where expr evaluates the value of an offset into the packet from a base offset which may be ether, ip, ip6, udp, tcp, or icmp. The size value specifies the size of the field. If not given, 1 is assumed. Other legal values are 2 and 4. For example,

ether[0] & 1 = 1
is equivalent to multicast
ether[2:4] = 0xffffffff
is equivalent to broadcast.
ip[ip[0] & 0xf * 4 : 2] = 2049
is equivalent to udp[0:2] = 2049
ip[0] & 0xf > 5
selects IP packets with options.
ip[6:2] & 0xffffffff = 0
eliminates IP fragments.
udp and ip[6:2] & 0x1fff = 0 and udp[6:2] != 0
finds all packets with UDP checksums.
The length primitive may be used to obtain the length of the packet. For instance “length > 60” is equivalent to “greater 60”, and “ether[length − 1]” obtains the value of the last byte in a packet.

and
Perform a logical AND operation between two boolean values. The AND operation is implied by the juxtaposition of two boolean expressions, for example “dinky pinky” is the same as “dinky AND pinky”.

or or
Perform a logical OR operation between two boolean values. A comma may be used instead, for example, “dinky, pinky” is the same as “dinky OR pinky”.

snoop(1M)
Perform a logical NOT operation on the following boolean value. This operator is evaluated before AND or OR.

**slp**

True if the packet is an SLP packet.

**sctp**

True if the packet is an SCTP packet.

**osf**

True if the packet is an OSPF packet.

---

**Examples**

**EXAMPLE 1** Using the snoop Command

Capture all packets and display them as they are received:

eexample# snoop

Capture packets with host funky as either the source or destination and display them as they are received:

eexample# snoop funky

Capture packets between funky and pinky and save them to a file. Then inspect the packets using times (in seconds) relative to the first captured packet:

eexample# snoop -o cap funky pinky

eexample# snoop -i cap -t r | more

To look at selected packets in another capture file:

eexample# snoop -i pkts -p 99,108

NFS: ----- SUN NFS -----  
NFS:
NFS: Proc = 11 (Rename)
EXAMPLE 1  Using the snoop Command  (Continued)

To view just the NFS packets between sunroof and boutique:

eexample# snoop -i pkts rpc nfs and sunroof and boutique
1 0.0000  boutique -> sunroof  NFS C GETATTR FH=8E6C
2 0.0046  sunroof -> boutique  NFS R GETATTR OK
3 0.0080  boutique -> sunroof  NFS C RENAME FH=8E6C MTra00192 to .nfs08

To save these packets to a new capture file:

eexample# snoop -i pkts -o pkts.nfs rpc nfs sunroof boutique

To view encapsulated packets, there will be an indicator of encapsulation:

eexample# snoop ip-in-ip
sunroof -> boutique ICMP Echo request  (1 encap)

If -V is used on an encapsulated packet:

eexample# snoop -V ip-in-ip
sunroof -> boutique ETHER Type=0800 (IP), size = 118 bytes
sunroof -> boutique IP D=172.16.40.222 S=172.16.40.200 LEN=104, ID=27497
sunroof -> boutique IP D=10.1.1.2 S=10.1.1.1 LEN=84, ID=27497
sunroof -> boutique ICMP Echo request

EXAMPLE 2  Setting Up A More Efficient Filter

To set up a more efficient filter, the following filters should be used toward the end of the expression, so that the first part of the expression can be set up in the kernel: greater, less, port, rpc, nofrag, and relop. The presence of OR makes it difficult to split the filtering when using these primitives that cannot be set in the kernel. Instead, use parentheses to enforce the primitives that should be OR’d.

To capture packets between funky and pinky of type tcp or udp on port 80:

eexample# snoop funky and pinky and port 80 and tcp or udp

Since the primitive port cannot be handled by the kernel filter, and there is also an OR in the expression, a more efficient way to filter is to move the OR to the end of the expression and to use parentheses to enforce the OR between tcp and udp:

eexample# snoop funky and pinky and (tcp or udp) and port 80
Exit Status  0  Successful completion.
           1  An error occurred.

Files  /dev/audio  Symbolic link to the system’s primary audio device.
       /dev/null   The null file.
       /etc/hosts  Host name database.
       /etc/rpc    RPC program number data base.
       /etc/services Internet services and aliases.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/network/network-clients</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Obsolete</td>
</tr>
</tbody>
</table>

See Also  dladm(1M), ipadm(1M), netstat(1M), hosts(4), rpc(4), services(4), attributes(5),
           audio(7I), ipnet(7D), bufmod(7M), dlpi(7P), pfmod(7M)

Warnings  The processing overhead is much higher for real-time packet interpretation. Consequently,
the packet drop count may be higher. For more reliable capture, output raw packets to a file
using the -o option and analyze the packets offline.

Unfiltered packet capture imposes a heavy processing load on the host computer, particularly
if the captured packets are interpreted real-time. This processing load further increases if
verbose options are used. Since heavy use of snoop may deny computing resources to other
processes, it should not be used on production servers. Heavy use of snoop should be
restricted to a dedicated computer.

snoop does not reassemble IP fragments. Interpretation of higher level protocol halts at the
end of the first IP fragment.

snoop may generate extra packets as a side-effect of its use. For example it may use a network
name service (NIS) to convert IP addresses to host names for display. Capturing into a file for
later display can be used to postpone the address-to-name mapping until after the capture
session is complete. Capturing into an NFS-mounted file may also generate extra packets.

Setting the snaplen (-s option) to small values may remove header information that is needed
to interpret higher level protocols. The exact cutoff value depends on the network and
protocols being used. For NFS Version 2 traffic using UDP on 10 Mb/s Ethernet, do not set snaplen less than 150 bytes. For NFS Version 3 traffic using TCP on 100 Mb/s Ethernet, snaplen should be 250 bytes or more.

snoop requires information from an RPC request to fully interpret an RPC reply. If an RPC reply in a capture file or packet range does not have a request preceding it, then only the RPC reply header will be displayed.
soconfig – configure transport providers for use by sockets

 Synopsis
 /usr/sbin/soconfig -d dir
 /usr/sbin/soconfig -f file
 /usr/sbin/soconfig -F name [-h hint] [-m modname]
    -t family:type:protocol[,...]
 /usr/sbin/soconfig family type protocol [module | path]
 /usr/sbin/soconfig -l [-np]

 Description
 The soconfig utility configures the transport provider driver for use with sockets. It specifies
 how the family, type, and protocol parameters in the socket(3SOCKET) call are mapped to
 the name of a transport provider such as /dev/tcp. This utility can be used to add an
 additional mapping or remove a previous mapping.

 The soconfig utility is also used to configure socket filters.

 The init(1M) utility uses soconfig with the sock2path.d(4) file during the booting
 sequence.

 Options
 The following options are supported:

 -d dir
   Set up the soconfig configuration for each driver according to the information stored in
   the files in dir.

 -f file
   Set up the soconfig configuration for each driver according to the information stored in
   file. A soconfig file consists of lines of at least the first three fields listed below, separated by
   spaces:

   family type protocol [module | path]

   These fields are described in the OPERANDS section below.

   An example of file can be found in the EXAMPLES section below.

 -F name [-h hint] [-m modname] -t family:type:protocol[,...]
   Update socket filter configuration. If only the name is specified, then the filter is
   unconfigured. Otherwise, the filter will be configured.

   The following are options associated with the -F option.

   -h hint
     Placement hint for the filter. If the placement cannot be satisfied, then the configuration
     request will fail. The hint can be one of the following:

     top
       The filter should be placed on top, closest to the socket.
The filter should be placed on the bottom, closest to the protocol.

The filter should be placed above the filter specified by name. The filter will lie closer to the socket than name.

The filter should be placed below the filter specified by name. The filter will lie closer to the socket than name.

Name of the filter module. The module must be located in the socketmod namespace. If unspecified, then the module name is expected to be the same as the filter name.

Socket tuple for the filter. The fields making up the tuple are described in the OPERANDS section. The configuration will fail if any of the socket tuples refer to a socket that uses a transport provider that does not support socket filters. STREAMS-based transport providers are not supported by socket filters.

Dump the in-kernel socket configuration table. This option has the following suboptions:

Do not convert socket family, type, and protocol to string representation.

Display machine-parseable output.

The following operands are supported:

The protocol family as listed in the /usr/include/sys/socket.h file, expressed as an integer. This file is contained in the system/header package, which might not be part of your Solaris distribution.

The socket type as listed in the /usr/include/sys/socket.h file, expressed as an integer. This file is contained in the system/header package, which might not be part of your Solaris distribution.

The protocol number as specified in the family-specific include file, expressed as an integer. For example, for AF_INET this number is specified in /usr/include/netinet/in.h. An unspecified protocol number is denoted with the value zero.
The module name or path name of a device that corresponds to the transport provider, such as tcp or /dev/tcp. Modules must reside in kernel/socketmod. A device name must begin with /dev. If this parameter is specified, the configuration will be added for the specified family, type, and protocol. If this parameter is not specified, the configuration will be removed.

**Examples**

**EXAMPLE 1** Setting Up a Module

The following example sets up a module for family AF_INET and type SOCK_STREAM:

```
example# soconfig 2 0 tcp
```

The following example sets up /dev/tcp for family AF_INET and type SOCK_STREAM:

```
example# soconfig 2 0 /dev/tcp
```

The following is a sample file used with the -f option. Comment lines begin with a hash mark (#):

```
# Family Type Protocol Module | Path
2 2 0 tcp
2 2 6 tcp
1 1 0 udp
2 1 17 udp
1 2 0 /dev/ticotsord
1 1 0 /dev/ticlts
2 4 0 icmp
```

**EXAMPLE 2** Configuring a Socket Filter

The following command configures a socket filter, foo, which has the loadable module named foomod. The filter will automatically be attached to all AF_INET TCP sockets.

```
example# soconfig -F foo -m foomod -t 2:2:0,2:2:6
```

The following command unconfigures the filter foo.

```
example# soconfig -F foo
```

**Files**

`/etc/sock2path.d`

Directory containing files with mappings from sockets to transport providers.

*Network Interface Guide*
soladdapp(1M)

Name soladdapp – add an application to the Solstice application registry

Synopsis /usr/snadm/bin/soladdapp [-r registry] -n name -i icon -e executable [args]

Description soladdapp adds an application to the Solstice application registry. After it is added, the application is displayed in the Solstice Launcher main window (see solstice(1M)).

Options -r registry Define the full path name of the Solstice registry file.
-n name Define the name of the tool to be registered.
-i icon Define the full path name of the tool icon.
-e executable Define the full path name of the tool.
args Specify any arguments to use with the tool.

When executed without options, soladdapp uses /opt/SUNWadm/etc/.solstice_registry (the default registry path).

Return Values 0 on success
1 on failure
2 if the registry is locked
3 if the entry is a duplicate.

Examples EXAMPLE 1 A sample display of the soladdapp command.
The following adds an application called Disk Manager to the Solstice application registry for display in the Solstice Launcher main window.

```
# soladdapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"
-i /opt/SUNWdsk/etc/diskmgr.xpm -e /opt/SUNWdsk/bin/diskmgr
```

Files /opt/SUNWadm/etc/.solstice_registry The default registry path.

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWsadml</td>
</tr>
</tbody>
</table>

See Also soldelapp(1M), solstice(1M), attributes(5)

Notes Globally registered applications are used by local and remote users sharing the software in a particular /opt directory. They can be added only using soladdapp.
soldelapp – remove an application from the Solstice application registry

**Synopsis**  
`/usr/snadm/bin/soldelapp [-r registry] -n name`

**Description**  
soldelapp removes an application from the Solstice application registry. After removal, the application is no longer displayed in the Solstice Launcher main window (see **solstice(1M)**).

**Options**  
- `-r registry` Define the full path name of the Solstice registry file.
- `-n name` Define the name of the tool to be removed.

When executed without options, soldelapp uses `/opt/SUNWadm/etc/.solstice_registry` (the default registry path).

**Return Values**  
- 0  on success
- 1  on failure
- 2  if the registry is locked
- 3  if `name` is not found in the registry
- 4  if the named registry or default registry is not found

**Examples**  
**EXAMPLE 1** A sample display of the soldelapp command.
The following removes an application called Disk Manager from the Solstice application registry and the Solstice Launcher main window.

```
# soldelapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"
```

**Files**  
`/opt/SUNWadm/etc/.solstice_registry` The default registry file.

soladdapp(1M), solstice(1M), attributes(5)

**Notes**  
Globally registered applications are used by local and remote users sharing the software in a particular `/opt` directory. They can be removed only using soldelapp.
Name  solstice – access system administration tools with a graphical user interface

Synopsis  /bin/solstice

Description  solstice used on a system presents the Solstice Launcher, a graphical user interface that provides access to the Solstice AdminSuite product family of system administration tools. The tools that appear in the launcher depend on what Solstice products you installed on your system.

Help is available by using the Help button.

Usage  The Solstice Launcher allows you to do the following tasks:

- **Launch applications**
  Use the Solstice Launcher to launch system administration tools.

- **Register applications**
  Use the Solstice Launcher to add and register applications locally with the launcher.

- **Remove applications**
  Use the Solstice Launcher to remove locally registered applications.

- **Customize application properties**
  Use the Solstice Launcher to show, hide, or remove applications in the launcher, reorder the icons, change the launcher window width, modify applications properties, and add applications.

Files  /$HOME/.solstice_registry  Local registry information.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWssadm1</td>
</tr>
</tbody>
</table>

See Also  soladdapp(1M), soldelapp(1M), attributes(5)

Notes  The Solstice Launcher adds or removes local applications that are private to the user (not local to the system) only. The properties of globally registered applications that are used by local and remote users sharing the software from a particular /opt directory cannot be modified from the Solstice Launcher. To register global applications for use by local and remote users, use the soladdapp(1M) command. To remove globally registered applications, use the soldelapp(1M) command.
The `sppptun` utility is used to configure and query the Solaris PPP tunneling device driver, `/dev/sppptun`. Currently, only PPP over Ethernet (PPPoE) is supported, so the `plumb` and `unplumb` arguments are used to specify Ethernet interfaces that are to be used for PPPoE, and the `query` option lists the plumbed interfaces.

The use of `sppptun` to add interfaces is similar to the use of `ifconfig(1M)` to add interfaces to IP. The plumbing is done once for each interface, preferably at system start-up time, and is not normally manipulated on a running system. If multiple instances of PPP are run over a single interface, they share the plumbing to that interface. Plumbing for each session is not required (and not possible for PPPoE).

The proper way to plum interfaces for PPPoE is to list the interfaces, one per line, in the `/etc/ppp/pppoe.if` file. If alternate Ethertype (SAP) values are necessary, then include the PPPoE Session and Discovery Stage values as hexadecimal on the same line. The line format is:

```
interface [session [discovery]]
```

The defaults are the Ethertypes specified in RFC 2516, and most users should not need to set these values. See the examples for one possible use.

When specified with no additional arguments, the `plumb` argument lists the protocols that are supported by the utility. These are the strings that are used as the `protocol` argument below.

```
sppptun plumb
```

This plumbs a new interface into the driver. The `protocol` parameter is `ppoe` for the PPP-carrying "Session Stage" connection or `pppoed` for the PPPoE "Discovery Stage" connection. Both connections must be present for each Ethernet interface that is to be used for PPPoE. The `device` parameter is the path name of the Ethernet interface to use (use `ifconfig(1M)` to list available devices). If the path begins with `/dev/`, then this portion may be omitted.

The `-s sap` option can be specified to use an alternate Ethertype (SAP) for the selected protocol. The `sap` value must be given in
hexadecimal. Some access servers use Ethertypes for PPPoE different from those in RFC 2516. The defaults are 8864 for pppoe and 8863 for pppoe.

`sppptun unplumb interface`  This removes an existing interface from the driver and terminates any PPP sessions that were using the interface. The `interface` parameter is the name of the interface as reported when the interface was plumbed.

`sppptun query`  Displays the canonical names of all interfaces plumbed into the `/dev/sppptun` device driver.

### Examples

**EXAMPLE 1  Setting up to Use PPPoE on hme0**

Plumb the hme0 interface.

```
# sppptun plumb pppoe hme0
hme0:pppoed
# sppptun plumb pppoe hme0
hme0:pppine
```

Remove the hme0 interface.

```
# sppptun unplumb hme0:pppoed
# sppptun unplumb hme0:pppine
```

**EXAMPLE 2  Script to Remove All Plumbed Interfaces**

```
#!/bin/sh
for intf in `sppptun query`
do
    sppptun unplumb $intf
done
```

**EXAMPLE 3  Interoperating with 3COM HomeConnect Dual Link ADSL**

```
# dladm show-link
LINK CLASS MTU STATE OVER
nge0  phys 1500 up ..
# echo nge0 3c13 3c12 > /etc/ppp/pppoe.if
```

### Exit Status

The following exit values are returned:

- **0**: Successful completion.
- **1**: One or more errors occurred.
/etc/ppp/ppoe.if  list of Ethernet interfaces to be plumbed at boot time
/usr/sbin/sppptun  executable command
/dev/sppptun  Solaris PPP tunneling device driver

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999
spray - spray packets

/susr/sbin/spray [-c count] [-d delay] [-l length]
[-t nettype] host

spray sends a one-way stream of packets to host using RPC, and reports how many were received, as well as the transfer rate. The host argument can be either a name or an Internet address.

spray is not useful as a networking benchmark, as it uses unreliable connectionless transports, UDP for example. spray can report a large number of packets dropped when the drops were caused by spray sending packets faster than they can be buffered locally, that is, before the packets get to the network medium.

Options
- c count Specify how many packets to send. The default value of count is the number of packets required to make the total stream size 100000 bytes.
- d delay Specify how many microseconds to pause between sending each packet. The default is 0.
- l length The length parameter is the numbers of bytes in the Ethernet packet that holds the RPC call message. Since the data is encoded using XDR, and XDR only deals with 32 bit quantities, not all values of length are possible, and spray rounds up to the nearest possible value. When length is greater than 1514, then the RPC call can no longer be encapsulated in one Ethernet packet, so the length field no longer has a simple correspondence to Ethernet packet size. The default value of length is 86 bytes, the size of the RPC and UDP headers.
- t nettype Specify class of transports. Defaults to netpath. See rpc(3NSL) for a description of supported classes.

srptadm(1M)

**Name**
srptadm – administer SRP targets

**Synopsis**
srptadm modify-target [-e, --enable] [-d, --disable]
[-r, --reset] hca_guid
srptadm list-target [hca_guid]
srptadm modify-defaults [-e, --enable] [-d, --disable]
srptadm list-defaults

**Description**
The `srptadm` command manages SCSI RDMA Protocol (SRP) target ports within the SCSI Target Mode Framework described in `stmfadm(1M)` and `libstmf(3LIB)`. This allows SRP initiators to access SCSI Target Mode Framework (STMF) logical units using the SRP protocol.

`srptadm` is implemented as a set of subcommands with options and operands for each subcommand. These subcommands are described in their own section, below.

**Sub-commands**

**list-defaults**
Lists information about the default properties. This subcommand has no options.

**list-target [hca_guid]**
If `hca_guid` is specified, lists the properties of the target HCA. Otherwise, properties are listed for all HCAs.

**modify-defaults [-e, --enable] [-d, --disable]**
Modify default parameters.
- `-e, --enable`
  Enable SRP target creation for all HCAs that have not been explicitly disabled with `modify-target`.
- `-d, --disable`
  Disable SRP target creation for all HCAs that have not been explicitly enabled with `modify-target`.

**modify-target [-e, --enable] [-d, --disable] [-r, --reset hca_guid]**
Sets SRP Target properties for the specified HCA.
- `-e, --enable`
  Enables SRP target creation on this HCA.
- `-d, --disable`
  Disables SRP target creation on this HCA.
- `-r, --reset`
  Clears HCA-specific information and resets to defaults. The SRP Target, if any, associated with this HCA will not be modified as a result of this option until the SRP Target SMF service is restarted.
Operands The list-target and modify-target subcommands have the following operand.

\texttt{hca\_guid}

GUID of the InfiniBand Host Channel Adapter (HCA) on this system for which SRP Target Services can be provided. The GUID must be in one of the following forms:

- \texttt{3BA000100CD18} Base hex form.
- \texttt{0003BA000100CD18} Base hex form with leading zeroes.
- \texttt{hca:3BA000100CD18} Form from \texttt{cfgadm(1M)}.
- \texttt{eui.0003BA000100CD18} EUI form.

Usage If the default state is changed when the SRP service is \texttt{online}, the state of existing targets is not changed until the service is restarted.

Changing the target state takes effect immediately if the SRP target service is \texttt{online}. Targets set to \texttt{disabled} will be offline and removed; targets set to \texttt{enabled} will be immediately created.

Examples

\textbf{EXAMPLE 1} Listing Default Properties

The following command lists the default SRP Target Service properties.

```
# srptadm list-defaults
```

\textbf{EXAMPLE 2} Changing Default Behavior

The following command changes the default behavior of the SRP Target service to not create SRP Targets when the service is enabled.

```
# srptadm modify-defaults -d
```

\textbf{EXAMPLE 3} Listing Properties for Specific HCA

The following command lists SRP Target properties for a specific HCA.

```
# cfgadm | grep hca
hca:3BA000100CD18 IB-HCA connected configured ok
hca:3BA000100D030 IB-HCA connected configured ok
```

```
# srptadm list-target hca:3BA000100CD18
Target HCA 3BA000100CD18:
  Enabled : true
  SRP Target Name : eui.0003BA000100CD18
  Operational Status : online
```
EXAMPLE 4  Disabling Services for Specific HCA

The following command disables SRP Target services for a specific HCA.

```bash
# srptadm modify-target -d 3BA000100CD18
```

Use the `list-target` command to see the changes:

```bash
# srptadm list-target hca:3BA000100CD18
Target HCA 3BA000100CD18:
   Enabled    : false
   SRP Target Name : eui.0003BA000100CD18
   Operational Status : -
```

EXAMPLE 5  Re-enabling Target Services

The following command sequence re-enables SRP Target services and displays the SRP and STMF target properties.

```bash
# srptadm modify-target -e 3BA000100CD18
# srptadm list-target hca:3BA000100CD18
Target HCA 3BA000100CD18:
   Enabled    : true
   SRP Target Name : eui.0003BA000100CD18
   Operational Status : online
```

```bash
# stmfadm list-target -v eui.0003BA000100CD18
Target: eui.0003BA000100CD18
   Operational Status: Online
   Provider Name : srpt
   Alias : -
   Protocol : SRP
   Sessions : 0
```

sshd (Secure Shell daemon) is the daemon program for ssh(1). Together these programs replace rlogin and rsh, and provide secure encrypted communications between two untrusted hosts over an insecure network. The programs are intended to be as easy to install and use as possible.

sshd is the daemon that listens for connections from clients. It forks a new daemon for each incoming connection. The forked daemons handle key exchange, encryption, authentication, command execution, and data exchange.

This implementation of sshd supports SSH protocol version 2 only.

SSH Protocol Version 1
This protocol version is no longer supported in the daemon program. It is supported only in the client. See ssh(1) manual page for more information.

SSH Protocol Version 2
Each host has a host-specific DSA/RSA key used to identify the host. Forward security is provided through a Diffie-Hellman key agreement. This key agreement results in a shared session key. The rest of the session is encrypted using a symmetric cipher, currently 128/192/256-bit AES CBC or CTR, 128/256-bit ARCFOUR, Blowfish, or 3DES. The client selects the encryption algorithm to use from those offered by the server. Additionally, session integrity is provided through a cryptographic message authentication code (hmac-sha1, hmac-sha2-256, hmac-sha2-256-96, hmac-sha2-512, hmac-sha2-512-96, or hmac-md5).

Protocol version 2 provides a public key based user authentication method (PubKeyAuthentication) GSS-API based user authentication, conventional password authentication, and a generic prompt/reply protocol for password-based authentication.

Command Execution and Data Forwarding
If the client successfully authenticates itself, a dialog for preparing the session is entered. At this time the client can request things like allocating a pseudo-tty, forwarding X11 connections, forwarding TCP/IP connections, or forwarding the authentication agent connection over the secure channel.

Finally, the client either requests a shell or execution of a command. The sides then enter session mode. In this mode, either side may send data at any time, and such data is forwarded to/from the shell or command on the server side, and the user terminal on the client side.

When the user program terminates and all forwarded X11 and other connections have been closed, the server sends command exit status to the client, and both sides exit.

sshd can be configured using command-line options or the configuration file /etc/ssh/ssh_config, described in ssh_config(4). Command-line options override values specified in the configuration file.
sshd rereads its configuration file when it receives a hangup signal, SIGHUP, by executing itself with the name it was started as, that is, /usr/lib/ssh/sshd.

Host Access Control

The sshd daemon uses TCP Wrappers to restrict access to hosts. It uses the service name of sshd for hosts_access(). For more information on TCP Wrappers see tcpd(1M) and hosts_access(3) man pages, which are part of the SUNWsfman package (they are not SunOS man pages). TCP wrappers binaries, including libwrap, are in security/tcp-wrapper, a required package for service/network/ssh, the package containing sshd.

Options

The options for sshd are as follows:

- **b bits**
  Specifies the number of bits in the server key (the default is 768).

- **d**
  Debug mode. The server sends verbose debug output to the system log, and does not put itself in the background. The server also will not fork and will only process one connection. This option is only intended for debugging for the server. Multiple -d options increase the debugging level. Maximum is 3.

- **e**
  When this option is specified, sshd will send the output to standard error instead of to the system log.

- **f configuration_file**
  Specifies the name of the configuration file. The default is /etc/ssh/sshd_config. sshd refuses to start if there is no configuration file.

- **g login_grace_time**
  Gives the grace time for clients to authenticate themselves (the default is 300 seconds). If the client fails to authenticate the user within this number of seconds, the server disconnects and exits. A value of zero indicates no limit.

- **h host_key_file**
  Specifies a file from which a host key is read. This option must be given if sshd is not run as root (as the normal host key files are normally not readable by anyone but root). The default is /etc/ssh/ssh_host_key for protocol version 1, and /etc/ssh/ssh_host_rsa_key and /etc/ssh/ssh_host_dsa_key for protocol version 2. It is possible to have multiple host key files for the different protocol versions and host key algorithms.

- **h PKCS#11 URI**
  Instead of working with a host key file, work with a certificate and a private key stored in the PKCS#11 token. See also Using X.509 Certificates section below.

- **i**
  Specifies that sshd is being run from inetd. sshd is normally not run from inetd because it needs to generate the server key before it can respond to the client, and this may take tens of
seconds. Clients would have to wait too long if the key was regenerated every time. However, with small key sizes (for example, 512) using sshd from inetd may be reasonable.

-o option
Can be used to specify options in the format used in the configuration file. This is useful for specifying options for which there are no separate command-line flags.

-p port
Specifies the port on which the server listens for connections (the default is 22).

-q
Quiet mode. Nothing is sent to the system log. Normally the beginning, authentication, and termination of each connection is logged.

-t
Test mode. Check only the validity of the configuration file and the sanity of the keys. This is useful for updating sshd reliably as configuration options might change.

-D
When this option is specified sshd does not detach and does not become a daemon. This allows easy monitoring of sshd.

-4
Forces sshd to use IPv4 addresses only.

-6
Forces sshd to use IPv6 addresses only.

The $HOME/.ssh/authorized_keys file lists the public keys that are permitted for public key authentication (PubkeyAuthentication) in protocol version 2. The AuthorizedKeysFile configuration option can be used to specify an alternative file.

Each line of the file contains one key (empty lines and lines starting with a hash mark [#] are ignored as comments).

For each RSA key for protocol version 1, the file consists of the following space-separated fields:

options bits exponent modulus comment

For the public key for protocol version 2, the file consists of the following space-separated fields:

options key-type base64-encoding-key comment

For protocol version 2, key-type is one of ssh-rsa or ssh-dsa.
The options field is optional; its presence is determined by whether the line starts with a number. (The options field never starts with a number.) The bits, exponent, and modulus fields give the RSA key; the comment field is a convenient place for you to identify the key.

Lines in this file are usually several hundred bytes long (because of the size of the key modulus). You will find it very inconvenient to type them in; instead, copy the public key file and edit it.

Permissions of this file must be set so that it is not world or group writable. See the StrictModes option of sshd_config(4).

The options (if present) consist of comma-separated option specifications. No spaces are permitted, except within double quotes. The following option specifications are supported:

- **from="pattern-list"**
  Specifies that, in addition to public key authentication, the canonical name of the remote host must be present in the comma-separated list of patterns ('*' and '?' serve as wildcards). The list can also contain negated patterns by prefixing the patterns with '!' If the canonical host name matches a negated pattern, the key is not accepted.

  The purpose of this option is to give you the option of increasing security: public key authentication by itself does not trust the network or name servers or anything but the key. However, if someone manages to steal the key, possession of the key would permit the intruder to log in from anywhere in the world. This option makes using a stolen key more difficult, because name servers and routers would have to be compromised, in addition to just the key.

- **command="command"**
  Specifies that the command is executed whenever this key is used for authentication. The command supplied by the user (if any) is ignored. The command is run on a pty if the client requests a pty; otherwise it is run without a pty. If an 8-bit clean channel is required, one must not request a pty or should specify no-pty. You can include a quote in the command by escaping it with a backslash. This option might be useful to restrict certain public keys from performing a specific operation. An example is a key that permits remote backups but nothing else. Note that the client can specify TCP/IP and/or X11 forwarding unless they are explicitly prohibited from doing so. Also note that this option applies to shell, command, or subsystem execution.

- **environment="NAME=value"**
  Specifies that the string NAME=value is to be added to the environment when logging in using this key. Environment variables set this way override other default environment values. Multiple options of this type are permitted. Environment processing is disabled by default and is controlled via the PermitUserEnvironment option.

- **no-port-forwarding**
  Forbids TCP/IP forwarding when this key is used for authentication. Any port forward requests by the client will return an error. This might be used, for example, in connection with the command option.
no-X11-forwarding
   Forbids X11 forwarding when this key is used for authentication. Any X11 forward
   requests by the client will return an error.

no-agent-forwarding
   Forbids authentication agent forwarding when this key is used for authentication.

no-pty
   Prevents tty allocation (a request to allocate a pty will fail).

permitopen="host:port"
   Limit local ssh -L port forwarding such that it can connect only to the specified host and
   port. IPv6 addresses can be specified with an alternative syntax: host/port. You can invoke
   multiple permitopen options, with each instance separated by a comma. No pattern
   matching is performed on the specified hostnames. They must be literal domains or
   addresses.

ssh_known_hosts File Format

The /etc/ssh/ssh_known_hosts and $HOME/.ssh/known_hosts files contain host public
keys for all known hosts. The global file should be prepared by the administrator (optional),
and the per-user file is maintained automatically: whenever the user connects from an
unknown host its key is added to the per-user file.

For the RSA key for protocol version 1, these files consist of the following space-separated
fields:

hostnames bits exponent modulus comment

For the public key for protocol version 2, these files consist of the following space-separated
fields:

hostnames key-type base64-encoding-key comment

For protocol version 2, key-type is one of ssh-rsa or ssh-dsa.

Hostnames is a comma-separated list of patterns (* and ? act as wildcards); each pattern in
turn is matched against the canonical host name (when authenticating a client) or against the
user-supplied name (when authenticating a server). A pattern can also be preceded by ! to
indicate negation: if the host name matches a negated pattern, it is not accepted (by that line)
even if it matched another pattern on the line.

Alternately, hostnames can be stored in a hashed form, which hides host names and addresses
should the file's contents be disclosed. Hashed hostnames start with a vertical bar (!) character. Only one hashed hostname can appear on a single line and none of the above
negation or wildcard operators may be applied.

Bits, exponent, and modulus are taken directly from the RSA host key; they can be obtained,
for example, from /etc/ssh/ssh_host_rsa_key.pub. The optional comment field continues
to the end of the line, and is not used.

Lines starting with a hash mark (#) and empty lines are ignored as comments.
When performing host authentication, authentication is accepted if any matching line has the proper key. It is thus permissible (but not recommended) to have several lines or different host keys for the same names. This will inevitably happen when short forms of host names from different domains are put in the file. It is possible that the files contain conflicting information; authentication is accepted if valid information can be found from either file.

The lines in these files are typically hundreds of characters long. You should definitely not type in the host keys by hand. Rather, generate them by a script or by taking `/etc/ssh/ssh_host_rsa_key.pub` and adding the host names at the front.

### Environment Variables

`sshd` sets the following environment variables for commands executed by ssh users:

- **DISPLAY**
  Indicates the location of the X11 server. It is automatically set by `sshd` to point to a value of the form `hostname:n`, where `hostname` indicates the host where the shell runs, and `n` is an integer greater than or equal to 1. `ssh` uses this special value to forward X11 connections over the secure channel. Unless you have important reasons to do otherwise, you should not set `DISPLAY` explicitly, as that will render the X11 connection insecure and will require you to manually copy any required authorization cookies.

- **HOME**
  Set to the path of the user’s home directory.

- **LANG**, **LC_ALL**, **LC_COLLATE**, **LC_CTYPE**, **LC_MESSAGES**, **LC_MONETARY**, **LC_NUMERIC**, **LC_TIME**
  A locale setting. The locale defaults to that of `sshd` (usually the system-wide default locale), or is negotiated between the client and server during initial key exchange (as per RFC 4253).

Following initial key exchange, each of the variables can be overridden in the following sequence:

1. If a locale setting is set in a client’s environment and that client supports “Environment Variable Passing” (see RFC 4254), then the setting will be passed over to the server side.
2. If the public key authentication method was used to authenticate the server and the `PermitUserEnvironment` variable in `sshd_config(4)` is set to yes on the server side, then the setting can be changed through the use of the `environment` option in the client’s `AuthorizedKeysFile` file.
3. The setting can be changed in the client’s `~/.ssh/environment` file on the server.

See `PermitUserEnvironment` in `sshd_config(4)` as to when the `AuthorizedKeysFile` and `~/.ssh/environment` files are processed and used for setting the user environment.

- **LOGNAME**
  Synonym for `USER`. Set for compatibility with systems that use this variable.

- **MAIL**
  Set to point to the user’s mailbox.
SSH_AUTH_SOCK
Indicates the path of a unix-domain socket used to communicate with the agent.

SSH_CONNECTION
Identifies the client and server ends of the connection. The variable contains four space-separated values: client IP address, client port number, server IP address and server port number.

SSH_CLIENT
Identifies the client end of the connection. The variable contains three space-separated values: client IP address, client port number, and server port number.

SSH_TTY
Set to the name of the tty (path to the device) associated with the current shell or command. If the current session has no tty, this variable is not set.

TZ
Indicates the present timezone, if TIMEZONE is set in /etc/default/login or if TZ was set when the daemon was started.

HZ
If set in /etc/default/login, the daemon sets it to the same value.

SHELL
The user's shell, if ALTSHELL=YES in /etc/default/login.

PATH
Set to the value of PATH or SUPATH (see login(1)) in /etc/default/login, or, if not set, to /usr/bin:/bin.

USER
Set to the name of the user logging in.

Additionally, sshd reads $HOME/.ssh/environment and adds lines of the format VARNAME=value to the environment.

**Examples**
In the following examples, certain lines might wrap due to line length limits in your display. You should nevertheless consider the wrapped line as a single line.

**EXAMPLE1**
**authorized_key File Entries**
The following are examples of authorized_key file entries for protocol 1:

```
1024 33 12121...312314325 ylo@foo.bar
from="*.niksula.hut.fi,!pc.niksula.hut.fi" 1024 35 23...2334 ylo@niksula
command="dump /home",no-pty,no-port-forwarding 1024 33 23...2323 backup.hut.fi
```
EXAMPLE 2 authorized_key File Entries for Protocol 2
The following are examples of authorized_key file entries for protocol 2:

```
ssh-rsa AAAAB3NzaC1y.....EU88ovYKg4GfclWGCYTw8= ylo@foo.bar
from="*.niksula.hut.fi" ssh-rsa AAAAB3NzaC....uw8= ylo@niksula
command="dump /home",no-pty,no-port-forwarding ssh-rsa AA...
```

EXAMPLE 3 ssh_known_hosts File Entries for Protocol 1
The following are examples of ssh_known_hosts file entries for protocol 1:

closenet,closenet.hut.fi,...,130.233.208.41 1024 37 159...93 closenet.hut.fi

EXAMPLE 4 ssh_known_hosts File Entries for Protocol 2
The following are examples of ssh_known_hosts file entries for protocol 2:

closenet,closenet.hut.fi,...,130.233.208.41 ssh-rsa AA...

EXAMPLE 5 Using X.509 Public Key Authentication
The following example of user authentication should help you understand how the X.509 public key authentication works. Steps to use X.509 certificates/keys for host authentication are very similar. Note that we use the same token (soft token) for both the TA certificate and the user certificate, which would not normally be the case.

Create a self-signed trusted anchor certificate and a user certificate signed by the trusted anchor private key. Configure the SSH daemon for certificate validation, and run the SSH client with the user certificate generated in the previous step as its user identity.

Replace user name “PUT-YOUR-USERNAME-HERE” with an existing (your) user name on the server side.

```
# Generate a trusted anchor certificate/key pair in the
# default token (soft token).
pktool gencert keystore=pkcs11 label=authority \    
    subject="CN=authority" serial=0x01

# Export the trusted anchor certificate (and, after that,
# put it to /etc/ssh/cert directory).
pktool export keystore=pkcs11 outfile=ta.cert objtype=cert 
    label=authority outformat=pem

# Generate a user certificate signed by the trusted anchor
# private key and then import the certificate into the
# token.
pktool gencsr keystore=pkcs11 label=user \    
    outcsr=user.csr subject="CN=<PUT-YOUR-USERNAME-HERE>" 
pktool signcsr keystore=pkcs11 signkey=authority \    
    csr=user.csr serial=0x02 issuer="CN=authority" 
```
EXAMPLE 5 Using X.509 Public Key Authentication  (Continued)

```
outcert=user.cert
pktool import keystore=pkcs11 infile=user.cert label=user

# Create a new policy file.
kmfcfg create dbfile=/etc/ssh/policy.xml policy=ssh \
  ta-name=search mapper-name=cn

# Start the SSH daemon in a debug mode to test the configuration. Use a different port so that you do not 
# clash with the already running daemon.
/usr/lib/ssh/sshd -p 2222 -ddd -o \
  -o TrustedAnchorKeystore=/etc/ssh/cert \ 
  -o KMFPolicyDatabase=/etc/ssh/policy.xml \ 
  -o KMFPolicyName=ssh

# Run the client in a debug mode to test the configuration
# (will ask for a PIN for the token, use the 'pinfile'
# attribute if you do not want to set PIN for each
# invocation).
# Note that the space and the hash-sign in the PKCS#11 URI are
# percent-encoded. Percent-encoding is in particular important when
# used from config file. Otherwise the '#' would be mistaken for a
# comment and token name matching would fail!
ssh -p 2222 -vvv -o \
  IdentityFile="
  "pkcs11:object=user;token=Sun%20Software%20PKCS%2311%20softtoken" \
  <PUT-YOUR-USERNAME-HERE>@localhost
```

Before you use the softtoken you should set its PIN by means of the setpin subcommand. See `pktool(1)` for more information.

**Exit Status** The following exit values are returned:

- **0** Successful completion.
- **>0** An error occurred.

**Files** `/etc/default/login`

Contains defaults for several `sshd_config` parameters, environment variables, and other environmental factors.

The following parameters affect environment variables (see `login(1)` and descriptions of these variables, above):

- `TIMEZONE`
- `HZ`
- `ALTSHELL`
- `PATH`
The following /etc/default/login parameters supply default values for corresponding
sshd_config(4) parameters:

- CONSOLE (see PermitRootLogin in sshd_config(4))
- PASSREQ (see PermitEmptyPasswords in sshd_config(4))
- TIMEOUT (see LoginGraceTime in sshd_config(4))

The following /etc/default/login parameters:

- UMASK
- ULIMIT

...set the umask(2) and file size limit of, respectively, the shells and commands spawned by
sshd.

Finally, two /etc/default/login parameters affect the maximum allowed login attempts
per-connection using interactive user authentication methods (for example, keyboard-interactive but not public key), as per login(1):

- RETRIES
- SYSLOG_FAILED_LOGINS

/etc/ssh/sshd_config

Contains configuration data for sshd. This file should be writable by root only, but it is
recommended (though not necessary) that it be world-readable.

/etc/ssh/ssh_host_key
/etc/ssh/ssh_host_dsa_key
/etc/ssh/ssh_host_rsa_key

Contains the private part of the host key. This file should only be owned by root, readable
only by root, and not accessible to others. sshd does not start if this file is
group/world-accessible.

/etc/ssh/ssh_host_key.pub
/etc/ssh/ssh_host_dsa_key.pub
/etc/ssh/ssh_host_rsa_key.pub

Contains the public part of the host key. This file should be world-readable but writable
only by root. Its contents should match the private part. This file is not used for encryption;
it is provided only for the convenience of the user so its contents can be copied to known
hosts files. These files are created using ssh-keygen(1).

/var/run/sshd.pid

Contains the process ID of the sshd listening for connections. If there are several daemons
running concurrently for different ports, this contains the pid of the one started last. The
content of this file is not sensitive; it can be world-readable. You can use the PidFile
keyword in sshd_config to specify a file other than /var/run/sshd.pid. See
sshd_config(4).
/etc/ssh/ssh_known_hosts and $HOME/.ssh/known_hosts
These files are consulted when using rhosts with public key host authentication to check
the public key of the host. The key must be listed in one of these files to be accepted. The
client uses the same files to verify that the remote host is the one it intended to connect.
These files should be writable only by root or the owner. /etc/ssh/ssh_known_hosts
should be world-readable, and $HOME/.ssh/known_hosts can but need not be
world-readable.

/etc/nologin
If this file exists, sshd refuses to let anyone except root log in. The contents of the file are
displayed to anyone trying to log in, and non-root connections are refused. The file should
be world-readable.

$HOME/.ssh/authorized_keys
Lists the public keys (RSA or DSA) that can be used to log into the user's account. This file
must be readable by root. This might, on some machines, imply that it is world-readable if
the user's home directory resides on an NFS volume. It is recommended that it not be
accessible by others. The format of this file is described above. Users will place the contents
of their identity.pub, id_dsa.pub and/or id_rsa.pub files into this file, as described in
ssh-keygen(1).

$HOME/.rhosts
This file contains host-username pairs, separated by a space, one per line. The given user on
the corresponding host is permitted to log in without password. The same file is used by
rlogind and rshd. The file must be writable only by the user; it is recommended that it not be
accessible by others. It is also possible to use netgroups in the file. Either host or user
name may be of the form +@groupname to specify all hosts or all users in the group.

$HOME/.shosts
For ssh, this file is exactly the same as for .rhosts. However, this file is not used by rlogin
and rshd, so using this permits access using SSH only.

/etc/hosts.equiv
This file is used during .rhosts authentication. In its simplest form, this file contains host
names, one per line. Users on these hosts are permitted to log in without a password,
provided they have the same user name on both machines. The host name can also be
followed by a user name; such users are permitted to log in as any user on this machine
(except root). Additionally, the syntax +@group can be used to specify netgroups. Negated
entries start with a hyphen (-).

If the client host/user is successfully matched in this file, login is automatically permitted,
provided the client and server user names are the same. Additionally, successful RSA host
authentication is normally required. This file must be writable only by root; it is
recommended that it be world-readable.

Warning: It is almost never a good idea to use user names in hosts.equiv. Beware that it
really means that the named user(s) can log in as anybody, which includes bin, daemon,
adm, and other accounts that own critical binaries and directories. For practical purposes, using a user name grants the user root access. Probably the only valid use for user names is in negative entries. This warning also applies to rsh/rlogin.

/etc/ssh/moduli
A private file.

/etc/ssh/hosts.equiv
This file is processed exactly as /etc/hosts.equiv. However, this file might be useful in environments that want to run both rsh/rlogin and ssh.

$HOME/.ssh/environment
This file is read into the environment at login (if it exists). It can contain only empty lines, comment lines (that start with #), and assignment lines of the form name=value. The file should be writable only by the user; it need not be readable by anyone else. Environment processing is disabled by default and is controlled by means of the PermitUserEnvironment option.

$HOME/.ssh/rc
If this file exists, it is run with /bin/sh after reading the environment files but before starting the user's shell or command. If X11 spoofing is in use, this will receive the proto cookie pair in standard input (and DISPLAY in environment). This must call xauth in that case.

The primary purpose of $HOME/.ssh/rc is to run any initialization routines that might be needed before the user's home directory becomes accessible; AFS is a particular example of such an environment. If this file exists, it is run with /bin/sh after reading the environment files, but before starting the user's shell or command. It must not produce any output on stdout; stderr must be used instead. If X11 forwarding is in use, it will receive the proto cookie pair in its standard input and DISPLAY in its environment. The script must call xauth because sshd will not run xauth automatically to add X11 cookies.

This file will probably contain some initialization code followed by something similar to:

```bash
if read proto cookie && [ -n "$DISPLAY" ] then
  if [ "echo $DISPLAY | cut -c1-10' = 'localhost:' "]
    then
      # X11UseLocalhost=yes
      echo add unix:'echo $DISPLAY |
      cut -c11-' $proto $cookie
    else
      # X11UseLocalhost=no
      echo add $DISPLAY $proto $cookie
    fi | xauth -q -
  fi
fi
```
If this file does not exist, `/etc/ssh/sshrc` is run, and if that does not exist, `xauth` is used to store the cookie. `$HOME/.ssh/rc` should be writable only by the user, and need not be readable by anyone else.

`/etc/ssh/sshrc`  
Similar to `$HOME/.ssh/rc`. This can be used to specify machine-specific login-time initializations globally. This file should be writable only by root, and should be world-readable.

**Security**  
sshd supports the use of several user authentication mechanisms: a public key system where keys are associated with users (through users' `authorized_keys` files), a public key system where keys are associated with hosts (see the `HostbasedAuthentication` configuration parameter), a GSS-API based method (see the `GssAuthentication` and `GssKeyEx` configuration parameters) and three initial authentication methods: `none`, `password`, and a generic `prompt_reply` protocol, `keyboard-interactive`.

sshd negotiates the use of the GSS-API with clients only if it has a GSS-API acceptor credential for the "host" service. This means that, for GSS-API based authentication, the server must have a Kerberos V keytab entry (see below) or the equivalent for any other GSS-API mechanism that might be installed.

In order for Kerberos authentication to work, a `host/<FQDN>` Kerberos principal must exist for each Fully Qualified Domain Name associated with the `in.sshd` server. Each of these hosts must have a `keytab` entry in the `/etc/krb5/krb5.keytab` file on the `in.sshd` server. An example principal might be:

`host/bigmachine.eng.example.com`

See `kadmin(1M)` or `gkadmin(1M)` for instructions on adding a principal to a `krb5.keytab` file. See Oracle Solaris 11.1 Administration: Security Services for a discussion of Kerberos authentication.

GSS-API authorization is covered in `gss_auth_rules(5)`.

sshd uses `pam(3PAM)` for the three initial authentication methods as well as for account management, session management, and password management for all authentication methods.

Specifically, `sshd` calls `pam_authenticate()` for the "none," "password" and "keyboard-interactive" SSHv2 userauth types. Other SSHv2 authentication methods do not call `pam_authenticate()`. `pam_acct_mgm()` is called for each authentication method that succeeds.

`pam_setcred()` and `pam_open_session()` are called when authentication succeeds and `pam_close_session()` is called when connections are closed.

`pam_open_session()` and `pam_close_session()` are also called when SSHv2 channels with ptys are opened and closed.
Each SSHv2 userauth type has its own PAM service name:

<table>
<thead>
<tr>
<th>SSHv2 Userauth</th>
<th>PAM Service Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>sshd-none</td>
</tr>
<tr>
<td>password</td>
<td>sshd-password</td>
</tr>
<tr>
<td>keyboard-interactive</td>
<td>sshd-kbdint</td>
</tr>
<tr>
<td>pubkey</td>
<td>sshd-pubkey</td>
</tr>
<tr>
<td>hostbased</td>
<td>sshd-hostbased</td>
</tr>
<tr>
<td>gssapi-with-mic</td>
<td>sshd-gssapi</td>
</tr>
<tr>
<td>gssapi-keyex</td>
<td>sshd-gssapi</td>
</tr>
</tbody>
</table>

If `pam_acct_mgmt()` returns `PAM_NEW_AUTHTOK_REQD` (indicating that the user's authentication tokens have expired), then `sshd` forces the use of "keyboard-interactive" userauth, if version 2 of the protocol is in use. The "keyboard-interactive" userauth will call `pam_chauthtok()` if `pam_acct_mgmt()` once again returns `PAM_NEW_AUTHTOK_REQD`. By this means, administrators are able to control what authentication methods are allowed for SSHv2 on a per-user basis.

To establish host-based authentication, you must perform the following steps:

- Configure the client.
- Configure the server.
- Publish known hosts.
- Make appropriate entries in `/etc/ssh/hosts.equiv` and `~/.ssh/hosts`.

These steps are expanded in the following paragraphs.

- On a client machine, in the system-wide client configuration file, `/etc/ssh/ssh_config`, you must have the entry:

```
HostbasedAuthentication yes
```

See `ssh_config(4)` and `ssh-keysign(1M)`.

- On the server, in the system-wide server configuration file, `/etc/ssh/sshd_config`, you must have the entry:

```
HostbasedAuthentication yes
```

If per-user `.ssh` files are to be allowed (see last step), in the same file, you must have:

```
IgnoreRhosts no
```

See `sshd_config(4)` for a description of these keywords.
To publish known hosts, you must have entries for the clients from which users will be allowed host-based authentication. Make these entries in either or both of the system-wide file (/etc/ssh/ssh_known_hosts) or the per-user file (~/.ssh/known_hosts).

Note that sshd uses .shosts, not .rhosts. If you want the functionality provided by .rhosts, but do not want to use rlogin or rsh because of their security shortcomings, you can use .shosts in conjunction with sshd. To use this feature, make appropriate entries in /etc/ssh/shosts.equiv and ~/.shosts, in the format specified in rhosts(4).

For the vast majority of network environments, .shosts is preferred over .rhosts.

SSH commands can work with X.509v3 certificates when used as host keys and/or user identities. When used this way, PKCS#11 URIs can be used instead of plain filenames to locate keys and certificates. Host keys, user identities, and their corresponding certificates used for X.509 public key authentication can be stored only in PKCS#11 tokens. The only PKCS#11 URI attributes used by SSH are object, token, and pinfile. If no hardware keystore is available, the PKCS#11 softtoken keystore can be used.

For certificate validation (a server that authenticates a user, or a client that authenticates a server), the KMF policy needs a certificate mapper. Mappers are not set in the default policy file. See TrustedAnchorKeystore, KMFPolicyDatabase, and KMFPolicyName options in sshd_config(4), and see libkmf(3LIB) for more information.

Self-signed certificates can only be used as host keys, never as user identities. If a self-signed certificate is used or if a host certificate cannot be validated on the client side due to a missing relevant trusted anchor certificate, the SSH client offers to store the key in the known_host database, as is currently done with plain public keys. Only the public key is extracted from the certificate and stored in the database, thus maintaining the current format. The reason for accepting such a certificate on the client side is that the initial host Key Exchange is not restartable. Given this, if a server uses certificates as its only host key(s), a client that is unable to validate the certificate would otherwise be denied from logging in.

See the EXAMPLES section for guidance on how to use the X.509 authentication.

To configure sshd to run OpenSSL in FIPS-140 mode, the variable UseFIPS140 is set to yes. SunSSH can still delegate cryptographic operations for user/host authentication to other parts of Solaris that might or might not be FIPS-140 certified. The default value of the UseOpenSSLEngine option is no; the setting of UseOpenSSLEngine to yes does not have an effect in FIPS mode.

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/network/ssh</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>
The interface stability of /etc/ssh/moduli is Private.

libkmf(3LIB), pam(3PAM), rhosts(4), ssh_config(4), sshd_config(4), attributes(5),
gss_auth_rules(5), kerberos(5), pam_roles(5), pkcs11_softtoken(5), smf(5)

See the discussion of the .k5login file in krb5_auth_rules(5).

Notes The sshd service is managed by the service management facility, smf(5), under the service
identifier:

svc:/network/ssh:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can
be performed using svcadm(1M). The service's status can be queried using the svcs(1)
command.

sshd always sets PAM_RHOST and sets PAM_AUSER in the case of host-based userauth. This
behavior allows for remote logins to roles using host-based authentication. See pam_roles(5).
ssh-keysign – ssh helper program for host-based authentication

**Synopsis**

ssh-keysign

**Description**

ssh-keysign is used by ssh(1) to access the local host keys and generate the digital signature required during host-based authentication with SSH protocol version 2. This signature is of data that includes, among other items, the name of the client host and the name of the client user.

ssh-keysign is disabled by default and can be enabled only in the global client configuration file /etc/ssh/ssh_config by setting HostbasedAuthentication to yes.

ssh-keysign is not intended to be invoked by the user, but from ssh. See ssh(1) and sshd(1M) for more information about host-based authentication.

**Files**

/etc/ssh/ssh_config Controls whether ssh-keysign is enabled.

/etc/ssh/ssh_host_dsa_key
/etc/ssh/ssh_host_rsa_key These files contain the private parts of the host keys used to generate the digital signature. They should be owned by root, readable only by root, and not accessible to others. Because they are readable only by root, ssh-keysign must be set-uid root if host-based authentication is used.

**Security**

ssh-keysign will not sign host-based authentication data under the following conditions:

- If the HostbasedAuthentication client configuration parameter is not set to yes in /etc/ssh/ssh_config. This setting cannot be overridden in users’ ~/.ssh/ssh_config files.
- If the client hostname and username in /etc/ssh/ssh_config do not match the canonical hostname of the client where ssh-keysign is invoked and the name of the user invoking ssh-keysign.

In spite of ssh-keysign's restrictions on the contents of the host-based authentication data, there remains the ability of users to use it as an avenue for obtaining the client's private host keys. For this reason host-based authentication is turned off by default.

statd–network status monitor

/statd

statd is an intermediate version of the status monitor. It interacts with lockd(1M) to provide the crash and recovery functions for the locking services on NFS. statd keeps track of the clients with processes which hold locks on a server. When the server reboots after a crash, statd sends a message to the statd on each client indicating that the server has rebooted. The client statd processes then inform the lockd on the client that the server has rebooted. The client lockd then attempts to reclaim the lock(s) from the server.

statd on the client host also informs the statd on the server(s) holding locks for the client when the client has rebooted. In this case, the statd on the server informs its lockd that all locks held by the rebooting client should be released, allowing other processes to lock those files.

lockd is started by automountd(1M), mount_nfs(1M), and share(1M) if NFS automounts are needed.

_files_ /var/statmon/sm lists hosts and network addresses to be contacted after a reboot
/var/statmon/sm.bak lists hosts and network addresses that could not be contacted after last reboot
/var/statmon/state includes a number which changes during a reboot
/usr/include/rpcssvc/sm_inter.x contains the rpcgen source code for the interface services provided by the statd daemon.

System Administration Guide: IP Services

Notes The crash of a server is only detected upon its recovery.

The statd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/nfs/status
Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

If it is disabled, it will be enabled by `mount_nfs(1M), share_nfs(1M), and automountd(1M)` unless its application/auto_enable property is set to false.
**Name**  
`stclient` – Service Tag Administration Program

**Synopsis**  
`stclient` 
`-x | -E [-r root_dir]`  
`-a [-i instance_URN] -p product_name -e product_version`  
`-t product_URN [-F parent_URN] -p product_parent`  
`[-I product_defined_instance_id] -m product_vendor -A platform_arch`  
`-z container -S source [-r root_dir]`  
`-u -i instance_URN -F parent_URN -I product_defined_instance_id`  
`[-r root_dir]`  
`-d -i instance_URN [-r root_dir]`  
`-g -i instance_URN [-r root_dir]`  
`-f -t product_URN [-r root_dir]`  
`-h`  
`-v`

**Description**  
The `stclient` command displays, finds, adds, updates and deletes records in the Service Tag registry. The registry is in the XML file `/var/sadm/servicetag/registry/servicetag.xml`, and contains the inventory of the product instances installed in the machine. Each record has a unique product instance identifier which is generated when the service tag is added in the registry. This product instance identifier is used as a key when finding, updating or deleting the service tag records. The extract option prints out the registry contents in XML format in stdout.

The `stclient` command also runs in interactive mode. This mode is invoked by running `stclient` without any parameters. A menu of all the available options are displayed, and the user is prompted to enter different parameters depending on the option chosen.

Any user can extract or get the contents of the registry, but only users with the appropriate privileges, the “svctag” user, or the creator of the service tag is authorized to update or delete a service tag record.

**Options**  
The following options are supported:

- `-p product_name`  
  Sets the product name of the service tag to be added. For example, “stclient -p “Solaris 10 Operating System”” sets the product name to the “Solaris 10 Operating System”.

- `-e product_version`  
  Sets the product version of the service tag to be added. For example, “stclient -e 5.10” sets the product version to “5.10”.

- `-t product_URN`  
  Sets the Sun product unique identifier of the service tag to be added. For example, “stclient -t urn:uuid:5005588c-36f3-11d6-9cc-fc96f718e113” sets
the Sun product unique identifier to “urn:uuid:5005588c-36f3-11d6-9cecfc96f718e113”.

-1 instance_URN
Sets the product instance unique identifier of the service tag. For example, “stclient -i 3a444ab2-1dd2-11b2-a69d-830020782a6b” sets the product instance unique identifier to “3a444ab2-1dd2-11b2-a69d-830020782a6b” This field may also be set when the service tag is added but is not typically used. The generation of the instance ID is normally left to the stclient.

-F product_parent_URN
Sets the Sun product unique identifier of parent product. For example, “stclient -F urn:uuid:5005588c-36f3-11d6-9cecfc96f718e113” sets the Sun product unique identifier of parent product to “urn:uuid:5005588c-36f3-11d6-9cecfc96f718e113”.

-P product_parent
Sets the parent product of the service tag. For example, “stclient -P JES” sets the product parent to “JES”.

-I product_defined_instance_id
Sets the product defined instance identifier. For example, “stclient -I ser:abc-klm-000-7190” sets the product defined instance identifier to “ser:abc-klm-000-7190”.

-m product_vendor
Sets the vendor of the product. For example, “stclient -m Sun” sets the product vendor to “Sun”.

-A platform_arch
Sets the platform architecture that the product is running on. For example, “stclient -A sparc” sets the platform architecture to “sparc”.

-z container
Sets the container that the product is running on. For example, “stclient -z “global zone”” sets the container to “global zone”.

-S source
Sets the source of this service tag, naming the entity that created it.

-r root_dir
Sets the root directory where the command searches for the registry. The command searches /var/sadm/servicetag/registry by default. When this option is used, the command looks for the Registry in the specified root directory, (for example, “-r /home/user1” searches /home/user1/var/sadm/servicetag). This is typically used for testing.
Operands

Function Letters  The function portion of the key is specified by one of the following letters:

- x  Extract. Extracts and prints the contents of the Service Tag registry in XML format. An alternate root directory may be specified for testing purposes.
- a  Add. Adds a service tag in the registry. A unique product instance identifier may be supplied and is automatically generated if not provided. This field is returned by the command. The required fields for add are product name, product version, product URN, product parent, vendor, platform architecture, container and source.
- u  Update. Updates a service tag in the registry using the product instance URN as the key. The parent URN and product defined instance id fields can be updated.
- d  Delete. Deletes a service tag in the registry using the product instance URN as the key.
- E  Extract Environment. Enumerates to standard output the environmental or "agent" information associated with the registered Service Tags on this system.
- g  Get. Gets and prints a service tag from the registry using the product instance URN as the key.
- f  Find. Finds and prints all the instance URNs of a given product URN.
- h  Help. Displays the command options.
- v  Version. Displays the version number of the command.

Exit Status  The following exit values are returned:

- 0  Successful completion.
- > 0  An error occurred.

Examples  

**EXAMPLE 1**  Adding a Service Tag in the Registry

To add a service tag, enter the following:

```bash
# stclient -a -p "Java Enterprise Web Server 6.0" -v 6.0 \ 
  -t urn:uuid:f2b8b59c-6eba-11d7-986f-9f5d47ec72fe \ 
  -P Java Enterprise Server -m Sun -A sparc -z global -S patch
```

The screen displays the following:

```
Java Enterprise Web Server 6.0 6.0 added
Product instance URN=urn:st:7fc61914-1dd2-11b2-b992-830020782a6b
```

**EXAMPLE 2**  Updating a Service Tag in the Registry

To update a service tag, enter the following:
EXAMPLE 2  Updating a Service Tag in the Registry  (Continued)

# stclient -u -i 7fc61914-1dd2-11b2-b992-830020782a6b \
 -I urn:st:product.defined.id

The screen displays the following:
Service tag updated

EXAMPLE 3  Extracting a Service Tag Registry
To extract a service tag, enter the following:

# stclient -x

The screen displays output similar to the following:
<?xml version="1.0" encoding="UTF-8"?>
<registry urn="urn:uuid:1234ab-00e1-11b3-98737646873" version="1.0">
    <service_tag>
       .
       .
       .
    </service_tag>
</registry>

EXAMPLE 4  Finding all product instances
To find all product instances, enter the following:

# stclient -f -t urn:uuid:f2b8b59c-6eba-11d7-986f-9f5d47ec72fe \
   fc61914-1dd2-11b2-b992-830020782a6b

EXAMPLE 5  Listing the Environmental Information
To list the environmental information associated with the registered Service Tags on this
system, enter the following:

# stclient -E

The screen displays output similar to the following:
<?xml version="1.0" encoding="UTF-8"?>
<agent>
    <agent_urn>urn:st:af15ee62-0bb3-ef2d-fa96-85a11996cc71</agent_urn>
       .
       .
    </system_info>
</agent>
See environ(5) for descriptions of the following environment variables that affect the execution of stclient: LANG, LC_ALL, LC_TYPE, LC_MESSAGES, and NLSPATH.

stmfadm online-target target-name
stmfadm offline-target target-name
stmfadm remove-hg-member -g, --group-name group-name group-member...
stmfadm remove-tg-member -g, --group-name group-name group-member...
stmfadm remove-view -l, --lu-name lu-name entry-name

Description  
The stmfadm command configures logical units within the SCSI Target Mode Framework
(STMF) framework. The framework and this man page use the following terminology:

initiator  
A device responsible for issuing SCSI I/O commands to a SCSI target and logical unit.
**target**
A device responsible for receiving SCSI I/O commands for a logical unit.

**logical unit**
A device within a target responsible for executing SCSI I/O commands.

**logical unit number**
The identifier of a logical unit within a target.

**initiator group**
An initiator group is a set of one or more initiators that are combined for the purposes of being applied to a view (see below). Unless the -F is used with the add-hg-member subcommand, an initiator cannot be a member of more than one initiator group.

**target group**
A target group is a set of one or more SCSI target ports that are treated the same when creating a view (see below). The set of logical units that a particular SCSI initiator can see is determined by the combined set of views.

Each logical unit has a set of view entries, and each view entry specifies a target group, host group, and a LUN. An initiator from that host group, when connecting through that target group, is able to identify and connect to that logical unit using the specified LUN. You can use views to restrict the set of logical units that a specific initiator can see, and assign the set of LUNs that will be used.

**view**
A view defines the association of an initiator group, a target group, and a logical unit number with a specified logical unit. Any view entry added to a logical unit must not be in conflict with existing view entries for that logical unit. A view entry is considered to be in conflict when an attempt is made to duplicate the association of any given initiator, target and logical unit number. As an example, logical unit LU_0 has the following view entry associated with it:

```
Logical Unit: LU_0
View Entry: 0
  initiator group: HostA
  target group: All targets
  logical unit number: 32
```

If you attempted the following:

```
# stmfs add-view -n 31 -h HostA LU_0
```

...the operation would return an error with a message indicating that the view entry is in conflict with one or more existing view entries. This conflict arises because the existing view entry, 0, already has mapped LU_0 to logical unit number 32 for the initiator group HostA.
Sub-commands

The stmfadm command supports the subcommands listed below.

### add-view

```
add-view [-n, --lun logical-unit-number -t, --target-group group-name -h, --host-group group-name] lu-name
```

Add a logical unit view entry to a logical unit lu-name, where lu-name is the STMF name for the logical unit as displayed by the list-lu subcommand. The add-view subcommand provides the user with a mechanism to implement access control for a logical unit and also provides a means of assigning a logical unit number to a logical unit for a given set of initiators and targets. A logical unit will not be available to any initiators until at least one view is applied. Each view entry gets assigned an entry name, which can be used to reference the entry in the remove-view and list-view subcommands.

add-view supports the following options:

- **-n, --lun logical-unit-number**
  logical-unit-number is an integer in the range 0-16383 to be assigned to the logical unit for this view entry. If this option is not specified, a logical unit number will be assigned by the STMF framework.

- **-t, --target-group group-name**
  group-name is the name of a target group previously created using the STMF create-tg subcommand. If this option is not specified, the logical unit will be available through all targets.

- **-h, --host-group group-name**
  group-name is the name of an host group previously created using the STMF create-hg subcommand. If this option is not specified, the logical unit will be available to all initiators that log in to the STMF framework.

### add-hg-member

```
add-hg-member [-F, --force] -g group-name group-member...
```

Add a host group member to a host group. group-name must be an existing group created using the create-hg subcommand. group-member can be specified as

```
name_type.name_value
```

where name_type can be one of the following:

- **wwn**
- **iqn**
- **eui**
- **eui**

...and name_value is the value of the initiator name. As an example, to add a fibre channel initiator port world-wide name `200000e08b909221` to the host group HostA, the command would be:

```
# stmfadm add-hg-member -g HostA wwn.200000e08b909221
```

To add an iSCSI initiator node member with the name

```
iqn.1986-03.com.sun:01.46f7e262
e262
to HostA, the command would be:

```
# stmfadm add-hg-member -g HostA iqn.1986-03.com.sun:01.46f7e262
```

Alternatively, members can be specified using their SCSI name string identifiers. To add the two initiators above using their SCSI name string identifiers, the commands would be:
stmfadm add-hg-member -g HostA eui.200000e08b909221
stmfadm add-hg-member -g HostA iqn.1986-03.com.sun:01.46f7e262

With the -F option, host group member can be a member of more than one host group. Without this option, a host group member can be a member of only one group.

add-tg-member -g group-name group member...
Add a target group member to a target group. group-name must be an existing group created using the create -tg subcommand. group member can be specified as name_type.name_value, where name_type can be one of the following:

wwn
iqn
eui

...and name_value is the value of the target name. As an example, to add a fibre channel target port world-wide name 501000e092376af7 to the target group TG0, the command would be:

# stmfadm add-tg-member -g TG0 wwn.501000e092376af7

To add an ISCSI target member with the name iqn.1986-03.com.sun:target.01.01110 to TG0, the command would be:

# stmfadm add-tg-member -g TG0 iqn.1986-03.com.sun:target.01.01110

Alternatively, members can be specified using their SCSI name string identifiers. To add the two targets above using their SCSI name string identifiers, the commands would be:

# stmfadm add-tg-member -g TG0 eui.501000e092376af7
# stmfadm add-tg-member -g TG0 iqn.1986-03.com.sun:target.01.01110

A target group member cannot be a member of more than one target group.

create-hg group-name
Create an initiator group with the name group-name. group-name is a string of Unicode characters with a maximum length of 255. The group name must be unique within the STMF system.

create-lu [-p, -lu-prop logical-unit-property=val -s, -size size] lu-file
Create a logical unit that can be registered with STMF. For the -p option, logical-unit-property can be one of the following properties:

alias
Up to 255 characters, representing a user-defined name for the device. The default is the name of the backing store.

blk
Specifies the block size for the device. The default is 512, but do not set this value higher than 4096 KB.
guid
Thirty-two hexadecimal ASCII characters representing a valid NAA Registered
Extended Identifier. The default is set by the STMF to a generated value.

host-id
Eight hexadecimal ASCII characters representing the host ID assignment. This will be
used to generate the globally unique identifier (GUID) for the logical unit. The default is
the value returned by hostid(1).

meta
Metadata file name. When specified, will be used to hold the SCSI metadata for the
logical unit. There is no default.

gid-url
Up to 1024 characters representing a Management Network Address URL. More than
one URL can be passed as a single parameter by using space-delimited URLs enclosed
inside a single pair of quotation marks (").

oui
Organizational Unique Identifier. Six hexadecimal ASCII characters representing the
IEEE OUI company ID assignment. This will be used to generate the device identifier
(GUID). The default is 00144F.

pid
Sixteen characters of product identification SCSI SPC-3. This value will be reflected in
the Standard INQUIRY data returned for the device. The default is COMSTAR.

serial
Serial Number. Specifies the SCSI Vital Product Data Serial Number (page 80h). It is a
character value up to 252 bytes in length. There is no default value.

vid
Eight characters of vendor identification per SCSI SPC-3. This value will be reflected in
the Standard INQUIRY data returned for the device. The default is SUN.

wcd
Write-back cache disable. Specify true or false to determine write-back cache disable
behavior. The default is the write-back cache setting of the backing store device specified
by the lu-file argument.

wcms
Write cache setting changeable. Specified as true or false. When true, a SCSI MODE
SELECT from the initiator can change the WRITE CACHE ENABLE bit on the caching mode
page. When false, the WRITE CACHE ENABLE bit is not changeable. This setting does not
impact the ability for stmfadm or a libstmf(3LIB) function to modify the write cache
disable setting. The default setting is true.

wp
Write-protect bit. Specify true or false to determine whether the device reports as
write-protected. The default is false.
For the -s option, size is an integer followed by one of the following letters, to indicate a unit of size:

- k kilobyte
- m megabyte
- g gigabyte
- t terabyte
- p petabyte
- e exabyte

lu-file is the file to be used as the backing store for the logical unit. If the -s option is not specified, the size of the specified lu-file will be used as the size of the logical unit. Logical units registered with the STMF require space for the metadata to be stored. When a zvol is specified as the backing store device, the default will be to use a special property of the zvol to contain the metadata. For all other devices, the default behavior will be to use the first 64k of the device. An alternative approach would be to use the meta property in a create-lu command to specify an alternate file to contain the metadata. It is advisable to use a file that can provide sufficient storage of the logical unit metadata, preferably 64k.

create-tg group-name
Create a target group with the name group-name. group-name is a string of Unicode characters with a maximum length of 255. The group name must be unique within the STMF system.

delete-hg group-name
Delete the host group that identified by group-name.

delete-lu lu-name
Deletes an existing logical unit that was created using stmfadm create-lu. This effectively unloads the logical unit from the STMF framework. Any existing data on the logical unit remains intact.

delete-tg group-name
Delete the target group that identified by group-name.

import-lu lu-file
Imports and loads a logical unit into the STMF that was previously created using stmfadm create-lu and was then deleted from the STMF using stmfadm delete-lu. On success, the logical unit is again made available to the STMF. lu-file is the filename used in the stmfadm create-lu command. If this logical unit is using a separate metadata file, the filename in the meta property value that was used in the stmfadm create-lu command must be used here.
list-hg [-v, --verbose] [host-group-name...]
Lists information for the host group in the system referenced by host-group-name. If host-group-name is not specified, all host groups in the system will be listed. If the -v or --verbose option is specified, all members within a host group are displayed.

list-lu [-v, --verbose] [lu-name...]
Lists information for the logical unit in the system referenced by lu-name. If lu-name is not specified, all logical units in the system will be listed. If the -v or --verbose option is specified, additional information about the logical unit will be displayed.

list-target [-v, --verbose] [target-name...]
Lists information for the target port in the system referenced by target-name. If target name is not specified, all target ports in the system will be listed. If the -v or --verbose option is specified, additional information about the target along with SCSI session information for logged-in initiators is displayed.

list-tg [-v, --verbose] [target-group-name...]
Lists information for the target group in the system referenced by target-group-name. If target-group-name is not specified, all target groups in the system will be listed. If the -v or --verbose option is specified, all members within a target group are displayed.

list-view [-v, --verbose] [-l, --lu-name lu-name [entry-name...]]
Lists the view entry for the logical unit referenced by lu-name. If entry-name is not specified, all view entries for the specified logical unit will be listed.

If the -v option is specified, additional information about logical-unit-number assigned per host associated with the view are displayed.

modify-lu [-p, --lu-prop logical-unit-property=val -s, --size size, -f, --file]
lu-name [lu-file]
Modifies attributes of a logical unit created using the stmfdm create-lu command. For the -p option, logical-unit-property can be one of the following properties:

alias
Up to 255 characters, representing a user-defined name for the device. The default is the name of the backing store.

mgmt-url
Up to 1024 characters representing a Management Network Address URL. More than one URL can be passed as a single parameter by using space-delimited URLs enclosed inside a single pair of quotation marks ('').

wcd
Write-back cache disable. Specify true or false to determine write-back cache disable behavior. The default is the write-back cache setting of the backing store device specified by the lu-file argument.
wp
Write-protect bit. Specify `true` or `false` to determine whether the device reports as write-protected. The default is `false`.

wcms
Write cache setting changeable. Specified as `true` or `false`. When `true`, a SCSI MODE SELECT from the initiator can change the WRITE CACHE ENABLE bit on the caching mode page. When false, the WRITE CACHE ENABLE bit is not changeable. This setting does not impact the ability for `stmfadm` or a `libstmf(3LIB)` function to modify the write cache disable setting. The default setting is `true`.

For the `-s` option, `size` is an integer followed by one of the following letters, to indicate a unit of size:

- `k` kilobyte
- `m` megabyte
- `g` gigabyte
- `t` terabyte
- `p` petabyte
- `e` exabyte

`lu-name` is the guid of the logical unit to be modified. If the `-f` option is specified, the operand is interpreted as a file name. This provides the ability to modify a logical unit that is not currently imported into the STMF.

`online-lu lu-name`
Online a logical unit currently registered with the STMF.

`online-target target-name`
Online the specified target.

`offline-lu lu-name`
Offline a logical unit currently registered with the STMF.

`offline-target target-name`
Offline the specified target.

`list-state`
Lists the operational and configuration state of the STMF.

`remove-hg-member -g group-name group member`
Removes a host group member from a host group. `group-name` must be an existing group created using the `create-hg` subcommand. `group member` can be specified as `name_type.name_value`, where `name_type` can be one of the following:
...and \texttt{name\_value} is the value of the initiator name. As an example, to remove the fibre channel initiator port world-wide name \texttt{200000e08b909221} from the host group \texttt{HostA}, the command would be:

\texttt{stmfadm remove-hg-member -g HostA \texttt{wwn.200000e08b909221}}

To remove the iSCSI initiator node member with the name \texttt{iqn.1986-03.com.sun:01.46f7e262} from \texttt{HostA}, the command would be:

\texttt{stmfadm remove-hg-member -g HostA \texttt{iqn.1986-03.com.sun:01.46f7e262}}

Alternatively, members can be specified using their SCSI name string identifiers. To remove the two initiators above using their SCSI name string identifiers, the commands would be:

\texttt{stmfadm remove-hg-member -g HostA \texttt{eui.200000e08b909221}}
\texttt{stmfadm remove-hg-member -g HostA \texttt{iqn.1986-03.com.sun:01.46f7e262}}

\texttt{stmfadm remove-tg-member -g \texttt{group-name} \texttt{groupmember}}

Removes a target group member from a target group. \texttt{group-name} must be an existing group created using the \texttt{create-tg} subcommand. \texttt{groupmember} can be specified as \texttt{name\_type.name\_value}, where \texttt{name\_type} can be one of the following:

\texttt{wwn}
\texttt{iqn}
\texttt{eui}

...and \texttt{name\_value} is the value of the target name. As an example, to remove the fibre channel target port world-wide name \texttt{501000e092376af7} from the target group \texttt{TG0}, the command would be:

\texttt{stmfadm remove-tg-member -g TG0 \texttt{wwn.501000e092376af7}}

To remove the iSCSI target member with the name \texttt{iqn.1986-03.com.sun:target.01.01110} from \texttt{TG0}, the command would be:

\texttt{stmfadm remove-tg-member -g TG0 \texttt{iqn.1986-03.com.sun:target.01.01110}}

Alternatively, members can be specified using their SCSI name string identifiers. To remove the two targets above using their SCSI name string identifiers, the commands would be:

\texttt{stmfadm remove-tg-member -g TG0 \texttt{eui.501000e092376af7}}
\texttt{stmfadm remove-tg-member -g TG0 \texttt{iqn.1986-03.com.sun:target.01.01110}}

\texttt{stmfadm remove-view -l, \texttt{--lu-name} \texttt{lu-name entry-name}}

Removes one or more logical unit view entries from a logical unit.
Creating a Host group with Two Initiator Ports

The following commands use the `create-hg` and `add-hg-member` subcommands to create a host group and add two initiator ports to that host group.

```
# stmfadm create-hg host-group-a
# stmfadm add-hg-member -g host-group-a wwn.210105b0000d92d0
```

Adding a View Entry to a Logical Unit

The following command uses the `add-view` subcommand to allow access from `host-group-a` to a logical unit.

```
# stmfadm add-view -h host-group-a 6000AE40C5000000000046FC4FEA001C
```

Listing a View Entry

The following command uses the `list-view` subcommand to list all view entries for the specified logical unit.

```
# stmfadm list-view -l 6000AE40C5000000000046FC4FEA001C
View Entry: 0
  Host group : host-group-a
  Target group : All
  LUN : 0
```

**Name**

`stmsboot` – administration program for the Solaris I/O multipathing feature

**Synopsis**

```
/usr/sbin/stmsboot [-D (fp | mpt | mpt_sas | iscsi)] [-d | -e | -u]
       | -L | -l controller_number
```

**Description**

The Solaris I/O multipathing feature is a multipathing solution for storage devices that is part of the Solaris operating environment. This feature was formerly known as Sun StorEdge Traffic Manager (STMS) or MPxIO.

The `stmsboot` program is an administrative command to manage enumeration of multipath–capable devices with Solaris I/O multipathing. Solaris I/O multipathing-enabled devices are enumerated under `scsi_vhci(7D)`, providing multipathing capabilities. Solaris I/O multipathing-disabled devices are enumerated under the physical controller.

In the `/dev` and `/devices` trees, Solaris I/O multipathing-enabled devices receive new names that indicate that they are under Solaris I/O multipathing control. This means a device will have a different name from its original name (after enabling) when it is under Solaris I/O multipathing control. The `stmsboot` command automatically updates `/etc/vfstab` and `dump` configuration to reflect the device names changes when enabling or disabling Solaris I/O multipathing. One reboot is required for changes to take effect.

**Options**

The following options are supported:

- `e [-D fp | mpt | mpt_sas | iscsi]`
  Enables Solaris I/O multipathing on all supported multipath-capable controller ports, including `fp(7d)`, `mpt(7D)`, `mpt_sas(7D)`, and `iscsi(7D)` port drivers. Multipath–capable ports include fibre channel (`fp(7d)`) controller ports and SAS (`mpt(7D) or mpt_sas(7D)`) controller ports. Following this enabling, you are prompted to reboot. During the reboot, `vfstab` and the dump configuration will be updated to reflect the device name changes. Specifying `-D mpt`, `-D mpt_sas`, or `-D fp` limits the enabling operation to ports attached using the specified driver.

- `d [-D fp | mpt | mpt_sas | iscsi]`
  Disables Solaris I/O multipathing on all supported multipath-capable controller ports, including `fp(7d)`, `mpt(7D)`, `mpt_sas(7D)`, and `iscsi(7D)` port drivers. Multipath–capable ports include fibre channel (`fp(7d)`) controller ports and SAS (`mpt(7D) or mpt_sas(7D)`) controller ports. Following this disabling, you are prompted to reboot. During the reboot, `vfstab` and the dump configuration will be updated to reflect the device name changes. Specifying `-D mpt`, `-D mpt_sas`, or `-D fp` limits the disabling operation to ports attached using the specified driver.

- `u [-D fp | mpt | mpt_sas | iscsi]`
  Updates `vfstab` and the dump configuration after you have manually modified the configuration to have Solaris I/O multipathing enabled or disabled on specific `fp(7d)`, `mpt(7D)`, `mpt_sas(7D)`, and `iscsi(7D)` controller ports. This option prompts you to reboot. During the reboot, `vfstab` and the dump configuration will be updated to reflect the device name changes.
Display the device name changes from non-Solaris I/O multipathing device names to Solaris I/O multipathing device names for multipath-enabled controller ports. If Solaris I/O multipathing is not enabled, then no mappings are displayed.

controller_number
Display the device name changes from non-Solaris I/O multipathing device names to Solaris I/O multipathing device names for the specified controller. If Solaris I/O multipathing is not enabled, then no mappings are displayed.

Note that mpt_sas has MPxIO turned on by default. This means that when using the -L or -l option with -D mpt_sas, stmsboot does not display any non-multipathed and multipathed device names.

Usage
The primary function of stmsboot is to control the enabling and disabling of Solaris I/O multipathing on the host. The utility automatically updates /etc/vfstab(4) and /usr/sbin/dumpadm(1M) configuration to reflect device name changes. The system administrator is responsible for modifying application configuration (for example, backup software, DBMS, and so forth) to reflect updated device names.

The -L and -l options display the mapping between multipathed and non-multipathed device names. These options function only after changes to the Solaris I/O multipathing configuration have taken effect, that is, following the reboot after invoking stmsboot -e.

ZFS datasets, including ZFS root datasets, are correctly handled by stmsboot.

Examples
EXAMPLE 1  Enabling Solaris I/O Multipathing
To enable Solaris I/O multipathing for all multipath-capable controllers, run:

```
# stmsboot -e
```

To enable Solaris I/O multipathing on multipath-capable mpt(7D) controller ports, enter:

```
# stmsboot -D mpt -e
```

To enable Solaris I/O multipathing on multipath-capable mpt_sas(7D) controller ports, enter:

```
# stmsboot -D mpt_sas -e
```

To enable Solaris I/O Multipathing on multipath-capable fibre channel controller ports, enter:

```
# stmsboot -D fp -e
```

To enable Solaris I/O Multipathing on multipath-capable iSCSI controller ports, enter:

```
# stmsboot -D iscsi -e
```
Disabling Solaris I/O Multipathing

To disable Solaris I/O multipathing on all multipath-capable controllers, enter:

```
# stmsboot -d
```

To disable Solaris I/O multipathing on multipath-capable `mpt(7D)` controller ports, enter:

```
# stmsboot -D mpt -d
```

To disable Solaris I/O multipathing on multipath-capable `mpt_sas(7D)` controller ports, enter:

```
# stmsboot -D mpt_sas -d
```

To disable Solaris I/O multipathing on multipath-capable iSCSI controller ports, enter:

```
# stmsboot -D iscsi -d
```

To disable Solaris I/O multipathing on multipath-capable fibre channel controller ports, enter:

```
# stmsboot -D fp -d
```

Enabling Solaris I/O Multipathing on Selected Ports

To enable Solaris I/O multipathing on specific fibre channel controller ports and disable the feature on others, manually edit the `/etc/driver/drv/fp.conf` file. (See `fp(7d)`.) The following command will update `vfstab(4)` and `dumpadm(1M)` configuration to reflect the changed device names:

```
# stmsboot -u
```

A similar procedure involving the `/etc/driver/drv/mpt.conf` file should be followed for devices attached by means of the `mpt(7D)` driver. For devices attached by means of the `iscsi(7D)` driver, follow a similar procedure that uses the `/etc/driver/drv/iscsi.conf` file.

Solaris SAN Configuration and Multipathing Guide (see http://docs.oracle.com)

Consult a particular storage product’s system administrator’s guide and release notes for further information specific to that product.
Solaris I/O multipathing is not supported on all devices. After enabling Solaris I/O multipathing, only supported devices are placed under Solaris I/O multipathing control. Non-supported devices remain unchanged.

For Solaris releases prior to the current release, the -e and -d options replace mpxio-disable property entries with a global mpxio-disable entry in fp.conf.

The following applies to Sun StoreEdge T3, 3910, 3960, 6120, and 6320 storage subsystems.

To place your Sun StorEdge disk subsystem under Solaris I/O multipathing control, in addition to enabling Solaris I/O multipathing, the mp_support of the subsystem must be set to mpxio mode. The preferred sequence is to change the subsystem's mp_support to mpxio mode, then run stmsboot -e. If Solaris I/O multipathing is already enabled but the subsystem's mp_support is not in mpxio mode, then change the mp_support to mpxio mode and run stmsboot -u.

Refer to the Sun StorEdge Administrator's Guide for your subsystem for more details.

The ufsdump(1M) command records details of filesystem dumps in /etc/dumpdates (see ufsdump(4)). Among other items, the entries contain device names. An effect of the "active" stmsboot options (-e, -d, and -u) is to change the device name of a storage device.

Because stmsboot does not modify dumpdates, entries will refer to obsolete device names, that is, device names that were in effect before Solaris I/O multipathing configuration changes were performed. In this situation ufsdump will behave as if no previous dump of the filesystem had been performed. A level 0 dump will be performed.

If possible, invoke stmsboot -e before installing Sun Cluster software. After executing stmsboot, install Sun Cluster software normally.

If Sun Cluster software is installed before executing stmsboot, follow this procedure:

On each machine in the cluster where Solaris I/O multipathing is required, execute:

```
# stmsboot -e
```

...and allow the system to reboot.

When the system comes up, enter the following two commands:

1. `#/usr/cluster/bin/scdidadm -C`
2. `#/usr/cluster/bin/scdidadm -r`

The preceding commands update did mappings with new device names while preserving did instance numbers for disks that are connected to multiple cluster nodes. did instance numbers of the local disks might not be preserved. For this reason, the did disk names for local disks might change.

The remaining steps are required only if local did number changes require editing of /etc/vfstab. If such editing is not required, run /usr/cluster/bin/scgdevs from each node in the cluster to complete the procedure.

---

**Notes**

Solaris I/O multipathing is not supported on all devices. After enabling Solaris I/O multipathing, only supported devices are placed under Solaris I/O multipathing control. Non-supported devices remain unchanged.

For Solaris releases prior to the current release, the -e and -d options replace mpxio-disable property entries with a global mpxio-disable entry in fp.conf.

The following applies to Sun StoreEdge T3, 3910, 3960, 6120, and 6320 storage subsystems.

To place your Sun StorEdge disk subsystem under Solaris I/O multipathing control, in addition to enabling Solaris I/O multipathing, the mp_support of the subsystem must be set to mpxio mode. The preferred sequence is to change the subsystem's mp_support to mpxio mode, then run stmsboot -e. If Solaris I/O multipathing is already enabled but the subsystem's mp_support is not in mpxio mode, then change the mp_support to mpxio mode and run stmsboot -u.

Refer to the Sun StorEdge Administrator's Guide for your subsystem for more details.

The ufsdump(1M) command records details of filesystem dumps in /etc/dumpdates (see ufsdump(4)). Among other items, the entries contain device names. An effect of the "active" stmsboot options (-e, -d, and -u) is to change the device name of a storage device.

Because stmsboot does not modify dumpdates, entries will refer to obsolete device names, that is, device names that were in effect before Solaris I/O multipathing configuration changes were performed. In this situation ufsdump will behave as if no previous dump of the filesystem had been performed. A level 0 dump will be performed.

If possible, invoke stmsboot -e before installing Sun Cluster software. After executing stmsboot, install Sun Cluster software normally.

If Sun Cluster software is installed before executing stmsboot, follow this procedure:

On each machine in the cluster where Solaris I/O multipathing is required, execute:

```
# stmsboot -e
```

...and allow the system to reboot.

When the system comes up, enter the following two commands:

1. `#/usr/cluster/bin/scdidadm -C`
2. `#/usr/cluster/bin/scdidadm -r`

The preceding commands update did mappings with new device names while preserving did instance numbers for disks that are connected to multiple cluster nodes. did instance numbers of the local disks might not be preserved. For this reason, the did disk names for local disks might change.

The remaining steps are required only if local did number changes require editing of /etc/vfstab. If such editing is not required, run /usr/cluster/bin/scgdevs from each node in the cluster to complete the procedure.
3. Update /etc/vfstab to reflect any new did disk names for your local disks.
4. Reboot the system.

To disable the Solaris multipathing feature, use stmsboot -d (instead of stmsboot -e), then follow the procedure above.

To view mappings between the old and new device names, run stmsboot -L. To view did device name mappings, run /usr/cluster/bin/scdidadm -L.

With active-passive storage arrays, it is possible that while your host is rebooting the array controller could failover the path that a particular target is using. In this scenario, fsck(1M) will fail to open the physical path listed in /etc/vfstab. The svc:/system/filesystem/local:default SMF service will transition to a maintenance state as a result. To rectify this, consult the documentation for your storage array to failback the path. The mpathadm(1M) can assist with determining the active and passive path(s).

**Limitations**

On x86 platforms, the current Solaris release does not support disabling Solaris I/O multipathing of boot devices attached by means of fibre channel. Solaris I/O multipathing is always enabled for supported fibre channel-attached boot devices. Disabling Solaris I/O multipathing in this situation must be performed on a per-port basis. See fp(7d).

Executing devfsadm -C removes obsolete device entries that stmsboot relies on. This will prevent correct operation of the -d option for boot devices (regardless of platform type) and the -L option.
**Name**  
strace – print STREAMS trace messages

**Synopsis**  
strace [mid sid level]...

**Description**  
strace without arguments writes all STREAMS event trace messages from all drivers and modules to its standard output. These messages are obtained from the STREAMS log driver (see `log(7D)`). If arguments are provided, they must be in triplets of the form mid, sid, level, where mid is a STREAMS module ID number, sid is a sub-ID number, and level is a tracing priority level. Each triplet indicates that tracing messages are to be received from the given module/driver, sub-ID (usually indicating minor device), and priority level equal to, or less than the given level. The token all may be used for any member to indicate no restriction for that attribute.

The format of each trace message output is:

<seq> <time> <ticks> <level> <flags> <mid> <sid> <text>

- `<seq>`: trace sequence number
- `<time>`: time of message in `hh:mm:ss`
- `<ticks>`: time of message in machine ticks since boot
- `<level>`: tracing priority level
- `<flags>`: E: message is also in the error log F: indicates a fatal error N: mail was sent to the system administrator (hardcoded as root)
- `<mid>`: module ID number of source
- `<sid>`: sub-ID number of source
- `<text>`: formatted text of the trace message

Once initiated, strace will continue to execute until terminated by the user.

**Examples**

**EXAMPLE**

A sample output of the `strace` command:

The following example outputs all trace messages from the module or driver whose module ID is 41:

```
strace 41 all all
```

The following example outputs those trace messages from driver or module ID 41 with sub-IDs 0, 1, or 2:

```
strace 41 0 1 41 1 1 41 2 0
```

Messages from sub-IDs 0 and 1 must have a tracing level less than or equal to 1. Those from sub-ID 2 must have a tracing level of 0.

STREAMS Programming Guide

Notes  ▪ There is no restriction to the number of strace processes opening the STREAMS log driver at a time.

▪ The log-driver records the list of the triplets specified in the command invocation, and compares each potential trace message against this list to decide if it should be formatted and sent up to the strace process. Hence, long lists of triplets will have a greater impact on overall STREAMS performance. Running strace will have the most impact on the timing of the modules and drivers generating the trace messages that are sent to the strace process. If trace messages are generated faster than the strace process can handle them, some of the messages will be lost. This last case can be determined by examining the sequence numbers on the trace messages output.
### Name
strclean – STREAMS error logger cleanup program

### Synopsis
strclean [-a age] [-d logdir]

### Description
strclean is used to clean up the STREAMS error logger directory on a regular basis (for example, by using cron. By default, all files with names matching error.* in /var/adm/streams that have not been modified in the last three days are removed.

### Options
The following options are supported:
- `-a age` The maximum age in days for a log file can be changed using the `-a` option.
- `-d logdir` A directory other than `/var/adm/streams` can be specified using the `-d` option.

### Examples
**EXAMPLE**
A sample of using the `strclean` command.

This example has the same result as running `strclean` with no arguments:
```
example% strclean -d /var/adm/streams -a 3
```

### Files
`/var/adm/streams/error.*`

### Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>

**STREAMS Programming Guide**

### Notes
`strclean` is typically run from `cron` on a daily or weekly basis.
strerr - STREAMS error logger daemon

**Synopsis**

`strerr`

**Description**

`strerr` receives error log messages from the STREAMS-based log driver (see `log(7D)`) and appends them to a log file. The resultant error log files reside in the directory `/var/adm/streams`, and are named `error.mm-dd`, where `mm` is the month and `dd` is the day of the messages contained in each log file.

The format of an error log message is:

```markdown
<seq> <time> <ticks> <flags> <mid> <sid> <text>
```

- `<seq>` error sequence number
- `<time>` time of message in hh:mm:ss
- `<ticks>` time of message in machine ticks since boot priority level
- `<flags>` T: the message was also sent to a tracing process F: indicates a fatal error N: send mail to the system administrator (hardcoded as root)
- `<mid>` module ID number of source
- `<sid>` sub-ID number of source
- `<text>` formatted text of the error message

Messages that appear in the error log are intended to report exceptional conditions that require the attention of the system administrator. Those messages which indicate the total failure of a STREAMS-based driver or module should have the F flag set. Those messages requiring the immediate attention of the administrator will have the N flag set, which causes the error logger to send the message to the system administrator using `mail`. The priority level usually has no meaning in the error log but will have meaning if the message is also sent to a tracer process.

Once initiated, `strerr` continues to execute until terminated by the user. It is commonly executed asynchronously.

**Files**

`/var/adm/streams/error.mm-dd` error log file.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

`STREAMS Programming Guide`
There is no restriction to the number of `strerr` processes opening the STREAMS-based log driver at a time.

If a module or driver is generating a large number of error messages, running the error logger will cause a degradation in STREAMS performance. If a large burst of messages are generated in a short time, the log driver may not be able to deliver some of the messages. This situation is indicated by gaps in the sequence numbering of the messages in the log files.

**Notes**
**Name**
sttydefs – maintain line settings and hunt sequences for TTY ports

**Synopsis**
```
/usr/sbin/sttydefs [-a ttylabel [-b] [-f final-flags]
   [-i initial-flags] [-n nextlabel]

/usr/sbin/sttydefs -l [ttylabel]
/usr/sbin/sttydefs -r ttylabel
```

**Description**

sttydefs is an administrative command that maintains the line settings and hunt sequences for the system's TTY ports by making entries in, and deleting entries from the `/etc/ttydefs` file.

sttydefs with a `-a` or `-r` option may be invoked only by the super-user. sttydefs with `-l` may be invoked by any user on the system.

**Options**
The following options are supported:

- `-a ttylabel`
  Add a record to the `ttydefs` file, using `ttylabel` as its label. The following describes the effect of the `-b`, `-n`, `-i`, or `-f` options when used in conjunction with the `-a` option:

- `-b`
  Enable autobaud. Autobaud allows the system to set the line speed of a given TTY port to the line speed of the device connected to the port without the user's intervention.

- `-f final-flags`
  Specify the value to be used in the `final-flags` field in `/etc/ttydefs`. `final-flags` must be in a format recognized by the `stty` command. `final-flags` are the `termio(7I)` settings used by `ttymon` after receiving a successful connection request and immediately before invoking the service on the port. If this option is not specified, `sttydefs` will set `final-flags` equal to the `termio(7I)` flags 9600 and `sane`.

- `-i initial-flags`
  Specify the value to be used in the `initial-flags` field in `/etc/ttydefs`. `initial-flags` must be in a format recognized by the `stty` command. These flags are used by `ttymon` when searching for the correct baud rate. They are set prior to writing the prompt. If this option is not specified, `sttydefs` will set `initial-flags` equal to the `termio(7I)` flag 9600.

- `-n nextlabel`
  Specify the value to be used in the `nextlabel` field in `/etc/ttydefs`. If this option is not specified, `sttydefs` will set `nextlabel` equal to `ttylabel`.

- `-l [ttylabel]`
  If a `ttylabel` is specified, `sttydefs` displays the record from `/etc/ttydefs` whose TTY label matches the specified `ttylabel`. If no `ttylabel` is specified, `sttydefs` displays the entire contents of `/etc/ttydefs`. `sttydefs` verifies that each entry it displays is correct and that the entry's `nextlabel` field references an existing

- `-r ttylabel`
  Remove any record in the `ttydefs` file that has `ttylabel` as its label.
If successful, sttydefs will exit with a status of 0. sttydefs -l will generate the requested information and send it to standard output.

**Examples**

**EXAMPLE 1** A sample of sttydefs command.

The following command lists all the entries in the ttydefs file and prints an error message for each invalid entry that is detected.

```
example# sttydefs -l
```

The following shows a command that requests information for a single label and its output:

```
example# sttydefs -l 9600
```

```
9600:9600 hupcl erase ^h:9600 sane ixany tab3 hupcl erase ^h::4800
```

```
tylabel: 9600
initial flags: 9600 hupcl erase ^h
final flags: 9600 sane ixany tab3 hupcl erase ^h
autobaud: no
nextlabel: 4800
```

The following sequence of commands will add the labels 1200, 2400, 4800, and 9600 and put them in a circular list:

```
sttydefs -a 1200 -n 2400 -i 1200 -f "1200 sane"
sttydefs -a 2400 -n 4800 -i 2400 -f "2400 sane"
sttydefs -a 4800 -n 9600 -i 4800 -f "4800 sane"
sttydefs -a 9600 -n 1200 -i 9600 -f "9600 sane"
```

**Files**
/ etc/ ttydefs

attributes(5), termio(7I)
su (1M)

Name
su – become superuser or another user

Synopsis
su [-] [username [arg...]]

Description
The su command allows one to become another user without logging off or to assume a role. The default user name is root (superuser).

To use su, the appropriate password must be supplied (unless the invoker is already root). If the password is correct, su creates a new shell process that has the real and effective user ID, group IDs, and supplementary group list set to those of the specified username. Additionally, the new shell’s project ID is set to the default project ID of the specified user. See getprojent(3PROJECT), setproject(3PROJECT). The new shell will be the shell specified in the shell field of username’s password file entry (see passwd(4)). If no shell is specified, /usr/bin/sh is used (see sh(1)). If superuser privilege is requested and the shell for the superuser cannot be invoked using exec(2), /sbin/sh is used as a fallback. To return to normal user ID privileges, type an EOF character (CTRL-D) to exit the new shell.

Any additional arguments given on the command line are passed to the new shell. When using programs such as sh, an arg of the form -c string executes string using the shell and an arg of -r gives the user a restricted shell.

To create a login environment, the command “su –” does the following:

- In addition to what is already propagated, the LC* and LANG environment variables from the specified user’s environment are also propagated.
- Propagate TZ from the user’s environment. If TZ is not found in the user’s environment, su uses the TZ value from the TIMEZONE parameter found in /etc/default/login.
- Set MAIL to /var/mail/new_user.

If the first argument to su is a dash (-), the environment will be changed to what would be expected if the user actually logged in as the specified user. Otherwise, the environment is passed along, with the exception of $PATH, which is controlled by PATH and SUPATH in /etc/default/su.

All attempts to become another user using su are logged in the log file /var/adm/sulog (see sulog(4)).

Security
su uses pam(3PAM) with the service name su for authentication, account management, and credential establishment.

Examples
EXAMPLE 1 Becoming User bin While Retaining Your Previously Exported Environment
To become user bin while retaining your previously exported environment, execute:

  example% su bin
EXAMPLE 2  Becoming User bin and Changing to bin's Login Environment

To become user bin but change the environment to what would be expected if bin had originally logged in, execute:

example% su - bin

EXAMPLE 3  Executing command with user bin's Environment and Permissions

To execute command with the temporary environment and permissions of user bin, type:

example% su - bin -c "command args"

Environment Variables

Variables with _LD_ prefix are removed for security reasons. Thus, su bin will not retain previously exported variables with _LD_ prefix while becoming user bin.

If any of the LC_ * variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of su for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_ * variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how su behaves.

LC_CTYPE  Determines how su handles characters. When LC_CTYPE is set to a valid value, su can display and handle text and filenames containing valid characters for that locale. su can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. su can also handle EUC characters of 1, 2, or more columns widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES  Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

Files

$HOME/.profile
  user's login commands for sh and ksh

/etc/passwd
  system's password file

/etc/profile
  system-wide sh and ksh login commands

/var/adm/sulog
  log file

/etc/default/su
  the default parameters in this file are:
SULOG  If defined, all attempts to su to another user are logged in the indicated file.

CONSOLE  If defined, all attempts to su to root are logged on the console.

PATH  Default path. (/usr/bin:)

SUPATH  Default path for a user invoking su to root. (/usr/sbin:/usr/bin)

SYSLOG  Determines whether the syslog(3C) LOG_AUTH facility should be used to log all su attempts. LOG_NOTICE messages are generated for su's to root, LOG_INFO messages are generated for su's to other users, and LOG_CRIT messages are generated for failed su attempts.

/etc/default/login
the default parameters in this file are:

SLEEPTIME  If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

Both su and login(1) are affected by the value of SLEEPTIME.

TIMEZONE  Sets the TZ environment variable of the shell.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>

**sulogin(1M)**

**Name**  
sulogin – access single-user mode

**Synopsis**  
sulogin

**Description**  
The `sulogin` utility is automatically invoked by `init` when the system is first started. It prompts the user to type a user name and password to enter system maintenance mode (single-user mode) or to type EOF (typically CTRL-D) for normal startup (multi-user mode). The user should never directly invoke `sulogin`. The user must have the `solaris.system.maintenance` authorization.

The `sulogin` utility can prompt the user to enter the root password on a variable number of serial console devices, in addition to the traditional console device. See `consadm(1m)` and `msglog(7D)` for a description of how to configure a serial device to display the single-user login prompt.

**Files**  
`/etc/default/sulogin`  
Default value can be set for the following flag:

- **PASSREQ**  
  Determines if login requires a password. Default is `PASSREQ=YES`.

`/etc/default/login`  
Default value can be set for the following flag:

- **SLEEPTIME**  
  If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

  Both `su(1M)` and `login(1)` are affected by the value of `SLEEPTIME`.

**Attributes**  
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

**See Also**  
auths(1), login(1), consadm(1m), init(1M), su(1M), attributes(5), msglog(7D)

**Notes**  
By default, the root user has all authorizations.

Granting the `solaris.system.maintenance` authorization to the Console User Rights Profile may have an undesirable side effect of granting the currently logged in user maintenance mode access. The `solaris.system.maintenance` authorization should be directly granted to appropriate users rather than through the Console User Rights Profile.
suriadm — administer shared objects based on storage URIs

Synopsis
/usr/sbin/suriadm command [options] [operands]

   /usr/sbin/suriadm parse [-H] [-o p,p,...] URI
   /usr/sbin/suriadm map [-H] [-o p,p,...] URI
   /usr/sbin/suriadm lookup-mapping [-H] [-o p,p,...] URI
   /usr/sbin/suriadm unmap URI
   /usr/sbin/suriadm lookup-mapping [-t uri-type] [-H]
                     [-o p,p,...] device-name

Description
The suriadm command line administration tool allows system users to manage storage objects via storage URIs. The command allows to parse, map, unmap, query the state of mappings and look up storage URIs.

Supported Storage URIs
Supported storage URIs are defined in suri(5) manual page.

Sub-commands
The following subcommands are supported:

parse [-H] [-o p,p,...] URI
   Parses a given URI and displays a default list of properties. With -H, a header is omitted from the output. With -o, only properties from the list provided are displayed. The -o option implies output on one line, with property values separated by tabs, meant to be further processed by another command.

   Allowed property names for the -o option are: uri-type, uri, path, mapped-dev, initiator, target, luname, hostname, and port.

map [-H] [-o p,p,...] URI
   Parses a storage URI, configures the storage subsystem if necessary to instantiate a device corresponding to the URI provided, and displays the device path. If the device is already instantiated, the map operation only looks up the device path.

   For an iSCSI URI, this subcommand will add a send-targets discovery address(es) a hostname resolves to if a URI authority section is present.

   For logical unit and dev URI types, this subcommand has no effect on system configuration.

lookup-mapping [-H] [-o p,p,...] URI
   Parses a URI and looks up an existing mapping between a storage URI and the shared storage object represented by a local system device path. Default list of properties is displayed. Options -H and -o have the same meaning as for the parse subcommand.

unmap URI
   Parses and unmaps an object presumably mapped before. Does not display any properties or accept any options.

   For an iSCSI URI, this subcommand removes discovery addresses to which a hostname from a URI authority section resolves, if present.
For logical unit and `dev` URI types, this subcommand has no effect on system configuration.

`lookup-uri [-t uri-type] dev-name`
Looks up and displays URIs based on a local system device path. Allowed URI types for `-t` are `dev`, `lu`, and `iscsi`. If the `-t` option is not specified, the output consists of all URIs that match the device path for any URI type.

### Examples

**EXAMPLE 1** Parsing a URI and Displaying Properties

The following command parses an iSCSI URI and displays a default list of properties.

```bash
$ suriadm parse iscsi://10.0.0.1:3260/luname.naa.0123456789abcdef
PROPERTY VALUE
uri-type iscsi
hostname 10.0.0.1
port 3260
luname naa.0123456789abcdef
```

**EXAMPLE 2** Mapping an iSCSI URI and Displaying a Device Name

The following command maps an iSCSI URI and displays a mapped local system device name. The effect of this command is to automatically add a `send-targets` discovery address if one is not already present.

```bash
$ suriadm suriadm map iscsi://127.0.0.1/luname.naa.\600144F0F4977D4000004F7EC8F00001
PROPERTY VALUE
mapped-dev /dev/dsk/c0t600144F0F4977D4000004F7EC8F00001d0s2
```

**EXAMPLE 3** Looking Up Mapping

The following command looks up an existing iSCSI mapping.

```bash
$ suriadm lookup-mapping iscsi://127.0.0.1/luname.naa.\600144F0F4977D4000004F7EC8F00001
PROPERTY VALUE
mapped-dev /dev/dsk/c0t600144F0F4977D4000004F7EC8F00001d0s2
```

**EXAMPLE 4** Parsing a Logical Unit URI

The following command parses an initiator/target/luname logical unit URI.

```bash
$ suriadm parse lu:initiator.naa.2101001b32ae7ab5,\target.naa.2100001d38009fb0,luname.naa.500000e012942880
PROPERTY VALUE
uri-type lu
luname naa.500000e012942880
initiator naa.2101001b32ae7ab5
target naa.2100001d38009fb0
```
EXAMPLE 5  Mapping a Logical Unit URI, Looking Up URIs
The following command sequence maps a logical unit URI, then looks up the matched logical unit URIs based on a found device name.

```
$ suriadm map lu:luname.naa.5000c5000288fa25
PROPERTY       VALUE
mapped-path    /dev/dsk/c7t26d0s2
```

```
$ suriadm lookup-uri -t lu /dev/dsk/c7t26d0s2
lu:luname.naa.5000c5000288fa25
lu:initiator.naa.500605b000ae7010,target.naa.\n5001636000019c11,naa.5000c5000288fa25
```

EXAMPLE 6  Looking Up Matching URIs
The following command looks up all URIs that match a specific device name without specifying a URI type.

```
$ suriadm lookup-uri /dev/dsk/c7t26d0s2
lu:luname.naa.5000c5000288fa25
lu:initiator.naa.500605b000ae7010,target.naa.\n5001636000019c11,naa.5000c5000288fa25
dev:dsk/c7t26d0s2
```

EXAMPLE 7  Parsing a URI, Displaying Selected Properties
The following command parses a URI and displays only selected properties, all on the same line, separated by tabs, and with no header.

```
$ suriadm map -Ho uri-type,luname,mapped-path \
lu:luname.naa.5000c5000288fa25
lu       naa.5000c5000288fa25 /dev/dsk/c7t26d0s2
```

EXAMPLE 8  Looking Up Logical Unit URIs
The following command looks up logical unit URIs for a device accessible by means of multiple paths.

```
$ suriadm lookup-uri -t lu /dev/dsk/c11t200000001d38089fb0d0
lu:luname.naa.2000001d38089fb0
lu:initiator.naa.2101001b32ae7ab5,target.naa.2100001d38089fb0,luname.\nnaa.2000001d38089fb0
lu:initiator.naa.2100001b328e7ab5,target.naa.2200001d38089fb0,luname.\nnaa.2000001d38089fb0
```

EXAMPLE 9  Trying to Parse Incorrect URI
The following command attempts to parse a syntactically incorrect URI.

```
$ suriadm parse lu:luname.naa.0123456789
Failed to parse URI "lu:luname.naa.0123456789": GUID part in "luname.naa.GUID" not 16 or 32 character hexadecimal
```
EXAMPLE 9  Trying to Parse Incorrect URI  (Continued)

number: "0123456789"

EXAMPLE 10  Trying to Map LU URI with Inaccessible LU

The following command attempts to map an LU URI with a logical unit name not accessible from the system.

$ suriadm map lu:luname.naa.0123456789abcdef
Failed to map URI "lu:luname.naa.0123456789abcdef": No such logical unit "naa.0123456789abcdef" found

EXAMPLE 11  Looking Up URI for Non-Existent Device Path

The following command attempts to lookup a URI for a non-existent device path.

$ suriadm lookup-uri /dev/dsk/nonexistent
Failed to map "/dev/dsk/nonexistent" to URI: No such device: "/dev/dsk/nonexistent"

Exit Status  0
  Command succeeded.

>0
  Command failed.

Small Computer System Interface-3 (SCSI-3)

Notes  When an iSCSI URI is used, the svc:/network/iscsi/initiator service must be enabled, unless a parse operation is being performed. If this service is disabled and an iSCSI URI is being processed, the iSCSI initiator service will be automatically enabled temporarily. The service is never disabled through the suriadm command.
svadm(1M)

Name  svadm – command line interface to control Availability Suite Storage Volume operations

Synopsis  svadm -h
          svadm -v
          svadm [-C tag]
          svadm [-C tag] -i
          svadm [-C tag] -e { -f config_file | volume}
          svadm [-C tag] -d { -f config_file | volume}
          svadm [-C tag] -r { -f config_file | volume}

Description  The svadm command controls the Storage Volume (SV) driver by providing facilities to enable and disable the SV driver for specified volumes, and to dynamically reconfigure the system.

Options  If you specify no arguments to an svadm command, the utility displays the list of volumes currently under SV control. svadm supports the following options:

- -C tag
  On a clustered node, limits operations to only those volumes belonging to the cluster resource group, or disk group name, specified by tag. This option is illegal on a system that is not clustered. The special tag, local, can be used to limit operations to only those volumes that cannot switch over to other nodes in the cluster.

- -d
  Disables the SV devices specified on the command line or in the configuration file. If -C tag is specified with this option, then the volume should be in this cluster disk group.

- -e
  Enables the SV devices specified on the command line or in the configuration file. Details of the volume are saved in the current configuration. See dscfg(1M). If -C tag is specified with this option, then the volume should be in this cluster disk group.

- -f config_file
  Specifies a configuration file that contains a list of volumes. A command reads this volume list and then performs the operation. The format of the config_file is a simple list of volume pathnames, one per line. Blank lines and lines starting with the comment character (#) are ignored.

- -h
  Displays the svadm usage summary.

- -i
  Displays extended status for the volumes currently under SV control.

- -r
  When a config_file is specified, reconfigure the running system to match the configuration specified in the config_file. When the -C option is specified, compare the cluster tag for each
volume and change it to `cluster_tag`. If a volume is specified with this option, it is valid only to reconfigure the cluster tag associated with the volume. The `-e` or `-d` options should be used to enable or disable single volumes.

```
-v
```
Displays the SV version number.

**Usage**
When an SV volume is enabled, normal system call access to the device (see `Intro(2)`) is redirected into the StoreEdge architecture software. This allows standard applications to use StorageTek features such as Sun StorageTek Point-in-Time Copy and Remote Mirror Software.

The `svadm` command generates an entry in the Availability Suite log file, `/var/adm/ds.log` (see `ds.log(4)`), when performing enable (-e) and disable (-d) operations.

svcadm – manipulate service instances

Synopsis

```
svcadm [-v] enable [-rst] {FMRI | pattern}...
/svcadm [-v] disable [-st] {FMRI | pattern}...
/svcadm [-v] restart {FMRI | pattern}...
/svcadm [-v] refresh {FMRI | pattern}...
/svcadm [-v] clear {FMRI | pattern}...
/svcadm [-v] mark [-It] instance_state
  {FMRI | pattern}...
/svcadm [-v] delegate [-s] restarter_FMRI svc|inst_FMRI
  [ svc|inst_FMRI ... ]
/svcadm [-v] milestone [-d] milestone_FMRI
```

Description

svcadm issues requests for actions on services executing within the service management facility (see smf(5)). Actions for a service are carried out by its assigned service restarter agent. The default service restarter is svc.startd (see svc.startd(1M)).

Options

The following options are supported:

- v  Print actions verbosely to standard output.

Subcommands

Common Operations

The subcommands listed below are used during the typical administration of a service instance.

For subcommands taking one or more operands, if the operand specifies a service (instead of a service instance), and that service has only a single instance, svcadm operates on that instance. If an abbreviated FMRI (a fault management resource identifier) or pattern matches more than one service, a warning message is displayed and that operand is ignored. See smf(5).

In the case that the service has more than one instance, svcadm return a non-zero exit status.

enable [-rst] {FMRI | pattern}... Enables the service instances specified by the operands. For each service instance, the assigned restarter will try to bring it to the online state. This action requires permission to modify the "general" property group of the service instance (see smf_security(5)).

If the -r option is specified, svcadm enables each service instance and recursively enables its dependencies.
If the -s option is specified, svcadm enables each service instance and then waits for each service instance to enter the online or degraded state. svcadm will return early if it determines that the service cannot reach these states without administrator intervention.

If the -t option is specified, svcadm temporarily enables each service instance. Temporary enable only lasts until reboot. This action requires permission to modify the "restarter_actions" property group of the service instance (see smf_security(5)). By default, enable is persistent across reboot.

**disable [-st] [FMRI|pattern]...**

Disables the service instance specified by the operands. For each service instance, the assigned restarter will try to bring it to the disabled state. This action requires permission to modify the "general" property group of the service instance (see smf_security(5)).

If the -s option is specified, svcadm disables each service instance and then waits for each service instance to enter the disabled state. svcadm will return early if it determines that the service cannot reach this state without administrator intervention.

If the -t option is specified, svcadm temporarily disables each service instance. Temporary disable only lasts until reboot. This action requires permission to modify the "restarter_actions" property group of the service instance (see smf_security(5)). By default, disable is persistent across reboot.

**restart [FMRI|pattern]...**

Requests that the service instances specified by the operands be restarted. This action requires permission to modify the "restarter_actions" property group of the service instance (see smf_security(5)). Restarting a service is implemented by most restarters as a full service "stop" followed by a "start".

This subcommand can restart only those services that are in the online or degraded states, as those states are defined in smf(5).

**refresh [FMRI|pattern]...**

For each service instance specified by the operands, requests that the assigned restarter update the service's running configuration snapshot with the values from
the current configuration. Some of these values take effect immediately (for example, dependency changes). Other values do not take effect until the next service restart. See the restarter and service documentation for more information.

If the service is managed by `svc.startd(1M)`, the `refresh` method will be invoked if it exists to request the service reread its own configuration. For other restarters, see the restarter documentation.

This action requires permission to modify the “restarter_actions” property group of the service instance (see `smf_security(5)`).

clear [FMRI] pattern... For each service instance specified by the operands, if the instance is in the maintenance state, signal to the assigned restarter that the service has been repaired. If the instance is in the degraded state, request that the assigned restarter take the service to the online state. This action requires permission to modify the “restarter_actions” property group of the service instance (see `smf_security(5)`).

Exceptional Operations

The following subcommands are used for service development, management of services by higher level frameworks, and temporary administrative manipulation.

delegate [-s] restarter_FMRI svc|inst_FMRI [ svc|inst_FMRI ... ]
Change the restarter assignment for the given `inst_FMRI` to the restarter specified by `restarter_FMRI`. The special token `master` will set the delegated restarter to the master restarter, `svc.startd(1M)`. The special token `reset` will set the delegated restarter back to the original, file-backed restarter by removing the restarter customization. Redelegation requires a restart operation to take effect. Not all restarters support the same underlying application model, so not all potential delegations will result in a functioning service instance; see the manual page for the specific restarters involved in the operation to determine compatibility.

If the restarter does not exist or is disabled, the service instances will not be delegated and an error will be returned. If the restarter exists but is in an offline or maintenance state, the instances will be delegated but may not transition back to an online state. A warning message will be printed.

If the `-s` option is specified, `svcadm` delegates each service instance and then waits for each service instance to enter the online state, if previously online, or waits for the general/restarter property group or property to be updated. `svcadm` will return early if it determines that the service cannot reach these states without administrator intervention.
mark [-It] instance_state [FMRI | pattern]...

If instance_state is "maintenance", then for each service specified by the operands, svcadm requests that the assigned restarter place the service in the maintenance state. See svc.startd(1M) and inetd(1M) for a detailed description of the actions taken for each restarter.

If instance_state is "degraded", then for services specified by the operands in the online state, svcadm requests that the restarters assigned to the services move them into the degraded state.

If the -I option is specified, the request is flagged as immediate.

The -t option is only valid for maintenance requests. When this option is specified, the request is flagged as temporary, and its effect will only last until the next reboot.

milestone [-d] milestone_FMRI

If milestone_FMRI is the keyword "none", all services other than the master restarter, svc:/system/svc/restarter:default, will be temporarily disabled.

If milestone_FMRI is the keyword "all", temporary enable and disable requests for all services will be nullified.

If milestone_FMRI is one of the following:

svc:/milestone/single-user:default
svc:/milestone/multi-user:default
svc:/milestone/multi-user-server:default

then temporary enable and disable requests for the indicated service and all services it depends on (directly or indirectly) will be nullified. All other services will be temporarily disabled.

Changing the system’s current milestone with the “milestone” subcommand will not change the current run level of the system. To change the system’s run level, invoke /usr/sbin/init directly.

This action requires permission to modify the “options_ovr” property group of the svc:/system/svc/restarter:default service instance (see smf_security(5)).

The -d option immediately changes the milestone to the requested milestone, as above. Additionally, it makes the specified milestone the default boot milestone, which persists across reboot. The default milestone is defined by the options/milestone property on the master restarter, svc:/system/svc/restarter:default. If this property is absent, "all" is the default. This action requires permission to modify the “options” property group of the svc:/system/svc/restarter:default service instance (see smf_security(5)).
Operands  The following operands are supported:

FMRI   An FMRI that specifies one or more instances. FMRIs can be abbreviated by specifying the instance name, or the trailing portion of the service name. For example, given the FMRI:

    svc:/network/smtp:sendmail

All the following are valid abbreviations:

    sendmail
    :sendmail
    smtp
    smtp:sendmail
    network/smtp

While the following are invalid:

    mail
    network
    network/smt

If the FMRI specifies a service, then the command applies to all instances of that service. Abbreviated forms of FMRIs are unstable, and should not be used in scripts or other permanent tools.

pattern   A pattern that is matched against the FMRIs of service instances according to the “globbing” rules described by fnmatch(5). If the pattern does not begin with “svc:”, then “svc:/” is prepended.

If an abbreviated FMRI or pattern matches more than one service, a warning message is displayed and that operand is ignored.

Examples  EXAMPLE 1  Restarting a Service Instance

The following command restarts the NFS server. The full FMRI for the default service instance is: svc:/network/nfs/server:default

However, you can abbreviate the full FMRI as follows:

    # svcadm restart nfs/server

EXAMPLE 2  Disabling the Standard HTTP Server

The following command disables the standard HTTP server, using an abbreviated FMRI:

    $ svcadm disable http
EXAMPLE 3  Enabling an Instance and Its Dependent Instances
The following command enables the foo:bar instance, and all instances on which it depends:
$ svcadm enable -r foo:bar

EXAMPLE 4  Synchronously enabling an instance
The following command enables the foo:bar instance. The command will not return until the instance comes online or svcadm determines it is not possible for the service to come online.
$ svcadm enable -s foo:bar

EXAMPLE 5  Restricting and Restoring the Running Services
The following command restricts the running services to single user mode:
# svcadm milestone milestone/single-user
The following command restores the running services:
# svcadm milestone all

Exit Status  The following exit values are returned:
0  Successful completion.
1  A fatal error occurred. One or more error messages are displayed on standard error.
2  Invalid command line options were specified.
3  svcadm determined that a service instance that it was waiting for could not reach the desired state without administrator intervention due to a problem with the service instance itself.
4  svcadm determined that a service instance that it was waiting for could not reach the desired state without administrator intervention due to a problem with the service’s dependencies.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The interactive output is Uncommitted. The invocation and non-interactive output are Committed.
The amount of time `svcadm` will spend waiting for services and their dependencies to change state is implicitly limited by their method timeouts. For example, a service using the default restarter whose start method hangs will be transitioned to the maintenance state when its timeout expires. `svcadm` will then consider it impossible for this service to come online without administrator intervention.

Attempts to synchronously enable a service which depends (directly or indirectly) on a file may fail with an exit status indicating that dependencies are unsatisfied if the caller does not have the privileges necessary to search the directory containing the file. This limitation may be removed in a future Solaris release.

Attempts to synchronously enable a service which depends (directly or indirectly) on a file may fail with an exit status indicating that dependencies are unsatisfied if the caller does not have the privileges necessary to search the directory containing the file. This limitation may be removed in a future Solaris release.
svcbundle(1M)

Name
svcbundle – create an SMF service bundle

Synopsis
svcbundle [-i | -o output_file] -s name=value...
svcbundle help [name]

Description
The svcbundle command is used to generate SMF manifests. The manifest is specified by multiple -s options. To generate a manifest, you must specify service-name and start-method. The other NV pairs are optional and allow the user to specify more details of the service. The svccfg(1M) validate command will be run on the generated manifest to detect any templating conflicts.

You can also use svcbundle to generate profiles. See bundle-type below.

The second synopsis prints a help message on standard out listing all legal names. Alternatively, you can specify help and a name to see a discussion of legal values for that name.

In order to reduce the burden on the user, svcbundle makes several simplifying assumptions when generating a manifest. You can edit the generated manifest if these assumptions are not correct for your application:

- The generated manifest is intended to be used with the master restarter, svc.startd(1M).
- A dependency on svc:/milestone/multi-user will be generated to keep the service from starting too early. See rc.script below for an exception to this.
- The bundle name will be the same as the value provided for service-name.
- Timeouts for all exec_methods will be 60 seconds.

By using the -i option, you can get svcbundle to do much of the work of installing the service. It will automatically save the generated manifest in /lib/svc/manifest/site or the profile in /etc/svc/profile/site. The name of the generated file will be the basename of the service name that is specified with -s service-name, and the file will have an .xml extension. Warning: svcbundle will overwrite any existing file with that name.

svcbundle will then restart the manifest-import service to process the newly created file and incorporate it into SMF. In the manifest case, svcbundle will then wait for the service to enter a final state -- one of online, disabled, or maintenance. At the start of this wait period, svcbundle will print:

svcbundle: waiting for service to reach final_state state

...where final_state is enabled or disabled. It is safe to interrupt svcbundle after this message appears.

Clearly, to use the -i option, you need sufficient authorizations to create the file in these restricted directories and to restart the manifest-import service. See smf_security(5).
This section discusses name/value (NV) pairs. The generated bundle is entirely defined by the use of multiple -s options on the command line. Each NV pair is of the form name=value where name and name come from this list:

**bundle-type**
Type of service bundle to generate. Legal values are manifest and profile. manifest is the default.

**duration**
Synonym for model.

**enabled**
Indicates whether or not the instance should be enabled. Legal values are true and false. The default value is true.

**model**
Sets the service model. This is the value of the startd/duration property. Refer to `svc.startd(1M)`. Model can be set to one of the following values:
- contract
- daemon — synonym for contract
- child
- wait — synonym for child
- transient

The default is transient.

**instance-name**
Name of the instance. The default value is default.

**instance-property=pg_name:prop_name:prop_type:value**
**service-property=pg_name:prop_name:prop_type:value**
These options are used to create a property group named pg_name in the instance or service, and it will have a type of application. The PG will have a single property named prop_name with a single value that is of type prop_type. Property groups with multiple properties can be created by invoking *-property multiple times. Zero or more *-property= declarations can be used.

The property type can be defaulted by using two consecutive colons. See “Examples,” below. For manifests, a default property type of astring will be used. Profiles do not require that the property be specified, since it can usually be determined from other sources of information.

**rc-script=script_path:run_level**
This NV pair causes svcbundle to emit a manifest that facilitates conversion of a legacy rc script to an SMF service. script_path is the path to the rc script and run_level is the run level (see `init(1M)`) where the rc script runs. script_path is used to generate the start and stop exec_method elements in the manifest. The exec attribute will be set to:
script_path

`run_level` is used to generate dependencies, so that the script runs at the appropriate time during booting.

refresh-method

The command to execute when a service is refreshed. Whitespace is allowed in the value. The value can include method tokens introduced by a percent sign (`%`), as documented in `smf_method(5)`. The default value is `:true`.

service-name

Name of the service. This NV pair is required.

start-method

The command to execute when the service is started. Whitespace is allowed in the value. The method tokens that are introduced by `%` as documented in `smf_method(5)` are allowed and will be placed in the manifest for expansion by the restarter. `:true` is allowed. This NV pair is required for manifests unless the `rc-script` NV pair is specified. It is not required for profiles.

stop-method

The command to execute when the service is stopped. It accepts values like start-method and also accepts `:kill`. `:true` is the default value for transient services and `:kill` for contract and child services.

Options

The following command-line options are supported:

- `i`
  Install the generated file. See "Description" for details.

- `o output_file`
  Specifies the name of the file to be created.

- `s name=value`
  Specifies a name/value pair. See "Extended Description" for details.

If neither `-i` nor `-o` are specified, the generated file will be written to stdout.

Examples

EXAMPLE 1  Creating Manifest for Transient Service

The following command creates a manifest for a simple transient service. Since transient services are the default for `svcbundle`, you can specify the manifest with just two options.

```
# svcbundle -s service-name=site/sneezy \
-s start-method=/lib/svc/method/sneezy
```

EXAMPLE 2  Creating Manifest for Daemon Service

The following command creates a manifest for a daemon service.

```
# svcbundle -s service-name=site/sneezy \
-s start-method=/lib/svc/method/sneezy \
```
EXAMPLE 2  Creating Manifest for Daemon Service  (Continued)

-s model=daemon

EXAMPLE 3  Creating Manifest for Daemon Service with Stop and Refresh Commands

The following command creates a manifest for a daemon service with stop and refresh commands.

# svcbundle -s service-name=site/sleepy \ 
-s start-method="/lib/svc/method/sleepy %m" \ 
-s stop-method="/lib/svc/method/sleepy %m" \ 
-s refresh-method="/lib/svc/method/sleepy %m" \ 
-s model=daemon

EXAMPLE 4  Creating Manifest with Instance Properties

The following command creates a manifest with instance properties.

# svcbundle -s service-name=system/happy \ 
-s start-method="/lib/svc/method/happy" \ 
-s instance-property=config:velocity:count:50 \ 
-s instance-property=config:color:astring:red

The generated manifest will create a service instance with a config property group containing two properties, velocity and color.

EXAMPLE 5  Creating Manifest for rc Script Conversion

The following command creates a manifest to assist in converting an rc script. This example assumes that the rc script runs at the multiuser level and does not start a daemon.

# svcbundle -s service-name=doc \ 
-s rc-script="/etc/init.d/doc:2"

The conscientious user will modify the rc script to include /lib/svc/share/smf_include.sh.

EXAMPLE 6  Generating Profile to Modify Service Property

The following command generates a profile to set the nfsmapid_domain property of the grumpy service.

# svcbundle -s bundle-type=profile \ 
-s service-name=network/nfs/grumpy \ 
-s service-property=nfs-props:nfsmapid_domain:astring:grumpy

EXAMPLE 7  Using the Default Property Type

The following command sets the property type for config/color defaults to astring.
**EXAMPLE 7** Using the Default Property Type  

```bash
# svcbundle -s service-name=system/happy \
-s start-method=/lib/svc/method/happy \ 
-s instance-property=config:color::red
```

**EXAMPLE 8** Installing the Manifest

The following command uses the `-i` option to install the manifest. In this example the generated manifest will be written to `/lib/svc/manifest/site/bashful.xml`, since `bashful` is the basename of the service name.

```bash
# svcbundle -i -s service-name=application/bashful \ 
-s start-method=/opt/bashful/start
```

svcbundle: waiting for application/bashful to reach enabled state

**Attributes** See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

**See Also** svs(1), init(1M), svc.startd(1M), svccfg(1M), service_bundle(4), attributes(5), smf_method(5), smf_security(5), smf_template(5)
Name  svccfg – import, export, and modify service configurations

Synopsis  
/usr/sbin/svccfg [-v] [-s FMRI]

/usr/sbin/svccfg [-v] [-s FMRI] subcommand [args]...

/usr/sbin/svccfg [-v] [-s FMRI] -f command-file

Description  The svccfg command manipulates data in the service configuration repository. svccfg can be invoked interactively, with an individual subcommand, or by specifying a command file that contains a series of subcommands.

Changes made to an existing service in the repository typically do not take effect for that service until the next time the service instance is refreshed. See the refresh subcommand, below, or the refresh subcommand in the svcadm(1M) man page for more details.

Options  The following options are supported:

 `-f command-file`
   Reads and executes svccfg subcommands from command-file.

 `-s FMRI`
   Selects the entity indicated by FMRI (a fault management resource identifier) before executing any subcommands. If `-f command-file` is not provided and no subcommands are specified on the command line, then masked entities will be treated as nonexistent. See smf(5).

 `-v`
   Verbose.

Subcommands  Subcommands are divided into the categories specified in the subsections that follow.

All subcommands that accept FMRI also accept abbreviated or globbed patterns. Instances and services can be abbreviated by specifying the instance name, or the trailing portion of the service name. For example, given the FMRI:

svc:/network/smtp:sendmail

All the following are valid abbreviations:

 sendmail
 :sendmail
 smtp
 smtp:sendmail
 network/smtp

While the following are invalid:

 mail
 network
 network/smt
Abbreviated forms of FMRIs are unstable, and should not be used in scripts or other permanent tools. If a pattern matches more than one instance or service, an error message is printed and no action is taken.

**General Subcommands**

end
exit
quit

Exits immediately.

repository [-p prefix] repfile

Uses repfile as a repository. By default, svccfg(1M) uses the system repository.

Use repository only with files from the identical version of Solaris, including patches, that you are currently running. Do not use this subcommand with the system repository, /etc/svc/repository.db.

If you use svccfg repository to pre-populate the SMF repository before deployment time, use -p option to specify the root prefix for the system standard location for manifests imported with import. This prefix will be replaced by /lib/svc/manifest and /var/svc/manifest once the repository is on a live system. If manifests from your -p directory do not appear in a system standard location at runtime, the services associated with them will be removed.

set [-v|-V]

Sets optional behavior. If no options are specified, set displays the options currently in effect.

- v
  Turns on verbose mode.

- V
  Turns off verbose mode.

**Service Manifest and Profile Subcommands**

apply [-n] [-v] file | directory

If the argument is a service profile or manifest, apply the configuration to the admin layer of the SMF repository. Services, instances, property groups, and properties will be created as necessary.

If the type attribute of a property or property group is unspecified, an attempt will be made to determine the type from existing type settings or from the service template. If a type cannot be determined, a warning will be presented and the service will be skipped so inconsistent data will not be introduced into a service and instance. Nonexistent services and instances are ignored.

To use the relaxed element definitions in a profile, the following definitions need to be added to the DOCTYPE entry:

`<!ENTITY % profile "INCLUDE">`
`<!ENTITY % manifest "IGNORE">`
Services and instances modified by the profile will be refreshed. If -n is specified, the profile is processed and no changes are applied to the SMF repository. Any syntax error found will be reported on stderr and an exit code of 1 will be returned. See smf(5) for a description of service profiles. This command requires privileges to modify properties in the service and instance. See smf_security(5) for the privileges required to modify properties.

Services and instances in the manifest or profile will be validated against template data in the manifest and the repository, and warnings will be issued for all template violations. See smf_template(5) for a description of templates. If the -V option is specified, manifests that violate the defined templates will fail to import. In interactive invocations of svccfg, -V is the default behavior.

If the argument to apply is a directory, all profiles found under that directory tree will get applied as described above. The subcommand fails if a specified file or any file found under a specified directory is not a service profile.

extract [-a] [-l layer] [fmri] [ > file]
Displays a service profile for the specified FMRI or the whole system if an FMRI is not specified.

If -l is supplied, a list of layers can be selected from which to extract values. The -l option requires a layer name and takes the arguments: manifest, system-profile, site-profile, admin, current, all. current and all are synonyms, and select the highest-layer values. Multiple layers can be comma-separated or specified with multiple -l options.

If -l is not supplied, the default is -l admin, site-profile.

If a property is defined in multiple selected layers, only the highest layer is exported in the profile.

Without the -a option, property groups containing protected information (identified by the presence of the read_authorization property—see smf_security(5)) will be extracted without their property values. When the -a option is specified, all values will be extracted. An error results if there are insufficient privileges to read these values.

If an FMRI is given and that FMRI is a service, the profile will contain customizations only for that service and the instances of the service. If the provided FMRI is an instance, the profile will contain customizations for the service and the instance provided.

export [-a] service_FMRI [ > file]
Running svccfg export is equivalent to:

svccfg extract -l current [-a] service_FMRI [ > file]

import [-V] [file | directory]
svccfg import on a file in a system-managed filesystem location (subdirectories of /lib/svc/manifest and /var/svc/manifest) invokes: svcadm restart manifest-import.
Placing your manifests in a system-managed location and invoking svcadm restart manifest-import to import them is the recommended practice.

svccfg import on files in other locations imports their properties as administrative customization into the admin layer. It is equivalent to:

svccfg apply [file | directory]

inventory file
If file is determined to be a service manifest or profile, then the FMRI of the services and instances the file describes are printed. For each service, the FMRI of its instances are displayed before the FMRI of the service.

validate [file | fmri]
The validate subcommand can operate on a manifest file, an instance FMRI, or the current instance or snapshot entity selection. When an argument is specified, svccfg will check to see whether the specified file exists. If the file exists, it will be validated. If a file of the specified name does not exist, the argument is treated as an FMRI pattern. If a conflict arises between a filename and an FMRI, use the svc: and file: prefixes to tell svccfg how to interpret the argument.

When you specify a file, the file is processed in a manner similar to import -V, but no changes are made to the repository. If any errors are detected, svccfg displays the errors and exits with a nonzero exit status.

For an instance fmri, instance entity selection, or snapshot entity selection, the specified instance in its composed form (see “Properties and Property Groups” in smf(5)) will be validated against template data in the repository. Instance FMRI and instance entity selections use the “running” snapshot for validation. Warnings will be issued for all template violations. See smf_template(5) for a description of templates.

An "entity" refers to a scope, service, or service instance.

add name
A new entity with the given name is created as a child of the current selection. See smf_security(5) for the privileges required to create entities.

delete [-f] {name | fmri}
The named child of the current selection or the entity specified by fmri is deleted. Attempts to delete service instances in the “online” or “degraded” state will fail unless the -f flag is specified. If a service or service instance has a "dependents" property group of type "framework", then for each of its properties with type "astring" or "fmri", if the property has a single value which names a service or service instance then the dependency property group in the indicated service or service instance with the same name as the property will be deleted. See smf_security(5) for the privileges required to delete service configurations.
Invoking the `delete` subcommand with an FMRI that identifies a service with a manifest in a standard location only masks, and does not delete, that service's definition. To delete a service, you must delete its manifest, then restart the manifest-import service with the following command:

```
# svcadm restart manifest-import
```

Note that reimporting a manifest does not remove a mask.

Use the `liscust` subcommand with the `-M` option to list masked services. See EXAMPLES for an example of unmasking a service.

See `smf(5)` for a description of the Oracle Solaris service management facility.

```
list [pattern]
```

The child entities of the current selection whose names match the glob pattern `pattern` are displayed (see `fnmatch(5)`). ‘properties’ is also listed for property-bearing entities, namely services and service instances.

```
refresh
```

Commit the values from the current configuration to the running snapshot, making them available for use by the currently selected instance. If the repository subcommand has not been used to select a repository, direct the instance's restarter to reread the updated configuration. If the selection is a service, all instances of the service will be refreshed.

```
select {name | fmri}
```

If the argument names a child of the current selection, it becomes the current selection. Otherwise, the argument is interpreted as an FMRI and the entity that the argument specifies becomes the current selection.

```
unselect
```

The parent of the current selection becomes the current selection.

```
addpg name type [flags]
```

Adds a property group with the given `name` and type to the current selection. `flags` is a string of characters which designates the flags with which to create the property group. 'P' represents SCF_PG_FLAG_NONPERSISTENT (see `scf_service_add_pg(3SCF)`). See `smf_security(5)` for the privileges required to create property groups.

```
addpropvalue pg/name [type:] value
```

Adds the given value to a property. If `type` is given and the property exists, then if `type` does not agree with the property's `type`, the subcommand fails. If the `pg` does not exist, `addpropvalue` will create one if it can find the `pg` type and flags in the template definitions. If the selection is an instance, `addpropvalue` will look for the `pg` type and flags in the service before looking up the template definitions. If no `pg` type and flags are found, the subcommand will fail. The values may be enclosed in double-quotes. String values containing double-quotes or backslashes must be enclosed by double-quotes and the contained double-quotes and backslashes must be quoted by backslashes. Nonexistent properties are created, in which case the `type` specifier must be present. See
SCF_VALUE_CREATE(3SCF) for a list of available property types. See SMF_SECURITY(5) for the privileges required to modify properties. The new value will be appended to the end of the list of property values associated with the property.

delcust [-M] [pattern]
Delete any administrative customizations for the current selection. If an argument is supplied, it is taken as a glob pattern and only property groups and properties with names that match the argument are deleted.

If there is no current selection, no changes are made and the subcommand fails.

If -M is supplied, delete only masked entities.

To see what customizations delcust would remove, use listcust with the same options. As delcust can potentially remove all administrative customizations on the current selection, always run listcust first to determine you are removing what you intend to.

delpg name
Deletes the property group name of the current selection. See SMF_SECURITY(5) for the privileges required to delete property groups.

If the property group is backed by a manifest or profile, it is masked. See SMF(5).

delprop pg[/name]
Deletes the named property group or property of the current selection. See SMF_SECURITY(5) for the privileges required to delete properties.

delpropvalue pg/name globpattern
Deletes all values matching the given glob pattern in the named property. Succeeds even if no values match. See SMF_SECURITY(5) for the privileges required to modify properties.

describe [-v] [-t] [propertygroup/property]
Describes either the current or the possible settings.

When invoked without arguments, describe gives basic descriptions (if available) of the currently selected entity and all of its currently set property groups and properties. A property group or specific property can be queried by specifying either the property group name, or the property group name and property name, separated by a slash (/), as an argument.

The -v option gives all information available, including descriptions for current settings, constraints, and other possible setting choices.

The -t option shows only the template data for the selection (see SMF_TEMPLATE(5)), and does not display the current settings for property groups and properties.

editprop [-a]
Comments of commands to reproduce the property groups and properties of the current selection are placed in a temporary file and the program named by the VISUAL environment variable is invoked to edit it. If VISUAL is not defined, EDITOR is used instead. If both
environment variables are not defined, then the default editor vi(1) is used. Upon completion, the commands in the temporary file are executed. See smf_security(5) for the privileges required to create, modify, or delete properties.

By default editprop will not display SMF infrastructure property groups such as framework, dependency, templates, firewall, and notification parameters or properties templated with visibility hidden. If an instance is selected, the composed view of the properties are placed in the temporary file. The -a option will place all properties in the temporary file, including properties in SMF infrastructure property groups and those templated with visibility hidden.

`listpg [pattern]`
Displays the names, types, and flags of property groups of the current selection. If an argument is given, it is taken as a glob pattern and only property groups with names which match the argument are listed.

In interactive mode, a basic description of the property groups is also given.

`listprop [-l layer...] [-f | -o format] [pattern]`
Lists property groups and properties of the current selection. For property groups, names, types, and flags are listed. For properties, names (prepended by the property group name and a slash (/)), types, and values are listed. See scf_value_create(3SCF) for a list of available property types. If an argument is supplied it is taken as a glob pattern and only property groups and properties with names which match the argument are listed.

With the -l option, print the layer the value came from. The -l option requires a layer, and takes the arguments: manifest, system-profile, site-profile, admin, current, all. current prints the same property values as listprop without -l, along with the layer that value was defined in.

The -f and -o options are mutually exclusive. -f prints the file, if any, a property came from. -o allows field selection. Selectable fields include:

```
proppname       the property name
pgname          the property group name
instname        the instance name
servicename     the service name
layer           the layer
proptype        the property type
value           the property value
file            the source file
masked          whether the property group or property is currently masked
time            the time this property last changed
```
setenv [-i | -s] [-m method_name] envvar value
Sets a method environment variable for a service or instance by changing the
“environment” property in the method_name property group, if that property group has
type “method”. If method_name is not specified and the -i option is used, the
“method_context” property group is used, if an instance is currently selected. If the -s
option is used and a service is currently selected, its “method_context” property group is
used. If the -s option is used and an instance is currently selected, the “method_context”
property group of its parent is used. If neither the -i option nor the -s option is used, the
“start” property group is searched for in the currently selected entity and, if an instance is
currently selected, its parent is also searched. If the “inetd_start” property group is not
located, it is searched for in a similar manner.

Once the property is located, all values which begin with envvar followed by a “=” are
removed, and the value “envvar=value” is added. See smf_security(5) for the privileges
required to modify properties.

setprop pg/name = [[type: value]
setprop pg/name = [type: ] ([values ...])
Sets the name property of the pg property group of the current selection to the given values
of type type. See scf_value_create(3SCF) for a list of available property types. If the pg
does not exist setprop will create one if it can find the pg type and flags in the template
definitions. If the selection is an instance, setprop will look for the pg type and flags in the
service before looking up the template definitions. If no pg type and flags are found, the
subcommand will fail. If the named property does not exist, it is created, as long as the type
is specified. If the property already exists and the type disagrees with the existing type on
the property, the subcommand fails. If no type and no value are provided, setprop will
delete all values for the pg/name. Values may be enclosed in double-quotes. String values
which contain double-quotes or backslashes must be enclosed by double-quotes and the
contained double-quotes and backslashes must be quoted by backslashes. Multiple values
will be stored in the order in which they are specified. See smf_security(5) for the privileges
required to create or modify properties.

unsetenv [-i | -s] [-m method_name] envvar
Removes a method environment variable for a service or instance by changing the
“environment” property in the method_name property group, if that property group has
type “method”. If `method_name` is not specified and the `-i` option is used, the "method_context" property group is used, if an instance is currently selected. If the `-s` option is used and a service is currently selected, its "method_context" property group is used. If the `-s` option is used and an instance is currently selected, the "method_context" property group of its parent is used. If neither the `-i` option nor the `-s` option is used, the "start" property group is searched for in the currently selected entity and, if an instance is currently selected, its parent is also searched. If the "inetc_start" property group is not located, it is searched for in a similar manner.

Once the property is located, all values which begin with `envvar` followed by "=" are removed. See `smf_security(5)` for the privileges required to modify properties.

### setnotify

Sets notifications parameters for software events and Fault Management problem lifecycle events in the SMF repository.

#### -g

Used to set system-wide notification parameters for SMF state transition. See `smf(5)`. These notification parameters are set in `svc:/system/svc/global:default` regardless of any `svccfg` current selection. This subcommand refreshes all instances it modifies.

#### class

Comma-separated list of FMA Event classes or aliases. See `smf(5)` Notification Parameters.

#### tset

Comma-separated list of SMF state transitions. See `smf(5)` Notification Parameters.

#### notification parmeters

URI format for each notification mechanism implemented: For SMTP use:

```
mailto:addr[?header1=value1[&header2=value2]]
```

...or:

```
mailto:{[active] | [inactive]}
```

...and for SNMP traps use:

```
snmp:{[active] | [inactive]}
```

The parameter `msg_template` defined in `smtp-notify(1M)` can be set as a header value in the `mailto` URI. For example:

```
mailto:root@localhost?msg_template=<path to template file>
```

SNMP traps are directed to the host as defined by the `trapsink` directive in `/etc/net-snmp/snmp/snmpd.conf` or as specified by the SNMP trap notification daemon. See `smtp-notify(1M)`.

The notification parameters are specific to the class or tset specified and overwrite preexisting notification parameters. The active/inactive form does not overwrite
previous notification parameters. It just switches on or off the notification mechanism for the specified class or tset. Setting notification parameters implicitly sets them as active.

```
listnotify [-g] [tset] | class
```

Displays the existing notification parameters for the specified class or tset. With the -g option, the notification parameters in svc:/system/svc/global:default are displayed. If tset is omitted, all is implied.

```
delnotify [-g] tset | class
```

Delete the existing notification parameters for the specified class or tset. With the -g option, the notification parameters in svc:/system/svc/global:default are deleted.

```
listsnap
```

Displays snapshots available for the currently selected instance.

```
revert [snapshot]
```

Reverts the administrative customizations of the currently selected instance and its service to those recorded in the named snapshot. If no argument is given, use the currently selected snapshot and deselect it on success. The changed property values can be made active via the refresh subcommand of svcadm(1M). See smf_security(5) for the privileges required to change properties.

```
selectsnap [name]
```

Changes the current snapshot to the one named by name. If no name is specified, deselect the currently selected snapshot. Snapshots are read-only.

```
refresh
```

Commit the values from the current configuration to the running snapshot, making them available for use by the currently selected instance. If the repository subcommand has not been used to select a repository, direct the instance’s restarter to reread the updated configuration.

**Examples**

**EXAMPLE 1  Importing a Service Description**

The following example imports a service description for the seismic service in the XML manifest specified on the command line.

```
# svccfg import /var/svc/manifest/site/seismic.xml
```

Note that the manifest must follow the format specified in service_bundle(4).

**EXAMPLE 2  Exporting a Service Description**

To export a service description on the local system:

```
# svccfg export dumpadm > /tmp/dump.xml
```
EXAMPLE 3  Deleting a Service Instance
To delete a service instance:

# svccfg delete network/inetd-upgrade:default

EXAMPLE 4  Checking Properties in an Alternate Repository
To examine the state of a service's properties after loading an alternate repository, use the sequence of commands shown below. One might use such commands, for example, to determine whether a service was enabled in a particular repository backup.

# svccfg
svc:/> repository /etc/svc/repository-boot
svc:/> select telnet:default
svc:/network/telnet:default> listprop general/enabled
general/enabled boolean false
svc:/network/telnet:default> exit

EXAMPLE 5  Enabling Debugging
To modify LD_PRELOAD for a start method and enable the use of libumem(3LIB) with debugging features active:

$ svccfg -s system/service setenv LD_PRELOAD libumem.so
$ svccfg -s system/service setenv UMEM_DEBUG default

EXAMPLE 6  Using describe Subcommand
The following command illustrates the use of the describe subcommand.

# svccfg -s console-login describe ttymon
  ttymon     application
  ttymon/device  astring /dev/console
     terminal device to be used for the console login prompt
  ttymon/label   astring console
     appropriate entry from /etc/ttydefs
  ...

EXAMPLE 7  Configuring Notification Preferences
The following command configures notification preferences for SMF service state transition events.

# svccfg setnotify -g from-online,to-maintenance \ mailto:admin@somehost.com

EXAMPLE 8  Enabling SNMP Notifications
The following command enables SNMP notifications for Fault Management events.

# svccfg setnotify problem-diagnosed,problem-updated \ mailto:admin@somehost.com snmp:
**EXAMPLE 9  Listing Notification Settings**

The following command lists notification settings for Fault Management events.

```
# svccfg listnotify problem-diagnosed,problem-updated
Event: problem-diagnosed
  Notification Type: smtp
    active: true
    to: admin@somehost.com
  Notification Type: snmp
    active: true

Event: problem-updated
  Notification Type: smtp
    active: true
    to: admin@somehost.com
  Notification Type: snmp
    active: true
```

**EXAMPLE 10  Unmasking a Service**

The following sequence of commands shows the existence of the service `mysvc`, that `mysvc` is masked, and finally unmask the service.

```
$ svcs -l mysvc
fmri    svc:/system/mysvc:default
name    Manifest to test snapshots
enabled true
state   online
next_state none
state_time January 13, 2012 09:42:55 AM MST
logfile /var/svc/log/system-mysvc:default.log
restarter svc:/system/svc/restarter:default
manifest /lib/svc/manifest/test/mysvc.xml
dependency require_all/none svc:/system/filesystem/local (online)

[ Note manifest file in standard location. ]

# svccfg delete -f mysvc
$ svcs mysvc
svcs: Pattern 'mysvc' doesn't match any instances
STATE    STIME    FMRI

[ Not listed because service is masked. ]

$ svccfg listcust -M | grep mysvc
svc:/system/mysvc manifest MASKED
  manifestfiles/lib_svc_manifest_test_mysvc_xml astring admin \ MASKED /lib/svc/manifest/test/mysvc.xml
svc:/system/mysvc:default manifest MASKED
EXAMPLE 10  Unmasking a Service  (Continued)

[ First line, above, shows that service is masked. Masking is propagated down, so the instance is also masked as shown in the last line. ]

# svcfg -s svc:/system/mysvc delcust
Deleting customizations for service: system/mysvc
$ svcscs mysvc
STATE   STIME       FMRI
online   9:48:25   svc:/system/mysvc:default

[ Masking has been removed. ]

EXAMPLE 11  Setting a Multi-Value Property

The following command sets a multi-value property. Note that the property is enclosed in single quotes so that the parentheses and double quotes do not need to be escaped.

# svcfg -s svc:/stooges setprop foo/bar = astring:\n\'("moe" "Curly" "Larry")\'

EXAMPLE 12  Clearing All Values from a Property Using setprop

The following command uses setprop to clear all values from a property.

# svcfg -s svc:/stooges setprop foo/bar =

EXAMPLE 13  Clearing All Values from a Property Using delpropvalue

The following command uses delpropvalue to clear all values from a property.

# svcfg -s svc:/stooges delpropvalue foo/bar *

EXAMPLE 14  Setting Property with Embedded Whitespace

The following command shows the correct use of quotation marks when setting a property whose value is a string with embedded whitespace.

# svcfg -s svc:inst setprop pg/prop = astring "without single quotes, shells eat double quotes"

Environmental Variables

EDITOR  The command to run when the editprop subcommand is used. The default editor is vi(1).

Exit Status  The following exit values are returned:

0  Successful execution.
One or more subcommands resulted in failure. Error messages are written to the standard error stream.

Invalid command line options were specified.

svc.configd is the repository daemon for the Service Management Facility. svc.configd is invoked automatically during system startup, and restarted if any failures occur. svc.configd should never be invoked directly.

Interaction with svc.configd is by way of libscf(3LIB) and the command line tools: svcs(1), svcprop(1), svcadm(1M), and svccfg(1M).

Name  svc.ipfd – IP Filter firewall monitoring daemon

Synopsis  /lib/svc/bin/svc.ipfd

svc:/network/ipfilter:default

Description  The svc.ipfd daemon monitors actions on services that use firewall configuration and initiates update services’ IP Filter configuration. The daemon allows the system to react to changes in system’s firewall configuration in an incremental fashion, at a per-service level.

A service’s firewall policy is activated when it is enabled, deactivated when it is disabled, and updated when its configuration property group is modified. svc.ipfd monitors the services management facility (SMF) repository for these actions and invokes the IP Filter rule-generation process to carry out the service’s firewall policy.

This daemon is started by the network/ipfilter service either through the start or refresh method. Thus, the daemon inherits the environment variables and credentials from the method and runs as root with all zone privileges.

Firewall Static Configuration  A static definition describes a service’s network resource configuration that is used to generate service-specific IPF rules. The per-service firewall_context property group contains a service’s static definition, similar to the inetd property group in inetd managed services. This property group supports:

firewall_context/name
  For non-inetd services. The IANA name or RPC name, equivalent to the inetd/name property.

firewall_context/isrpc
  For non-inetd services. A boolean property where a true value indicates an RPC service, equivalent to the inetd/isrpc property. For RPC services, the value of firewall_context/name is not an IANA name but is either an RPC program number or name. See rpc(4).

Additionally, some services may require a mechanism to generate and supply their own IPF rules. An optional property ipf_method, provides a mechanism to allow such custom rule generation:

firewall_context/ipf_method
  A command. Normally a script that generates IPF rules for a service. The framework does not generate rules for services with this property definition. Rather, the framework expects these services to provide their own rules.

A service’s ipf_method specifies a command that takes an additional argument, its own fault management resource identifier (FMRI), and generates the service’s firewall rules and outputs those rules to stdout. To generate rules for a service with the ipf_method property, the framework execs the command specified in ipf_method, passing the service FMRI as the additional argument, and stores the rules for that service by redirecting the command output,
the rules, to the service's rule file. Because an `ipf_method` is executed from the context of either the `network/ipfilter start` or `refresh` method process, it inherits the execution context and runs as root.

The service static configuration is delivered by the service developer and not intended to be modified by users. These properties are only modified upon installation of an updated service definition.

**Firewall Policy Configuration**
A per-service property group, `firewall_config`, stores the services' firewall policy configuration. Because `network/ipfilter:default` is responsible for two firewall policies, the Global Default and Global Override system-wide policies (as explained in `ipfilter(5)`), it has two property groups, `firewall_config_default` and `firewall_config_override`, to store the respective system-wide policies.

Below are the properties, their possible values, and corresponding semantics:

**policy**
The policy has the following modes:

- **none policy mode**
  No access restriction. For a global policy, this mode allows all incoming traffic. For a service policy, this mode allows all incoming traffic to its service.

- **deny policy mode**
  More restrictive than none. This mode allows incoming traffic from all sources except those specified in the `apply_to` property.

- **allow policy mode**
  Most restrictive mode. This mode blocks incoming traffic from all sources except those specified in the `apply_to` property.

**apply_to**
A multi-value property listing network entities to enforce the chosen policy mode. Entities listed in `apply_to` property will be denied if policy is deny and allowed if policy is allow.

The syntax for possible values are:

- **host**: `host:IP` e.g. `host:192.168.84.14`
- **subnet**: `network:IP/netmask` e.g. `network:129.168.1.5/24`
- **ippool**: `pool:pool number` e.g. `pool:77`
- **interface**: `if:interface_name` e.g. `if:e1000g0`

**exceptions**
A multi-value property listing network entities to be excluded from the `apply_to` list. For example, when deny policy is applied to a subnet, exceptions can be made to some hosts in that subnet by specifying them in the exceptions property. This property has the same value syntax as `apply_to` property.

For individual network services only:
firewall_config/policy
A service's policy can also be set to use_global. Services with use_global policy mode inherits the Global Default firewall policy.

For the Global Default only:

firewall_config_default/policy
Global Default policy, firewall_config property group in svc:/network/ipfilter:default, can also be set to custom. Users can set policy to custom to use prepopulated IP Filter configuration, for example, an existing IP Filter configuration or custom configurations that cannot be provided by the framework. This Global Default-only policy mode allows users to supply a text file containing the complete set of IPF rules. When custom mode is selected, the specified set of IPF rules is complete and the framework will not generate IPF rules from configured firewall policies.

firewall_config_default/custom_policy_file
A file path to be used when Global Default policy is set to custom. The file contains a set of IPF rules that provide the desired IP Filter configuration. For example, users with existing IPF rules in /etc/ipf/ipf.conf can execute the following commands to use the existing rules:

1. Set custom policy:
   
   `# svccfg -s ipfilter:default setprop \
   firewall_config_default/policy = astring: "custom"`

2. Specify custom file:
   
   `# svccfg -s ipfilter:default setprop \
   firewall_config_default/custom_policy_file = astring: \
   
   
   
   "\n   
   /etc/ipf/ipf.conf"`

3. Refresh configuration:
   
   `# svcadm refresh ipfilter:default`

firewall_config_default/open_ports
Non-service program requiring allowance of its incoming traffic can request that the firewall allow traffic to its communication ports. This multi-value property contains protocol and port(s) tuple in the form:

"{tcp | udp}:{PORT | PORT-PORT}"

Initially, the system-wide policies are set to none and network services' policies are set to use_global. Enabling network/ipfilter activates the firewall with an empty set of IP Filter rules, since system-wide policy is none and all services inherit that policy. To configure a more restrictive policy, use svccfg(1M) to modify network services and system-wide policies.

A user configures firewall policy by modifying the service's firewall_config property group. A new authorization, solaris.smf.value.firewall.config, is created to allow delegation

svc.ipfd(1M)
of the firewall administration privilege to users. Users with Service Operator privileges will need this new authorization to be able to configure firewall policy.

**Firewall Availability**

During boot, a firewall is configured for enabled services prior to the starting of those services. Thus, services are protected on boot. While the system is running, administrative actions such as service restarting, enabling, and refreshing may cause a brief service vulnerability during which the service runs while its firewall is being configured.

`svc.ipfd` monitors a service's start and stop events and configures or unconfigures a service's firewall at the same time that SMF is starting or stopping the service. Because the two operations are simultaneous, there is a possible window of exposure (less than a second) if the service is started before its firewall configuration completed. RPC services typically listen on ephemeral addresses, which are not known until the services are actually running. Thus RPC services are subjected to similar exposure since their firewalls are not configured until the services are running.

**Developer Documentation**

Services providing remote capabilities are encouraged to participate in the firewall framework to control network access to the service. While framework integration is not mandatory, remote access to services that are not integrated in the framework may not function correctly when a system-wide policy is configured.

Integrating a service into the framework is as straightforward as defining two additional property groups and their corresponding properties in the service manifest. IP Filter rules are generated when a user enables the service. In the non-trivial case of custom rule generation, where a shell script is required, there are existing scripts that can be used as examples.

The additional property groups, `firewall_config` and `firewall_context`, stores firewall policy configuration and provides static firewall definition, respectively. Below is a summary of new property groups and properties and their appropriate default values.

**Firewall policy configuration:**

`firewall_config`

Access to the system is protected by a new authorization definition and a user-defined property type. The new authorization should be assigned to the property group `value_authorization` property in a way such as:

```
<propval name='value_authorization' type='astring'
value='solaris.smf.value.firewall.config' />
```

A third party should follow the service symbol namespace convention to generate a user-defined type. Sun-delivered services can use `com.sun.fw_configuration` as the property type.

See “Firewall Policy Configuration,” above, for more information.

`firewall_config/policy`

This property's initial value should be `use_global` since services, by default, inherit the Global Default firewall policy.
firewall_config/apply_to
An empty property, this property has no initial value.

firewall_config/exceptions
An empty property, this property has no initial value.

Firewall static definition:

firewall_context
A third party should follow service symbol namespace convention to generate a
user-defined type, Sun delivered services can use com.sun/fw_definition as the property
type.

See “Firewall Static Configuration,” above, for more information.

firewall_context/name
Service with well-known, IANA defined port, which can be obtained by
getservbyname(3SOCKET). The service's IANA name is stored in this property. For RPC
services, the RPC program number is stored in this property.

firewall_context/isrpc
For RPC services, this property should be created with its value set to true.

firewall_context/ipf_method
In general, the specified firewall policy is used to generate IP Filter rules to the service's
communication port, derived from the firewall_context/name property. Services that do
not have IANA-defined ports and are not RPC services will need to generate their own IP
Filter rules. Services that generate their own rules may choose not to have
firewall_context/name and firewall_context/isrpc properties. See the following
services:

svc:/network/ftp:default
svc:/network/nfs/server:default
svc:/network/ntp:default

...and others with the ipf_method for guidance.

Name  svc.startd – Service Management Facility master restarter

Synopsis  /lib/svc/bin/svc.startd

svc:/system/svc/restarter:default

Description  svc.startd is the master restarter daemon for Service Management Facility (SMF) and the default restarter for all services. svc.startd starts, stops, and restarts services based on administrative requests, system failures, or application failures.

svc.startd maintains service state, as well as being responsible for managing faults in accordance with the dependencies of each service.

svc.startd is invoked automatically during system startup. It is restarted if any failures occur. svc.startd should never be invoked directly.

See smf_restarter(5) for information on configuration and behavior common to all restarters.

svcs(1) reports status for all services managed by the Service Configuration Facility. svcadm(1M) allows manipulation of service instances with respect to the service’s restarter.

Environment Variables  Environment variables with the “SMF_” prefix are reserved and may be overwritten.

svc.startd supplies the “SMF_” environment variables specified in smf_method(5) to the method. PATH is set to “/usr/sbin:/usr/bin” by default. By default, all other environment variables supplied to svc.startd are those inherited from init(1M).

Duplicate entries are reduced to a single entry. The value used is undefined. Environment entries that are not prefixed with “<name>=” are ignored.

Restarter Options  svc.startd is not configured by command line options. Instead, configuration is read from the service configuration repository. You can use svccfg(1M) to set all options and properties.

The following configuration variables in the options property group are available to developers and administrators:

boot_messages

An astring (as defined in scf_value_is_type; see scf_value_create(3SCF)) that describes the default level of messages to print to the console during boot. The supported message options include quiet and verbose. The quiet option prints minimal messages to console during boot. The verbose option prints a single message per service started to indicate success or failure. You can use the boot -m option to override the boot_messages setting at boot time. See kernel(1M).

logging

Control the level of global service logging for svc.startd. An astring (as defined in scf_value_is_type; see scf_value_create(3SCF)) that describes the default level of messages to log to syslog (see syslog(3C) and svc.startd’s global logfile,
The supported message options include `quiet`, `verbose`, and `debug`. The `quiet` option sends error messages requiring administrative intervention to the console, `syslog` and `svc.startd`'s global log file. The `verbose` option sends error messages requiring administrative intervention to the console, `syslog` and `svc.startd`'s global log file, and information about errors which do not require administrative intervention to `svc.startd`'s global log file. A single message per service started is also sent to the console. The `debug` option sends `svc.startd` debug messages to `svc.startd`'s global log file, error messages requiring administrative intervention to the console, `syslog` and `svc.startd`'s global log file, and a single message per service started to the console.

**milestone**
An FMRI which determines the milestone used as the default boot level. Acceptable options include only the major milestones:

```
svc:/milestone/single-user:default
svc:/milestone/multi-user:default
svc:/milestone/multi-user-server:default
```

or the special values `all` or `none`. `all` represents an idealized milestone that depends on every service. `none` is a special milestone where no services are running apart from the master `svc:/system/svc/restarter:default`. By default, `svc.startd` uses `all`, a synthetic milestone that depends on every service. If this property is specified, it overrides any `initdefault` setting in `inittab(4)`.

**system/reconfigure**
Indicates that a reconfiguration reboot has been requested. Services with actions that must key off of a reconfiguration reboot may check that this property exists and is set to 1 to confirm a reconfiguration boot has been requested.

This property is managed by `svc.startd` and should not be modified by the administrator.

Configuration errors, such as disabling `svc.startd` are logged by `syslog`, but ignored.

**SERVICE STATES**
Services managed by `svc.startd` can appear in any of the states described in `smf(5)`. The state definitions are unmodified by this restarter.

**SERVICE REPORTING**
In addition to any logging done by the managed service, `svc.startd` provides a common set of service reporting and logging mechanisms.

Reporting properties `svc.startd` updates a common set of properties on all services it manages. These properties are a common interface that can be used to take action based on service instance health. The `svcs(1)` command can be used to easily display these properties.

**restarter/state**
**restarter/next_state**
The current and next (if currently in transition) state for an instance.
restarter/auxiliary_state
A caption detailing additional information about the current instance state. The auxiliary state available for services managed by svc.startd is:

    maintenance
    fault_threshold_reached
    stop_method_failed
    administrative_request
    custom

disabled

restarter/auxiliary_custom_state
When restarter/auxiliary_custom_state is set to custom, a method-provided caption detailing additional information about the current instance state.

restarter/auxiliary_reason
When restarter/auxiliary_custom_state is set to custom, a method-provided string detailing additional information about the current instance state.

restarter/auxiliary_textdomain
When restarter/auxiliary_custom_state is set to custom, a method-provided textdomain in which restarter/auxiliary_reason may be localized.

restarter/state_timestamp
The time when the current state was reached.

restarter/contract
The primary process contract ID, if any, that under which the service instance is executing.

Logs

By default, svc.startd provides logging of significant restarter actions for the service as well as method standard output and standard error file descriptors to

/var/svc/log/service:instance.log. The level of logging to system global locations like

/var/svc/log svc.startd.log and syslog is controlled by the options/logging property.

SERVICE DEFINITION
When developing or configuring a service managed by svc.startd, a common set of properties are used to affect the interaction between the service instance and the restarter.

Methods

The general form of methods for the fork/exec model provided by svc.startd are presented in smf_method(5). The following methods are supported as required or optional by services managed by svc.startd.

refresh Reload any appropriate configuration parameters from the repository or config file, without interrupting service. This is often implemented using SIGHUP for
Start the service. Return success only after the application is available to consumers. Fail if a conflicting instance is already running, or if the service is unable to start.

This method is required.

Stop the service. In some cases, the stop method can be invoked when some or all of the service has already been stopped. Only return an error if the service is not entirely stopped on method return.

This method is required.

If the service does not need to take any action in a required method, it must specify the :true token for that method.

svc.startd honors any method context specified for the service or any specific method. The method expansion tokens described in smf_method(5) are available for use in all methods invoked by svc.startd.

Properties

An overview of the general properties is available in smf(5). The specific way in which these general properties interacts with svc.startd follows:

general/enabled

If enabled is set to true, the restarter attempts to start the service once all its dependencies are satisfied. If set to false, the service remains in the disabled state, not running.

general/restarter

If this FMRI property is empty or set to svc:/system/svc/restarter:default, the service is managed by svc.startd. Otherwise, the restarter specified is responsible (once it is available) for managing the service.

general/single_instance

If single_instance is set to true, svc.startd only allows one instance of this service to transition to online or degraded at any time.

Additionally, svc.startd managed services can define the optional properties listed below in the startd property group.

startd/duration

The duration property defines the service's model. It can be set to transient, child also known as "wait" model services, or contract (the default).
**startd/ignore_error**

The `ignore_error` property, if set, specifies a comma-separated list of ignored events. Legitimate string values in that list are `core` and `signal`. The default is to restart on all errors.

**startd/need_session**

The `need_session` property, if set to true, indicates that the instance should be launched in its own session. The default is not to do so.

**startd/utmpx_prefix**

The `utmpx_prefix` string property defines that the instance requires a valid utmpx entry prior to start method execution. The default is not to create a utmpx entry.

---

**SERVICE METHOD SPECIAL REQUESTS**

A service may use `smf_method_exit()` to request special consideration for the state transition in progress. If such requests are made by means of `exit()`, without using `smf_method_exit()`, they will be treated as described in SERVICE FAILURES below.

When a start or refresh method requests `$SMF_EXIT_TEMP_DISABLE`, `svc.startd` will temporarily disable the service and place it in the disabled state without running its stop method. If appropriate, the start or refresh method may explicitly invoke the stop method to gracefully shut down any processes it may have started prior to returning `$SMF_EXIT_TEMP_DISABLE`.

When a contract service requests `$SMF_EXIT_TEMP_TRANSIENT` from a start or refresh method, `svc.startd` will complete the service transition currently in progress, and will treat the service as if it were transient.

When a stop method requests `$SMF_EXIT_TEMP_DISABLE` or `$SMF_EXIT_TEMP_TRANSIENT`, `svc.startd` will treat it as if it had returned `$SMF_EXIT_ERR_OK`.

When a non-contract service requests `$SMF_EXIT_TEMP_TRANSIENT` from a start or refresh method, `svc.startd` will treat it as if it had returned `$SMF_EXIT_ERR_OK`.

**SERVICE FAILURE**

Except under the conditions described in SERVICE METHOD SPECIAL REQUESTS, `svc.startd` assumes that a method has failed if it returns a non-zero exit code or if it fails to complete before the timeout specified expires. If `$SMF_EXIT_ERR_CONFIG` or `$SMF_EXIT_ERR_FATAL` is returned, `svc.startd` immediately places the service in the maintenance state. For all other failures, `svc.startd` places the service in the offline state. If a service is offline and its dependencies are satisfied, `svc.startd` tries again to start the service (see `smf(5)`).

If a contract or transient service does not return from its start method before its defined timeout elapses, `svc.startd` sends a `SIGKILL` to the method, and returns the service to the offline state.

If five failures happen in a row, or if the service is restarting due to an error more than once every ten minutes, `svc.startd` places the service in the maintenance state.

The conditions of service failure are defined by a combination of the service model (defined by the `startd/duration` property) and the value of the `startd/ignore_error` property.
A contract model service fails if any of the following conditions occur:

- all processes in the service exit
- any processes in the service produce a core dump
- a process outside the service sends a service process a fatal signal (for example, an administrator terminates a service process with the `pkill` command)

The last two conditions may be ignored by the service by specifying `core` and/or `signal` in `startd/ignore_error`.

Defining a service as transient means that `svc.startd` does not track processes for that service. Thus, the potential faults described for contract model services are not considered failures for transient services. A transient service only enters the maintenance state if one of the method failure conditions occurs.

“wait” model services are restarted whenever the child process associated with the service exits. A child process that exits is not considered an error for “wait” model services, and repeated failures do not lead to a transition to maintenance state.

LEGACY SERVICES  
`soc.startd` continues to provide support for services invoked during the startup run level transitions. Each `/etc/rc?.d` directory is processed after all managed services which constitute the equivalent run level milestone have transitioned to the online state. Standard init scripts placed in the `/etc/rc?.d` directories are run in the order of their sequence numbers.

The milestone to run-level mapping is:

<table>
<thead>
<tr>
<th>milestone</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>milestone/single-user</td>
<td>Single-user (S)</td>
</tr>
<tr>
<td>milestone/multi-user</td>
<td>Multi-user (2)</td>
</tr>
<tr>
<td>milestone/multi-user-server</td>
<td>Multi-user with network services (3)</td>
</tr>
</tbody>
</table>

Additionally, `soc.startd` gives these legacy services visibility in SMF by inserting an instance per script into the repository. These legacy instances are visible using standard SMF interfaces such as `svcs(1)`, always appear in the LEGACY-RUN state, cannot be modified, and cannot be specified as dependencies of other services. The initial start time of the legacy service is captured as a convenience for the administrator.

Files

| `/var/svc/log` | Directory where `soc.startd` stores log files. |
| `/etc/svc/volatile` | Directory where `soc.startd` stores log files in early stages of boot, before `/var` is mounted read-write. |

Example  
**EXAMPLE 1**  
Turning on Verbose Logging

To turn on verbose logging, type the following:
EXAMPLE 1  Turning on Verbose Logging  (Continued)

    # /usr/sbin/svccfg -s system/svc/restarter:default
    svc:/system/svc/restarter:default> addpg options application
    svc:/system/svc/restarter:default> setprop options/logging = \ 
    astring: verbose
    svc:/system/svc/restarter:default> exit

This request will take effect on the next restart of svc.startd.

The `swap` utility provides a method of adding, deleting, and monitoring the system swap areas used by the memory manager.

### Options

The following options are supported:

```bash
/usr/sbin/swap -a [swapname] [swaplow] [swaplen]
```

Add the specified swap area. This option can only be used by an administrator who is assigned the File System Management rights profile or by root. `swapname` is the name of the swap area or regular file. For example, on system running a UFS root file system, specify a slice, such as `/dev/dsk/c0t0d0s1`, or a regular file for a swap area. On a system running a ZFS file system, specify a ZFS volume, such as `/dev/zvol/dsk/rpool/swap`, for a swap area. Using a regular file for swap is not supported on a ZFS file system. In addition, you cannot use the same ZFS volume for both the swap area and a dump device when the system is running a ZFS root file system.

`swaplow` is the offset in 512-byte blocks into the file where the swap area should begin. `swaplen` is the desired length of the swap area in 512-byte blocks. The value of `swaplen` can not be less than 16. For example, if `n` blocks are specified, then `(n-1)` blocks would be the actual swap length. `swaplen` must be at least one page in length. The size of a page of memory can be determined by using the `pagesize` command. See `pagesize(1)`. Since the first page of a swap file is automatically skipped, and a swap file needs to be at least one page in length, the minimum size should be a multiple of 2 pagesize bytes. The size of a page of memory is machine-dependent.

`swaplow + swaplen` must be less than or equal to the size of the swap file. If `swaplen` is not specified, an area will be added starting at `swaplow` and extending to the end of the designated file. If neither `swaplow` nor `swaplen` are specified, the whole file will be used except for the first page. Swap areas are normally added automatically during system startup by the `/usr/sbin/swapadd` script. This script adds all swap areas which have been specified in the `/etc/vfstab` file; for the syntax of these specifications, see `vfstab(4)`.

You can encrypt a ZFS volume used as a swap device by specifying the `encrypted` option in `vfstab(4)` and specifying the `encryption` property for the ZFS volume. See `zfs(1M)`.

To use an NFS or local file system `swapname`, you should first create a file using `mkfile(1M)`. A local file system swap file can now be added to the running system by just running the `swap -a` command. For NFS mounted swap files, the server needs to export the file. Do this by performing the following steps:

1. Add the following line to `/etc/dfs/dfstab:`
2. Run `shareall(1M)`.

3. Have the client add the following line to `/etc/vfstab`:

   ```
   server:path-to-swap-file - local-path-to-swap-file nfs \
   - - local-path-to-swap-file - - swap - -
   ```

4. Have the client run `mount`:

   ```
   # mount local-path-to-swap-file
   ```

5. The client can then run `swap -a` to add the swap space:

   ```
   # swap -a local-path-to-swap-file
   ```

   **-d** `swapname`

   Delete the specified swap area. This option can only be used by the super-user. `swapname` is the name of the swap file: for example, `/dev/dsk/c0t0d0s1` or a regular file. `swaplow` is the offset in 512-byte blocks into the swap area to be deleted. If `swaplow` is not specified, the area will be deleted starting at the second page. When the command completes, swap blocks can no longer be allocated from this area and all swap blocks previously in use in this swap area have been moved to other swap areas.

   **-h**

   All sizes are scaled to a human readable format. Scaling is done by repetitively dividing by 1024.

   **-k**

   Write the files sizes in units of 1024 bytes.

   **-l**

   List the status of all the swap areas. The output has five columns:

   path
   The path name for the swap area.

   dev
   The major/minor device number in decimal if it is a block special device; zeroes otherwise.

   swaplo
   The `swaplow` value for the area in 512-byte blocks.

   blocks
   The `swaplen` value for the area in 512-byte blocks.

   free
   The number of 512-byte blocks in this area that are not currently allocated.
The list does not include swap space in the form of physical memory because this space is not associated with a particular swap area.

If `swap -l` is run while `swapname` is in the process of being deleted (by `swap -d`), the string INDEL will appear in a sixth column of the swap stats.

```
-s
```
Print summary information about total swap space usage and availability:

- `allocated`  
The total amount of swap space in bytes currently allocated for use as backing store.

- `reserved`  
The total amount of swap space in bytes not currently allocated, but claimed by memory mappings for possible future use.

- `used`  
The total amount of swap space in bytes that is either allocated or reserved.

- `available`  
The total swap space in bytes that is currently available for future reservation and allocation.

These numbers include swap space from all configured swap areas as listed by the `-l` option, as well swap space in the form of physical memory.

**Usage**  
A block device larger than 2 Gbytes can be fully utilized for swap up to $2^{63} - 1$ bytes.

**Environment Variables**  
See `environ(5)` for descriptions of the following environment variables that affect the execution of `swap`: `LC_CTYPE` and `LC_MESSAGE`.

**Attributes**  
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

**See Also**  
`pagesize(1), mkfile(1M), shareall(1M), zfs(1M), getpagesize(3C), vfstab(4), attributes(5), largefile(5)`

**Notes**  
For information about setting up a swap area with ZFS, see the `ZFS Administration Guide`.

**Warnings**  
No check is done to determine if a swap area being added overlaps with an existing file system.
The `sxadm` command controls and configures Solaris security extensions both at the system level (global zone, non-global zone) and at the process level (`/usr/sbin/sxadm exec`).

The `enable` and `disable` subcommands enable and disable a given security extension system-wide. The `-c` option passes extension-specific configuration information to enable. The `delcust` subcommand resets an extension to the out-of-the-box default configuration.

The `info` subcommand reports the status of security extensions for the current zone. The `-p` option produces easily parseable output for external consumers.

The `exec` subcommand allows you to control the status of a given security extension at the process level. The specified command is executed with the security extension configured as expressed by any `-s extension=value` entry following the `exec` subcommand. Security extensions that are configured on the command line are inherited by child processes.

Security extensions for a process are determined during `exec(2)` and become effective for a process upon exit from the `exec(2)` system call. Extensions persist for the lifetime of the process until the process exits or calls `exec(2)` again.

ASLR activates the randomization of key areas of the process such as stack, `brk`-based heap, memory mappings, and so forth.

By default, the global zone and all non-global zones boot with ASLR enabled only for tagged binaries. Tagged binaries are built using the link-editor's `-z aslr` option. See the Address Space Layout Randomization (ASLR) section in the *Developer's Guide to Oracle Solaris 11 Security* for more details. Many core Solaris binaries are tagged with ASLR enabled. The `sxadm enable, disable, and restore` subcommands can be used to configure ASLR system-wide.

ASLR configuration values for `sxadm enable` are:

- `model=all`  
  Enable ASLR for all processes.

- `model=tagged-files`  
  Enable ASLR for tagged binaries only.

- `model=default`  
  Follow system default. Currently: `tagged-files`  

ASLR configuration values for the `sxadm exec` command are:

- `aslr=enable`  
  Enable ASLR for the process.
aslr=disable Disable ASLR for the process.

ASLR is not supported for Solaris 10 Containers.

**Sub-commands** The `sxadm` command has the following subcommands:

```bash
sxadm enable [-c conf=value[,conf=value,...] extension[,extension]]
```
Enable the specified extension for the current zone. The `-c` option allows `sxadm` to pass configuration information for the specific extension.

Multiple extensions and multiple configuration values can both be specified on the command line, although if the configuration value does not apply to all extensions, the command will fail. Most common uses of this command are thus:

```bash
% sxadm enable extension1 extension2
```

Also:

```bash
% sxadm enable -c prop=value,prop2=value2 extension
```

See the Examples section for more examples.

```bash
sxadm disable extension[,extension]
```
Disable the specified extension for the current zone.

```bash
sxadm delcust extension[,extension]
```
Restore the extension to the default (out-of-the-box) configuration.

```bash
sxadm info [-p] [extension]
```
Report information on the status of all security extensions for the current zone. If `-p` is specified, the output is displayed in an easily parseable format. Specifying an `extension` on the command line filters for the specific extension.

Machine parseable output is a list of colon-separated fields:

```bash
extension_name:status[.extra]:configuration[.extra]
```

where:

- `extension_name` The name of the extension.
- `status` The current status for the extension (enabled or disabled).
- `extra` Represents (significant) extra information that the extension wishes to report. As an example, in the ASLR case, if ASLR is enabled, `extra` can either be `tag` or `all` depending on the model.
- `configuration` The stored configuration for the extension (enabled, disabled, or system default)

The characters colon (`:`), null sign (`\0`), and newline (`\n`) are not permitted for any of the components, `extension_name`, `status`, `extra`, and `configuration`.
sxadm exec -s [extension=value]... command
Execute the specified command with a specific configuration for security extensions. For each security extension not explicitly configured on the command line, the system configuration is used. Child processes eventually spawned by command inherit the same security extension configuration that was specified on the command line. set-uids and privileged binaries do not inherit any configuration. Multiple configurations can be expressed on a single command line using multiple -s options. If the same extension is configured more than once, the last occurrence takes precedence. For example:

```
% sxadm exec -s aslr=disable -s aslr=enable /usr/bin/pmap
```
...executes /usr/bin/pmap with aslr enabled.

The sxadm exec subcommand is designed to accommodate the common case in which a debugger is applied to a single process started directly by the debugger. It may not be sufficient for more complex scenarios. In such cases, it may be necessary to use sxadm to change the system or zone level security extension defaults, or to apply per-object tagging using the ld(1) utility, in order to facilitate debugging.

sxadm help [subcommand]
Display usage information about sxadm or more detailed information for each subcommand.

Examples

**EXAMPLE 1 Executing pmap Binary**
The sxadm command below executes the pmap binary with ASLR disabled at runtime.

```
bash$ pmap self
# memory addresses are randomized
101731: pmap self
101731: pmap self
0000000000400000 28K r-x-- /usr/bin/pmap
0000000000417000 4K rw--- /usr/bin/pmap
0000000000418000 8K rw--- /usr/bin/pmap
000003B0E8DF8000 36K rw--- [ heap ]
[...
FFFF843B809000 344K r-x-- /lib/amd64/ld.so.1
FFFF843B80FE000 12K rwx-- /lib/amd64/ld.so.1
FFFF843B8101000 8K rwx-- /lib/amd64/ld.so.1
FFFFFBF4A14E0000 12K rw--- [ stack ]
total 2592K
```

```
bash$ sxadm exec aslr=disable /usr/bin/pmap self
101733: /usr/bin/pmap self
101733: /usr/bin/pmap self
0000000000400000 28K r-x-- /usr/bin/pmap
0000000000417000 4K rw--- /usr/bin/pmap
0000000000418000 40K rw--- [ heap ]
[...]
```

EXAMPLE 2  Displaying Information about the Security Extensions Configuration

The following sxadm info commands display information about the security extensions configuration.

bash$ sxadm info -p
aslr:enabled.tagged-files:system default.default
bash$ sxadm info
EXTENSION STATUS CONFIGURATION
aslr enable (tagged-files) system default (default)
bash$ sxadm enable -c model=all aslr
bash$ sxadm info
EXTENSION STATUS CONFIGURATION
aslr enable (all) enable (all)
bash$ sxadm info -p
aslr:enabled.all:enabled.all

EXAMPLE 3  Reset to Default Configuration

The following command sxadm delcust command restores the extension to the default, out-of-the-box configuration.

bash$ sxadm info
EXTENSION STATUS CONFIGURATION
aslr enable (all) enable (all)
bash$ sxadm delcust aslr
bash$ sxadm info
EXTENSION STATUS CONFIGURATION
aslr enable (tagged-files) system default (default)

EXAMPLE 4  Running a Debugging Session

The following command sequence illustrates a debugging session being conducted with ASLR disabled.

bash$ sxadm exec -s aslr=disable /bin/bash
bash$
# Because all processes (except privileged ones) inherit the (disabled)
# aslr configuration mdb, truss & co will have repeatable results.

bash$ truss -t mmap /bin/true
mmap(0x00000000, 32, PROT_READ|PROT_WRITE, MAP_PRIVATE|MAP_ANON, -1, 0)
EXAMPLE 4  Running a Debugging Session  (Continued)

= 0xFE5B0000
mmap(0x00000000, 4096, PROT_READ|PROT_WRITE, MAP_PRIVATE|MAP_ANON, -1, 0)  
= 0xFE5A0000
mmap(0x00000000, 4096, PROT_READ|PROT_WRITE, MAP_PRIVATE|MAP_ANON, -1, 0)  
= 0xFE590000
[...]  
bash$  truss -t mmap /bin/true

Name  sync – update the super block
Synopsis  sync
Description  sync executes the sync system primitive. If the system is to be stopped, sync must be called to ensure file system integrity. It will flush all previously unwritten system buffers out to disk, thus assuring that all file modifications up to that point will be saved. See sync(2) for details.

### Name
`syncinit` – set serial line interface operating parameters

### Synopsis
```
/usr/sbin/syncinit device
    [ [baud_rate] | [keyword=value,...] | [single-word option]]
```

### Description
The `syncinit` utility allows the user to modify some of the hardware operating modes common to synchronous serial lines. This can be useful in troubleshooting a link, or necessary to the operation of a communications package.

If run without options, `syncinit` reports the options as presently set on the port. If options are specified, the new settings are reported after they have been made.

### Options
Options to `syncinit` normally take the form of a keyword, followed by an equal sign and a value. The exception is that a baud rate may be specified as a decimal integer by itself. Keywords must begin with the value shown in the options table, but may contain additional letters up to the equal sign. For example, \`loop=\` and \`loopback=\` are equivalent.

The following options are supported:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Value</th>
<th>Effect</th>
</tr>
</thead>
</table>
| `loop`  | yes   | Set the port to operate in internal loopback mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. The Digital Phase-Locked Loop (DPLL) may not be used as a clock source in this mode. If no other clocking options have been specified, perform the equivalent of `txc=baud` and `rxc=baud`.
|         | no    | Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of `txc=txc` and `rxc=rxc`.
| `echo`  | yes   | Set the port to operate in auto-echo mode. The transmit data output is electrically disconnected from the transmitter and tied to the receive data input. Incoming receive data is still visible. Use of this mode in combination with local loopback mode has no value, and should be rejected by the device driver. The auto-echo mode is useful to make a system become the endpoint of a remote loopback test.
|         | no    | Disable auto-echo mode.
| `nrzi`  | yes   | Set the port to operate with NRZI data encoding.
|         | no    | Set the port to operate with NRZ data encoding.
| `txc`   | `txc` | Transmit clock source will be the TxC signal (pin 15).
|         | `rxc` | Transmit clock source will be the RxC signal (pin 17).
| `baud`  |      | Transmit clock source will be the internal baud rate generator.
| `pll`   |      | Transmit clock source will be the output of the DPLL circuit.
Receive clock source will be the RxC signal (pin 17).

Receive clock source will be the TxC signal (pin 15).

Receive clock source will be the internal baud rate generator.

Receive clock source will be the output of the DPLL circuit.

Set the baud rate to integer bits per second.

There are also several single-word options that set one or more parameters at a time:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Equivalent to Options:</th>
</tr>
</thead>
<tbody>
<tr>
<td>external</td>
<td>txc=txc rxc=rxc loop=no</td>
</tr>
<tr>
<td>sender</td>
<td>txc=baud rxc=rxc loop=no</td>
</tr>
<tr>
<td>internal</td>
<td>txc=pll rxc=pll loop=no</td>
</tr>
<tr>
<td>stop</td>
<td>speed=0</td>
</tr>
</tbody>
</table>

**Examples**

**EXAMPLE 1** Using `syncinit`

The following command sets the first CPU port to loop internally, using internal clocking and operating at 38400 baud:

```
example# syncinit zsh0 38400 loop=yes
device: /dev/zsh ppa: 0
speed=38400, loopback=yes, echo=no, nrzi=no, txc=baud, rxc=baud
```

The following command sets the same port's clocking, local loopback and baud rate settings to their default values:

```
example# syncinit zsh0 stop loop=no
device: /dev/zsh ppa: 0
speed=0, loopback=no, echo=no, nrzi=no, txc=txc, rxc=rxc
```

**Attributes** See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

**See Also**

`syncloop(1M), syncstat(1M), Intro(2), ioctl(2), attributes(5), zsh(7D)`

**Diagnostics**

`device` missing minor device number

The name `device` does not end in a decimal number that can be used as a minor device number.
bad speed: arg

The string arg that accompanied the speed= option could not be interpreted as a decimal integer.

Bad arg: arg

The string arg did not make sense as an option.

ioctl failure code = errno

An ioctl(2) system call failed. The meaning of the value of errno may be found in Intro(2).

Warnings

Do not use syncinit on an active serial link, unless needed to resolve an error condition. Do not use this command casually or without being aware of the consequences.
The `syncloop` command performs several loopback tests that are useful in exercising the various components of a serial communications link.

Before running a test, `syncloop` opens the designated port and configures it according to command line options and the specified test type. It announces the names of the devices being used to control the hardware channel, the channel number (paa) corresponding to the `device` argument, and the parameters it has set for that channel. It then runs the loopback test in three phases.

The first phase is to listen on the port for any activity. If no activity is seen for at least four seconds, `syncloop` proceeds to the next phase. Otherwise, the user is informed that the line is active and that the test cannot proceed, and the program exits.

In the second phase, called the "first-packet" phase, `syncloop` attempts to send and receive one packet. The program will wait for up to four seconds for the returned packet. If no packets are seen after five attempts, the test fails with an excoriating message. If a packet is returned, the result is compared with the original. If the length and content do not match exactly, the test fails.

The final phase, known as the "multiple-packet" phase, attempts to send many packets through the loop. Because the program has verified the integrity of the link in the first-packet phase, the test will not fail after a particular number of timeouts. If a packet is not seen after four seconds, a message is displayed. Otherwise, a count of the number of packets received is updated on the display once per second. If it becomes obvious that the test is not receiving packets during this phase, the user may wish to stop the program manually. The number and size of the packets sent during this phase is determined by default values, or by command line options. Each returned packet is compared with its original for length and content. If a mismatch is detected, the test fails. The test completes when the required number of packets have been sent, regardless of errors.

After the multiple-packet phase has completed, the program displays a summary of the hardware event statistics for the channel that was tested. The display takes the following form:

```
CRC errors  Aborts  Overruns  Underruns  In<-Drops->  Out
0           0        0        0          0           0
```

This is followed by an estimated line speed, which is an approximation of the bit rate of the line, based on the number of bytes sent and the actual time that it took to send them.

**Options** The options for `syncloop` are described in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>syncloop – synchronous serial loopback test program</td>
<td>The <code>syncloop</code> command performs several loopback tests that are useful in exercising the various components of a serial communications link.</td>
</tr>
</tbody>
</table>
| /usr/sbin/syncloop [-cdlstv] device | Before running a test, `syncloop` opens the designated port and configures it according to command line options and the specified test type. It announces the names of the devices being used to control the hardware channel, the channel number (paa) corresponding to the `device` argument, and the parameters it has set for that channel. It then runs the loopback test in three phases.

The first phase is to listen on the port for any activity. If no activity is seen for at least four seconds, `syncloop` proceeds to the next phase. Otherwise, the user is informed that the line is active and that the test cannot proceed, and the program exits.

<td>100</td>
<td>Specifies the number of packets to be sent in the multiple-packet phase.</td>
</tr>
<tr>
<td>-d</td>
<td>hex_data_byte</td>
<td>random</td>
<td>Specifies that each packet will be filled with bytes with the value of hex_data_byte.</td>
</tr>
<tr>
<td>-l</td>
<td>packet_length</td>
<td>100</td>
<td>Specifies the length of each packet in bytes.</td>
</tr>
<tr>
<td>-s</td>
<td>line_speed</td>
<td>9600</td>
<td>Bit rate in bits per second.</td>
</tr>
<tr>
<td>-v</td>
<td></td>
<td></td>
<td>Sets verbose mode. If data errors occur, the expected and received data is displayed.</td>
</tr>
<tr>
<td>-t</td>
<td>test_type</td>
<td>none</td>
<td>A number, from 1 to 4, that specifies which test to perform. The values for test_type are as follows: 1: Internal loopback test. Port loopback is on. Transmit and receive clock sources are internal (baud rate generator). 2: External loopback test. Port loopback is off. Transmit and receive clock sources are internal. Requires a loopback plug suitable to the port under test. 3: External loopback test. Port loopback is off. Transmit and receive clock sources are external (modem). Requires that one of the local modem, the remote modem, or the remote system be set in a loopback configuration. 4: Test using predefined parameters. User defines hardware configuration and may select port parameters using the syncinit(1M) command.</td>
</tr>
</tbody>
</table>

All numeric options except -d are entered as decimal numbers (for example, -s 19200). If you do not provide the -t test_type option, syncloop prompts for it.

**Examples**

**EXAMPLE 1**  A sample display of using the syncloop command.

In the following command syncloop uses a packet length of 512 bytes over the first CPU port:

```
example# syncloop -l 512 zsh0
```

In response to the above command, syncloop prompts you for the test option you want.

The following command performs an internal loopback test on the first CPU port, using 5000 packets and a bit rate of 56Kbps:

```
example# syncloop -t 1 -s 56000 -c 5000 zsh0
```

syncinit(1M), syncstat(1M), attributes(3), zsh(7D)

Diagnostics  
device missing minor device number  
The name device does not end in a decimal number that can be used as a minor device number.

invalid packet length: nnn  
The packet length was specified to be less than zero or greater than 4096.

poll: nothing to read  
The poll(2) system call indicates that there is no input pending and/or that output would be blocked if attempted.

poll: nothing to read or write.  
len xxx should be yyy  
The packet that was sent had a length of yyy, but was received with a length of xxx.

nnn packets lost in outbound queueing  
nnn packets lost in inbound queueing  
A discrepancy has been found between the number of packets sent by syncloop and the number of packets the driver counted as transmitted, or between the number counted as received and the number read by the program.

Warnings  
To allow its tests to run properly, as well as prevent disturbance of normal operations, syncloop should only be run on a port that is not being used for any other purpose at that time.
**Name**  
syncstat – report driver statistics from a synchronous serial link

**Synopsis**  
/usr/sbin/syncstat [-c] device [interval]

**Description**  
The `syncstat` command reports the event statistics maintained by a synchronous serial device driver. The report may be a single snapshot of the accumulated totals, or a series of samples showing incremental changes. Prior to these it prints the device name being used to query a particular device driver, along with a number indicating the channel number (ppa) under control of that driver.

Event statistics are maintained by a driver for each physical channel that it supports. They are initialized to zero at the time the driver module is loaded into the system, which may be either at boot time or when one of the driver’s entry points is first called.

The `device` argument is the name of the serial device as it appears in the `/dev` directory. For example, `zsh0` specifies the first on-board serial device.

The following is a breakdown of `syncstat` output:

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>speed</strong></td>
<td>The line speed the device has been set to operate at. It is the user’s responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.</td>
</tr>
<tr>
<td>ipkts</td>
<td>The total number of input packets.</td>
</tr>
<tr>
<td>opkts</td>
<td>The total number of output packets.</td>
</tr>
<tr>
<td>undrun</td>
<td>The number of transmitter underrun errors.</td>
</tr>
<tr>
<td>ovrrun</td>
<td>The number of receiver overrun errors.</td>
</tr>
<tr>
<td>abort</td>
<td>The number of aborted received frames.</td>
</tr>
<tr>
<td>crc</td>
<td>The number of received frames with CRC errors.</td>
</tr>
<tr>
<td>isize</td>
<td>The average size (in bytes) of input packets.</td>
</tr>
<tr>
<td>osize</td>
<td>The average size (in bytes) of output packets.</td>
</tr>
</tbody>
</table>

**Options**  
- `-c`  
Clear the accumulated statistics for the device specified. This may be useful when it is not desirable to unload a particular driver, or when the driver is not capable of being unloaded.

- `interval`  
syncstat samples the statistics every `interval` seconds and reports incremental changes. The output reports line utilization for input and output in place of average packet sizes. These are the relationships between bytes transferred and the baud rate, expressed as percentages. The loop repeats indefinitely, with a column heading printed every twenty lines for convenience.
Examples

Example 1  Sample output from the syncstat command:

eexample# syncstat zsh0

speed ipkts opkts undrun ovrrun abort crc isize osize
9600 15716 17121 0 0 1 3 98 89

eexample# syncstat -c zsh0

speed ipkts opkts undrun ovrrun abort crc isize osize
9600 0 0 0 0 0 0 0 0

In the following sample output a new line of output is generated every five seconds:

eexample# syncstat zsh0 5

ipkts opkts undrun ovrrun abort crc iutil outil
12 10 0 0 0 0 5% 4%
22 60 0 0 0 0 3% 90%
36 14 0 0 0 1 51% 2%

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  syncinit(1M), syncloop(1M), attributes(5), zsh(7D)

Diagnostics

bad interval: arg  The argument arg is expected to be an interval and could not be understood.

device missing minor device number  The name device does not end in a decimal number that can be used as a minor device number.

baud rate not set  The interval option is being used and the baud rate on the device is zero. This would cause a divide-by-zero error when computing the line utilization statistics.

Warnings

Underrun, overrun, frame-abort, and CRC errors have a variety of causes. Communication protocols are typically able to handle such errors and initiate recovery of the transmission in which the error occurred. Small numbers of such errors are not a significant problem for most protocols. However, because the overhead involved in recovering from a link error can be much greater than that of normal operation, high error rates can greatly degrade overall link throughput. High error rates are often caused by problems in the link hardware, such as
cables, connectors, interface electronics or telephone lines. They may also be related to excessive load on the link or the supporting system.

The percentages for input and output line utilization reported when using the *interval* option may occasionally be reported as slightly greater than 100% because of inexact sampling times and differences in the accuracy between the system clock and the modem clock. If the percentage of use greatly exceeds 100%, or never exceeds 50%, then the baud rate set for the device probably does not reflect the speed of the modem.
sysconfig(1M)

Name  sysconfig – unconfigure or reconfigure a Solaris instance

Synopsis  
/usr/sbin/sysconfig

/usr/sbin/sysconfig configure [-s] [-c config_profile.xml | dir]
        [-d destructive] [-g system]

/usr/sbin/sysconfig unconfigure [-s] [-d destructive]
        [-g system]

/usr/sbin/sysconfig create-profile [-o output_file [-l logfile]
        [-v verbosity] [-b] [-g system]

Description  The sysconfig utility is the interface for unconfiguring and reconfiguring a Solaris instance. A Solaris instance is defined as a boot environment in either a global or a non-global zone.

There are three operations that are performed using the sysconfig utility: unconfiguration, configuration, and profile creation.

When sysconfig is called with the unconfigure subcommand, the system is unconfigured and left in an unconfigured state.

System configuration can occur either interactively or non-interactively. If the configure sub-command is invoked without a profile, the SCI Tool is activated and walks the user through the system configuration process. If the configure subcommand is invoked with a profile, then the configuration reads the profile and the configuration occurs non-interactively. The result in either case is a new system configuration.

The sysconfig command can also be used to generate a system configuration profile using the create-profile subcommand. The resulting profile is used with the sysconfig configure subcommand to configure systems non-interactively. Valid profile names include an .xml extension.

Configuration of a system can be performed either interactively, using the System Configuration Interactive (SCI) Tool, or non-interactively, using a system configuration profile.

The SCI tool configures the target system in an interactive way using a text user interface. It can also be used to collect information generated by the user that describes the desired configuration of the target system. The tool then generates a system configuration profile containing the desired system configuration.

The SCI tool supports configuration of freshly installed or unconfigured systems. It is designed to provide system configuration for newly created non-global zones and during text installation. If there is a need to modify the configuration of an already configured system utilizing SCI tool, such a system has to be unconfigured first before SCI tool can run.
The functional groupings that can be configured on a system are network, location, users, identity, and kbd_layout. Groupings can also be unconfigured and left in an unconfigured state. The default values for unconfigured groupings are shown below.

The following groupings are configurable.

<td>unconfigured</td>
</tr>
</tbody>
</table>

Sub-commands  This section describes supported subcommands and their associated options.

unconfigure [-s] [-g system] [--destructive]
Unconfigure a system and leave it in the unconfigured state.

- s
  Shut the system down after the unconfiguration completes.

- g system
  If -g is not specified, the user will be queried for confirmation before system configuration occurs.

--destructive
  Do not preserve system data that is normally preserved during unconfiguration. By specifying this flag, the user indicates to any groupings unconfigured that data they would ordinarily preserve might be deleted.

configure [-s] [-g system] [-c config_profile.xml|dir] [--destructive]
Configure or reconfigure a system. The configure subcommand has access to the same options as the unconfigure subcommand. It also includes the following additional option.
-c config_profile.xml | dir
Provides a profile or a directory of profiles to apply during configuration. If a profile is applied, the configuration step occurs non-interactively. If no profile is provided, the interactive system configuration tool is used for the configuration of the system.

All profiles must have an .xml file extension.

If you supply a directory to -c, all profiles in that directory must be valid (correctly formed) configuration profiles.

create-profile [-o output_file] [-l logfile] [-v verbosity] [-b] [-g grouping,...]
Run the SCI tool and create a system configuration profile. The default location for the profile is /system/volatile/profile/sc_profile.xml. The configuration generated is not applied to the system.

-o output_file
Replace the default profile location with output_file for the configuration profile.

-l logfile, --log-location=logfile
Location of the log file. The default is /var/tmp/install/sysconfig.log

-v verbosity, --log-level=verbosity
Verbosity level, one of error, warn, info, debug, or input. These are in order of increasing verbosity, from least to most. The default is info.

-b
Black-and-white version of SCI tool.

Examples

**EXAMPLE 1 Unconfiguring and Shutting Down**
The following command unconfigures the system and leaves it in an unconfigured state. By default, if no grouping is specified, the groupings for the whole system are unconfigured.

```
# sysconfig unconfigure -s
```

**EXAMPLE 2 Unconfiguring the System**
The following command unconfigures the system groupings and leaves the system unconfigured.

```
# sysconfig unconfigure -g system
```

**EXAMPLE 3 Reconfiguring System Using SCI Tool**
The following command brings up the SCI Tool to reconfigure a system.

```
# sysconfig configure
```

**EXAMPLE 4 Reconfiguring Using a Profile**
The following command reconfigures a system using a profile.

```
# sysconfig configure -c some_profile.xml
```
EXAMPLE 5  Creating and Using a Profile
The following sequence of commands creates a profile, then uses it to reconfigure a system.

# sysconfig create-profile -o /tmp/myprofile.xml
# sysconfig configure -g system -c /tmp/myprofile.xml

EXAMPLE 6  Configuring the System in a Zone
The following command configures the system in a zone.

# zlogin ZONENAME
root@ZONENAME# sysconfig configure -g system

Exit Status  0
   Success.
>0
   Failure.

sysdef(1M)

Name  sysdef – output system definition

Synopsis  /usr/sbin/sysdef [-i] [-n namelist]
          /usr/sbin/sysdef [-h] [-d] [-i] [-D]

Description  The sysdef utility outputs the current system definition in tabular form. It lists all hardware devices, as well as pseudo devices, system devices, loadable modules, and the values of selected kernel tunable parameters.

It generates the output by analyzing the named bootable operating system file (namelist) and extracting the configuration information from it.

The default system namelist is /dev/kmem.

Options

  -i  Prints the configuration information from /dev/kmem. This is the default and only needs to be specified if the configuration information from both /dev/kmem and the system file specified with the "-n namelist" option is needed.

  -n namelist  Specifies a namelist other than the default (/dev/kmem). The namelist specified must be a valid bootable operating system.

  -h  Prints the identifier of the current host in hexadecimal. If sysdef -h is executed within a non-global zone and the zone emulates a host identifier, then the zone's host identifier is printed. This numeric value is not guaranteed to be unique.

  -d  The output includes the configuration of system peripherals formatted as a device tree.

  -D  For each system peripheral in the device tree, display the name of the device driver used to manage the peripheral.

Examples  EXAMPLE 1  Sample output format

The following example displays the format of the sysdef -d output:

example% sysdef -d
Node 'SUNW,Ultra-5_10', unit #1
   Node 'packages', unit #1 (no driver)
      Node 'terminal-emulator', unit #1 (no driver)

**Name**
syseventadm – sysevent event specification administration

**Synopsis**
syseventadm add [-R rootdir] [-v vendor] [-p publisher]
[-c class] [-s subclass] [-u username] path [args]
syseventadm remove [-R rootdir] [-v vendor] [-p publisher]
[-c class] [-s subclass] [-u username] [path [args]]
syseventadm list [-R rootdir] [-v vendor] [-p publisher]
[-c class] [-s subclass] [-u username] [path [args]]
syseventadm restart

**Description**
The syseventadm command is an administrative front-end to add, remove and list sysevent event handlers. You can also restart the sysevent daemon by use of the restart command. syseventadm can only be run by root.

The syseventadm add command adds a handler for a sysevent event specified by at least one of vendor, publisher or class. If class is specified, it may be qualified with a sub-class. Only the values specified for vendor, publisher, class and sub-class when adding the handler are matched against sysevent events to determine if the specification matches the event and the handler should be run. path is the full pathname of the command to be run in response to matching events, with optional arguments (args). If username is specified, the command is invoked as user username, otherwise as root.

The syseventadm remove command removes handlers for matching sysevent event specifications. Event specifications may be matched by specifying at least one of vendor, publisher, class, username or path. If class is specified, it may be qualified with a sub-class. Any of vendor, publisher, class, subclass, username, path or args not specified match the corresponding fields of all events. Handlers for all matching specifications are removed.

The syseventadm list command lists the handlers for matching sysevent event specifications using the same match criteria as the remove command but without the requirement that at least one of vendor, publisher, class, username or path be specified. With no match criteria, all specifications are listed. The list command output format is:
[vendor=vendor] [publisher=publisher] [class=class] [subclass=subclass]
[username=username] path [args] where each of class, subclass, vendor, publisher and username is listed only if part of the match criteria for the listed specification is present.

The syseventadm restart command informs the syseventd daemon to reread the sysevent registry after a change has been made by adding or removing one or more sysevent handler specifications.

**Argument Macro Substitution**
The sysevent handling facility provides extensive macro capability for constructing the command line arguments to be executed in response to an event. Macro expansion applies only to the command line args specified for an event handler, with macros expanded with data from the event itself. Pre-defined macros are provided for the event class, subclass, publisher and vendor information. Macros not matching one of the pre-defined macro names cause the
attribute list attached to the event to be searched for an attribute of that name, with the value of the matching attribute substituted on the command line.

Macros are introduced by the $ character, with the macro name being the following token separated by a SPACE or TAB character. If the macro name is embedded in text, it may be delineated by ${ and }. A \ before the $ causes macro expansion not to occur.

$class The class string defining the event $publisher The publisher string defining the event $sequence The sequence number of the event. $subclass The subclass string defining the event $timestamp The timestamp of the event. $vendor The vendor string defining the event

Macro names other than those pre-defined are compared against the attribute list provided with the event. An attribute with name matching the macro name causes the value of the attribute to be substituted as ASCII text on the generated command line.

Use of a macro for which no attribute with that name is defined, or for which multiple attributes with that name are provided, cause an error and the command is not invoked.

Attributes with signed data types (DATA_TYPE_INT16, DATA_TYPE_INT32 and DATA_TYPE_INT64) are expanded as decimal digits.

Attributes with unsigned data types (DATA_TYPE_BYTE, DATA_TYPE_UINT16, DATA_TYPE_UINT32, DATA_TYPE_UINT64 and DATA_TYPE_HTTIME) are expanded as hexadecimal digits with a 0x prefix.

Attributes with string data type (DATA_TYPE_STRING) are expanded with the string data. The data is not quoted. If it desired that the quoted strings be generated on the command line, put quotes around the macro call in the arguments.

Array types are expanded with each element expanded as defined for that scalar type, with a space separating each element substitution.

Options The add, list and remove subcommands support the following options:

-c class Specify the event class, class.

-p publisher Specify the event publisher, publisher.

-R rootdir Specify an alternate root path, rootdir.

Note - The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone’s file system,
might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-s subclass  Specify the event subclass, subclass.
-u username  Specify the username (username) to invoke the command.
-v vendor    Specify the vendor (vendor) that defines the event. Events defined by third-party software should specify the company's stock symbol as vendor. Oracle-defined events use SUNW.

Operands  The add, list and remove subcommands support the following options:

args  Command arguments
path  Full path of command to be run in response to event

Examples  EXAMPLE 1  Adding an Event Handler

The following example adds an event handler for an event defined by vendor MYCO ("My Company"), class EC_ENV and sub-class ESC_ENV_TEMP. The command to be run is 
/opt/MYCOenv/bin/ec_env_temp, with arguments being the class name, sub-class name and pathname derived from the event attributes. The $ characters are preceded by a backslash to circumvent shell interpretation. There is no need to restart the service after the change since the registry is maintained on $ALTROOT.

# syseventadm add -R \ALTROOT -v MYCO -c EC_ENV -s ESC_ENV_TEMP \
/opt/MYCOenv/bin/ec_env_temp \class \$class \$subclass \$pathname

Note the caveat on the use of the -R option in the description of that option, above.

EXAMPLE 2  Removing an Event Handler

The following example removes the event handler added in Example 1.

# syseventadm remove -R \ALTROOT -v MYCO -c EC_ENV -s ESC_ENV_TEMP \
/opt/MYCOenv/bin/ec_env_temp \class \$class \$subclass \$pathname

Note the caveat on the use of the -R option in the description of that option, above.

EXAMPLE 3  Listing Event Handlers

The following example lists all event handlers for events of class EC_ENV, subclass ESC_ENV_TEMP, as defined by vendor MYCO:

# syseventadm list -v MYCO -c EC_ENV -s ESC_ENV_TEMP \" \
/vendor=MYCO class=EC_ENV subclass=ESC_ENV_TEMP \" \
/opt/MYCOenv/bin/ec_env_temp \${class} \${subclass} \${pathname}
Example 4  Listing Event Handlers
The following example lists all event handlers defined by vendor VRTS.

```
# syseventadm list -v VRTS
```

Example 5  Removing Event Handlers
The following example removes all event handlers defined by vendor VRTS, and restarts service.

```
# syseventadm remove -v VRTS
# syseventadm restart
```

Example 6  Listing All Event Handlers Specified to Run a Command
The following example lists all event handlers specified to run the command /opt/MYCOenv/bin/ec_env_temp:

```
# syseventadm list /opt/MYCOenv/bin/ec_env_temp
```

Example 7  Removing Event Handlers and Restarting Service
The following example removes all event handlers specified to run the command /opt/MYCOenv/bin/ec_env_temp, and restarts service:

```
# syseventadm remove /opt/MYCOenv/bin/ec_env_temp
# syseventadm restart
```

Exit Status  The following exit values are returned:

- 0  Successful completion.
- 1  No matching event specification found (remove or list commands only).
- 2  Incorrect command usage.
- 3  Permission denied.
- 4  Command failed.
- 5  Out of memory.

See Also  syseventd(1M), sysevent_post_event(3SYSEVENT), attributes(5), ddi_log_sysevent(9F)
To avoid upgrade problems, packages delivering a sysevent event handler should install the event handler by running `syseventadm` from the package's postinstall script. The event handler can then be removed by running `syseventadm` from the package's preremove script using the same arguments as when added.
Name  syseventconfd – kernel system event command invocation daemon

Synopsis  
/usr/lib/sysevent/syseventconfd [-r rootdir]

Description  syseventconfd is the user-level daemon that invokes user-level commands in response to kernel system events received from syseventd(1M).

Options  The following options are supported:

- `r rootdir`  Cause syseventconfd to use an alternate root path when creating its door. The root path must match the root path used to invoke syseventd.

Files  
/etc/sysevent/syseventconfd_event_service
syseventconfd event service door file

/usr/lib/sysevent/modules/sysevent_conf_mod.so
syseventd loadable module (SLM) managing sysevent.conf files

Notes  The syseventconfd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/sysevent:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
Name

syseventd – kernel system event notification daemon

Synopsis

/usr/lib/sysevent/syseventd [-d debug_level] [-r rootdir]

Description

syseventd is a user-level daemon that accepts delivery of system event buffers from the
kernel. Once an event buffer has been delivered to syseventd, it, in turn, attempts to
propagate the event to all interested end event subscribers.

Event subscribers take the form of a syseventd loadable module (SLM). syseventd passes the
event buffer to each of its subscribers and in return expects a notification as to the successful or
unsuccessful delivery attempt.

Upon successful delivery of the event buffer to all interested event subscribers, syseventd
frees the event buffer from the kernel event queue.

Options

The following option is supported:

- d debug_level  Enable debug mode. Messages are printed to the invoking user’s terminal.

Exit Status

The following exit values are returned:

0  Successful completion.
non-zero  An error occurred.

svcs(1), svcadm(1M), syseventconfd(1M), attributes(5), smf(5)
The syseventd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/sysevent:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
syslogd reads and forwards system messages to the appropriate log files or users, depending upon the priority of a message and the system facility from which it originates. The configuration file /etc/syslog.conf (see syslog.conf(4)) controls where messages are forwarded. syslogd logs a mark (timestamp) message every markinterval minutes (default 20) at priority LOG_INFO to the facility whose name is given as mark in the syslog.conf file.

A system message consists of a single line of text, which may be prefixed with a priority code number enclosed in angle-brackets (< >); priorities are defined in <sys/syslog.h>.

syslogd reads from the STREAMS log driver, /dev/log, and from any transport provider specified in /etc/netconfig, /etc/net/transport/hosts, and /etc/net/transport/services.

syslogd reads the configuration file when it starts up, and again whenever it receives a HUP signal (see signal.h(3HEAD)), at which time it also closes all files it has open, re-reads its configuration file, and then opens only the log files that are listed in that file. syslogd exits when it receives a TERM signal.

As it starts up, syslogd creates the file /var/run/syslog.pid, if possible, containing its process identifier (PID).

If message ID generation is enabled (see log(7D)), each message will be preceded by an identifier in the following format: [ID msgid facility priority]. msgid is the message's numeric identifier described in msgid(1M), facility and priority are described in syslog.conf(4). [ID 123456 kern.notice] is an example of an identifier when message ID generation is enabled.

If the message originated in a loadable kernel module or driver, the kernel module's name (for example, ufs) will be displayed instead of unix. See EXAMPLES for sample output from syslogd with and without message ID generation enabled.

In an effort to reduce visual clutter, message IDs are not displayed when writing to the console; message IDs are only written to the log file. See EXAMPLES.

The /etc/default/syslogd file contains the default parameter settings, which are in effect if neither the -t nor -T option is selected.

The recommended way to allow or disallow message logging is through the use of the service management facility (smf(5)) property:

svc:/system/system-log/config/log_from_remote

This property specifies whether remote messages are logged. log_from_remote=true is equivalent to the -t command-line option and false is equivalent to the -T command-line option. The default value for log_from_remote is false. See NOTES, below.
LOG_FROM_REMOTE
Specifies whether remote messages are logged. LOG_FROM_REMOTE=NO is equivalent to the -t command-line option. The default value for LOG_FROM_REMOTE is YES.

**Options**
The following options are supported:

- `d`
  Turn on debugging. This option should only be used interactively in a root shell once the system is in multi-user mode. It should not be used in the system start-up scripts, as this will cause the system to hang at the point where syslogd is started.

- `f configfile`
  Specify an alternate configuration file.

- `m markinterval`
  Specify an interval, in minutes, between mark messages.

- `p path`
  Specify an alternative log device name. The default is /dev/log.

- `T`
  Enable the syslogd UDP port to turn on logging of remote messages. This is the default behavior.

- `t`
  Disable the syslogd UDP port to turn off logging of remote messages.

**Examples**

**EXAMPLE 1**  syslogd Output Without Message ID Generation Enabled
The following example shows the output from syslogd when message ID generation is not enabled:

```
Sep 29 21:41:18 cathy unix: alloc /: file system full
```

**EXAMPLE 2**  syslogd Output with ID generation Enabled
The following example shows the output from syslogd when message ID generation is enabled. The message ID is displayed when writing to log file/var/adm/messages.

```
Sep 29 21:41:18 cathy ufs: [ID 845546 kern.notice] alloc /: file system full
```

**EXAMPLE 3**  syslogd Output with ID Generation Enabled
The following example shows the output from syslogd when message ID generation is enabled when writing to the console. Even though message ID is enabled, the message ID is not displayed at the console.

```
Sep 29 21:41:18 cathy ufs: alloc /: file system full
```
The following commands enable syslogd to accept entries from remote systems.

```
# svcadm restart svc:/system/system-log
```

### Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

### See Also

logger(1), svc(1), msgid(1M), svcadm(1M), svcfg(1M), syslog(3C), syslog.conf(4), attributes(5), signal.h(3HEAD), smf(5), log(7D)

### Notes

The mark message is a system timestamp, and so it is only defined for the system on which syslogd is running. It can not be forwarded to other systems.

When syslogd receives a HUP signal, it attempts to complete outputting pending messages, and close all log files to which it is currently logging messages. If, for some reason, one (or more) of these files does not close within a generous grace period, syslogd discards the pending messages, forcibly closes these files, and starts reconfiguration. If this shutdown procedure is disturbed by an unexpected error and syslogd cannot complete reconfiguration, syslogd sends a mail message to the superuser on the current system stating that it has shut down, and exits.

Care should be taken to ensure that each window displaying messages forwarded by syslogd (especially console windows) is run in the system default locale (which is syslogd's locale). If
this advice is not followed, it is possible for a syslog message to alter the terminal settings for that window, possibly even allowing remote execution of arbitrary commands from that window.

The syslogd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/system-log:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

When syslogd is started by means of svcadm(1M), if a value is specified for LOG_FROM_REMOTE in the /etc/defaults/syslogd file, the SMF property

svc:/system/system-log/config/log_from_remote

is set to correspond to the LOG_FROM_REMOTE value and the /etc/default/syslogd file is modified to replace the LOG_FROM_REMOTE specification with the following comment:

# LOG_FROM_REMOTE is now set using svccfg(1m), see syslogd(1m).

If neither LOG_FROM_REMOTE nor svc:/system/system-log/config/log_from_remote are defined, the default is to log remote messages.

On installation, the initial value of svc:/system/system-log/config/log_from_remote is false.
tapes creates symbolic links in the /dev/rmt directory to the actual tape device special files under the /devices directory tree. tapes searches the kernel device tree to see what tape devices are attached to the system. For each equipped tape drive, the following steps are performed:

1. The /dev/rmt directory is searched for a /dev/rmt/n entry that is a symbolic link to the /devices special node of the current tape drive. If one is found, this determines the logical controller number of the tape drive.
2. The rest of the special devices associated with the drive are checked, and incorrect symbolic links are removed and necessary ones added.
3. If none are found, a new logical controller number is assigned (the lowest-unused number), and new symbolic links are created for all the special devices associated with the drive.

Tapes does not remove links to non-existent devices; these must be removed by hand.

Tapes is run each time a reconfiguration-boot is performed, or when add_drv(1M) is executed.

Notice to Driver Writers

Tapes(1M) considers all devices with the node type DDI_NT_TAPE to be tape devices; these devices must have their minor name created with a specific format. The minor name encodes operational modes for the tape device and consists of an ASCII string of the form [ l,m,h,c,u ][ b ][ n ].

The first character set is used to specify the tape density of the device, and are named low (l), medium (m), high (h), compressed (c), and ultra (u). These specifications only express a relative density; it is up to the driver to assign specific meanings as needed. For example, 9 track tape devices interpret these as actual bits-per-inch densities, where l means 800 BPI, m means 1600 BPI, and h means 6250 BPI, whereas 4mm DAT tapes defines l as standard format, and m, h, c and u as compressed format. Drivers may choose to implement any or all of these format types.

During normal tape operation (non-BSD behavior), once an EOF mark has been reached, subsequent reads from the tape device return an error. An explicit IOCTL must be issued to space over the EOF mark before the next file can be read. b instructs the device to observe BSD behavior, where reading at EOF will cause the tape device to automatically space over the EOF mark and begin reading from the next file.

n or no-rewind-on-close instructs the driver to not rewind to the beginning of tape when the device is closed. Normal behavior for tape devices is to reposition to BOT when closing. See mtio(7I).
The minor number for tape devices should be created by encoding the device's instance number using the tape macro MTMINOR and ORing in the proper combination of density, BSD behavior, and no-rewind flags. See mtio(7).

To prevent tapes from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using the node type string DDI_NT_TAPE when calling ddi_create_minor_node(9F).

**Options**
The following options are supported:

- `r root_dir` Causes tapes to presume that the /dev/rmt directory tree is found under `root_dir`, not directly under `/`.

**Errors**
If tapes finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the /dev directory, since it cannot determine which of the two alternative logical to physical mappings is correct. The links should be manually corrected or removed before another reconfiguration boot is performed.

**Examples**

**EXAMPLE 1 Creating Tape Device Nodes From Within the Driver's attach() Function**

This example demonstrates creating tape device nodes from within the xktape driver's `attach(9E)` function.

```c
#include <sys/mtio.h>
struct tape_minor_info {
    char *minor_name;
    int minor_mode;
};
/*
 * create all combinations of logical tapes
 */
static struct tape_minor_info example_tape[] = {
    {"", 0}, /* default tape */
    {"l", MT_DENSITY1},
    {"lb", MT_DENSITY1 | MT_BSD},
    {"lbn", MT_DENSITY1 | MT_BSD | MT_NOREWIND},
    {"m", MT_DENSITY2},
    {"mb", MT_DENSITY2 | MT_BSD},
    {"mbn", MT_DENSITY2 | MT_BSD | MT_NOREWIND},
    {"h", MT_DENSITY3},
    {"hb", MT_DENSITY3 | MT_BSD},
    {"hbn", MT_DENSITY3 | MT_BSD | MT_NOREWIND},
    {"c", MT_DENSITY4},
    {"cb", MT_DENSITY4 | MT_BSD},
    {"cbn", MT_DENSITY4 | MT_BSD | MT_NOREWIND},
    {NULL, 0},
};
```
Creating Tape Device Nodes From Within the Driver's attach() Function (Continued)

```c
int xktapeattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance;
    struct tape_minor_info *mdp;
    /* other stuff in attach... */
    instance = ddi_get_instance(dip);

    for (mdp = example_tape; mdp->minor_name != NULL; mdp++) {
        ddi_create_minor_node(dip, mdp->minor_name, S_IFCHR,
                              (MTMINOR(instance) | mdp->minor_mode), DDI_NT_TAPE, 0);
    }
}
```

Installing the xktape driver on a Sun Fire 4800, with the driver controlling a SCSI tape (target 4 attached to an `isp(7D)` SCSI HBA) and performing a reconfiguration-boot creates the following special files in `/devices`.

```bash
# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/SUNW,isptwo@4
  crw-rw-rw- 1 root  sys  33,136 Aug 29  00:02 xktape@4,0:
  crw-rw-rw- 1 root  sys  33,200 Aug 29  00:02 xktape@4,0:
  crw-rw-rw- 1 root  sys  33,204 Aug 29  00:02 xktape@4,0:bn
  crw-rw-rw- 1 root  sys  33,152 Aug 29  00:02 xktape@4,0:c
  crw-rw-rw- 1 root  sys  33,216 Aug 29  00:02 xktape@4,0:cb
  crw-rw-rw- 1 root  sys  33,220 Aug 29  00:02 xktape@4,0:cbn
  crw-rw-rw- 1 root  sys  33,156 Aug 29  00:02 xktape@4,0:cn
  crw-rw-rw- 1 root  sys  33,144 Aug 29  00:02 xktape@4,0:h
  crw-rw-rw- 1 root  sys  33,208 Aug 29  00:02 xktape@4,0:hb
  crw-rw-rw- 1 root  sys  33,212 Aug 29  00:02 xktape@4,0:hb
  crw-rw-rw- 1 root  sys  33,148 Aug 29  00:02 xktape@4,0:hn
  crw-rw-rw- 1 root  sys  33,128 Aug 29  00:02 xktape@4,0:l
  crw-rw-rw- 1 root  sys  33,192 Aug 29  00:02 xktape@4,0:lb
  crw-rw-rw- 1 root  sys  33,196 Aug 29  00:02 xktape@4,0:ln
  crw-rw-rw- 1 root  sys  33,132 Aug 29  00:02 xktape@4,0:ln
  crw-rw-rw- 1 root  sys  33,136 Aug 29  00:02 xktape@4,0:m
  crw-rw-rw- 1 root  sys  33,200 Aug 29  00:02 xktape@4,0:mb
  crw-rw-rw- 1 root  sys  33,204 Aug 29  00:02 xktape@4,0:mbn
  crw-rw-rw- 1 root  sys  33,140 Aug 29  00:02 xktape@4,0:nn
  crw-rw-rw- 1 root  sys  33,140 Aug 29  00:02 xktape@4,0:nn
```

`/dev/rmt` will contain the logical tape devices (symbolic links to tape devices in `/devices`).

```bash
# ls -l /dev/rmt
/dev/rmt/0    -> ../../devices/...../xktape@4,0:
/dev/rmt/0b   -> ../../devices/...../xktape@4,0:bn
```

Writing Device Drivers

Bugs  tapes silently ignores malformed minor device names.
th_define - create fault injection test harness error specifications

Synopsis

th_define [-n name -i instance| -P path] [-a acc_types]
[-r reg_number] [-l offset [length]]
[-c count [failcount]] [-o operator operand]
[-f acc_chk] [-w max_wait_period [report_interval]]

or

th_define [-n name -i instance| -P path]
[-a log [acc_types] [-r reg_number] [-l offset [length]]]
[-c count [failcount]] [-s collect_time] [-p policy]
[-x flags] [-C comment_string]
[-e fixup_script [args]]

or

th_define [-h]

Description

The th_define utility provides an interface to the bus_ops fault injection bofi device driver for defining error injection specifications (referred to as errdefs). An errdef corresponds to a specification of how to corrupt a device driver’s accesses to its hardware. The command line arguments determine the precise nature of the fault to be injected. If the supplied arguments define a consistent errdef, the th_define process will store the errdef with the bofi driver and suspend itself until the criteria given by the errdef become satisfied (in practice, this will occur when the access counts go to zero).

You use the th_manage(1M) command with the start option to activate the resulting errdef. The effect of th_manage with the start option is that the bofi driver acts upon the errdef by matching the number of hardware accesses—specified in count, that are of the type specified in acc_types, made by instance number instance—of the driver whose name is name, (or by the driver instance specified by path) to the registerset (or DMA handle) specified by reg_number, that lie within the range offset to offset + length from the beginning of the registerset or DMA handle. It then applies operator and operand to the next failcount matching accesses.

If acc_types includes log, th_define runs in automatic test script generation mode, and a set of test scripts (written in the Korn shell) is created and placed in a sub-directory of the current directory with the name <driver>.test.<id> (for example, glm.test.978177106). A separate, executable script is generated for each access handle that matches the logging criteria. The log of accesses is placed at the top of each script as a record of the session. If the current directory is not writable, file output is written to standard output. The base name of each test file is the driver name, and the extension is a number that discriminates between different access handles. A control script (with the same name as the created test directory) is generated that will run all the test scripts sequentially.

Executing the scripts will install, and then activate, the resulting error definitions. Error definitions are activated sequentially and the driver instance under test is taken offline and brought back online before each test (refer to the -e option for more information). By default, logging applies to all PIO accesses, all interrupts, and all DMA accesses to and from areas
mapped for both reading and writing. You can constrain logging by specifying additional
acc_types, reg_number, offset and length. Logging will continue for count matching accesses,
with an optional time limit of collect_time seconds.

Either the -n or -P option must be provided. The other options are optional. If an option
(other than -a) is specified multiple times, only the final value for the option is used. If an
option is not specified, its associated value is set to an appropriate default, which will provide
maximal error coverage as described below.

Options The following options are available:

- **-n name** Specify the name of the driver to test. (String)
- **-i instance** Test only the specified driver instance (-1 matches all instances of driver). (Numeric)
- **-P path** Specify the full device path of the driver to test. (String)
- **-r reg_number** Test only the given register set or DMA handle (-1 matches all register sets and DMA handles). (Numeric)
- **-a acc_types** Only the specified access types will be matched. Valid values for the acc_types argument are log, pio, pio_r, pio_w, dma, dma_r, dma_w and intr. Multiple access types, separated by spaces, can be specified. The default is to match all hardware accesses.

If acc_types is set to log, logging will match all PIO accesses, interrupts and DMA accesses to and from areas mapped for both reading and writing. log can be combined with other acc_types, in which case the matching condition for logging will be restricted to the specified additional acc_types. Note that dma_r will match only DMA handles mapped for reading only; dma_w will match only DMA handles mapped for writing only; dma will match only DMA handles mapped for both reading and writing.

- **-l offset [length]** Constrain the range of qualifying accesses. The offset and length arguments indicate that any access of the type specified with the -a option, to the register set or DMA handle specified with the -r option, lie at least offset bytes into the register set or DMA handle and at most offset + length
bytes into it. The default for offset is 0. The default for length is the maximum value that can be placed in an offset_t C data type (see types.h). Negative values are converted into unsigned quantities. Thus, th_define l 0 -1 is maximal.

-c count [failcount]

Wait for count number of matching accesses, then apply an operator and operand (see the -o option) to the next failcount number of matching accesses. If the access type (see the -a option) includes logging, the number of logged accesses is given by count + failcount - 1. The -1 is required because the last access coincides with the first faulting access.

Note that access logging may be combined with error injection if failcount and operator are nonzero and if the access type includes logging and any of the other access types (pio, dma and intr). See the description of access types in the definition of the -a option, above.

When the count and failcount fields reach zero, the status of the errdef is reported to standard output. When all active errdefs created by the th_define process complete, the process exits. If acc_types includes log, count determines how many accesses to log. If count is not specified, a default value is used. If failcount is set in this mode, it will simply increase the number of accesses logged by a further failcount - 1.

-o operator [operand]

For qualifying PIO read and write accesses, the value read from or written to the hardware is corrupted according to the value of operator:

EQ operand is returned to the driver.

OR operand is bitwise ORed with the real value.

AND operand is bitwise ANDed with the real value.

XOR operand is bitwise XORed with the real value.
For PIO write accesses, the following operator is allowed:

**NO**  Simply ignore the driver's attempt to write to the hardware.

Note that a driver performs PIO via the `ddi_getX()`, `ddi_putX()`, `ddi_rep_getX()` and `ddi_rep_putX()` routines (where `X` is 8, 16, 32 or 64). Accesses made using `ddi_getX()` and `ddi_putX()` are treated as a single access, whereas an access made using the `ddi_rep_*()` routines are broken down into their respective number of accesses, as given by the `repcount` parameter to these DDI calls. If the access is performed via a DMA handle, `operator` and `value` are applied to every access that comprises the DMA request. If interference with interrupts has been requested then the operator may take any of the following values:

**DELAY**  After `count` accesses (see the `-c` option), delay delivery of the next `failcount` number of interrupts for `operand` number of microseconds.

**LOSE**  After `count` number of interrupts, fail to deliver the next `failcount` number of real interrupts to the driver.

**EXTRA**  After `count` number of interrupts, start delivering `operand` number of extra interrupts for the next `failcount` number of real interrupts.

The default value for `operand` and `operator` is to corrupt the data access by flipping each bit (XOR with `-1`).

If the `acc_chk` parameter is set to 1 or `pio`, then the driver's calls to `ddi_check_acc_handle(9F)` return `DDI_FAILURE` when the access count goes to 1. If the `acc_chk` parameter is set to 2 or `dma`, then the driver's calls to `ddi_check_dma_handle(9F)` return `DDI_FAILURE` when the access count goes to 1.
-w max_wait_period [report_interval]

Constrain the period for which an error definition will remain active. The option applies only to non-logging errdefs. If an error definition remains active for max_wait_period seconds, the test will be aborted. If report_interval is set to a nonzero value, the current status of the error definition is reported to standard output every report_interval seconds. The default value is zero.

The status of the errdef is reported in parsable format (eight fields, each separated by a colon (:) character, the last of which is a string enclosed by double quotes and the remaining seven fields are integers):

ft:mt:ac:fc:chk:ec:"message" which are defined as follows:

ft The UTC time when the fault was injected.
mt The UTC time when the driver reported the fault.
ac The number of remaining non-faulting accesses.
fc The number of remaining faulting accesses.
chk The value of the acc_chk field of the errdef.
ce The number of fault reports issued by the driver against this errdef (mt holds the time of the initial report).
s The severity level reported by the driver.
"message" Textual reason why the driver has reported a fault.

-h Display the command usage string.

-s collect_time If acc_types is given with the -a option and includes log, the errdef will log accesses for collect_time seconds (the default is to log until the log becomes full). Note that, if the errdef
specification matches multiple driver handles, multiple logging errdefs are registered with the bofi driver and logging terminates when all logs become full or when collect_time expires or when the associated errdefs are cleared. The current state of the log can be checked with the th_manage(1M) command, using the broadcast parameter. A log can be terminated by running th_manage(1M) with the clear_errdefs option or by sending a SIGALRM signal to the th_define process. See alarm(2) for the semantics of SIGALRM.

Applicable when the acc_types option includes log. The parameter modifies the policy used for converting from logged accesses to errdefs. All policies are inclusive:

- Use rare to bias error definitions toward rare accesses (default).
- Use operator to produce a separate error definition for each operator type (default).
- Use common to bias error definitions toward common accesses.
- Use median to bias error definitions toward median accesses.
- Use maximal to produce multiple error definitions for duplicate accesses.
- Use unbiased to create unbiased error definitions.
- Use onebyte, twobyte, fourbyte, or eightbyte to select errdefs corresponding to 1, 2, 4 or 8 byte accesses (if chosen, the -xr option is enforced in order to ensure that ddi_rep_*() calls are decomposed into multiple single accesses).
- Use multibyte to create error definitions for multibyte accesses performed using ddi_rep_get*() and ddi_rep_put*().

Policies can be combined by adding together these options. See the NOTES section for further information.
-x flags  Applicable when the acc_types option includes log. The flags parameter modifies the way in which the bof1 driver logs accesses. It is specified as a string containing any combination of the following letters:

- w  Continuous logging (that is, the log will wrap when full).
- t  Timestamp each log entry (access times are in seconds).
- r  Log repeated I/O as individual accesses (for example, a ddi_rep_get16(9F) call which has a repcount of N is logged N times with each transaction logged as size 2 bytes. Without this option, the default logging behavior is to log this access once only, with a transaction size of twice the repcount).

-C comment_string  Applicable when the acc_types option includes log. It provides a comment string to be placed in any generated test scripts. The string must be enclosed in double quotes.

-e fixup_script [args]  Applicable when the acc_types option includes log. The output of a logging errdefs is to generate a test script for each driver access handle. Use this option to embed a command in the resulting script before the errors are injected. The generated test scripts will take an instance offline and bring it back online before injecting errors in order to bring the instance into a known fault–free state. The executable fixup_script will be called twice with the set of optional args—once just before the instance is taken offline and again after the instance has been brought online. The following variables are passed into the environment of the called executable:

- DRIVER_PATH  Identifies the device path of the instance.
- DRIVER_INSTANCE  Identifies the instance number of the device.
The `DRIVER_UNCONFIGURE` flag indicates that the instance is about to be taken offline. The `DRIVER_CONFIGURE` flag signifies that the instance has just been brought online.

Typically, the executable ensures that the device under test is in a suitable state to be taken offline (unconfigured) or in a suitable state for error injection (for example, configured, error-free, and servicing a workload). A minimal script for a network driver could be:

```bash
#!/bin/ksh

driver=xyznetdriver
ifnum=$driver$DRIVER_INSTANCE

if [[ $DRIVER_CONFIGURE -eq 1 ]]; then
    ifconfig $ifnum plumb
    ifconfig $ifnum ...
    ifworkload start $ifnum
elif [[ $DRIVER_UNCONFIGURE -eq 1 ]]; then
    ifworkload stop $ifnum
    ifconfig $ifnum down
    ifconfig $ifnum unplumb
fi
exit $?
```

The `-e` option must be the last option on the command line.

If the `-a log` option is selected but the `-e` option is not given, a default script is used. This script repeatedly attempts to detach and then re-attach the device instance under test.

### Examples

```
Examples of Error Definitions

th_define -n foo -i 1 -a log

Logs all accesses to all handles used by instance 1 of the foo driver while running the default workload (attaching and detaching the instance). Then generates a set of test scripts to inject appropriate error definitions while running that default workload.

th_define -n foo -i 1 -a log pio
```
Logs PIO accesses to each PIO handle used by instance 1 of the foo driver while running the default workload (attaching and detaching the instance). Then generates a set of test scripts to inject appropriate errdefs while running that default workload.

```
th_define -n foo -i 1 -p onebyte median -e fixup arg -now
```

Logs all accesses to all handles used by instance 1 of the foo driver while running the workload defined in the fixup script fixup with arguments arg and -now. Then generates a set of test scripts to inject appropriate errdefs while running that workload. The resulting error definitions are requested to focus upon single byte accesses to locations that are accessed a median number of times with respect to frequency of access to I/O addresses.

```
th_define -n se -l 0x20 1 -a pio_r -o OR 0x4 -c 10 1000
```

Simulates a stuck serial chip command by forcing 1000 consecutive read accesses made by any instance of the se driver to its command status register, thereby returning status busy.

```
th_define -n foo -i 3 -r 1 -a pio_r -c 0 1 -f 1 -o OR 0x100
```

Causes 0x100 to be ORed into the next physical I/O read access from any register in register set 1 of instance 3 of the foo driver. Subsequent calls in the driver to ddi_check_acc_handle() return DDI_FAILURE.

```
th_define -n foo -i 3 -r 1 -a pio_r -c 0 1 -o OR 0x0
```

Causes 0x0 to be ORed into the next physical I/O read access from any register in register set 1 of instance 3 of the foo driver. This is of course a no-op.

```
th_define -n foo -i 3 -r 1 -l 0x8100 1 -a pio_r -c 0 10 -o EQ 0x70003
```

Causes the next ten next physical I/O reads from the register at offset 0x8100 in register set 1 of instance 3 of the foo driver to return 0x70003.

```
th_define -n foo -i 3 -r 1 -l 0x8100 1 -a pio_w -c 100 3 -o AND 0xfffffffffffffff
```

The next 100 physical I/O writes to the register at offset 0x8100 in register set 1 of instance 3 of the foo driver take place as normal. However, on each of the three subsequent accesses, the 0x1000 bit will be cleared.

```
th_define -n foo -i 3 -r 1 -l 0x8100 0x10 -a pio_r -c 0 1 -f 1 -o XOR 7
```

Causes the bottom three bits to have their values toggled for the next physical I/O read access to registers with offsets in the range 0x8100 to 0x8110 in register set 1 of instance 3 of the foo driver. Subsequent calls in the driver to ddi_check_acc_handle() return DDI_FAILURE.

```
th_define -n foo -i 3 -a pio_w -c 0 1 -o NO 0
```
Prevents the next physical I/O write access to any register in any register set of instance 3 of the foo driver from going out on the bus.

```
th_define -n foo -i 3 -l 0 8192 -a dma_r -c 0 1 -o OR 7
```

Causes 0x7 to be ORed into each long long in the first 8192 bytes of the next DMA read, using any DMA handle for instance 3 of the foo driver.

```
th_define -n foo -i 3 -r 2 -l 0 8 -a dma_r -c 0 1 -o OR 0x7070707070707070
```

Causes 0x70 to be ORed into each byte of the first long long of the next DMA read, using the DMA handle with sequential allocation number 2 for instance 3 of the foo driver.

```
th_define -n foo -i 3 -l 256 256 -a dma_w -c 0 1 -f 2 -o OR 7
```

Causes 0x7 to be ORed into each long long in the range from offset 256 to offset 512 of the next DMA write, using any DMA handle for instance 3 of the foo driver. Subsequent calls in the driver to ddi_check_dma_handle() return DDI_FAILURE.

```
th_define -n foo -i 3 -r 0 -l 0 8 -a dma_w -c 100 3 -o AND 0xffffffffffffefff
```

The next 100 DMA writes using the DMA handle with sequential allocation number 0 for instance 3 of the foo driver take place as normal. However, on each of the three subsequent accesses, the 0x1000 bit will be cleared in the first long long of the transfer.

```
th_define -n foo -i 3 -a intr -c 0 6 -o LOSE 0
```

Causes the next six interrupts for instance 3 of the foo driver to be lost.

```
th_define -n foo -i 3 -a intr -c 30 1 -o EXTRA 10
```

When the thirty-first subsequent interrupt for instance 3 of the foo driver occurs, a further ten interrupts are also generated.

```
th_define -n foo -i 3 -a intr -c 0 1 -o DELAY 1024
```

Causes the next interrupt for instance 3 of the foo driver to be delayed by 1024 microseconds.

**Notes**

The policy option in the `th_define -p` syntax determines how a set of logged accesses will be converted into the set of error definitions. Each logged access will be matched against the chosen policies to determine whether an error definition should be created based on the access.

Any number of policy options can be combined to modify the generated error definitions.

**Bytewise Policies**

These select particular I/O transfer sizes. Specifying a byte policy will exclude other byte policies that have not been chosen. If none of the byte type policies is selected, all transfer sizes are treated equally. Otherwise, only those specified transfer sizes will be selected.
Create errdefs for one byte accesses (ddi_get8())
Create errdefs for two byte accesses (ddi_get16())
Create errdefs for four byte accesses (ddi_get32())
Create errdefs for eight byte accesses (ddi_get64())
Create errdefs for repeated byte accesses (ddi_rep_get*())

The frequency of access to a location is determined according to the access type, location and transfer size (for example, a two-byte read access to address A is considered distinct from a four-byte read access to address A). The algorithm is to count the number of accesses (of a given type and size) to a given location, and find the locations that were most and least accessed (let maxa and mina be the number of times these locations were accessed, and mean the total number of accesses divided by total number of locations that were accessed). Then a rare access is a location that was accessed less than

\[(mean - mina) / 3 + mina\]

times. Similarly for the definition of common accesses:

\[maxa - (maxa - mean) / 3\]

A location whose access patterns lies within these cutoffs is regarded as a location that is accessed with median frequency.

Create errdefs for locations that are rarely accessed.
Create errdefs for locations that are commonly accessed.
Create errdefs for locations that are accessed with median frequency.

If a transaction is duplicated, either a single or multiple errdefs will be written to the test scripts, depending upon the following two policies:

Create multiple errdefs for locations that are repeatedly accessed.
Create a single errdef for locations that are repeatedly accessed.

For each location, a default operator and operand is typically applied. For maximal test coverage, this default may be modified using the operators policy so that a separate errdef is created for each of the possible corruption operators.

See Also kill(1), th_manage(1M), alarm(2), ddi_check_acc_handle(9F), ddi_check_dma_handle(9F)
th_manage – manage the fault injection test harness

**Synopsis**
```
th_manage name instance command
   th_manage path command
```

**Description**
`th_manage` applies the action specified by `command` to the instance specified by `instance` of the driver specified by `name` (or the driver instance specified by `path`). The driver instance must be running fault injection specifications (errdefs) defined by `th_define(1M)`.

`th_manage` supports several commands that operate on the driver instance specified by `name` and `instance` (or `path`). The commands are:

- **broadcast**
  Awaken all `th_define` processes, causing them to display their current status and exit if the errdef is now defunct (that is, if `count`, `failcount`, and `acc_chk` are all zero).

- **clear_acc_chk**
  Awaken all `th_define` processes. If `count` and `failcount` are already zero, then set `acc_chk` to zero, so that `th_define` exits once it has displayed its status.

- **clear_errdefs**
  Awaken all `th_define` processes. `count`, `failcount` and `acc_chk` are all set to zero so that all `th_define` commands exit once they have displayed their status.

- **clear_errors**
  Awaken all `th_define` processes. If `count` is already zero, set `failcount` and `acc_chk` to zero, so that `th_define` exits once it has displayed its status.

- **get_handles**
  List all the access handles.

- **start**
  Begin or resume execution of all errdefs.

- **stop**
  Suspend all errdefs for this `name` and `instance` (or `path`).

**Examples**

**Example 1** Useful Commands

To begin the tests, enter:
```
# th_manage foo 0 start
```

To check the status of the errdefs, enter:
```
# th_manage foo 0 broadcast
```

This causes each `th_define` process to print out its current status.

If the driver has reported a fatal error, you can take the driver offline using `libdevice`, clear the error condition by entering:
```
# th_manage foo 0 clear_acc_chk
```
EXAMPLE 1 Useful Commands (Continued)

or

```
# th_manage foo 0 clear_errors
```

and bring the driver online again using `libdevice`.

To terminate testing, enter:

```
# th_manage foo 0 clear_errdefs
```

See Also th_define(1M)
tic (1M)

**Name**
tic – terminfo compiler

**Synopsis**
tic [-v [n]] [-c] file

**Description**
The command tic translates a terminfo file from the source format into the compiled format. The results are placed in the directory /usr/share/lib/terminfo. The compiled format is necessary for use with the library routines in curses(3CURSES).

If the environment variable TERMINFO is set, the compiled results are placed there instead of /usr/share/lib/terminfo.

Total compiled entries cannot exceed 4096 bytes. The name field cannot exceed 128 bytes. Terminal names exceeding 14 characters will be truncated to 14 characters and a warning message will be printed.

**Options**
The following options are supported:

- `-c` Specifies to check only file for errors. Errors in use= links are not detected.

- `-v[n]` Specify that (verbose) output be written to standard error trace information showing tic’s progress. The optional integer n is a number from 1 to 10, indicating the desired level of detail of information. If n is omitted, the default level is 1. If n is specified and greater than 1, the level of detail is increased.

**Operands**
file Contains one or more terminfo terminal descriptions in source format [see terminfo(4)]. Each description in the file describes the capabilities of a particular terminal. When a use=entry-name field is discovered in a terminal entry currently being compiled, tic reads in the binary from /usr/share/lib/terminfo to complete the entry. (Entries created from file will be used first. If the environment variable TERMINFO is set, that directory is searched instead of /usr/share/lib/terminfo.) tic duplicates the capabilities in entry-name for the current entry, with the exception of those capabilities that are explicitly defined in the current entry.

**Files**
/usr/share/lib/terminfo/?/* Compiled terminal description database

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

**See Also**
captoinfo(1M), infocmp(1M), curses(3CURSES), terminfo(4), attributes(5)

**Notes**
When an entry, for example, entry_name_1, contains a use=entry_name_2 field, any canceled capabilities in entry_name_2 must also appear in entry_name_1 before use= for these capabilities to be canceled in entry_name_1.
The **tncfg** utility creates, modifies, and displays the configuration of various networking properties related to Trusted Extensions. The command requires that the SMF service, `svc:/system/labeld` is enabled. It can be executed only in the global zone.

A template is a collection of network security properties that define the rules for labeling packets received from remote hosts. Four host types are supported: `cipso`, `unlabeled`, `adaptive`, and `netif`. Each template must specify one of these four host types. Hosts that are trusted to specify their own labels are assigned to `cipso` templates. Otherwise, hosts can be assigned to `unlabeled` or `adaptive` templates. When using a `unlabeled` template, a single default label must be specified. When using an `adaptive` template, the default label is not specified. Instead, the label is derived from the default label of the IP interface on which the packet is received.

The labeling properties of an IP interface are specified using the `netif` template type. For `netif` templates, the host address properties correspond to local interfaces, instead of remote hosts. These templates should be used when separate single-level networks are connected to corresponding labeled zones. Therefore, the default label of a `netif` template must equal the label of every zone with a network interface whose IP address matches a host address in that template. Furthermore, the lower-link corresponding to any such matching zone interfaces can only be assigned to other zones sharing the same label.

Hosts can be specified using hostnames, IP addresses, or masks. When masks are used, a prefix length that specifies how many bits are required for a match must be appended. Hosts cannot be assigned to more than one template. When masks are used, the entry with the longest matching prefix is used to associate a host with a template. Packets from hosts without a matching template are dropped.

Each template must include an upper and lower bound specifying the accreditation range of accepted labels. Additionally, up to four auxiliary labels can be specified to enumerate labels outside of this range. Services bound to multilevel ports can accept packets from hosts whose labels are within the accreditation range, or match one of the auxiliary labels.

Normally, the template settings and their corresponding hosts are persistently maintained in local files or by means of an LDAP directory, depending on the `-S` option. These settings are automatically loaded into kernel memory when the user commits the updates. If the `-e` (ephemeral) option is specified, only the current in-memory properties are displayed and updated. However, the list of hosts associated with an in-memory template is generally incomplete. To view the matching template for a specific host, use the `get` subcommand.
By default, an unlabeled template, admin_low, is installed with a default label of ADMIN_LOW, and two mask entries matching any IPv4 or IPv6 address, so that the global zone is initially able to contact any unlabeled hosts. It is recommended to remove these two mask entries once your network security policy is established. An additional template, cipso, is installed with no matching hosts. By default all local IP addresses are implicitly associated with this template, but it is recommended that they should be explicitly added to this or a new cipso-type template.

Searches for template and host entries are resolved in the order specified by means of the name service configuration file, /etc/nsswitch.conf. The keywords, tnrhdb and tnrhttp, are used to specify the search order for hosts and templates, respectively. Both the files and ldap repositories are supported, but it is recommended to specify files first.

Creating or modifying a template requires the authorization solaris.label.network.manage, which is included in the Object Label Management rights profile.

Zones
Zones are isolated execution environments described in zones(5). Trusted Extensions requires a zone brand called labeled to which special properties apply. Each labeled zone must have a unique label property at which it executes processes. This is also the label at which it will accept packets from remote hosts for services bound to single-level ports. Explicit multilevel port can also be specified. Services with the privilege net_bindmlp can bind to these ports, and accept packets within the accreditation range or the auxiliary label set associated with the remote host.

Non-global zones must be configured using zonecfg(1M) prior to configuring these properties. In general, updates to each zone’s properties, including the global zone, are applied when it is booted. However, the multilevel port properties of running zones are reloaded into kernel memory when updates are committed. If the -e (ephemeral) option is specified, the zone must be in the ready or running state, and only its multilevel port properties can be updated.

Creating or modifying a zone’s trusted networking properties requires the authorization solaris.label.zone.manage, which is included in the Object Label Management rights profile.

Properties
The set of valid properties depends on whether the -t or -z option was used. The two sets are referred to as the template context and the zone context.

Only a single property value can be specified at a time. Values containing white space must be quoted. An equal sign is required between the property and its value.

The values that can be specified in the template context properties are described below.

name=template_name
The initial value for the name is specified using -t option using the command line. If the name is changed, the current template properties are applied to the newly named template.
In this way an existing template can be cloned for subsequent editing. However, to avoid conflicts, the host entries from the initial template are not copied to the new template. The specified name must not match an existing template.

**host_type=cipso|unlabeled|adaptive|netif**

When the unlabeled or netif host types are used, the value specified using the the def_label property is implicitly applied to the received packets. The cipso host type is used for hosts that are trusted to explicitly label their packets. The adaptive host type is used for hosts whose label is derived from the interface on which their packets are received. The default is unlabeled.

**def_label=sensitivity_label**

The default label assigned to IP packets that are not explicitly labeled by means of cipso or IPsec.

**doi=integer**

A positive integer specifying the Domain of Interpretation for the binary representation of the labels. The default is 1.

**min_label=sensitivity_label**

The minimum label in the accreditation range for IP packets that are accepted by multilevel services.

**max_label=sensitivity_label**

The maximum label in the accreditation range for IP packets that are accepted by multilevel services.

**aux_label=sensitivity_label**

Additional labels, outside of the accreditation range, for IP packets that are accepted by multilevel services. Up to four labels may be specified, using the add subcommand repetitively.

**host=hostname/IP address[/prefix]**

A hostname or an IP address to which the template properties apply. For IP addresses, both IPv4 and IPv6 formats can be used, followed by an optional slash and prefix length specifying the number of bits to match against IP addresses. The IPv4 address 0.0.0.0 has an implied prefix length of zero, and matches any IPv4 address. Multiple host values can be specified, using the add subcommand repetitively. There is no specific limit.

The values that may be specified in the zone context properties are described below.

**name=zone_name**

The name of the zone, which must have previously been configured using zonecfg(1M). The initial value for the name is specified using -z option on the command line. If the name is changed, the current zone properties are applied to the newly named zone. In this way an existing template can be cloned for subsequent editing. However, to avoid conflicts, the initial label value is not copied to the new zone configuration. The specified name must correspond to an existing zone without a trusted networking configuration.
primary=yes|no
Although multiple zones can share a single sensitivity label, at most one zone for each label can have its primary property set to yes. This indicates that the zone should be selected as the target of any operation that specifies only a label instead of a zone name, such as choosing the label of a desktop workspace, sharing an IP address, or relabeling a file.

By default all zones are created with their primary property set to yes, unless an existing primary zone with a matching label already exists. Primary zones are not required for any label except admin_low, which is reserved for the global zone. When primary is set to no, the desktop packages are not installed by default.

label=sensitivity_label
The sensitivity label of the zone. It must be unique if the zone’s primary property is set to yes. Otherwise, if the session is interactive, the user is given the option to set the zone’s primary property to no. The global zone value must be admin_low.

visible=yes|no
Specifies whether the zone responds to ping requests from hosts whose labels don’t match the zone’s label. The default is no.

mlp_private=port|[-port2]/tcp|udp
A single port number, or a range of ports that privileged services can bind to and then accept requests from clients whose labels are with the accreditation range or the set of auxiliary labels specified in their matching templates. The port specification must be followed by a protocol, either tcp or udp. This value applies to all interfaces that are private to the zone. Multiple mlp_private values can be specified, using the add subcommand repetitively. This is only limited by the number of available ports.

mlp_shared=port|[-port2]/tcp|udp
A single port number, or a range of ports that privileged services can bind to and then accept requests from clients whose labels are with the accreditation range or the set of auxiliary labels specified in their matching templates. The port specification must be followed by a protocol, either tcp or udp. This value applies to any all-zones interfaces, and must not overlap with the mlp_shared ports specifications for other zones. Multiple mlp_shared values can be specified, using the add subcommand repetitively. This is only limited by the number of available ports.

Options  The following options are supported:

- e
  Specifies that the data is ephemeral, affecting only what is currently loaded into kernel memory.

- f command_file
  Specifies the name of tncfg command file. command_file is a text file of tncfg subcommands, one per line.
-t template
   Specifies the template name. If the named template does not exist, a new template is
   created. If neither -t nor -z is specified, the template context is assumed using cisco as the
default template name.

-S repository
   The valid repositories are files and ldap. The repository specifies which name service will
   be updated. The default repository is files.

-z zone
   Specifies the zone name. The zone must have previously been configured by means of
   zonecfg(1M).

**Sub-commands**

Subcommands can be provided on the command line or interactively. Multiple
subcommands, separated by semicolons, can be specified on the command line by enclosing
the entire set in quotation marks. The lack of subcommands implies an interactive session,
during which auto-completion of subcommands can be invoked using the tab key.

The add, clear, and remove subcommands are used for properties that can accept multiple
values. However, only one value can be specified at a time.

Subcommands which can result in destructive actions or loss of work have an -F option to
force the action. If input is from a terminal device, the user is prompted when appropriate if
such a subcommand is given without the -F option. Otherwise, the action is disallowed, with a
diagnostic message written to standard error.

The following subcommands are supported:

add property-name=property-value
   Adds the specified value to the current property values. This subcommand can only be
   applied to properties that accept multiple values. Use the set subcommand for single-value
   properties.

clear property-name
   Clears all of the values for the property. Only those properties that accept multiple
   assignments, using the add subcommand, can be cleared.

commit
   Commits the current configuration from memory to stable storage and into the kernel. The
   configuration must be committed for the changes to take effect. Until the in-memory
   configuration is committed, you can remove changes with the revert subcommand. The
   commit operation is attempted automatically upon completion of a tncfg session. Since a
   configuration must be correct to be committed, this operation automatically does a verify.

delete [-F]
   Deletes the specified template or zone configuration from the current name service.
   Specify the -F option to force the action. If the deletion is allowed, its action is
   instantaneous and the session is terminated.
export [-f output-file]
   Displays configuration to standard output. Use the -f option to display the configuration
to output-file. This option produces output in a form suitable for use in a command file.

get host=hostname | IP address/prefix]
   Displays the template name corresponding to the specified host using the kernel's
   in-memory mapping.

help [usage] [subcommands] [properties] [subcommand] [property]
   Displays general help or help about a given topic.

info property-name
   Displays information about the current template or zone, or the specified property in a
   parseable format.

list
   Lists the names of the templates or zones that have been configured.

remove property-name=property-value
   Removes the specified value from the property. Only those properties that accept multiple
   assignments, using the add subcommand, can be removed.

set property-name=property-value
   Sets a given property name to the given value. Properties that can take multiple values are
   assigned using the add subcommand, instead of set.

verify
   Verifies the current configuration for correctness:
   ▪ The required properties are specified;
   ▪ the values are valid for each key word;
   ▪ the user is authorized to specify the values.

revert [-F]
   Causes the configuration to revert to the last committed state. The -F option can be used to
   force the action.

exit [-F]
   Exits the tncfg session. A commit is automatically attempted if needed. You can also use an
   EOF character to exit tncfg. The -F option can be used to force the action.

Examples

EXAMPLE 1 Using the info Subcommand

The command below displays the properties of a cipso template are displayed. The
subcommand is specified on the command line.

eample% tncfg -t cipso info
   name=cipso
   host_type=cipso
   doi=1
   min_label=ADMIN_LOW
EXAMPLE 1 Using the info Subcommand (Continued)

    max_label=ADMIN LOW
    host=10.5.233.74

EXAMPLE 2 Using the export Subcommand

The following example shows an interactive session that exports the configuration of a zone in a format that could be imported to another machine with an equivalent zone.

eexample% tncfg -t public
    tncfg:public> export
    set name=public
    set host_type=cipso
    set doi=1
    set def_label="PUBLIC"
    set min_label="PUBLIC"
    set max_label="CONFIDENTIAL : NEED TO KNOW"
    add aux_label="SANDBOX PLAYGROUND"
    add host=myserver.oracle.com
    add host=10.5.0.0/16
    tncfg:public> exit

EXAMPLE 3 Assigning Properties to a Zone

In the following example, the public zone is configured to be a multi-level NFS server.

eexample% tncfg -z public
    tncfg:public> info
        name=public
        label=PUBLIC
        visible=no
    tncfg:public> add mlp_private=111/tcp
    tncfg:public> add mlp_private=111/ucp
    tncfg:public> add mlp_private=2049/tcp
    tncfg:public> commit
    tncfg:public> exit

Exit Status  0

    Successful completion.

    1
    An error occurred.

Files  • /etc/security/tsol/tnrhtp
       • /etc/security/tsol/tnrhdb
       • /etc/security/tsol/tnzonecfg

Notes  The Labeled Zone Manager, txzonemgr(1M), is an alternative application for configuring Trusted Extensions. It invokes the tncfg command internally, and provides an interactive GUI-based user interface.
**tnchkdb**

**Name**
tnchkdb – check file syntax of trusted network databases

**Synopsis**
/usr/sbin/tnchkdb [-h path] [-t path] [-z path]

**Description**
`tnchkdb` checks the syntax of the `tnrhtp`, `tnrhdb`, and `tnzonecfg` databases. By default, the path for each file is:

- /etc/security/tsol/tnrhtp
- /etc/security/tsol/tnrhdb
- /etc/security/tsol/tnzonecfg

You can specify an alternate path for any or all of the files by specifying that path on the command line by using the `-h (tnrhdb)`, `-t (tnrhtp)` and `-z (tnzonecfg)` options. The options are useful when testing a set of modified files before installing the files as new system databases.

All three database files are checked for integrity. `tnchkdb` returns an exit status of 0 if all of the files are syntactically and, to the extent possible, semantically correct. If one or more files have errors, then an exit status of 1 is returned. If there are command line problems, such as an unreadable file, an exit status of 2 is returned. Errors are written to standard error.

To avoid cascading errors, when there are errors in `tnrhtp`, the template names in `tnrhdb` are not validated.

`tnchkdb` can be run at any label, but the standard `/etc/security/tsol` files are visible only in the global zone.

**Options**
- `-h [path]` Check path for proper `tnrhdb` syntax. If path is not specified, then check /etc/security/tsol/tnrhdb.
- `-t [path]` Check path for proper `tnrhtp` syntax. If path is not specified, then check /etc/security/tsol/tnrhtp.
- `-z [path]` Check path for proper `tnzonecfg` syntax. If path is not specified, then check /etc/security/tsol/tnzonecfg.

**Examples**

**EXAMPLE 1** Sample Error Message

The `tnchkdb` command checks for CIPSO errors. In this example, the `admin_low` template has an incorrect value of `ADMIN_HIGH` for its default label.

```bash
# tnchkdb
checking /etc/security/tsol/tnrhtp ...
 tnchkdb: def_label classification 7fff is invalid for cipso labels:
 line 14 entry admin_low
 tnchkdb: def_label compartments 241-256 must be zero for cipso labels:
 line 14 entry admin_low
checking /etc/security/tsol/tnrhdb ...
checking /etc/security/tsol/tnzonecfg ...
```
Files

Trusted Extensions Configuration and Administration

Notes  The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

It is possible to have inconsistent but valid configurations of tnrhtp and tnrhdb when LDAP is used to supply missing templates.
Name  tnctl – configure Trusted Extensions network parameters

Synopsis  
/usr/sbin/tnctl [-dfv] [-h host [/prefix] [:template]]
[-m zone:mlp:shared-mlp][-t template [:key=val [;key=val]]]
[-HTz] file

Description  tnctl provides an interface to manipulate trusted network parameters in the Solaris kernel.

As part of Solaris Trusted Extensions initialization, tnctl is run in the global zone by an 
smf(5) script during system boot. The tnctl command is not intended to be used during 
normal system administration. Instead, if a local trusted networking database file is modified, 
the administrator first issues tnchkdb(1M) to check the syntax, and then refreshes the kernel 
copy with this command:

```
# svcadm restart svc:/network/tnctl
```

See WARNINGS about the risks of changing remote host and template information on a running 
system.

Options  
- d  Delete matching entries from the kernel. The entries will be deleted from kernel cache table 
that matches the template host type. For example, if the template host type is NETIF, the 
entry will be deleted from the kernel interface cache; otherwise, the entry will be deleted 
from kernel host cache. If a template is not specified, tnctl attempts to delete the entry 
from kernel cache table.

When deleting MLPs, the MLP range must match exactly. MLPs are specified in the form:

```
port[-port]/protocol
```

Where port can be a number in the range 1 to 65535, or any known service (see 
services(4)), and protocol can be a number in the range 1 to 255, or any known protocol 
(see protocols(4)).

- f  Flush all kernel entries before loading the entries that are specified on the command line. 
The flush does not take place unless at least one entry parsed successfully. Both host cache 
and interface cache entries are flushed.

- v  Turn on verbose mode.

- h host[/prefix][:template]  
Update the kernel remote-host cache on the local host for the specified host or, if a template 
name is given, change the kernel’s cache to use the specified template. If prefix is not 
specified, then an implied prefix length is determined according to the rules used for 
interpreting the tnrhdb. If -d is specified, then a template name cannot be specified.
Modify the kernel's multilevel port (MLP) configuration cache for the specified zone. zone specifies the zone to be updated. mlp and shared-mlp specify the MLPs for the zone-specific and shared IP addresses. The shared-mlp field is effective in the global zone only.

Update the kernel's template cache for template or, if a list of key=val pairs is given, change the kernel's cache to use the specified entry. If -d is specified, then key=val pairs cannot be specified.

Load all template entries in file into the kernel cache.

Load all remote host entries in file into the kernel cache.

Load just the global zone's MLPs from file into the kernel cache. To reload MLPs for a non-global zone, reboot the zone:

```
# zoneadm -z non-global zone reboot
```

Trusted Extensions Configuration and Administration

Warnings

Changing a template while the network is up can change the security view of an undetermined number of hosts.

Notes

The functionality described on this manual page is available only if the system is configured with Trusted Extensions.
The `tnctl` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/tnctl
```

The service’s status can be queried by using `svcs(1)`. Administrative actions on this service, such as refreshing the kernel cache, can be performed using `svcadm(1M)`, as in:

```
svcadm restart svc:/network/tnctl
```
The `tnd` (trusted network daemon) initializes the kernel with trusted network databases and also reverts the databases. `tnd` follows the order specified in the `nsswitch.conf` file when loading configuration databases.

`tnd` is intended to be started from the `svc:/network/tnd smf(5)` service during the boot process in the global zone only when the system has been configured as an LDAP client. Systems that use only local files for the trusted network databases use `tnctl(1M)` instead of `tnd`.

`tnd` loads the following databases into the kernel: the remote host database, `tnrhdb`, and the remote-host template database, `tnrhtp`. `tnd` also periodically scans for changes in the associated LDAP database or local databases and updates the kernel cache accordingly.

If a local trusted networking database file is modified, the administrator should run `tnchkdb(1M)` to check the syntax, and should also run `svcadm refresh svc:/network/tnd` to initiate an immediate database scan by `tnd`.

`tnd` is intended to be started from an `smf(5)` script and to run in the global zone. The following `svcadm` commands signal `tnd` to perform specific actions:

- `svcadm refresh svc:/network/tnd` Initiates a rescan of the local and LDAP `tnrhdb` and `tnrhtp` databases. `tnd` updates the kernel database with any changes found.
- `svcadm disable svc:/network/tnd` Terminates the `tnd` daemon. No changes are made to the kernel database.

Running `tnd` in debug mode is determined by the value of the following service management facility (SMF) property:

```
tnd/debug_level = 0
```

A value of 0, as above, prevents debug information from being collected; 1 turns on debugging. The default value is 0. Debug output is sent to the `/var/tsol/tnd/log` log file.

The following command changes the polling interval to one hour, and puts this interval in the SMF repository. At the next boot, the `tnd` poll interval will be one hour.

```
# svccfg -s network/tnd setprop tnd/poll_interval=3600
```
EXAMPLE 1   Changing the Poll Interval   (Continued)

The following command changes the polling interval, but does not update the repository. At
the next boot, the tnd poll interval remains the default, 30 minutes.

# tnd -p 3600

**Trusted Extensions Configuration and Administration**

**Notes**  The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

The tnd service is managed by the service management facility, `smf(5)`, under the service identifier:

`svc:/network/tnd`

The service’s status can be queried by using `svcs(1)`. Administrative actions on this service, such as requests to restart the daemon, can be performed using `svcadm(1M)`, as in:

`svcadm restart svc:/network/tnd`
tninfo – print kernel-level network information and statistics

```
/usr/sbin/tninfo [-h hostname] [-i interface_ip_address]
                 [-m zone-name] [-t template]
```

### Description

**tninfo** provides an interface to retrieve and display kernel-level network information and statistics.

**Options**

- **-h hostname**
  - Display the security structure for the specified host in the remote-host cache. The output should reflect what is specified in the **tnrhdb** database.

- **-i interface_ip_address**
  - Display the template associated with the IP interface that hosts the IP address.

- **-m zone-name**
  - Display the MLP configuration associated with the specified zone. The output should reflect what is specified in the **tnzonecfg** database.

- **-t template**
  - Display the structure associated with the specified **template**. The output should reflect what is specified in the **tnrhtp** database.

### Examples

**EXAMPLE 1**  
**Displaying Remote Host Structures Cached in the Kernel**

This example shows the remote host structures cached in the kernel. The output reflects the definition in the **tnrhdb** database.

```bash
# tninfo -h machine1
IP address= 192.168.8.61
Template = cipso
```

**EXAMPLE 2**  
**Displaying Multilevel Ports for the Global Zone**

This example shows the kernel-cached MLPs for the global zone. The output reflects the definition in the **tnzonecfg** database, plus any dynamically allocated MLPs. **private** indicates zone-specific MLPs.

```bash
# tninfo -m global
private:23/tcp;111/tcp;111/udp;515/tcp;2049/tcp;6000-6003/tcp;
     32812/tcp;36698/ip;38634/tcp;64365/ip
shared: 6000-6003/tcp
```

**EXAMPLE 3**  
**Displaying the cipso and netif Template Definitions**

This example shows the kernel-cached **cipso** template definition. The output reflects the definition in the **tnrhtp** database.

```bash
# tninfo -t cipso
```

Remote Host Template Table Entries:

```
```
EXAMPLE 3  Displaying the cipso and netif Template Definitions  (Continued)

```
    template: cipso
    host_type: CIPSO
    doi: 1
    min sl: ADMIN LOW
    hex: ADMIN LOW
    max sl: ADMIN HIGH
    hex: ADMIN HIGH

    # tninfo -t netif
```

EXAMPLE 4  DisplayingTemplateNameAssociatedwithanIPInterface

The example command below shows the kernel-cached template name associated with the
interface on which the IP address is hosted.

```
    # tninfo -i 192.168.3.10
    IP address= 192.168.3.10
    Template = netif
```

**Files**

Trusted Extensions Configuration and Administration

Notes  The functionality described on this manual page is available only if the system is configured with Trusted Extensions.
tpmadm(1M)

Name  tpmadm – administer Trusted Platform Module

Synopsis  tpmadm status
           tpmadm init
           tpmadm clear [owner | lock]
           tpmadm auth
           tpmadm keyinfo [uuid]
           tpmadm deletekey uuid
           tpmadm migrate export  UUID [MigDataFile MigKeyfile]
           tpmadm migrate import  UUID [MigDataFile MigKeyfile [ParentUUID] [NewKeyUUID]]
           tpmadm pcrexend pcr [filename]
           tpmadm pcrreset pcr

Description  A Trusted Platform Module (TPM) is a hardware component that provides for protected key storage and reliable measurements of software used to boot the operating system. The tpmadm utility is used to initialize and administer the TPM so that it can be used by the operating system and other programs.

The TPM subsystem can store and manage an unlimited number of keys for use by the operating system and by users. Each key is identified by a Universally Unique Identifier, or UUID.

Although the TPM can hold only a limited number of keys at any given time, the supporting software automatically loads and unloads keys as needed. When a key is stored outside the TPM, it is always encrypted or “wrapped” by its parent key so that the key is never exposed in readable form outside the TPM.

Before the TPM can be used, it must be initialized by the platform owner. This process involves setting an owner password which is used to authorize privileged operations.

Although the TPM owner is similar to a traditional superuser, there are two important differences. First, process privilege is irrelevant for access to TPM functions. All privileged operations require knowledge of the owner password, regardless of the privilege level of the calling process. Second, the TPM owner is not able to override access controls for data protected by TPM keys. The owner can effectively destroy data by re-initializing the TPM, but he cannot access data that has been encrypted using TPM keys owned by other users.

Sub-commands  The following subcommands are used in the form:

# tpmadm <subcommand> [operand]
status
Report status information about the TPM. Output includes basic information about whether ownership of the TPM has been established, current PCR contents, and the usage of TPM resources such as communication sessions and loaded keys.

init
Initialize the TPM for use. This involves taking ownership of the TPM by setting the owner authorization password. Taking ownership of the TPM creates a new storage root key, which is the ancestor of all keys created by this TPM. Once this command is issued, the TPM must be reset using BIOS operations before it can be re-initialized.

auth
Change the owner authorization password for the TPM.

clear lock
Clear the count of failed authentication attempts. After a number of failed authentication attempts, the TPM responds more slowly to subsequent attempts, in an effort to thwart attempts to find the owner password by exhaustive search. This command, which requires the correct owner password, resets the count of failed attempts.

clear owner
Deactivate the TPM and return it to an unowned state. This operation, which requires the current TPM owner password, invalidates all keys and data tied to the TPM. Before the TPM can be used again, the system must be restarted, the TPM must be reactivated from the BIOS or ILOM pre-boot environment, and the TPM must be re-initialized using the tpmadm init command.

keyinfo [uuid]
Report information about keys stored in the TPM subsystem. Without additional arguments, this subcommand produces a brief listing of all keys. If the UUID of an individual key is specified, detailed information about that key is displayed.

deletekey uuid
Delete the key with the specified UUID from the TPM subsystem’s persistent storage.

migrate export UUID [MigDataFile MigKeyfile]
Create the initial migration blob and key for the persistent key UUID. If necessary, the user will be prompted for a password to access the key being migrated. Additionally, the user will be prompted to create an authorization password for the migration key. This operation creates two files: a migration blob (wrapped key) and a migration key to be used in future migrations. The output files will be named tpm-migration.dat and tpm-migration.key, unless they are specified on the command line. This operation will require TPM owner authorization as well as authorization passwords for any parent keys that must be loaded in order to load the key being exported. The user will be prompted for all authorization passwords as needed.

migrate import [MigDataFile MigKeyFile [ParentUUID] [NewKeyUUID]]
Import a key into the user’s persistent key DB. The key will be made a child of the given ParentUUID. If ParentUUID is not given, the imported key will be a child of the system.
MRK UUID. If NewKeyUUID is not given, the system will generate a new UUID and report it to the user upon completion of the command. The user will be prompted for the migration password used in the "export" step. When the migrate import command is given with no arguments, the import operation will attempt the migration of the SYSTEM MRK UUID to the current SRK in the system key db. When importing an MRK, the user must have the TPM Administration rights (see prof_attr) or have root privilege (euid == 0). This operation will require TPM owner authorization as well as authorization passwords for any parent keys that must be loaded in order to load the key being exported. The user will be prompted for all authorization passwords as needed.

pcrextend pcr [filename]
Create an SHA-1 hash of the contents of filename and perform a PCR Extend operation on the indicated PCR using the hash value as the data to be extended. If a filename is not specified, the data is read from stdin.

pcreset pcr
Reset the indicated PCR to its initial state (all zeros).

Exit Status
After completing the requested operation, tpmadm exits with one of the following status values.

0
  Successful termination.

1
  Failure. The requested operation could not be completed.

2
  Usage error. The tpmadm command was invoked with invalid arguments.

TCG Software Stack (TSS) Specifications:
https://www.trustedcomputinggroup.org/specs/TSS (as of the date of publication)

Notes
Tpmadm communicates with the TPM device through the tcsd service. Tcsd must be running before using the tpmadm command. If tcsd is not running, tpmadm will generate the following error:

Connect context: Communication failure (0x3011)
See `tcsd(8)` for more details.
traceroute(1M)

Name  traceroute – print the route packets take to network host

Synopsis  traceroute [-adFlnSvx] [-A addr_family] [-c traffic_class]
[-f first_hop] [-q gateway] [-g gateway...] | -r
[-I [iface] [-L flow_label] [-m max_hop]
[-P pause_sec] [-p port] [-r max_timeout]
[-q nqueries] [-s src_addr] [-t tos] [-w wait_time] host

[packetlen]

Description  The Internet is a large and complex aggregation of network hardware, connected by gateways. Tracking the route a packet follows can be difficult. The utility traceroute traces the route that an IP packet follows to another internet host.

The traceroute utility utilizes the both the IPv4 and IPv6 protocols. Use the -A option to override the default behavior. traceroute uses the IPv4 protocol ttl (time to live) field or the IPv6 field hop limit. It attempts to elicit an ICMP or ICMP6 TIME_EXCEEDED response from each gateway along the path, and a PORT_UNREACHABLE (or ECHO_REPLY if -I is used) response from the destination host. It starts by sending probes with a ttl or hop limit of 1 and increases by 1 until it either gets to the host, or it hits the maximum max_hop. The default maximum max_hop is 30 hops, but this can be set by the -m option.

Three probes are sent at each ttl (hop limit) setting, and a line is printed showing the ttl (hop limit), the hostname and the address of the gateway, and the rtt (round trip time) of each probe. The number of probes may be specifically set using the -q option. If the probe answers come from different gateways, the hostname and the address of each responding system will be printed. If there is no response within a 5 second timeout interval, an asterisk (*) is displayed for that probe. The -w option may be used to set the timeout interval. Other possible annotations that may appear after the time are:

!  the ttl (hop limit) value in the received packet is <= 1.

!H  host unreachable.

!X  communication administratively prohibited.

<!N>  ICMP (ICMP6) unreachable code N.

The following annotations appear only for IPv4:

!F  fragmentation needed. This should never occur. If this is seen, the associated gateway is broken.

!N  network unreachable.
protocol unreachable.

source route failed. It is likely that the gateway does not support source routing.

unreachable for the specified tos (type-of-service).

source host isolated or precedence problem.

The following annotations appear only for IPv6:

host unreachable for a reason other than lack of an entry in the routing table.

packet too big.

destination is not a neighbor.

unrecognized next header.

If almost all the probes result in some kind of unreachable code, then traceroute gives up and exits.

The destination host is not supposed to process the UDP probe packets, so the destination port default is set to an unlikely value. However, if some application on the destination is using that value, the value of port can be changed with the -p option.

The only mandatory parameter is the destination host name or IP number. The default probe datagram length is 40 bytes (60 bytes for IPv6), but this may be increased by specifying a packet length (in bytes) after the destination host name.

All integer arguments to traceroute can be specified in either decimal or hexadecimal notation. For example, packetlen can be specified either as 256 or 0x100.

Options

-A addr_family
Specify the address family of the target host. addr_family can be either inet or inet6. Address family determines which protocol to use. For an argument of inet, IPv4 is used. For inet6, IPv6 is used.

By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, traceroute will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.
Specify the address family `inet` or `inet6` to override the default behavior. If the argument specified is `inet`, `traceroute` will use the IPv4 address associated with the hostname. If none exists, `traceroute` will state that the host is unknown and exit. It will not try to determine if an IPv6 address exists in the name service database.

If the specified argument is `inet6`, `traceroute` will use the IPv6 address that is associated with the hostname. If none exists, `traceroute` will state that the host is unknown and exit.

- **-a**
  Probe all of the addresses of a multi-homed destination. The output looks like `traceroute` has been run once for each IP address of the destination. If this option is used together with `-A`, `traceroute` probes only the addresses that are of the specified address family. While probing one of the addresses of the destination, user can skip to the next address by sending a `SIGINT`, or exit `traceroute` by sending a `SIGQUIT` signal. See `signal(3C)`

- **-c** `traffic_class`
  Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the value of `traffic_class` set in the probe packet. This option is valid only on IPv6.

- **-d**
  Set the `SO_DEBUG` socket option.

- **-F**
  Turn off fragmentation. For IPv4, this means setting the Don’t Fragment bit. For IPv4 and IPv6, this means do not allow fragmentation as the datagrams are sent. If the packetlen exceeds the MTU, then `traceroute` may report that sending failed due to Message too long.

- **-f** `first_hop`
  Set the starting `ttl (hop limit)` value to `first_hop`, to override the default value 1. `traceroute` skips processing for those intermediate gateways which are less than `first_hop` hops away.

- **-g** `gateway`
  Specify a loose source route `gateway`. The user can specify more than one `gateway` by using `-g` for each gateway. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6. This option cannot be used with the `-r` option.

  Only users with the `{PRIV_NET_RAWACCESS}` privilege can specify a loose source route with this option.

- **-I**
  Use ICMP (ICMP6) `ECHO` instead of UDP datagrams.

- **-i** `iface`
  For IPv4, this option specifies a network interface to obtain the source IP address. This is normally only useful on a multi-homed host. The `-s` option is also another way to do this.
For IPv6, it specifies the network interface on which probe packets are transmitted. The argument can be either an interface index, for example, 1, 2, or an interface name, for example, er10, hme0.

-L flow_label
Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.

-l
Print the value of the ttl (hop limit) field in each packet received.

-m max_hop
Set the maximum ttl (hop limit) used in outgoing probe packets. The default is 30 hops, which is the same default used for TCP connections.

-n
Print hop addresses numerically rather than symbolically and numerically. This saves a nameserver address-to-name lookup for each gateway found on the path.

-P pause_sec
Specify a delay, in seconds, to pause between probe packets. This may be necessary if the final destination does not accept undeliverable packets in bursts. By default, traceroute sends the next probe as soon as it has received a reply. Note that pause_sec is a real number.

-p port
Set the base UDP port number used in probes. The default is 33434. traceroute hopes that nothing is listening on UDP ports (base+(nhops-1)*nqueries) to (base+(nhops*nqueries)-1) at the destination host, so that an ICMP (ICMP6) PORT_UNREACHABLE message will be returned to terminate the route tracing. If something is listening on a port in the default range, this option can be used to select an unused port range. nhops is defined as the number of hops between the source and the destination.

-Q max_timeout
Stop probing this hop after max_timeout consecutive timeouts are detected. The default value is 5. Useful in combination with the -q option if you have specified a large nqueries probe count.

-q nqueries
Set the desired number of probe queries. The default is 3.

-r
Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. This option can be used to send probes to a local host through an interface that has been dropped by the router daemon. See in.routed(1M). You cannot use this option if the -g option is used.

-S
Display a summary of how many probes were not answered for each hop.
Use the following address, which usually is given as a literal IP address, not a hostname, as the source address in outgoing probe packets. On multi-homed hosts, those with more than one IP address, this option can be used to force the source address to be something other than the IP address traceroute picks by default. If the IP address is not one of this machine's interface addresses, an error is returned and nothing is sent. For IPv4, when used together with the -i option, the given IP address should be configured on the specified interface. Otherwise, an error will be returned. In the case of IPv6, the interface name and the source address do not have to match.

Set the tos(type-of-service) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the tos value set in the probe packet. This option is valid only on IPv4.

Verbos output. For each hop, the size and the destination of the response packets is displayed. Also ICMP (ICMP6) packets received other than TIME_EXCEEDED and UNREACHABLE are listed as well.

Set the time, in seconds, to wait for a response to a probe. The default is 5 seconds.

Prevent traceroute from calculating checksums. Checksums are usually required for the last hop when using ICMP ECHO probes. This option is valid only on IPv4. See the -I option.

When specified from within a shared-IP zone, this option has no effect as the checksum is always calculated by the operating system in this case.

The following operands are supported:

- **host**
  The network host.

**Operands**

**Examples**

**EXAMPLE 1**  Sample Output From the traceroute Utility

Some sample output from the traceroute utility might be:

```
istanbul% traceroute london
traceroute: Warning: london has multiple addresses; \ 
  using 4::114:a00:20ff:ab3d:83ed
traceroute: Warning: Multiple interfaces found; \ 
  using 4::56:a00:20ff:fe03:8d6e @ eri0:2
traceroute to london (4::114:a00:20ff:ab3d:83ed), 30 hops max, \ 
  60 byte packets
1 frblg7c-86 (4::56:a00:20ff:fe1f:65a1) 1.786 ms 1.544 ms 1.719 ms
```
The target host, london, has both IPv4 and IPv6 addresses in the name service database. According to the default behavior, traceroute uses IPv6 address of the destination host.

EXAMPLE 2  Using the traceroute Utility For a Host Which has Only IPv4 Addresses

In the following examples, traceroute is tracking the route to host san francisco, which has only IPv4 addresses in the name service database. Therefore traceroute uses only IPv4 addresses. The following shows the 7-hop path that a packet would follow from the host istanbul to the host san francisco.

```
istanbul% traceroute san francisco
traceroute to san francisco (172.29.64.39), 30 hops max, 40 byte packets
1  frbldg7c-86 (172.31.86.1)  1.516 ms  1.283 ms  1.362 ms
2  bldg4-bldg4 (172.30.4.49)  1.978 ms  1.986 ms  13.996 ms
3  bldg6-bldg4 (172.30.4.49)  2.655 ms  3.042 ms  2.344 ms
4  ferbldg11a-001 (172.29.1.236)  2.636 ms  3.432 ms  3.830 ms
5  frbldg7b-153 (172.29.153.72)  3.452 ms  3.146 ms  2.962 ms
6  san francisco (172.29.64.39)  3.430 ms  3.312 ms  3.451 ms
```

EXAMPLE 3  Using the traceroute Utility With Source Routing

The following example shows the path of a packet that goes from istanbul to san francisco through the hosts cairo and paris, as specified by the -g option. The -I option makes traceroute send ICMP ECHO probes to the host san francisco. The -i option sets the source address to the IP address configured on the interface qe0.

```
istanbul% traceroute -g cairo -g paris -i qe0 -q 1 -I san francisco
traceroute to san francisco (172.29.64.39), 30 hops max, 56 byte packets
1  frbldg7c-86 (172.31.86.1)  2.012 ms
2  flrbldg7u (172.31.17.131)  4.960 ms
3  cairo (192.168.163.175)  4.894 ms
4  flrbldg7u (172.31.17.131)  3.475 ms
5  frbldg7c-017 (172.31.17.83)  4.126 ms
6  paris (172.31.86.31)  4.086 ms
7  frbldg7b-82 (172.31.82.1)  6.454 ms
8  bldg4-bldg4 (172.30.4.49)  6.518 ms
9  bldg6-bldg4 (172.30.4.49)  6.518 ms
10  ferbldg11a-001 (172.29.1.236)  9.108 ms
11  frbldg12b-153 (172.29.153.72)  9.634 ms
12  san francisco (172.29.64.39)  14.631 ms
```
The following exit values are returned:

0  Successful operation.

>0  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

See Also  netstat(1M), signal(3C), ping(1M), attributes(5), privileges(5), zones(5)

Warnings  This utility is intended for use in network testing, measurement and management. It should be used primarily for manual fault isolation. Because of the load it could impose on the network, it is unwise to use traceroute(1M) during normal operations or from automated scripts.
**Name**
trapstat – report trap statistics

**Synopsis**
/usr/sbin/trapstat [-t | -T | -e entry]
[ -C processor_set_id | -c cpulist] [-P] [-a]
[ -A cor|soc|bins | -k keys] [-o num] [-m]
[ -I statfile] [-O statfile]
[ -r rate] [ [interval [count]] | command | [args]]

/usr/sbin/trapstat -l [-t | -T]

**Description**
The `trapstat` utility gathers and displays run-time trap statistics on UltraSPARC-based systems. The default output is a table of trap types and CPU IDs, with each row of the table denoting a trap type and each column of the table denoting a CPU. If standard output is a terminal, the table contains as many columns of data as can fit within the terminal width; if standard output is not a terminal, the table contains at most six columns of data. By default, data is gathered and displayed for all CPUs; if the data cannot fit in a single table, it is printed across multiple tables. The set of CPUs for which data is gathered and displayed can be optionally specified with the `-c` or `-C` option.

Unless the `-r` option or the `-a` option is specified, the value displayed in each entry of the table corresponds to the number of traps per second. If the `-r` option is specified, the value corresponds to the number of traps over the interval implied by the specified sampling rate; if the `-a` option is specified, the value corresponds to the accumulated number of traps since the invocation of `trapstat`.

By default, `trapstat` displays data once per second, and runs indefinitely; both of these behaviors can be optionally controlled with the `interval` and `count` parameters, respectively. The `interval` is specified in seconds; the `count` indicates the number of intervals to be executed before exiting. Alternatively, `command` can be specified, in which case `trapstat` executes the provided command and continues to run until the command exits. A positive integer is assumed to be an `interval`; if the desired `command` cannot be distinguished from an integer, the full path of `command` must be specified.

UltraSPARC I (obsolete), II, and III handle translation lookaside buffer (TLB) misses by trapping to the operating system. TLB miss traps can be a significant component of overall system performance for some workloads; the `-t` option provides in-depth information on these traps. When run with this option, `trapstat` displays both the rate of TLB miss traps and the percentage of time spent processing those traps. Additionally, TLB misses that hit in the translation storage buffer (TSB) are differentiated from TLB misses that further miss in the TSB. (The TSB is a software structure used as a translation entry cache to allow the TLB to be quickly filled; it is discussed in detail in the *UltraSPARC II User’s Manual.*) The TLB and TSB miss information is further broken down into user- and kernel-mode misses.

Workloads with working sets that exceed the TLB reach may spend a significant amount of time missing in the TLB. To accommodate such workloads, the operating system supports multiple page sizes: larger page sizes increase the effective TLB reach and thereby reduce the number of TLB misses. To provide insight into the relationship between page size and TLB
miss rate, trapstat optionally provides in-depth TLB miss information broken down by page size using the -T option. The information provided by the -T option is a superset of that provided by the -t option; only one of -t and -T can be specified.

**Options**

The following options are supported:

- **-a**
  Displays the number of traps as accumulating, monotonically increasing values instead of per-second or per-interval rates.

- **-A cor**
  Aggregate output by core ID. Data rows having the same core ID are aggregated into one row. The columns are replaced with subtotals, by default. The -m option prints column averages, instead.

- **-A soc**
  Aggregate output by socket ID. Data rows having the same socket ID are aggregated into one row. The columns are replaced with subtotals, by default. The -m option prints column averages, instead.

- **-A bins**
  Aggregate the columns into a lesser number of bins within each sampling period, grouping them in the order in which they appear. The -m option may be used in order to compute the arithmetic mean instead of the subtotal. The -k sorting option may be used to change the column order prior to the binning step.

  Aggregation by ID (-A cor|soc) is processed before sorting (-k). Grouping by bins (-A bins) is done next. Finally, the number of output lines printed per interval may be limited by -o.

- **-c cpulist**
  Enables trapstat only on the CPUs specified by cpulist.

  cpulist can be a single processor ID (for example, 4), a range of processor IDs (for example, 4-6), or a comma separated list of processor IDs or processor ID ranges (for example, 4, 5, 6 or 4, 6-8).

- **-C processor_set_id**
  Enables trapstat only on the CPUs in the processor set specified by processor_set_id.

  trapstat modifies its output to always reflect the CPUs in the specified processor set. If a CPU is added to the set, trapstat modifies its output to include the added CPU; if a CPU is removed from the set, trapstat modifies its output to exclude the removed CPU. At most one processor set can be specified.

- **-e entrylist**
  Enables trapstat only for the trap table entry or entries specified by entrylist. A trap table entry can be specified by trap number or by trap name (for example, the level-10 trap can be specified as 74, 0x4A, 0x4a, or level-10).
entrylist can be a single trap table entry or a comma separated list of trap table entries. If the specified trap table entry is not valid, trapstat prints a table of all valid trap table entries and values. A list of valid trap table entries is also found in The SPARC Architecture Manual, Version 9 and the Sun Microelectronics UltraSPARC II User’s Manual. If the parsable option (-P) is specified in addition to the -e option, the format of the data is as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Timestamp (nanoseconds since start)</td>
</tr>
<tr>
<td>2</td>
<td>CPU ID</td>
</tr>
<tr>
<td>3</td>
<td>Trap number (in hexadecimal)</td>
</tr>
<tr>
<td>4</td>
<td>Trap name</td>
</tr>
<tr>
<td>5</td>
<td>Trap rate per interval</td>
</tr>
</tbody>
</table>

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 6; extant fields will remain unchanged.

-I statfile
Replay data previously saved in statfile. Create data files for replay by specifying -0. This option is especially useful for analyzing statistics on machines with large numbers of CPUs. The file may be reprocessed multiple times using different sorting and aggregation options.

The -I option is incompatible with an interval and count specification.

-k key1,...
Sort rows within each sampling period from highest to lowest by key1, then key2, and so on. Each key may be any of the row headers in the trapstat output, such as level-10, u-itlb-miss, and so forth.

Use trapstat -l to list all event names. Use -lt or -lT to list key names for the TLB formats.

-l
Lists trap table entries. By default, a table is displayed containing all valid trap numbers, their names and a brief description. The trap name is used in both the default output and in the entrylist parameter for the -e argument. If the parsable option (-P) is specified in addition to the -l option, the format of the data is as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Trap number in hexadecimal</td>
</tr>
<tr>
<td>2</td>
<td>Trap number in decimal</td>
</tr>
</tbody>
</table>
-m
Display the arithmetic mean value rather than the sum when the -b or -i is used to aggregate data over multiple CPUs.

-o num
Display only the first num rows within each sampling period, after applying sorting and aggregation options.

-O statfile
Save all data to statfile. This data may be replayed at a later time using -I.

Write to the standard output if the file name is – (hyphen).

The purpose of -O is to capture all available data. It is incompatible with the data reduction options: -A, -k, -m, and -o.

-p
Generates parsable output. When run without other data gathering modifying options (that is, -e, -t or -T), trapstat's the parsable output has the following format:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Timestamp (nanoseconds since start)</td>
</tr>
<tr>
<td>2</td>
<td>CPU ID</td>
</tr>
<tr>
<td>3</td>
<td>Trap number (in hexadecimal)</td>
</tr>
<tr>
<td>4</td>
<td>Trap name</td>
</tr>
<tr>
<td>5</td>
<td>Trap rate per interval</td>
</tr>
</tbody>
</table>

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 6; extant fields will remain unchanged.

-r rate
Explicitly sets the sampling rate to be rate samples per second. If this option is specified, trapstat's output changes from a traps-per-second to traps-per-sampling-interval.

-t
Enables TLB statistics.
A table is displayed with four principal columns of data: \texttt{itlb-miss, itsb-miss, dtlb-miss,} and \texttt{dtsb-miss}. The columns contain both the rate of the corresponding event and the percentage of CPU time spent processing the event. The percentage of CPU time is given only in terms of a single CPU. The rows of the table correspond to CPUs, with each CPU consuming two rows: one row for user-mode events (denoted with \texttt{u}) and one row for kernel-mode events (denoted with \texttt{k}). For each row, the percentage of CPU time is totalled and displayed in the rightmost column. The CPUs are delineated with a solid line. If the parsable option (\texttt{-P}) is specified in addition to the \texttt{-t} option, the format of the data is as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Timestamp (nanoseconds since start)</td>
</tr>
<tr>
<td>2</td>
<td>CPU ID</td>
</tr>
<tr>
<td>3</td>
<td>Mode (\texttt{k} denotes kernel, \texttt{u} denotes user.</td>
</tr>
<tr>
<td>4</td>
<td>I-TLB misses</td>
</tr>
<tr>
<td>5</td>
<td>Percentage of time in I-TLB miss handler</td>
</tr>
<tr>
<td>6</td>
<td>I-TSB misses</td>
</tr>
<tr>
<td>7</td>
<td>Percentage of time in I-TSB miss handler</td>
</tr>
<tr>
<td>8</td>
<td>D-TLB misses</td>
</tr>
<tr>
<td>9</td>
<td>Percentage of time in D-TLB miss handler</td>
</tr>
<tr>
<td>10</td>
<td>D-TSB misses</td>
</tr>
<tr>
<td>11</td>
<td>Percentage of time in D-TSB miss handler</td>
</tr>
</tbody>
</table>

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 12; extant fields will remain unchanged.

\texttt{-T}

Enables TLB statistics, with page size information. As with the \texttt{-t} option, a table is displayed with four principal columns of data: \texttt{itlb-miss, itsb-miss, dtlb-miss,} and \texttt{dtsb-miss}. The columns contain both the absolute number of the corresponding event, and the percentage of CPU time spent processing the event. The percentage of CPU time is given only in terms of a single CPU. The rows of the table correspond to CPUs, with each CPU consuming two sets of rows: one set for user-level events (denoted with \texttt{u}) and one set for kernel-level events (denoted with \texttt{k}). Each set, in turn, contains as many rows as there are page sizes supported (see \texttt{getpagesize(3C)}). For each row, the percentage of CPU time is totalled and displayed in the right-most column. The two sets are delineated with a dashed line; CPUs are delineated with a solid line. If the parsable option (\texttt{-P}) is specified in addition to the \texttt{-T} option, the format of the data is as follows:
### Field Contents

1. Timestamp (nanoseconds since start)
2. CPU ID
3. Mode (k denotes kernel, u denotes user)
4. Page size, in decimal
5. I-TLB misses
6. Percentage of time in I-TLB miss handler
7. I-TSB misses
8. Percentage of time in I-TSB miss handler
9. D-TLB misses
10. Percentage of time in D-TLB miss handler
11. D-TSB misses
12. Percentage of time in D-TSB miss handler

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 13; extant fields will remain unchanged.

#### Examples

**EXAMPLE 1** Using `trapstat` Without Options

When run without options, `trapstat` displays a table of trap types and CPUs. At most six columns can fit in the default terminal width; if (as in this example) there are more than six CPUs, multiple tables are displayed:

<table>
<thead>
<tr>
<th>vct name</th>
<th>cpu0</th>
<th>cpu1</th>
<th>cpu4</th>
<th>cpu5</th>
<th>cpu8</th>
<th>cpu9</th>
</tr>
</thead>
<tbody>
<tr>
<td>24 cleanwin</td>
<td>6446</td>
<td>4837</td>
<td>6368</td>
<td>2153</td>
<td>2623</td>
<td>1321</td>
</tr>
<tr>
<td>41 level-1</td>
<td>100</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>44 level-4</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>45 level-5</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>47 level-7</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>

</tr>
</tbody>
</table>

**EXAMPLE 3** Using \( \text{trapstat} \) with TLB Statistics

The `-t` option displays in-depth TLB statistics, including the amount of time spent performing TLB miss processing. The following example shows that the machine is spending 14.1 percent of its time just handling D-TLB misses:

```
example# \text{trapstat} -t
```

```
cpu m| itlb-miss %tim itsb-miss %tim | dtlb-miss %tim dtsb-miss %tim
-----+-------------------------------+-------------------------------+----
0 u  | 2571 0.3 | 0.0 0.0 | 10802 1.3 | 0.0 0.0 | 1.6
0 k  | 0.0 0.0  | 0.0 0.0 | 106420 13.4 | 184 0.1 | 13.6
1 u  | 3069 0.3 | 0.0 0.0 | 10983 1.2 | 100 0.0 | 1.6
1 k  | 27 0.0  | 0.0 0.0 | 106974 12.6 | 19 0.0 | 12.7
2 u  | 3033 0.3 | 0.0 0.0 | 11045 1.2 | 105 0.0 | 1.6
```
### EXAMPLE 3  Using `trapstat` with TLB Statistics

### EXAMPLE 4  Using `trapstat` with TLB Statistics and Page Size Information

By specifying the `-T` option, `trapstat` shows TLB misses broken down by page size. In this example, CPU 0 is spending 7.9 percent of its time handling user-mode TLB misses on 8K pages, and another 2.3 percent of its time handling user-mode TLB misses on 64K pages.

### EXAMPLE 5  Using `trapstat` with Entry Filtering

By specifying the `-e` option, `trapstat` displays statistics for only specific trap types. Using this option minimizes the probe effect when seeking specific data. This example yields statistics for only the `dtlb-prot` and `syscall-32` traps on CPUs 12 through 15:

```
```

---

**System Administration Commands - Part 2**

2437
EXAMPLE 6  Using trapstat with a Higher Sampling Rate

The following example uses the -r option to specify a sampling rate of 1000 samples per second, and filter only for the level-10 trap. Additionally, specifying the -P option yields parsable output.

Notice the timestamp difference between the level-10 events: 9,998,000 nanoseconds and 10,007,000 nanoseconds. These level-10 events correspond to the system clock, which by default ticks at 100 hertz (that is, every 10,000,000 nanoseconds).

example# trapstat -e level-10 -P -r 1000

```
1070400 0 4a level-10 0
2048600 0 4a level-10 0
3030400 0 4a level-10 1
4035800 0 4a level-10 0
5027200 0 4a level-10 0

26027000 0 4a level-10 0
```

EXAMPLE 7  Display Three CPUs with Highest cpu_mondo Rate

The following command displays the three CPUs with the highest cpu_mondo rate.

```
example% trapstat -k cpu_mondo -o 3 10 1
```

```
vct name | cpu0 cpu1 cpu61
--------------+----------------
 9  immu-miss | 0 0 0
24  cleanwin | 0 0 0
31  dmnu-miss | 0 0 0
41  level-1  | 0 0 0
46  level-6  | 0 0 0
```
EXAMPLE 7  Display Three CPUs with Highest cpu_mondo Rate  (Continued)

    49  level-9 | 0 0 0
    4a  level-10 | 100 31 16
    4d  level-13 | 23 15 8
    4e  level-14 | 100 32 18
    6c  dtlb-prot | 0 0 0
    7c  cpu_mondo | 24 16 9
    7d  dev_mondo | 0 0 0
    84  spill-user-32 | 0 0 0
    8c  spill-user-32-cln | 0 0 0
    98  spill-kern-64 | 423 180 102
    a4  spill-asuser-32 | 0 0 0
    ac  spill-asuser-32-cln | 0 0 0
    c4  fill-user-32 | 0 0 0
    cc  fill-user-32-cln | 0 1 0
    d8  fill-kern-64 | 295 165 94
    103 flush-wins | 0 0 0
    108 syscall-32 | 0 0 0
    122 get-psr | 0 0 0
    127 gethrtime | 0 0 0

EXAMPLE 8  Aggregating Multiple CPUs into Quartiles

The following commands aggregate 96 CPUs into quartiles by level-10 rate.

    example% trapstat -O /tmp/t1 -e level-10 10 1
    example% trapstat -I /tmp/t1 -A 4

<table>
<thead>
<tr>
<th>vct name</th>
<th>bin0 bin1 bin2 bin3</th>
</tr>
</thead>
<tbody>
<tr>
<td>4a level-10</td>
<td>440 340 305 306</td>
</tr>
</tbody>
</table>

EXAMPLE 9  Aggregating and Sorting Multiple CPUs

The following command aggregates 96 CPUs by core ID and sorts for the highest four.

    example% trapstat -A cor -e level-10 -k level-10 -o 4 10 1

<table>
<thead>
<tr>
<th>vct name</th>
<th>cor514 cor549 cor542 cor521</th>
</tr>
</thead>
<tbody>
<tr>
<td>4a level-10</td>
<td>197 120 111 106</td>
</tr>
</tbody>
</table>

Sun Microelectronics UltraSPARC II User’s Manual, January 1997, STP1031,

### Notes
When enabled, `trapstat` induces a varying probe effect, depending on the type of information collected. While the precise probe effect depends upon the specifics of the hardware, the following table can be used as a rough guide:

<table>
<thead>
<tr>
<th>Option</th>
<th>Approximate probe effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>3-5% per trap</td>
</tr>
<tr>
<td>-e</td>
<td>3-5% per specified trap</td>
</tr>
<tr>
<td>-t, -T</td>
<td>40-45% per TLB miss hitting in the TSB, 25-30% per TLB miss trap missing in the TSB</td>
</tr>
</tbody>
</table>

These probe effects are *per trap* not for the system as a whole. For example, running `trapstat` with the default options on a system that spends 7% of total time handling traps induces a performance degradation of less than one half of one percent; running `trapstat` with the -t or -T option on a system spending 5% of total time processing TLB misses induce a performance degradation of no more than 2.5%.

When run with the -t or -T option, `trapstat` accounts for its probe effect when calculating the `%tim` fields. This assures that the `%tim` fields are a reasonably accurate indicator of the time a given workload is spending handling TLB misses — regardless of the perturbing presence of `trapstat`.

While the `%tim` fields include the explicit cost of executing the TLB miss handler, they do *not* include the implicit costs of TLB miss traps (for example, pipeline effects, cache pollution, etc). These implicit costs become more significant as the trap rate grows; if high `%tim` values are reported (greater than 50%), you can accurately infer that much of the balance of time is being spent on the implicit costs of the TLB miss traps.

Due to the potential system wide degradation induced, only the super-user can run `trapstat`.

Due to the limitation of the underlying statistics gathering methodology, only one instance of `trapstat` can run at a time.
**ttymon** is a STREAMS-based TTY port monitor. Its function is to monitor ports, to set terminal modes, baud rates, and line disciplines for the ports, and to connect users or applications to services associated with the ports. Each instance of ttymon monitors one port, specified at startup. When an instance of ttymon is started, ttymon first initializes the line disciplines, if they are specified, and the speed and terminal settings. For ports with entries in `/etc/logindevperm`, device owner, group and permissions are set. (See `logindevperm(4)`.) The values used for initialization are taken from the appropriate entry in the TTY settings file. This file is maintained by the `sttydefs(1M)` command. Default line disciplines on ports are usually set up by the `autopush(1M)` command of the Autopush Facility.

ttymon then writes the prompt and waits for user input. If the user indicates that the speed is inappropriate by pressing the BREAK key, ttymon tries the next speed and writes the prompt again. When valid input is received, ttymon creates a `utmpx` entry (see `utmpx(4)`), and executes the login service for the port. Valid input consists of a string of at least one non-newline character, terminated by a carriage return.

If `autobaud` is enabled for a port, ttymon will try to determine the baud rate on the port automatically. Users must enter a carriage return before ttymon can recognize the baud rate and print the prompt. Currently, the baud rates that can be determined by `autobaud` are 110, 1200, 2400, 4800, and 9600.

The primary `smf(5)` service which invokes ttymon is `svc:/system/console-login`, which may have multiple service instances. Instances are described in greater detail below. The service provides a number of properties within the property group `ttymon` to control the invocation, as follows:

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>TTYMON OPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>device</td>
<td>astring</td>
<td>[-d device]</td>
</tr>
<tr>
<td>nohangup</td>
<td>boolean</td>
<td>[-h]</td>
</tr>
<tr>
<td>label</td>
<td>astring</td>
<td>[-l label]</td>
</tr>
<tr>
<td>modules</td>
<td>astring</td>
<td>[-m module1,module2]</td>
</tr>
<tr>
<td>prompt</td>
<td>astring</td>
<td>[-p prompt]</td>
</tr>
<tr>
<td>timeout</td>
<td>count</td>
<td>[-t timeout]</td>
</tr>
<tr>
<td>terminal_type</td>
<td>astring</td>
<td>[-T termtype]</td>
</tr>
</tbody>
</table>

If any value is the empty string or an integer set to zero, then the option is not passed to the ttymon invocation.

**svc:/system/console-login:default**

The default instance always represents the ttymon that offers login on the system hardware console.

See EXAMPLES for an example of how to modify settings for the system console.
Additional service instances are provided for the system's virtual consoles. If virtual consoles are not available, these services will automatically disable themselves. See `vtdaemon(1M)`.

svc:/system/console-login:{terma, termb}
svc:/system/console-login:terma and svc:/system/console-login:termb are provided as a convenience and can assist the user in setting up login services for additional ports /dev/term/a and /dev/term/b. These services are disabled by default.

The user can configure additional service instances for additional devices. This can be accomplished in any of these ways:
- Manually creating the service instance using `svccfg(1M)`.
- Creating the service in a service profile (see `smf(5)`).
- Creating a service manifest for additional service instance(s).

See EXAMPLES for an example of manually configuring the service using `svccfg`.

In most cases when an instance of the console-login service is misconfigured, it will transition itself to the maintenance state. Use `svcs -l` (see `svcs(1)`) to determine the location of the service's log file and consult the log for additional information.

In some error cases, the service may respawn indefinitely. Disable the service using `svcadm(1M)`, then consult the service log for additional messages or information to help resolve the problem.

`ttymon` uses `pam(3PAM)` for session management. The PAM configuration policy, specified in `/etc/pam.conf` or per-service files in `/etc/pam.d/`, specifies the modules to be used for `ttymon`. Here is a partial `pam.conf` file with an entry for `ttymon` using the UNIX session management module:

```
ttymon session required /usr/lib/security/pam_unix_session.so.1
```

The equivalent PAM configuration using `/etc/pam.d/` would be the following entry in `/etc/pam.d/ttymon`:

```
session required /usr/lib/security/pam_unix_session.so.1
```

If there are no entries for the `ttymon` service in `/etc/pam.conf` and the `/etc/pam.d/ttymon` file does not exist, then the entries for the “other” service in `/etc/pam.conf` will be used. If there are not any entries in `/etc/pam.conf` for the “other” service, then the entries in `/etc/pam.d/other` will be used.

The following options are supported:
- `-g` The `-g` option is required for historical reasons.
-device  device is the full path name of the port to which ttymon is to attach. If this option is not specified, file descriptor 0 must be set up by the invoking process to a TTY port.

-h  If the -h flag is not set, ttymon will force a hangup on the line by setting the speed to zero before setting the speed to the default or specified speed.

-ttylabel  ttylabel is a link to a speed and TTY definition in the ttydefs file. This definition tells ttymon at what speed to run initially, what the initial TTY settings are, and what speed to try next if the user indicates that the speed is inappropriate by pressing the BREAK key. The default speed is 9600 baud.

-modules  When initializing the port, ttymon will pop all modules on the port, and then push modules in the order specified. modules is a comma-separated list of pushable modules. Default modules on the ports are usually set up by the Autopush Facility.

-prompt  Allows the user to specify a prompt string. The default prompt is Login:.

-timeout  Specifies that ttymon should exit if no one types anything in timeout seconds after the prompt is sent.

-termtype  Sets the TERM environment variable to termtype.

-v  Enables verbose messaging.

Examples

**EXAMPLE 1** Setting the Terminal Type for the System Console

The following example sets the value of the terminal type (-T) option for the system console ttymon invocation:

```bash
# svccfg -s svc:/system/console-login:default \
  "setprop ttymon/terminal_type = xterm"
# svcadm refresh svc:/system/console-login:default
```

**EXAMPLE 2** Creating a Service Instance for an Additional Serial Device

In this example, the user wishes to configure an additional instance of the svc:/system/console-login service in order to offer login services over a terminal connected by means of a USB serial adapter. Assume that the USB serial port is present as /dev/term/1, and the user plans to connect a vt100 terminal to it. In this case, the service instance can be named term1 (or any other name) and defined as follows:

```bash
# svccfg -s svc:/system/console-login "add term1"
# SVC=svc:/system/console-login:term1
# svccfg -s $SVC "addpg ttymon application"
# svccfg -s $SVC "setprop ttymon/device = /dev/term/1"
# svccfg -s $SVC "setprop ttymon/terminal_type = vt100"
# svcadm refresh $SVC
# svcadm enable $SVC
```
If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of ttymon for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the “C” (U.S. style) locale determines how ttymon behaves.

**LC_CTYPE** Determines how ttymon handles characters. When LC_CTYPE is set to a valid value, ttymon can display and handle text and filenames containing valid characters for that locale. ttymon can also handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. In the “C” locale, only characters from ISO 8859-1 are valid.

**Files**

/etc/logindevperm
Contains information that is used by login(1) and ttymon to change the owner, group, and permissions of devices upon logging into or out of a console device.

**Oracle Solaris Administration: Common Tasks**

**Notes**

Service Access Facility (SAF and SAC) ttymon was formerly a component of the Service Access Facility and was invoked by sac, the Service Access Controller. This facility has been removed in this release of Solaris, and a conversion to SMF of relevant portions was performed.

Competition for Ports If a port is monitored by more than one ttymon, it is possible for the ttymons to send out prompt messages in such a way that they compete for input.

It is possible that two svc:/system/console-login service instances could refer to the same underlying device. For example, if the system's hardware console is connected (due to settings or autodetection in firmware) to serial port A, then both the svc:/system/console-login:default and svc:/system/console-login:terma services
will refer to same underlying hardware device. Care should be taken when defining or enabling additional service instances to avoid this situation, or the two `ttymons` will compete for input.
tunefs is designed to change the dynamic parameters of a file system that affect the layout policies. When using tunefs with a file system, the file system must be in /etc/vfstab. The parameters that can be changed are indicated by the options given below.

The following options are supported:

- **-a maxcontig**
  The maximum number of logical blocks, belonging to one file, that is allocated contiguously. The default is calculated as follows:
  \[ \text{maxcontig} = \frac{\text{disk drive maximum transfer size}}{\text{disk block size}} \]
  If the disk drive's maximum transfer size cannot be determined, the default value for maxcontig is calculated from kernel parameters as follows:
  - If \( \text{maxphys} \) is less than \( ufs\_maxmaxphys \), which is 1 Mbyte, then maxcontig is set to maxphys. Otherwise, maxcontig is set to \( ufs\_maxmaxphys \).
  - You can set maxcontig to any positive integer value. The actual value will be the lesser of what has been specified and what the hardware supports.

- **-d rotdelay**
  This parameter is obsolete as of the Solaris 10 release. The value is always set to 0, regardless of the input value.

- **-e maxbpg**
  Indicates the maximum number of contiguous logical blocks any single file can allocate from a cylinder group before it is forced to begin allocating blocks from another cylinder group. Typically this value is set to approximately one quarter of the total contiguous logical blocks in a cylinder group. The intent is to prevent any single file from using up all the blocks in a single cylinder group, thus degrading access times for all files subsequently allocated in that cylinder group.

  The effect of this limit is to cause big files to do long seeks more frequently than if they were allowed to allocate all the blocks in a cylinder group before seeking elsewhere. For file systems with exclusively large files, this parameter should be set higher.

- **-m minfree**
  Specifies the minimum free space threshold, or the percentage of space held back from normal users. This value can be set to 0. However, up to a factor of three in throughput will be lost over the performance obtained at a 10% threshold. Note: If the value is raised above the current usage level, users will be unable to allocate files until enough files have been deleted to get under the higher threshold.
The file system can either be instructed to try to minimize the time spent allocating blocks, or to try to minimize the space fragmentation on the disk. The default is time.

Generally, you should optimize for time unless the file system is over 90% full.

**Usage**

See `largefile(5)` for the description of the behavior of `tunefs` when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

`mkfs_ufs(1M), newfs(1M), attributes(5), largefile(5)`
Name  txzonemgr – Trusted Extensions Zone Manager configuration utility

Synopsis  /usr/sbin/txzonemgr [-c | -d[f] | -Z file]

Description  The txzonemgr shell script provides a simple, menu-based GUI wizard for creating, installing, initializing, and booting labeled zones on a system on which Trusted Extensions is enabled. The script also provides menu items for networking options, name services options, and making the global zone a client of an existing LDAP server. By default, all zones are configured to use the same name service and IP address as the global zone.

txzonemgr can also perform a limited set of commands in command-line mode instead of GUI mode, by using appropriate options, described below.

txzonemgr is run by roles granted in the Zone Management Rights Profile, or by root in the global zone.

Options  Without options, txzonemgr operates as a menu-based GUI. Using any options will result in command-line operation only. Except as specified below, options cannot be combined.

The following options are supported:

- c
  Create default zones. Requires that no zones already exist. The number, names, and attributes of the zones created is subject to change. However, typically a “public” zone and at least one other zone is created.

- d
  Destroy all zones. All zones will be halted, uninstalled, and deleted. Prompts for confirmation unless the -f option is also specified.

- f
  Force. Can be used with -d to override prompt for confirmation.

- Z file
  Create a set of zones using the list specified in the file. Each line in the file must contain a zone name and its corresponding label, separated by whitespace. The label should not be quoted even if it contains whitespace. If an existing zone named “snapshot” exists, all the specified zones are cloned from it. Otherwise the first zone in the list is installed, and then a snapshot zone is cloned from it. The remaining zones are then cloned from the snapshot. The zones are configured to require manual booting. However, when an authorized user assigns a valid label to a GNOME workspace, the corresponding zone is booted automatically.

Exit Status  No values are returned for GUI mode. For command-line operation, the following exit values are returned:

0
  Successful completion.
An error occurred.

Invalid usage.

**Attributes**

_Solaris Trusted Extensions Administrator's Procedures_

**Notes**
If administering zones from JDS, use txzonemgr rather than CDE actions.

txzonemgr uses the zenity command. For details, see the zenity(1) man page, which is not part of the SunOS collection.
The `tzreload` command notifies active (running) processes to reread timezone information. The timezone information is cached in each process, absent a `tzreload` command, is never reread until a process is restarted. In response to a `tzreload` command, active processes reread the current timezone information at the next call to `ctime(3C)` and `mktime(3C)`. The `tzreload` notification is sent to processes within the current zone.

tzreload causes processes which are using the system timezone (in `/etc/default/init`) to reread the contents of that file.

In addition to notifying active processes, the `tzreload` command also notifies `cron(1M)`, to reinitialize the job scheduler with the new timezone information.

Although `tzreload` reinitializes `cron(1M)`, applications that are affected by timezone changes still need to be restarted or reinitialized if they do not reread the new timezone information before timezone changes take place.

The timezone update service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/timezone/default
```

Administrative actions on this service, such as enabling, disabling, or requesting refresh, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Refreshing this service causes the `tzreload` command to be run, notifying running processes to reload their timezone caches. Disabling this service is not recommended.
Name  tzselect – select a time zone

Synopsis  /usr/bin/tzselect

Description  The tzselect program asks you a series of questions about the current location and outputs
the resulting time zone description to standard output. The output is suitable as a value for the
TZ environment variable.

All user interaction is through standard input and standard error.

Options  The tzselect command has no options.

Exit Status  The following exit values are returned:

0   Timezone information was successfully obtained.

>0  An error occurred.

Files  /usr/share/lib/zoneinfo directory containing timezone data files

</tr>
</tbody>
</table>

See Also  zdump(1M), zic(1M), ctime(3C), attributes(5)
The `uadmin` command provides control for basic administrative functions. This command is tightly coupled to the system administration procedures and is not intended for general use. It may be invoked only by the super-user.

Both the `cmd` (command) and `fcn` (function) arguments are converted to integers and passed to the `uadmin` system call. The optional `mdep` (machine dependent) argument is only available for the `cmd` values of 1 (A_REBOOT), 2 (A_SHUTDOWN), or 5 (A_DUMP). For any other `cmd` value, no `mdep` command-line argument is allowed.

When passing an `mdep` value that contains whitespaces, the string must be grouped together as a single argument enclosed within quotes, for example:

```
uadmin 1 1 "-s kernel/unix"
```

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

Shutting down or halting the system by means of `uadmin` does not update the boot archive. Avoid using this command after:

- editing of files such as `/etc/system`
- installing new driver binaries or kernel binaries
- updating existing driver binaries or kernel binaries.

Use `reboot(1M)` or `halt(1M)` instead.
The `ucodeadm` utility can be used to report running microcode revision on the processors, update microcode, or install microcode on the target system to be used during the boot process.

The `microcode-text-file` can be obtained from processor vendors.

**Options**

- **-v** Report microcode revision.
- **-u** `microcode-text-file` Update microcode on all cross-call interrupt ready processors.
- **-i** `microcode-text-file` Install microcode files on target system to be used during the next boot cycle. The text file name must have the vendor name prefix, such as "intel" or "amd".

By default the microcode files will be installed at:

```
/platform/i86pc/ucode/$VENDORSTR/
```

where `$VENDORSTR` is either "GenuineIntel" or "AuthenticAMD".

- **-R** `alternate path` Install microcode path in the alternate path.

**Examples**

**EXAMPLE 1** Reporting the Microcode Revision

The following example displays the microcode revision that is currently running:

```
# ucodeadm -v
```

**EXAMPLE 2** Updating the Processor Microcode

The following example updates the processor microcode to `intel-ucode.txt`:

```
# ucodeadm -u intel-ucode.txt
```

**EXAMPLE 3** Installing the Microcode on the Target System

The following example installs the microcode on the target system, `/export/ucode-path`:

```
# ucodeadm -i -R /export/ucode-path intel-ucode.txt
```

If an alternate path is used when installing the microcode on the target system, the installed microcode file is not used on the next boot cycle.

**Exit Status**

The following exit values are returned:

- 0 Successful completion.
An error occurred.

**Attributes**  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>

<td>Committed</td>
</tr>
</tbody>
</table>

**See Also**  `psradm(1M), psinfo(1M), attributes(5)`
ufsdump (1M)

**Name**
ufsdump – incremental file system dump

**Synopsis**
/usr/sbin/ufsdump [options] [arguments] files_to_dump

**Description**
ufsdump backs up all files specified by files_to_dump (usually either a whole file system or files within a file system changed after a certain date) to magnetic tape or disk file.

The ufsdump command can only be used on unmounted file systems, or those mounted read-only. Attempting to dump a mounted, read-write file system might result in a system disruption or the inability to restore files from the dump. Consider using the fssnap(1M) command to create a file system snapshot if you need a point-in-time image of a file system that is mounted.

**Options**

The following options are supported:

- **0–9**
  The “dump level.” All files specified by files_to_dump that have been modified since the last ufsdump at a lower dump level are copied to the dump_file destination (normally a magnetic tape device). For instance, if a “level 2” dump was done on Monday, followed by a “level 4” dump on Tuesday, a subsequent “level 3” dump on Wednesday would contain all files modified or added since the “level 2” (Monday) backup. A “level 0” dump copies the entire file system to the dump_file.

- **a** archive_file
  Archive file. Archive a dump table-of-contents in the specified archive_file to be used by ufsrestore(1M) to determine whether a file is in the dump file that is being restored.

- **b** factor
  Blocking factor. Specify the blocking factor for tape writes. The default is 20 blocks per write for tapes of density less than 6250BPI (bytes-per-inch). The default blocking factor for tapes of density 6250BPI and greater is 64. The default blocking factor for cartridge tapes (c option) is 126. The highest blocking factor available with most tape drives is 126. Note: the blocking factor is specified in terms of 512-byte blocks, for compatibility with tar(1).
Cartridge. Set the defaults for cartridge instead of the standard half-inch reel. This sets the density to 1000BPI and the blocking factor to 126. Since ufsdump can automatically detect the end-of-media, only the blocking parameter normally has an effect. When cartridge tapes are used, and this option is not specified, ufsdump will slightly miscompute the size of the tape. If the b, d, s or t options are specified with this option, their values will override the defaults set by this option.

Tape density. Not normally required, as ufsdump can detect end-of-media. This parameter can be used to keep a running tab on the amount of tape used per reel. The default density is 6250BPI except when the c option is used for cartridge tape, in which case it is assumed to be 1000BPI per track. Typical values for tape devices are:

- 1/2 inch tape
  6250 BPI

- 1/4 inch cartridge
  1000 BPI

The tape densities and other options are documented in the st(7D) man page.

Diskette. Obsolete option.

Dump file. Use dump_file as the file to dump to, instead of /dev/rmt/0. If dump_file is specified as --, dump to standard output.

If the name of the file is of the form machine:device, the dump is done from the specified machine over the network using rmt(1M). Since ufsdump is normally run by root, the name of the local machine must appear in the /.rhosts file of the remote machine. If the file is specified as user@machine:device, ufsdump will attempt to execute as the specified user on the remote machine. The specified user must have a .rhosts file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.

Autoload. When the end-of-tape is reached before the dump is complete, take the drive offline and wait up to two minutes for the tape drive to be ready again. This gives auto loading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.

Sets the tape label to string, instead of the default none. string may be no more than sixteen characters long. If it is longer, it is truncated and a warning printed; the dump will still be done. The tape label is specific to the ufsdump tape format, and bears no resemblance to IBM or ANSI-standard tape labels.
n
Notify all operators in the sys group that ufsdump requires attention by sending messages
to their terminals, in a manner similar to that used by the wall(1M) command. Otherwise,
such messages are sent only to the terminals (such as the console) on which the user
running ufsdump is logged in.

N device_name
Use device_name when recording information in /etc/dumpdates (see the u option) and
when comparing against information in /etc/dumpdates for incremental dumps. The
device_name provided can contain no white space as defined in scanf(3C) and is
case-sensitive.

o
Offline. Take the drive offline when the dump is complete or the end-of-media is reached
and rewind the tape. In the case of some autoloading 8mm drives, the tape is removed from
the drive automatically. This prevents another process which rushes in to use the drive,
from inadvertently overwriting the media.

s size
Specify the size of the volume being dumped to. Not normally required, as ufsdump can
detect end-of-media. When the specified size is reached, ufsdump waits for you to change
the volume. ufsdump interprets the specified size as the length in feet for tapes and
cartridges. The values should be a little smaller than the actual physical size of the media
(for example, 425 for a 450-foot cartridge). Typical values for tape devices depend on the c
option for cartridge devices:

1/2 inch tape
2300 feet
60-Mbyte 1/4 inch cartridge
425 feet
150-Mbyte 1/4 inch cartridge
700 feet

S
Size estimate. Determine the amount of space that is needed to perform the dump without
actually doing it, and display the estimated number of bytes it will take. This is useful with
incremental dumps to determine how many volumes of media will be needed.

t tracks
Specify the number of tracks for a cartridge tape. Not normally required, as ufsdump can
detect end-of-media. The default is 9 tracks. The t option is not compatible with the D
option. Values for Oracle-supported tape devices are:

60-Mbyte 1/4 inch cartridge
9 tracks
150-Mbyte 1/4 inch cartridge
18 tracks
T time_wait [hms]
  Sets the amount of time to wait for an autoload command to complete. This option is
  ignored unless the l option has also been specified. The default time period to wait is two
  minutes. Specify time units with a trailing h (for hours), m (for minutes), or s (for seconds).
  The default unit is minutes.

u
  Update the dump record. Add an entry to the file /etc/dumpdates, for each file system
  successfully dumped that includes the file system name (or device name as specified with
  the N option), date, and dump level.

v
  Verify. After each tape is written, verify the contents of the media against the source file
  system. If any discrepancies occur, prompt for new media, then repeat the
  dump/verification process. The file system must be unmounted. This option cannot be
  used to verify a dump to standard output.

w
  Warning. List the file systems that have not been backed up within a day. This information
  is gleaned from the files /etc/dumpdates and /etc/vfstab. When the w option is used, all
  other options are ignored. After reporting, ufsdump exits immediately.

W
  Warning with highlight. Similar to the w option, except that the W option includes all file
  systems that appear in /etc/dumpdates, along with information about their most recent
  dump dates and levels. File systems that have not been backed up within a day are
  highlighted.

Operands  The following operand is supported:

files_to_dump
  Specifies the files to dump. Usually it identifies a whole file system by its raw device name
  (for example, /dev/rdsk/c0t3d0s6). Incremental dumps (levels 1 to 9) of files changed
  after a certain date only apply to a whole file system. Alternatively, files_to_dump can
  identify individual files or directories. All named directories that may be examined by the
  user running ufsdump, as well as any explicitly-named files, are dumped. This dump is
  equivalent to a level 0 dump of the indicated portions of the filesystem, except that
  /etc/dumpdates is not updated even if the -u option has been specified. In all cases, the
  files must be contained in the same file system, and the file system must be local to the
  system where ufsdump is being run.

files_to_dump is required and must be the last argument on the command line.

If no options are given, the default is 9uf /dev/rmt/0 files_to_dump.
Usage  See `largefile(5)` for the description of the behavior of ufsdump when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples  

**Example 1** Using ufsdump

The following command makes a full dump of a root file system on c0t3d0, on a 150-MByte cartridge tape unit 0:

```
example# ufsdump 0 cfu /dev/rmt/0 /dev/rdsk/c0t3d0s0
```

The following command makes and verifies an incremental dump at level 5 of the usr partition of c0t3d0, on a 1/2 inch reel tape unit 1:

```
example# ufsdump 5 fuv /dev/rmt/1 /dev/rdsk/c0t3d0s6
```

Exit Status  While running, ufsdump emits many verbose messages. ufsdump returns the following exit values:

- 0  Normal exit.
- 1  Startup errors encountered.
- 3  Abort – no checkpoint attempted.

Files  

- `/dev/rmt/0`
  default unit to dump to
- `/etc/dumpdates`
  dump date record
- `/etc/group`
  to find group sys
- `/etc/hosts`
  to gain access to remote system with drive
- `/etc/vfstab`
  list of file systems

Attributes  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>
Fewer than 32 read errors on the file system are ignored.

Because each reel requires a new process, parent processes for reels that are already written hang around until the entire tape is written.

 UFSDUMP requires operator intervention on these conditions: end of volume, end of dump, volume write error, volume open error or disk read error (if there are more than a threshold of 32). In addition to alerting all operators implied by the n option, ufsdump interacts with the operator on ufstdump's control terminal at times when ufstdump can no longer proceed, or if something is grossly wrong. All questions ufstdump poses must be answered by typing yes or no, as appropriate.

Since backing up a disk can involve a lot of time and effort, ufstdump checkpoints at the start of each volume. If writing that volume fails for some reason, ufstdump will, with operator permission, restart itself from the checkpoint after a defective volume has been replaced.

It is vital to perform full, “level 0”, dumps at regular intervals. When performing a full dump, bring the machine down to single-user mode using shutdown(1M). While preparing for a full dump, it is a good idea to clean the tape drive and heads. Incremental dumps should be performed with the system running in single-user mode.

Incremental dumps allow for convenient backup and recovery of active files on a more frequent basis, with a minimum of media and time. However, there are some tradeoffs. First, the interval between backups should be kept to a minimum (once a day at least). To guard against data loss as a result of a media failure (a rare, but possible occurrence), capture active files on (at least) two sets of dump volumes. Another consideration is the desire to keep unnecessary duplication of files to a minimum to save both operator time and media storage. A third consideration is the ease with which a particular backed-up version of a file can be located and restored. The following four-week schedule offers a reasonable tradeoff between these goals.

<table>
<thead>
<tr>
<th>Week 1</th>
<th>Sun</th>
<th>Mon</th>
<th>Tue</th>

</tbody>
</table>

Although the Tuesday through Friday incrementals contain “extra copies” of files from Monday, this scheme assures that any file modified during the week can be recovered from the previous day’s incremental dump.
### Process Priority of ufsdump

*ufsdump* uses multiple processes to allow it to read from the disk and write to the media concurrently. Due to the way it synchronizes between these processes, any attempt to run *ufsdump* with a `nice` (process priority) of '−5' or better will likely make *ufsdump* run slower instead of faster.

### Overlapping Partitions

Most disks contain one or more overlapping slices because slice 2 covers the entire disk. The other slices are of various sizes and usually do not overlap. For example, a common configuration places *root* on slice 0, *swap* on slice 1, */opt* on slice 5 and */usr* on slice 6.

It should be emphasized that *ufsdump* dumps one *ufs* file system at a time. Given the above scenario where slice 0 and slice 2 have the same starting offset, executing *ufsdump* on slice 2 with the intent of dumping the entire disk would instead dump only the *root* file system on slice 0. To dump the entire disk, the user must dump the file systems on each slice separately.

### Bugs

The */etc/vfstab* file does not allow the desired frequency of backup for file systems to be specified (as */etc/fstab* did). Consequently, the `w` and `W` options assume file systems should be backed up daily, which limits the usefulness of these options.
**Synopsis**

```
/usr/sbin/ufsrestore i | r | R | t | x [abcdfhlmostvyLT]
[archive_file] [factor] [dumpfile] [n] [label]
[timeout] [filename]...
```

**Description**

The *ufsrestore* utility restores files from backup media created with the *ufs_dump* command. *ufsrestore*'s actions are controlled by the key argument. The key is exactly one function letter (i, r, R, t, or x) and zero or more function modifiers (letters). The key string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the key string.

*filename* arguments which appear on the command line, or as arguments to an interactive command, are treated as shell glob patterns by the x and t functions; any files or directories matching the patterns are selected. The metacharacters *, ?, and [ ] must be protected from the shell if they appear on the command line. There is no way to quote these metacharacters to explicitly match them in a filename.

The temporary files rstdir* and rstmode* are placed in /tmp by default. If the environment variable TMPDIR is defined with a non-empty value, that location is used instead of /tmp.

**Options**

**Function Letters**

You must specify one (and only one) of the function letters listed below. Note that i, x, and r are intended to restore files into an empty directory. The R function is intended for restoring into a populated directory.

- **i** Interactive. After reading in the directory information from the media, *ufsrestore* invokes a shell-like interface that allows you to browse through the dump file's directory hierarchy and select individual files to be extracted. Restoration has the same semantics as x (see below). See Interactive Commands, below, for a description of available commands.

- **r** Recursive. Starting with an empty directory and a level 0 dump, the r function recreates the filesystem relative to the current working directory, exactly as it appeared when the dump was made. Information used to restore incremental dumps on top of the full dump (for example, restoresyntable) is also included. Several *ufsrestore* runs are typical, one for each higher level of dump (0, 1, ..., 9). Files that were deleted between the level 0 and a subsequent incremental dump will not exist after the final restore. To completely restore a file system, use the r function to restore the level 0 dump, and again for each incremental dump. Although this function letter is intended for a complete restore onto a new file system (one just created with *newfs(1M)*), if the file system contains files not on the backup media, they are preserved.

- **R** Resume restoring. If an r-mode *ufsrestore* was interrupted, this function prompts for the volume from which to resume restoring and continues the restoration from where it was left off. Otherwise identical to r.
Table of contents. List each filename that appears on the media. If no filename argument is given, the root directory is listed. This results in a list of all files on the media, unless the h function modifier is in effect. The table of contents is taken from the media or from the specified archive file, when the a function modifier is used. The a function modifier is mutually exclusive with the x and r function letters.

Extract the named files from the media. Files are restored to the same relative locations that they had in the original file system.

If the filename argument matches a directory whose contents were written onto the media, and the h modifier is not in effect, the directory is recursively extracted, relative to the current directory, which is expected to be empty. For each file, the owner, modification time, and mode are restored (if possible).

If you omit the filename argument or specify ., the root directory is extracted. This results in the entire tape being extracted, unless the h modifier is in effect. With the x function, existing files are overwritten and ufsrestore displays the names of the overwritten files. Overwriting a currently-running executable can have unfortunate consequences.

Use the x option to restore partial file system dumps, as they are (by definition) not entire file systems.

Function Modifiers

<table>
<thead>
<tr>
<th>Function Modifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>Table of contents. List each filename that appears on the media. If no filename argument is given, the root directory is listed. This results in a list of all files on the media, unless the h function modifier is in effect. The table of contents is taken from the media or from the specified archive file, when the a function modifier is used. The a function modifier is mutually exclusive with the x and r function letters.</td>
</tr>
<tr>
<td>x</td>
<td>Extract the named files from the media. Files are restored to the same relative locations that they had in the original file system.</td>
</tr>
<tr>
<td>a archive_file</td>
<td>Read the table of contents from archive_file instead of the media. This function modifier can be used in combination with the t, i, or x function letters, making it possible to check whether files are on the media without having to mount the media. When used with the x and interactive (i) function letters, it prompts for the volume containing the file(s) before extracting them.</td>
</tr>
<tr>
<td>b factor</td>
<td>Blocking factor. Specify the blocking factor for tape reads. For variable length SCSI tape devices, unless the data was written with the default blocking factor, a blocking factor at least as great as that used to write the tape must be used; otherwise, an error will be generated. Note that a tape block is 512 bytes. Refer to the man page for your specific tape driver for the maximum blocking factor.</td>
</tr>
<tr>
<td>c</td>
<td>Convert the contents of the media in 4.1BSD format to the new ufs file system format.</td>
</tr>
<tr>
<td>d</td>
<td>Debug. Turn on debugging output.</td>
</tr>
</tbody>
</table>
| f dump_file       | Use dump_file instead of /dev/rmt/0 as the file to restore from. Typically dump_file specifies a tape drive. If dump_file is specified as ‘−’, ufsrestore reads from the standard input. This allows ufsdump(1M) and ufsrestore to be used in a pipeline to copy a file system:
example# ufsdump 0f − /dev/rdsk/c0t0d0s7 \ 
| (cd /home; ufsrestore xf −)

If the name of the file is of the form `machine:device`, the restore is done from the specified machine over the network using `rmt(1M)`. Since `ufsrestore` is normally run by root, the name of the local machine must appear in the `./rhosts` file of the remote machine. If the file is specified as `user@machine:device`, `ufsrestore` will attempt to execute as the specified user on the remote machine. The specified user must have a `rhosts` file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.

**h**

Extract or list the actual directory, rather than the files that it references. This prevents hierarchical restoration of complete subtrees from the tape.

**l**

Autoload. When the end-of-tape is reached before the restore is complete, take the drive off-line and wait up to two minutes (the default, see the `T` function modifier) for the tape drive to be ready again. This gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.

**L label**

The label that should appear in the header of the dump file. If the labels do not match, `ufsrestore` issues a diagnostic and exits. The tape label is specific to the `ufsdump` tape format, and bears no resemblance to IBM or ANSI-standard tape labels.

**m**

Extract by inode numbers rather than by filename to avoid regenerating complete pathnames. Regardless of where the files are located in the dump hierarchy, they are restored into the current directory and renamed with their inode number. This is useful if only a few files are being extracted.

**o**

Offline. Take the drive off-line when the restore is complete or the end-of-media is reached and rewind the tape. In the case of some autoloading 8mm drives, the tape is removed from the drive automatically.

**s n**

Skip to the `n`th file when there are multiple dump files on the same tape. For example, the command:

```
example# ufsrestore xfs /dev/rmt/0hn 5
```

would position you to the fifth file on the tape when reading volume 1 of the dump. If a dump extends over more than one volume, all volumes except the first are assumed to start at position 0, no matter what "s n" value is specified.
If "s n" is specified, the backup media must be at BOT (beginning of tape). Otherwise, the initial positioning to read the table of contents will fail, as it is performed by skipping the tape forward n - 1 files rather than by using absolute positioning. This is because on some devices absolute positioning is very time consuming.

timeout [hms]  Sets the amount of time to wait for an autoload command to complete. This function modifier is ignored unless the l function modifier has also been specified. The default timeout period is two minutes. The time units may be specified as a trailing h (hours), m (minutes), or s (seconds). The default unit is minutes.

v  Verbose.  ufsrestore displays the name and inode number of each file it restores, preceded by its file type.

y  Do not ask whether to abort the restore in the event of tape errors. ufsrestore tries to skip over the bad tape block(s) and continue as best it can.

Interactive Commands  ufsrestore enters interactive mode when invoked with the i function letters. Interactive commands are reminiscent of the shell. For those commands that accept an argument, the default is the current directory. The interactive options are:

add [filename]  Add the named file or directory to the list of files to extract. If a directory is specified, add that directory and its files (recursively) to the extraction list (unless the h modifier is in effect).

cd directory  Change to directory (within the dump file).

delete [filename]  Delete the current directory, or the named file or directory from the list of files to extract. If a directory is specified, delete that directory and all its descendents from the extraction list (unless the h modifier is in effect). The most expedient way to extract a majority of files from a directory is to add that directory to the extraction list, and then delete specific files to omit.

extract  Extract all files on the extraction list from the dump media. ufsrestore asks which volume the user wishes to mount. The fastest way to extract a small number of files is to start with the last volume and work toward the first. If "s n" is given on the command line, volume 1 will automatically be positioned to file n when it is read.

help  Display a summary of the available commands.

ls [directory]  List files in directory or the current directory, represented by a '.' (period). Directories are appended with a '/' (slash). Entries marked for extraction are prefixed with a '*' (asterisk). If the verbose option is in effect, inode numbers are also listed.
marked [directory]  Like `ls`, except only files marked for extraction are listed.

pager  Toggle the pagination of the output from the `ls` and `marked` commands. The pager used is that defined by the `PAGER` environment variable, or `more(1)` if that env var is not defined. The `PAGER` env var may include white-space-separated arguments for the pagination program.

pwd  Print the full pathname of the current working directory.

quit  `ufsrestore` exits immediately, even if the extraction list is not empty.

setmodes  Prompts: set owner/mode for `.` (period). Type y for yes to set the mode (permissions, owner, times) of the current directory `.` (period) into which files are being restored equal to the mode of the root directory of the file system from which they were dumped. Normally, this is what you want when restoring a whole file system, or restoring individual files into the same locations from which they were dumped. Type n for no, to leave the mode of the current directory unchanged. Normally, this is what you want when restoring part of a dump to a directory other than the one from which the files were dumped.

setpager command  Sets the command to use for paginating output instead of the default or that inherited from the environment. The `command` string may include arguments in addition to the command itself.

verbose  Toggle the status of the v modifier. While v is in effect, the `ls` command lists the inode numbers of all entries, and `ufsrestore` displays information about each file as it is extracted.

what  Display the dump header on the media.

Operands  The following operands are supported.

`filename`  Specifies the pathname of files (or directories) to be restored to disk. Unless the h function modifier is also used, a directory name refers to the files it contains, and (recursively) its subdirectories and the files they contain. `filename` is associated with either the x or t function letters, and must come last.

Usage  See `largefile(5)` for the description of the behavior of `ufsrestore` when encountering files greater than or equal to 2 Gbyte ( \(2^{31}\) bytes).

Exit Status  The following exit values are returned:

- 0  Successful completion.
- 1  An error occurred. Verbose messages are displayed.

Environment Variables  `PAGER`  The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is `more(1)`.
TMPDIR       Selects the directory for temporary files. Defaults to /tmp if not defined in the environment.

Files /dev/rmt/0       the default tape drive
$TMPDIR/rstdir*       file containing directories on the tape
$TMPDIR/rstmode*      owner, mode, and timestamps for directories
./restoresymtable     information passed between incremental restores

Attributes       See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also       more(1), mkfs(1M), mount(1M), rmt(1M), ufsdump(1M), ufsdump(4), attributes(5), largefile(5)

Diagnostics ufsrestore complains about bad option characters.

Read errors result in complaints. If y has been specified, or the user responds y, ufsrestore will attempt to continue.

If the dump extends over more than one tape, ufsrestore asks the user to change tapes. If the x or i function letter has been specified, ufsrestore also asks which volume the user wishes to mount. If the s modifier has been specified, and volume 1 is mounted, it is automatically positioned to the indicated file.

There are numerous consistency checks that can be listed by ufsrestore. Most checks are self-explanatory or can “never happen”. Common errors are given below.

Converting to new file system format
A dump tape created from the old file system has been loaded. It is automatically converted to the new file system format.

filename: not found on tape
The specified file name was listed in the tape directory, but was not found on the tape. This is caused by tape read errors while looking for the file, using a dump tape created on an active file system, or restoring a partial dump with the r function.

expected next file inumber, got inumber
A file that was not listed in the directory showed up. This can occur when using a dump tape created on an active file system.

Incremental tape too low
When doing an incremental restore, a tape that was written before the previous incremental tape, or that has too low an incremental level has been loaded.
Incremental tape too high
  When doing incremental restore, a tape that does not begin its coverage where the previous
  incremental tape left off, or one that has too high an incremental level has been loaded.

media read error: invalid argument
  Blocking factor specified for read is smaller than the blocking factor used to write data.

Tape read error while restoring
  Tape read error while skipping over inode number
  Tape read error while trying to resynchronize
  A tape read error has occurred
    If a file name is specified, then its contents are probably partially wrong. If an inode is being
    skipped or the tape is trying to resynchronize, then no extracted files have been corrupted,
    though files may not be found on the tape.

resync ufsrestore, skipped num
  After a tape read error, ufsrestore may have to resynchronize itself. This message lists the
  number of blocks that were skipped over.

Incorrect tape label. Expected ‘foo’, got ‘bar’.
  The L option was specified, and its value did not match what was recorded in the header of
  the dump file.

Notes  ufsrestore can get confused when doing incremental restores from dump tapes that were
  made on active file systems.

  A level 0 dump must be done after a full restore. Because ufsrestore runs in user mode, it
  has no control over inode allocation. This means that ufsrestore repositions the files,
  although it does not change their contents. Thus, a full dump must be done to get a new set of
  directories reflecting the new file positions, so that later incremental dumps will be correct.
System Administration Commands - Part 3
unshare(1M)

Name
unshare – make local resource unavailable for mounting by remote systems

Synopsis
unshare [-F protocol] [-a | [-t] [pathname | sharename]]

Description
The unshare command unpublishes a file system share, which makes a shared local file system unavailable for file sharing protocol. If the -F protocol option is omitted, then the first file sharing protocol listed in the /etc/dfs/fstypes file used as the default sharing protocol.

Options
-F protocol
Identify the file sharing protocol.

-a
Unpublish all active shares.

-t
Temporarily unpublish a share. By default, all shares are permanently unpublished.

Files
/etc/dfs/fstypes
List of file sharing protocols. NFS is the default file-sharing protocol.

/etc/dfs/sharetab
Contains a table of local resources published by the share command.

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcs</td>
</tr>
</tbody>
</table>

See Also
share(1M), shareall(1M), attributes(5)

Notes
If pathname or resourcename is not found in the share information, an error message is sent to standard error.

When an unshare command completes successfully, a client mounting a file system specified in that unshare command no longer has access to that file system.
unshare_nfs – make local NFS file systems unavailable for mounting by remote systems

**Synopsis**

```
unshare [-F nfs] pathname
```

**Description**

The `unshare` command makes local file systems unavailable for mounting by remote systems. The shared file system must correspond to a line with NFS as the `FSType` in the file `/etc/dfs/sharetab`.

**Options**

The following options are supported:

- `-F` This option may be omitted if NFS is the first file system type listed in the file `/etc/dfs/fstypes`.

**Files**

`/etc/dfs/fstypes`

`/etc/dfs/sharetab`

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/file-system/nfs</td>
</tr>
</tbody>
</table>

**See Also**

`nfsd(1M), share(1M), attributes(5)`

**Notes**

If the file system being unshared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) will be unshared.

For example, if `/export/foo` is a symbolic link to `/export/bar` (`/export/foo -> /export/bar`), the following `unshare` command will result in `/export/bar` as the unshared pathname (and not `/export/foo`):

```bash
example# unshare -F nfs /export/foo
```

For file systems that are accessed by NFS Version 4 clients, once the `unshare` is complete, all NFS Version 4 state (open files and file locks) are released and unrecoverable by the clients. If the intent is to share the file system after some administrative action, the NFS daemon (`nfsd`) should first be stopped and then the file system unshared. After the administrative action is complete, the file system would then be shared and the NFS daemon restarted. See `nfsd(1M)`
update_drv – modify device driver attributes

Synopsis

```
update_drv [-f | -v] [-n] driver_module
update_drv [-b basedir] [-f | -v] [-n] -a [-m 'permission']
    [-i 'identify-name'] [-P 'privilege'] [-p 'policy'] driver_module
update_drv [-b basedir] [-f | -v] [-n] -d [-m 'permission']
    [-i 'identify-name'] [-P 'privilege'] [-p 'policy'] driver_module
```

Description

The `update_drv` command informs the system about attribute changes to an installed device driver. It can be used to re-read the `driver.conf` file, or to add, modify, or delete a driver's minor node permissions or aliases.

Without options, `update_drv` reloads the `driver.conf` file.

Upon successfully updating the aliases, the driver binding takes effect upon reconfig boot or hotplug of the device.

Upon successfully updating the permissions, only the new driver minor nodes get created with the modified set of file permissions. Existing driver minor nodes do not get modified.

Options

The following options are supported:

- **-a**
  Add a `permission`, `aliases`, `privilege` or `policy` entry.

  With the `-a` option specified, a permission entry (using the `-m` option), or a driver's aliases entry (using the `-i` option), a device privilege (using the `-P` option) or a device policy (using the `-p` option), can be added or updated. If a matching minor node permissions entry is encountered (having the same driver name and the minor node), it is replaced. If a matching aliases entry is encountered (having a different driver name and the same alias), an error is reported.

  The `-a` and `-d` options are mutually exclusive.

- **-b basedir**
  Installs or modifies the driver on the system with a root directory of `basedir` rather than installing on the system executing `update_drv`.

  **Note** – The root file system of any non-global zones must not be referenced with the `-b` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

- **-d**
  Delete a `permission`, `aliases`, `privilege` or `policy` entry.

  The `-m permission`, `-i identify-name`, `-P privilege` or the `-p policy` option needs to be specified with the `-d` option.
The -d and -a options are mutually exclusive.

If the entry doesn’t exist update_drv returns an error.

-f
Force the system to reread the driver.conf file even if the driver module cannot be unloaded. See NOTES section for details.

Without this option, when removing an alias for a driver, update_drv updates the binding files for the next boot, but returns an error if one or more devices that reference the driver-alias binding remains. With the -f option, update_drv does not return an error if such devices remain.

-i 'identify-name'
A white-space separated list of aliases for the driver. If -a or -d option is not specified then this option is ignored. The identify-name string is mandatory. If all aliases need to be removed, rem_drv(1M) is recommended.

-m 'permission'
Specify a white-space separated list of file system permissions for the device node of the device driver. If -a or -d option is not specified then, this option is ignored. The permission string is mandatory.

-n
Do not try to load and attach device_driver, just modify the system configuration files for that driver.

-p 'policy'
With the -a option, policy is a white-space separated list of complete device policies. For the -d option, policy is a white space separated list of minor device specifications. The minor device specifications are matched exactly against the entries in /etc/security/device_policy, that is, no wildcard matching is performed.

-P 'privilege'
With the -a option, privilege is a comma separated list of additional driver privileges. For the -d option, privilege is a single privilege. The privileges are added to or removed from the /etc/security/extra_prv file.

-v
Verbose.

**Examples**

**EXAMPLE 1** Adding or Modifying an Existing Minor Permissions Entry

The following command adds or modifies the existing minor permissions entry of the clone driver:

example# update_drv -a -m 'llc1 777 joe staff' clone
EXAMPLE 2  Removing All Minor Permissions Entries
The following command removes all minor permission entries of the usbprn driver, the USB printer driver:

```
example# update_drv -d -m '* 0666 root sys' usbprn
```

EXAMPLE 3  Adding a Driver Aliases Entry
The following command adds a driver aliases entry of the ugen driver with the identity string of usb459,20:

```
example# update_drv -a -i "usb459,20" ugen
```

EXAMPLE 4  Re-reading the driver.conf File For the ohci Driver
The following command re-reads the driver.conf(4) file.

```
example# update_drv ohci
```

EXAMPLE 5  Requiring a Self-defined Privilege to Open a tcp Socket
The following command requires a self-defined privilege to open a tcp socket:

```
example# update_drv -a -P net_tcp -p 'write_priv_set=net_tcp read_priv_set=net_tcp' tcp
```

EXAMPLE 6  Establishing a Path-oriented Alias
The following command establishes a path-oriented alias to force a specific driver, qlt, to be used for a particular device path:

```
example# update_drv -a -i "/pci@8,600000/SUNW,qlc@4" qlt
```

Exit Status  The following exit values are returned:

0          Successful completion.

>0         An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  add_drv(1M), modunload(1M), rem_drv(1M), driver.conf(4), attributes(5), privileges(5)
Notes  If -a or -d options are specified, update_drv does not reread the driver.conf file.

A forced update of the driver.conf file reloads the driver.conf file without reloading the driver binary module. In this case, devices which cannot be detached reference driver global properties from the old driver.conf file, while the remaining driver instances reference global properties in the new driver.conf file.

It is possible to add an alias, which changes the driver binding of a device already being managed by a different driver. A force update with the -a option tries to bind to the new driver and report error if it cannot. If you specify more than one of the -m, -i, -P or -p options, a force flag tries to modify aliases or permissions. This is done even if the other operation fails and vice-versa.
Name
useradd – administer a new user login on the system

Synopsis
useradd [-A authorization [,.authorization...]]
   [-b base_dir] [-c comment] [-d dir] [-e expire]
   [-f inactive] [-g group] [-G group [,.group...]]
   [-K key=value] [-m [-k skel_dir]] [-p proiname]
   [-P profile [,.profile...]] [-R role [,.role...]]
   [-s shell] [-S repository] [-u uid [,-0]] login
useradd -D [-A authorization [,.authorization...]]
   [-b base_dir] [-s shell [-k skel_dir]] [-e expire]
   [-f inactive] [-g group] [-K key=value] [-p proiname]
   [-P profile [,.profile...]] [-R role [,.role...]]

Description
useradd adds a new user to the passwd, shadow, and user_attr databases in the files and
ldap repositories. The -A and -P options respectively assign authorizations and profiles to the
user. The -R option assigns roles to a user. The -p option associates a project with a user. The
-K option adds a key=value pair to user_attr entry for the user. Multiple key=value pairs may
be added with multiple -K options.

useradd also creates supplementary group memberships for the user (-G option) and creates
the home directory (-m option) for the user if requested. The new login remains locked until
the passwd(1) command is executed.

Specifying useradd -D with the -s, -k, -g, -b, -f, -e, -A, -P, -p, -R, or -K option (or any
combination of these options) sets the default values for the respective fields. See the -D
option, below. Subsequent useradd commands without the -D option use these arguments.

The system file entries created with this command have a limit of 2048 characters per line.
Specifying long arguments to several options can exceed this limit.

useradd requires that usernames be in the format described in passwd(4). A warning message
is displayed if these restrictions are not met. See passwd(4) for the requirements for
usernames.

An administrator must be granted the User Management Profile to be able to create a new
user. The authorizations required to set the various fields in passwd, shadow and user_attr
can be found in passwd(4), shadow(4), and user_attr(4). The authorizations required to
assign groups and projects can be found in group(4) and project(4).

Options
The following options are supported:

-A authorization
   One or more comma-separated authorizations defined in auth_attr(4). Only a user or
   role who has grant rights to the authorization can assign it to an account.

-b base_dir
   The base directory for new login home directories (see the -d option below. When a new
   user account is being created, base_dir must already exist unless the -m option or the -d
   option is also specified.
-c comment
Any text string. It is generally a short description of the login, and is currently used as the
field for the user’s full name. This information is stored in the user’s passwd entry.

-d dir | server:dir
Specifies the home directory path for the new user. If no server name is specified, the
specified directory is maintained in the passwd(4) database.

The optional server name specifies the host on which the home directory resides. Entries in
this form depend on the automounter, and are maintained in the auto_home map. The path
/home/username is maintained in the passwd(4) database. When the user subsequently
references /home/username, the automounter will mount the specified directory on
/home/username.

-D
Display the default values for group, base_dir, skel_dir, shell, inactive, expire, proj,
projname and key=value pairs. When used with the -g, -b, -f, -e, -A, -P, -p, -R, or -K
options, the -D option sets the default values for the specified fields. The default values are:

    group
        other (GID of 1)

    base_dir
        /export/home

    skel_dir
        /etc/skel

    shell
        /usr/bin/bash

    inactive
        0

    expire
        null

    auths
        null

    profiles
        null

    proj
        3

    projname
        default

    key=value (pairs defined in user_attr(4)
        not present
Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file /etc/datemsk. See getdate(3C).

If the date format that you choose includes spaces, it must be quoted. For example, you can enter 10/6/90 or October 6, 1990. A null value (""") defeats the status of the expired date. This option is useful for creating temporary logins.

The maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.

An existing group’s integer ID or character-string name. Without the -D option, it defines the new user’s primary group membership and defaults to the default group. You can reset this default value by invoking useradd -D -g group. GIDs 0-99 are reserved for allocation by the Solaris Operating System.

An existing group’s integer ID or character-string name. It defines the new user’s supplementary group membership. Duplicates between group with the -g and -G options are ignored. No more than NGROUPS_MAX groups can be specified. GIDs 0-99 are reserved for allocation by the Solaris Operating System.

A key=value pair to add to the user’s attributes. Multiple -K options may be used to add multiple key=value pairs. The generic -K option with the appropriate key may be used instead of the specific implied key options (-A, -P, -R, -p). See user_attr(4) for a list of valid key=value pairs. The “type” key is not a valid key for this option. Keys may not be repeated.

A directory that contains skeleton information (such as .profile) that can be copied into a new user’s home directory. This directory must already exist. The system provides the /etc/skel directory that can be used for this purpose.

Create the new user’s home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by group, where group is the user’s primary group. If the server name specified to the -d option is a remote host then the system will not attempt to create the home directory.

If the directory does not already exist and the parent directory is the mount point of a ZFS dataset, then a child of that dataset will be created and mounted at the specified location.
The user is delegated permissions to create ZFS snapshots and promote them. The newly created dataset will inherit the encryption setting from its parent. If it is encrypted, the user is granted permission to change its wrapping key.

-o
This option allows a UID to be duplicated (non-unique).

-P profile
One or more comma-separated execution profiles defined in prof_attr(4).

-p proname
Name of the project with which the added user is associated. See the proname field as defined in project(4).

-R role
One or more comma-separated execution profiles defined in user_attr(4). Roles cannot be assigned to other roles.

-s shell
Full pathname of the program used as the user’s shell on login. If unspecified, it will default to any value previously configured with the -D -s option. If no default has been set with -D -s, then /usr/bin/bash will be used. The value of shell must be a valid executable file.

-S repository
The valid repositories are files, ldap. The repository specifies which name service will be updated. The default repository is files. When the repository is files, the authorizations, profiles, and roles can be present in other name service repositories and can be assigned to a user in the files repository. When the repository is ldap, all the assignable attributes must be present in the ldap repository.

-u uid
The UID of the new user. This UID must be a non-negative decimal integer below MAXUID as defined in <sys/param.h>. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number will be 201. UIDs 0-99 are reserved for allocation by the Solaris Operating System.

Exit Status In case of an error, useradd prints an error message and exits with one of the following values:

1 No permission for attempted operation.

2 The command syntax was invalid. A usage message for the usermod command is displayed.

3 An invalid argument was provided to an option.

4 The gid or uid given with the -u option is already in use.

5 The password and shadow files are not consistent with each other. pwconv(1M) might be of use to correct possible errors. See passwd(4) and shadow(4).
The login to be modified does not exist, the gid or the uid does not exist.
The group, passwd, or shadow file is missing.
A group or user name is already in use.
Cannot update the passwd, shadow, or user_attr file.
Insufficient space to move the home directory (-m option).
Unable to create, remove, or move the new home directory.
Requested login is already in use.
Unexpected failure.
Unable to update the group database.
Unable to update the project database.
Insufficient authorization.
Does not have role.
Does not have profile.
Does not have privilege.
Does not have label.
Does not have group.
System not running Trusted Extensions.
Does not have project.
Unable to update auto_home.

Files
/etc/datemsk
/etc/passwd
/etc/shadow
/etc/group
/etc/skel
/usr/include/limits.h
/etc/user_attr

Managing User Accounts and User Environments in Oracle Solaris 11.1

Diagnostics In case of an error, useradd displays an error message and exits with a non-zero status.

The following indicates that login specified is already in use:
UX: useradd: ERROR: login is already in use. Choose another.

The following indicates that the uid specified with the -u option is not unique:
UX: useradd: ERROR: uid uid is already in use. Choose another.

The following indicates that the group specified with the -g option has not yet been created:
UX: useradd: ERROR: group group does not exist. Choose another.

The following indicates that the uid specified with the -u option is in the range of reserved UIDs (from 0-99):
UX: useradd: WARNING: uid uid is reserved.

The following indicates that the uid specified with the -u option exceeds MAXUID as defined in <sys/param.h>:
UX: useradd: ERROR: uid uid is too big. Choose another.

The following indicates that the /etc/passwd or /etc/shadow files do not exist:
UX: useradd: ERROR: Cannot update system files - login cannot be created.

The following indicates that the user executing the command does not have sufficient authorization to perform the operation:
UX: roleadd: ERROR: Permission denied.

The following indicates that an invalid directory was specified in a useradd command:
UX: invalid_directory is not a valid directory. Choose another.

Notes The useradd utility adds definitions to the passwd, shadow, group, project, and user_attr databases in the scope (default or specified). It will verify the uniqueness of the user name (or role) and user id and the existence of any group names specified against the external name service.
userdel(1M)

**Name**  userdel – delete a user’s login from the system

**Synopsis**  userdel [-r] [-S repository] login

**Description**  The `userdel` utility deletes a user account from the system and makes the appropriate account-related changes to the system file and file system.

An administrator must be granted the User Management Profile to be able to delete a user.

**Options**  The following options are supported:

- `-r`  Remove the user’s home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command. A ZFS dataset that was created for the user’s home directory will be removed. An `auto_home` entry that was added for the user will be deleted.

- `-S repository`  The valid repositories are `files`, `ldap`. The repository specifies which name service will be updated. The default repository is `files`.

**Operands**  The following operands are supported:

- `login`  An existing login name to be deleted.

**Exit Status**  The following exit values are returned:

- `0`  Successful completion.
- `2`  Invalid command syntax. A usage message for the `userdel` command is displayed.
- `6`  The account to be removed does not exist.
- `8`  The account to be removed is in use.
- `10`  Cannot update the `/etc/group` or `/etc/user_attr` file but the login is removed from the `/etc/passwd` file.
- `12`  Cannot remove or otherwise modify the home directory.

**Files**  
- `/etc/passwd`  system password file
- `/etc/shadow`  system file contain users’ encrypted passwords and related information
- `/etc/group`  system file containing group definitions
- `/etc/user_attr`  system file containing additional user attributes

**Attributes**  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>
The `userdel` utility deletes an account definition that is in the group, `passwd`, `shadow`, and `user_attr` databases in the files or ldap repository.

**See Also**  auths(1), passwd(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M), groupmod(1M), logins(1M), roleadd(1M), rolemod(1M), useradd(1M), usermod(1M), passwd(4), prof_attr(4), user_attr(4), attributes(5)

**Notes**  The `userdel` utility deletes an account definition that is in the group, `passwd`, `shadow`, and `user_attr` databases in the files or ldap repository.
usermod(1M)

Name  usermod – modify a user’s login information on the system

Synopsis  usermod [-u uid [-o]] [-g group] [-G [+|-]group [, group...]]
          [-d dir [-m]] [-s shell] [-c comment] [-l new_name]
          [-f inactive] [-e expire]
          [-A [+|-]authorization [, authorization]]
          [-P [+|-]profile [, profile]] [-R [+|-]role [, role]]
          [-K key[+|-]=value] [-S repository] login

Description  The usermod utility modifies a user’s login definition on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes.

The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options might exceed this limit.

An administrator must be granted the User Security Profile to modify the security attributes for an existing user. To be able to modify the non-security attributes of an existing user requires the User Management Profile. The authorizations required to set the various fields in passwd, shadow and user_attr can be found in passwd(4), shadow(4), and user_attr(4). The authorizations required to assign groups can be found in group(4).

Options  The following options are supported:

- A [+|-]authorization  
  One or more comma separated authorizations as defined in auth_attr(4). Only a user or role who has grant rights to the authorization can assign it to an account. This replaces any existing authorization setting. If no authorization list is specified, the existing setting is removed.

  A prefix + adds the authorization to the existing authorization; a prefix - removes the authorization from the existing authorization. With no prefix, authorization replaces the existing authorization.

- c comment  
  Specify a comment string. comment can be any text string. It is generally a short description of the login, and is currently used as the field for the user’s full name. This information is stored in the user’s passwd entry.

- d dir  
  Specify the new home directory of the user. It defaults to base_dir/login, where base_dir is the base directory for new login home directories, and login is the new login. This creates or modifies an auto_home entry for the user.

  The argument to the option can be specified as server:dir where server is the hostname of the machine on which the home directory resides and dir is the path to the user’s home directory. If the server is a remote host then the home directory needs to be created on the
remote host for the system to mount it, when the user logs in. If no server name is specified
then the home directory will be created on the host where the command is executed, when
the -m option is used.

- e expire
   Specify the expiration date for a login. After this date, no user will be able to access this
login. The expire option argument is a date entered using one of the date formats included
in the template file /etc/datemsk. See getdate(3C).

   For example, you may enter 10/6/90 or October 6, 1990. A value of "" defeats the
status of the expired date.

- f inactive
   Specify the maximum number of days allowed between uses of a login ID before that login
ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.

- g group
   Specify an existing group’s integer ID or character-string name. It redefines the user’s
primary group membership.

- G [+-] group
   An existing group’s integer ID or character-string name. It defines the new user’s
supplementary group membership. Duplicates between group with the -g and -G options
are ignored. No more than NGROUPS_MAX groups can be specified. GIDs 0-99 are reserved
for allocation by the Solaris Operating System.

   A prefix + adds the group to the existing group; a prefix - removes the group from the
existing group. With no prefix, group replaces the existing group.

- K [+-]= value
   Replace existing or add to a user’s key=value pair attributes. Multiple -K options can be
used to replace or add multiple key=value pairs. However, keys must not be repeated. The
generic -K option with the appropriate key can be used instead of the specific implied key
options (-A, -P, -R, -p). See user_attr(4) for a list of valid keys. Values for these keys are
usually found in man pages or other sources related to those keys. For example, see
project(4) for guidance on values for the project key. Use the command ppriv(1) with
the -v and -l options for a list of values for the keys defaultpriv and limitpriv. If no
value is specified, the existing key is removed.

   The keyword type can be specified with the value role or the value normal. When using
the value role, the account changes from a normal user to a role; using the value normal
keeps the account a normal user.

   As a role account, no roles (-R or roles=value) can be present.

   A prefix + adds the value to the existing value; a prefix - removes the value from the existing
value. With no prefix, value replaces the existing value.
The prefix +/- operation is applicable only to the following keys: auths, profiles, roles, project, limitpriv, and defaultpriv.

- \new_logname
Specify the new login name for the user. See passwd(4) for the requirements for usernames.

- m
Move the user's home directory to the new directory specified with the -d option. If the directory already exists, it must have permissions read/write/execute by group, where group is the user's primary group. If the server name specified to the -d option is a remote host then the system will not attempt to create the home directory.

If the directory does not already exist, a new ZFS dataset will be created. In the global zone, the dataset is created as rpool/export/home/rolename. For non-global zones, the dataset will be created as ROOT-dataset/export/home/rolename. The mountpoint for the ZFS dataset is /export/home/rolename by default. If -d path is specified and it is a path on the local machine, the dataset will be mounted at the specified location. The role is delegated permissions to create ZFS snapshots and promote them. The newly created dataset will inherit the encryption setting from its parent. If it is encrypted, the role is granted permission to change its wrapping key.

- o
This option allows the specified UID to be duplicated (non-unique).

-P [+-]profile
One or more comma-separated rights profiles defined in prof_attr(4). This replaces any existing profile setting in user_attr(4). If an empty profile list is specified, the existing setting is removed.

A prefix + adds the profile to the existing profile; a prefix - removes the profile from the existing profile. With no prefix, profile replaces the existing profile.

-R [+-]role
One or more comma-separated roles (see roleadd(1M)). This replaces any existing role setting. If no role list is specified, the existing setting is removed.

A prefix + adds the role to the existing role; a prefix - removes the role from the existing role. With no prefix, role replaces the existing role.

-s shell
Specify the full pathname of the program that is used as the user's shell on login. The value of shell must be a valid executable file.

-S repository
The valid repositories are files, ldap. The repository specifies which name service will be updated. The default repository is files. When the repository is files, the authorizations, profiles, and roles can be present in other name service repositories and can be assigned to a user in the files repository. When the repository is ldap, all the assignable attributes must be present in the ldap repository.
-u uid
   Specify a new UID for the user. It must be a non-negative decimal integer less than MAXUID
   as defined in <param.h>. The UID associated with the user’s home directory is not modified
   with this option; a user will not have access to their home directory until the UID is
   manually reassigned using chown(1).

Operands
   The following operands are supported:

   login
      An existing login name to be modified.

Examples
   EXAMPLE 1   Assigning Privileges to a User
      The following command adds the privilege that affects high resolution times to a user's initial,
      inheritable set of privileges.
      # usermod -K defaultpriv=basic,proc_clock_highres jdoe
      This command results in the following entry in user_attr:
      jdoe::::type=normal;defaultpriv=basic,proc_clock_highres

   EXAMPLE 2   Removing a Privilege from a User's Limit Set
      The following command removes the privilege that allows the specified user to create hard
      links to directories and to unlink directories.
      # usermod -K limitpriv=all,!sys_linkdir jdoe
      This command results in the following entry in user_attr:
      jdoe::::type=normal;defaultpriv=basic,limitpriv=all,!sys_linkdir

   EXAMPLE 3   Removing a Privilege from a User's Basic Set
      The following command removes the privilege that allows the specified user to examine
      processes outside the user's session.
      # usermod -K defaultpriv=basic,!proc_session jdoe
      This command results in the following entry in user_attr:
      jdoe::::type=normal;defaultpriv=basic,!proc_session;limitpriv=all

   EXAMPLE 4   Assigning a Role to a User
      The following command assigns a role to a user. The role must have been created prior to this
      command through use of roleadd(1M).
      # usermod -R mailadm jdoe
      This command results in the following entry in user_attr:
      jdoe::::type=normal;roles=mailadm;defaultpriv=basic;limitpriv=all
EXAMPLE 5  Removing All Profiles from a User

The following command removes all profiles that were granted to a user directly. The user will
still have any rights profiles that are granted by means of the PROFS_GRANTED key in
policy.conf(4).

    # usermod -P "" jdoe

Exit Status  In case of an error, usermod prints an error message and exits with one of the following values:

1    No permission for attempted operation.
2    The command syntax was invalid. A usage message for the usermod command is
displayed.
3    An invalid argument was provided to an option.
4    The gid or uid given with the -u option is already in use.
5    The password and shadow files are not consistent with each other. pwconv(1M) might
be of use to correct possible errors. See passwd(4) and shadow(4).
6    The login to be modified does not exist, the gid or the uid does not exist.
7    The group, passwd, or shadow file is missing.
9    A group or user name is already in use.
10   Cannot update the passwd, shadow, or user_attr file.
11   Insufficient space to move the home directory (-m option).
12   Unable to create, remove, or move the new home directory.
13   Requested login is already in use.
14   Unexpected failure.
16   Unable to update the group database.
17   Unable to update the project database.
18   Insufficient authorization.
19   Does not have role.
20   Does not have profile.
21   Does not have privilege.
22   Does not have label.
23   Does not have group.
24   System not running Trusted Extensions.
25   Does not have project.
Unable to update auto_home.

Files
/etc/group
    system file containing group definitions
/etc/datemsk
    system file of date formats
/etc/passwd
    system password file
/etc/shadow
    system file containing users' encrypted passwords and related information
/etc/user_attr
    system file containing additional user and role attributes

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

groupprog(1M), logins(1M), pwconv(1M), roledel(1M), roledel(1M), roledel(1M),
useradd(1M), userdel(1M), getdate(3C), auth_attr(4), passwd(4), policy.conf(4),
prof_attr(4), user_attr(4), attributes(5)

Notes
The usermod utility modifies definitions in the passwd, shadow, group, project, and
user_attr databases in the scope (default or specified). The utility will verify the uniqueness
of user name and user ID against the external name service.

The usermod utility uses the /etc/datemsk file, available with SUNWaccr, for date formatting.
utmpd - utmpx monitoring daemon

Synopsis utmpd [-debug]

Description The utmpd daemon monitors the /var/adm/utmpx file. See utmpx(4) (and utmp(4) for historical information).

utmpd receives requests from pututxline(3C) by way of a named pipe. It maintains a table of processes and uses poll(2) on /proc files to detect process termination. When utmpd detects that a process has terminated, it checks that the process has removed its utmpx entry from /var/adm/utmp. If the process' utmpx entry has not been removed, utmpd removes the entry. By periodically scanning the /var/adm/utmpx file, utmpd also monitors processes that are not in its table.

Options
-debug
Run in debug mode, leaving the process connected to the controlling terminal. Write debugging information to standard output.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files
/etc/default/utmpd
You can set default values for the flags listed below. For example: SCAN_PERIOD=600

SCAN_PERIOD
The number of seconds that utmpd sleeps between checks of /proc to see if monitored processes are still alive. The default is 300.

MAX_fds
The maximum number of processes that utmpd attempts to monitor. The default value is 4096.

WTMPX_UPDATE_FREQ
The number of seconds that utmpd sleeps between read accesses of the wtmpx file. The wtmpx file's last access time is used by init(1M) on reboot to determine when the operating system became unavailable. The default is 60.

/var/adm/utmpx
File containing user and accounting information for commands such as who(1), write(1), and login(1).

/proc
Directory containing files for processes whose utmpx entries are being monitored.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  svcs(1), init(1M), svcadm(1M), poll(2), pututxline(3C), proc(4), utmp(4), utmpx(4), attributes(5), smf(5)

Notes  If the filesystem holding /var/adm/wtmpx is mounted with options which inhibit or defer access time updates, an unknown amount of error will be introduced into the utmp DOWN_TIME record's timestamp in the event of an uncontrolled shutdown (for example, a crash or loss of power). Controlled shutdowns will update the modify time of /var/adm/wtmpx, which will be used on the next boot to determine when the previous shutdown occurred, regardless of access time deferral or inhibition.

The utmpd service is managed by the service management facility, smf(5), under the service identifier:
	svc:/system/utmp:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
**Name**

uucheck - check the uucp directories and permissions file

**Synopsis**

```
/usr/lib/uucp/uucheck [-v] [-x debug-level]
```

**Description**

uucheck checks for the presence of the uucp system required files and directories. uucheck also does error checking of the Permissions file (/etc/uucp/Permissions).

uucheck is executed during package installation. uucheck can only be used by the super-user or uucp.

**Options**

The following options are supported:

- **-v**
  
  Give a detailed (verbose) explanation of how the uucp programs will interpret the Permissions file.

- **-x debug-level**
  
  Produce debugging output on the standard output. debug-level is a number from 0 to 9. Higher numbers give more detailed debugging information.

**Files**

/etc/uucp/Devices
/etc/uucp/Limits
/etc/uucp/Permissions
/etc/uucp/Systems
/var/spool/locks/*
/var/spool/uucp/*
/var/spool/uucppublic/*

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTETYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

<td>service/network/uucp</td>
</tr>
</tbody>
</table>

**See Also**

uucp(1C), uustat(1C), uux(1C), uucico(1M), uusched(1M), attributes(5)

**Bugs**

The program does not check file/directory modes or some errors in the Permissions file such as duplicate login or machine name.
Name  uucico – file transport program for the uucp system

Synopsis  ```
/usr/lib/uucp/uucico [-f] [-c type] [-d spool-directory]
        [-i interface] [-r role-number] [-s system-name]
        [-x debug-level]
```

Description  uucico is the file transport program for uucp work file transfers.

Options  The following options are supported:

- `-f`  This option is used to "force execution" of uucico by ignoring the limit on the maximum number of uucicos defined in the /etc/uucp/Limits file.

- `-c type`  The first field in the Devices file is the "Type" field. The -c option forces uucico to only use entries in the "Type" field that match the user specified type. The specified type is usually the name of a local area network.

- `-d spool-directory`  This option specifies the directory spool-directory that contains the uucp work files to be transferred. The default spool directory is /var/spool/uucp.

- `-i interface`  This option defines the interface used with uucico. The interface only affects slave mode. Known interfaces are UNIX (default), TLI (basic Transport Layer Interface), and TLIS (Transport Layer Interface with Streams modules, read/write).

- `-r role-number`  The role-number 1 is used for master mode. role-number 0 is used for slave mode (default). When uucico is started by a program or cron, role-number 1 should be used for master mode.

- `-s system-name`  The -s option defines the remote system (system-name) that uucico will try to contact. It is required when the role is master; system-name must be defined in the Systems file.

- `-x debug-level`  Both uux and uucp queue jobs that will be transferred by uucico. These jobs are normally started by the uusched scheduler, for debugging purposes, and can be started manually. For example, the shell utry starts uucico with debugging turned on. The debug-level is a number between 0 and 9. Higher numbers give more detailed debugging information.

Name: uucleanup – uucp spool directory clean-up

Synopsis: /usr/lib/uucp/uucleanup [-C time] [-D time] [-m string]
          [-o time] [-s system] [-W time] [-x debug-level] [-X time]

Description: uucleanup will scan the spool directories for old files and take appropriate action to remove
them in a useful way:

- Inform the requester of send/receive requests for systems that cannot be reached.
- Return undeliverable mail to the sender.
- Deliver rnews files addressed to the local system.
- Remove all other files.

In addition, there is a provision to warn users of requests that have been waiting for a given
number of days (default 1 day). Note: uucleanup will process as if all option times were
specified to the default values unless time is specifically set.

This program is typically started by the shell uudemon.cleanup, which should be started by
cron(1M).

Options:

- `-C time`  Remove any C. files greater or equal to time days old and send appropriate
  information to the requester (default 7 days).
- `-D time`  Remove any D. files greater or equal to time days old, make an attempt to
  deliver mail messages, and execute rnews when appropriate (default 7 days).
- `-m string`  Include string in the warning message generated by the -W option. The
  default line is "See your local administrator to locate the problem".
- `-o time`  Delete other files whose age is more than time days (default 2 days).
- `-s system`  Execute for system spool directory only.
- `-W time`  Any C. files equal to time days old will cause a mail message to be sent to the
  requester warning about the delay in contacting the remote. The message
  includes the JOBID, and in the case of mail, the mail message. The
  administrator may include a message line telling whom to call to check the
  problem (-m option) (default 1 day).
- `-x debug-level`  Produce debugging output on standard output. debug-level is a single digit
  between 0 and 9; higher numbers give more detailed debugging
  information. (This option may not be available on all systems.)
- `-X time`  Any X. files greater or equal to time days old will be removed. The D. files
  are probably not present (if they were, the X. could get executed). But if
  there are D. files, they will be taken care of by D. processing (default 2 days).
Files
/usr/lib/uucp directory with commands used by uucleanup internally
/var/spool/uucp spool directory

Name  uusched – uucp file transport program scheduler

Synopsis  /usr/lib/uucp/uusched [-u debug-level] [-x debug-level]

Description  uusched is the uucp(1C) file transport scheduler. It is usually started by the daemon uudemon.hour that is started by cron(1M) from an entry in user uucp’s crontab file:

```
11,41 * * * * /etc/uucp/uucp/uudemon.hour
```

Options  The options are for debugging purposes only. debug-level is a number between 0 and 9. Higher numbers give more detailed debugging information:

The following options are supported:

- `-u debug-level`  Passes the `-u debug-level` option uucico(1M) as `-x debug-level`.
- `-x debug-level`  Outputs debugging messages from uusched.

Files  /etc/uucp/Devices

Uutry(1M)

Name
Uutry, uutry – attempt to contact remote system with debugging on

Synopsis
/usr/lib/uucp/Uutry [-r] [-c type] [-x debug-level] system-name

Description
Uutry is a shell script that is used to invoke uucico(1M) to call a remote site. Debugging is initially turned on and is set to the default value of 5. The debugging output is put in file /tmp/system-name.

Options
The following options are supported:

- r
  This option overrides the retry time that is set in file /var/uucp/.Status/system-name.

- c type
  The first field in the Devices file is the "Type" field. The -c option forces uucico to use only entries in the "Type" field that match the user-specified type. The specified type is usually the name of a local area network.

- x debug-level
depend-level is a number from 0 to 9. Higher numbers give more detailed debugging information.

Files
/etc/uucp/Devices
/etc/uucp/Limits
/etc/uucp/Permissions
/etc/uucp/Systems

uucp(1C), uux(1C), uucico(1M), attributes(5)
Name  uuxqt – execute remote command requests

Synopsis  /usr/lib/uucp/uuxqt [-s system] [-x debug-level]

Description  uuxqt is the program that executes remote job requests from remote systems generated by the use of the uux command. (mail uses uux for remote mail requests). uuxqt searches the spool directories looking for execution requests. For each request, uuxqt checks to see if all the required data files are available, accessible, and the requested commands are permitted for the requesting system. The Permissions file is used to validate file accessibility and command execution permission.

There are two environment variables that are set before the uuxqt command is executed:

-  **UU_MACHINE** is the machine that sent the job (the previous one).
-  **UU_USER** is the user that sent the job.

These can be used in writing commands that remote systems can execute to provide information, auditing, or restrictions.

Options  The following options are supported:

-  **-s system**  Specifies the remote system name.
-  **-x debug-level**  *debug-level* is a number from 0 to 9. Higher numbers give more detailed debugging information.

Files  /etc/uucp/Limits
/etc/uucp/Permissions
/var/spool/locks/*
/var/spool/uucp/*

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

**Name**  vbiosd – vbios daemon

**Synopsis**  vbiosd

**Description**  The vbiosd daemon is started at boot time to provide an execution environment for adapter-supplied VBIOS code that is used in graphics mode switching.

This mode switching occurs when exiting X, switching virtual terminals (see vtdaemon(1M) for more information), and during fast reboot.

**Attributes**  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface Stability</td>
<td>Uncommitted</td>
</tr>
</tbody>
</table>

**See Also**  svcs(1), svcadm(1M), vtdaemon(1M), attributes(5), smf(5)

**Notes**  The vbios daemon is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/vbiosd/default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
Name
vdiskadm – create and manage virtual disks

Synopsis
vdiskadm create -s size [-t type[:opt],[opt]
[-c comment] vdname

vdiskadm destroy [-r] vdname|snapshot

vdiskadm snapshot vdname@hostname

vdiskadm rollback [-r] snapshot

vdiskadm clone [-c comment] vdname|snapshot clone_vdname

vdiskadm export -x type[:opt] -d file|zvol|dsk vdname

vdiskadm convert [-t type[:opt]] vdname

vdiskadm translate [-i type[:opt]] -I input_file -x type[:opt]
-d output_file

vdiskadm help [command]

Description
The vdiskadm command manages virtual disks within dom0. In the SYNOPSIS above, vdname is the pathname of the virtual disk; it has a maximum length of MAXPATHLEN (1024 bytes).

vdiskadm is implemented as a set of subcommands, many with their own options and operands. These subcommands are described under “Subcommands,” below.

The following subsections describe concepts related to virtual disks.

Snapshots
A snapshot is a read-only copy of a virtual disk. Snapshots can be created extremely quickly and initially consume little space. As data within the active virtual disk changes, the snapshot consumes more data than would otherwise be shared with the active virtual disk.

Clones
A clone is a writable copy of a virtual disk. The default type of clone is a merged (that is, coalesced) copy of the original virtual disk. An example of a merged clone occurs when a virtual disk is comprised of several snapshots; a subsequent clone operation results in a new
virtual disk containing no snapshots. A clone will be of the same type as the original virtual
disk (that is, vmdk: fixed). When a merged clone is created there is no linkage back to the
original virtual disk or to any of its snapshots. This lack of linkage allows the merged clone to
be moved to another physical machine.

The values of numeric properties can be specified using human-readable suffixes, such as k,
KB, M, Gb, and so forth, up to Z for zettabyte). The following are all valid (and equal)
specifications:

1536M 1.5g 1.50GB

The following types and options of virtual disks are supported:

- vmdk:fixed
- vmdk:sparse
- vdi:fixed
- vdi:sparse
- vhd:fixed
- vhd:sparse
- raw:fixed

where vmdk is the native VMWare format, vdi is the native VirtualBox format, vhd is the native
Microsoft format, and raw describes a file that looks like a raw disk. A raw disk is always in
fixed format so that option can be explicitly set or implicitly understood.

If the type is not specified, the default value is vmdk. If the option is not specified, the default
value is fixed for type raw and sparse for types vmdk, vdi, and vhd.

Properties are divided into two types, native and user defined. Native properties either export
internal statistics or control vdiskadm behavior. In addition, native properties are either
editable or read-only. User-defined properties are arbitrary strings that have no effect on
vdiskadm behavior. You can use them to annotate virtual disks in a way that is meaningful in
your environment. User-defined property names must contain a colon (:) character, to
distinguish them from native properties.

Properties are associated only with the virtual disk and not with individual snapshots.

Every virtual disk has a set of native properties that export statistics about the virtual disk, as
well as control various behaviors.

The following are the native properties for a virtual disk:

- cdrom
  Boolean property that is true if the virtual disk is a CDROM.
- removable
  Boolean property that is true if the virtual disk is a removable media.
- readonly
  Boolean property that is true if the virtual disk is read-only. This property is read-only.
sectors
  Numeric property containing the number of disk sectors in the given virtual disk. This property is read-only.

name
  String property that is the name of the virtual disk. This property is read-only.

max-size
  Numeric property containing the maximum size of the virtual disk in bytes. This property is read-only.

effective-size
  Numeric property containing the effective size of the virtual disk, in bytes. The effective size includes the size of the data file and all snapshots. The effective size can exceed the maximum size. This property is read-only.

creation-time
  String property containing the date and time that the virtual disk was created. This property is read-only.

creation-time-epoch
  Numeric property describing the creation-time property in seconds since the epoch (seconds since 00:00:00 UTC, Jan. 1, 1970). This property is read-only.

modification-time
  String property containing the date and time of last modification to virtual disk. This property is read-only.

modification-time-epoch
  Numeric property describing the modification-time property in seconds since the epoch (seconds since 00:00:00 UTC, Jan. 1, 1970). This property is read-only.

description
  String property that contains the comment given when the virtual disk was created or cloned. This property is read-only.

type
  String property that contains the type of virtual disk: vmdk, vhd, vdi, or raw. This property is read-only.

sparse
  Boolean property that is true if the virtual disk is in sparse format. This property is read-only.

owner
  String property that contains the user name of the owner of the virtual disk. This property is editable.
The `vdiskadm` subcommands and their arguments are described in the following subsections.

### vdiskadm create

**vdiskadm create** `-s size [-t type[::opt],[opt]]`  
`[-c comment] vdname`

Creates a new virtual disk of the specified size and at the location specified by `vdname`. If `vdname` includes a path to the virtual disk, the directories that follow from that path will be created during creation of the virtual disk. This subcommand has the options listed below.

- `-t type[::opt], [opt]`
  Specifies the type of virtual disk to be created. The default type is `vmdk`. For `vmdk` and `vdi` types the default option is `sparse`. For type `raw` the default option is `fixed`.

- `-c comment`
  Comment that can be attached to virtual disk.

### vdiskadm destroy

**vdiskadm destroy** `[-r] vdname|snapshot`

Destroys the specified virtual disk or snapshot. By default, the destroy operation fails if the specified virtual disk contains snapshots. This subcommand has the option listed below.

- `-r`
  Recursively destroys the virtual disk, including all snapshots associated with the virtual disk.

### vdiskadm snapshot

**vdiskadm snapshot** `vdname@snapname`

Creates a snapshot of the virtual disk with the specified `snapshot`. This subcommand has no options.

### vdiskadm rollback

**vdiskadm rollback** `[-r] snapshot`

Roll back the virtual disk to a previous snapshot. When a virtual disk is rolled back, all data that has changed since the snapshot is discarded, and the virtual disk reverts to the state at the time of the snapshot. By default, the command refuses to roll back to a snapshot other than the most recent one. In order to roll back further, all intermediate snapshots must be destroyed by specifying the `-r` option. This subcommand has the option listed below.

- `-r`
  Recursively destroy any snapshots more recent than the one specified.

### vdiskadm clone

**vdiskadm** `[-c comment] vdname|snapshot clone_vdname`

Creates a clone of the specified snapshot or virtual disk. The clone is created with the type and option and the size of the virtual disk being cloned. If `clone_vdname` includes a path the directories that flow from that path will be created during creation of the cloned virtual disk. By default, a merged clone image is created. This subcommand has the option listed below.

- `-c comment`
  Comment that can be attached to cloned virtual disk.
vdiskadm move

Never used.

vdiskadm rename

vdiskadm rename vdnamenshaphot vdnamenshaphot

vdiskadm list

List all information about a virtual disk.

vdiskadm verify

vdiskadm verify vdnamenshaphot

vdiskadm prop-get

List all properties of a virtual disk.

vdiskadm prop-set

Set properties of a virtual disk.
vdiskadm prop-add vdiskadm -p property=value vdname

Adds the user-defined property with the specified value to the specified virtual disk. Returns an error if the property already exists. The user-defined property name must contain a colon character (:). This subcommand has the option listed below.

- p property=value
  Specifies the property being added.

vdiskadm prop-del vdiskadm prop-del -p property vdname

Deletes a user-defined property from the specified virtual disk. This subcommand has the option listed below.

- p property
  Specifies the property being deleted.

vdiskadm import vdiskadm import [-fnpqm] [-x type] -d file|zvol|dsk \ [-t type[:opt]] vdname

Creates a new virtual disk using data from a file or block device. The file may be in vdi, vhd, vmdk, or raw format. A block device is always assumed to be in raw format. This subcommand has the following options.

- f
  Returns a list of files that will be used in the import process.

- n
  Show output from import without actually running the import.

- p
  Displays files in an easily parsable format.

- q
  Run in quiet mode giving no output.

- m
  Move the imported file to virtual disk without copying the data.

- x type
  Specifies the type of virtual disk data being imported. If vdiskadm is unable to detect the imported file type, -x must be specified.

- d file|zvol|dsk
  File or block device containing data to be imported.

- t type[:opt]
  Specifies the type of virtual disk to be created on import. The default type is vmdk. For vmdk, vdi, and vhd types the default opt is sparse. For type raw the default opt is fixed.
vdiskadm export

Exports data from a virtual disk to a file or block device. This subcommand has the following options.

-\texttt{x type[:opt]}  
  Specifies the type of virtual disk data being exported.

-\texttt{-d file|zvol|dsk}  
  File or block device receiving data being exported.

vdiskadm convert

Converts a virtual disk into a different type virtual disk. This subcommand has the following option.

-\texttt{-t type[:opt]}  
  Specifies the type of virtual disk to be created upon conversion. The default type is \texttt{vmdk}. For \texttt{vmdk}, \texttt{vdi}, and \texttt{vhd} types the default \texttt{opt} is \texttt{sparse}. For type \texttt{raw} the default \texttt{opt} is \texttt{fixed}.

vdiskadm translate

Translate data from one virtual disk data type to another without creating a virtual disk. This subcommand has the following options.

-\texttt{-i type[:opt]}  
  Specifies the input type of virtual disk data being translated. If \texttt{vdiskadm} is unable to detect the input file type, \texttt{-i} must be specified.

-\texttt{-I input\_file}  
  File or block device containing data being translated.

-\texttt{x type[:opt]}  
  Specifies the output type of virtual disk data being translated. For \texttt{vmdk}, \texttt{vdi}, and \texttt{vhd} types the default \texttt{opt} is \texttt{sparse}. For type \texttt{raw} the default \texttt{opt} is \texttt{fixed}.

-\texttt{-d output\_file}  
  File or block device receiving data being translated. \texttt{output\_file} must not exist. The file will be created during translation.

vdiskadm help

Displays a general or command-specific help message. This subcommand has only the command name optional argument.

**Examples**

**EXAMPLE 1**  
Creating a vmdk Sparse File

The following command creates a virtual disk named disk1 of size 8 GB in the directory /guests/disks.

\texttt{# vdiskadm create -s 8g -t vmdk:sparse /guests/disks/disk1}
CREATE A SNAPSHOT

The following command creates a snapshot of the virtual disk located at /guests/disks/disk1. The snapshot is named install.

# vdiskadm snapshot /guests/disks/disk1@install

CREATE AND DESTROY SNAPSHOTS

The following commands create two snapshots, named install and bfu, of the virtual disk located at /guests/disks/disk1. The third command destroys the newly created snapshot install.

# vdiskadm snapshot /guests/disks/disk1@install
# vdiskadm snapshot /guests/disks/disk1@bfu
# vdiskadm destroy /guests/disks/disk1@install

ROLL BACK A VIRTUAL DISK

The following command reverts the contents of the virtual disk to the snapshot named install, deleting all intermediate snapshots.

# vdiskadm rollback -r /guests/disks/disk1@install

LIST A VIRTUAL DISK AND SNAPSHOTS

The following command lists all of the images associated with the virtual disk /guests/disks/disk1.

# vdiskadm list /guests/disks/disk1

disk1@install
disk1@bfu
disk1

CREATE A CLONE

The following command creates a new virtual disk that is a coalesced copy of the virtual disk /guests/disks/disk1. The clone is created in the same format (that is, vmdk:sparse) as the original virtual disk.

# vdiskadm clone /guests/disks/disk1 /guests/clone/clone_disk1

ADDITIONAL USER-DEFINED PROPERTY

The following command adds a user-defined property to the virtual disk and assigns it the specified value. This property name was chosen to represent the source and requirements of this virtual disk data using the required colon to delineate the fields.

# vdiskadm prop-add -p com.sun:required-nic=2 /guests/disks/disk1
EXAMPLE 8  Importing Existing vmdk Format File
The following command takes an existing vmdk format file and imports it to a virtual disk.

```
# vdiskadm import -d /downloads/appliance.vmdk /guests/import/disk1
```

EXAMPLE 9  Importing vmdk File and Converting to vhd
The following command takes an existing vmdk format file and, upon import, converts it to a vhd-type virtual disk.

```
# vdiskadm import -d /downloads/appliance.vmdk -t vhd \
/guests/import/disk1
```

EXAMPLE 10  Importing Data from zvol
The following command imports virtual disk data from a zvol and, upon import, converts it to a vmdk:fixed type virtual disk.

```
# vdiskadm import -d /dev/zvol/dsk/pool1/disk1 -t vmdk:fixed \ 
/guests/import/disk1
```

EXAMPLE 11  Exporting Data to Block Device
The following command takes an existing virtual disk and, upon export, converts it to a disk slice, of raw type.

```
# vdiskadm export -d /dev/dsk/c0t1d0s3 -x raw /guests/disks/disk1
```

EXAMPLE 12  Converting Virtual Disk Type
The following command takes an existing virtual disk and converts it (in place) to a different format type.

```
# vdiskadm convert -t vdi:fixed /guests/disks/disk1
```

EXAMPLE 13  Translating Data from One Type to Another
The following command translates data from a virtual disk format file to raw data written to a zvol without creating a virtual disk.

```
# vdiskadm translate -I /downloads/appliance.vmdk -x raw \ 
-d /dev/zvol/dsk/pool1/disk1
```

vdpd – VSI Discovery and Configuration Protocol daemon

**Synopsis**

```
/usr/lib/vdpd
svc:/network/evb/vdp:default
```

**Description**

vdpd is a system daemon that exchanges VSI (Virtual Station Interface or VNIC) information using VDP and ECP protocols, defined in the IEEE 802.1qbg specification. The vdpd daemon is controlled through the service management facility (SMF; see `smf`(5)) service instance:

```
svc:/network/evb/vdp:default
```

This means that `svcadm(1M)` must be used to start, stop, restart, and refresh the vdpd daemon. The daemon is enabled by default. To enable VDP exchanges for any VNIC created on the system, this daemon should be running.

The vdpd daemon has no options. Note that it is a Project Private interface.

**Examples**

**EXAMPLE 1** Enabling the vdpd Daemon

The following `svcadm` command enables the vdpd daemon.

```
# svcadm enable network/vdpd
# svcs network/vdpd
```

**EXAMPLE 2** Disabling the vdpd Daemon

The following `svcadm` command disables the vdpd daemon.

```
# svcadm disable network/vdpd
# svcs network/vdpd
```

IEEE Std 802.1 Qbg/D1.6: *Draft Standard for Local and Metropolitan Area Networks*–Virtual Bridged Local Area Networks; Amendment XX: *Edge Virtual Bridging*. 
Name  virt-convert -- convert virtual machines between formats

Synopsis  virt-convert [option]... input.vmx | input.ovf | input-dir
          [output.xml | output-dir]

Description  The virt-convert program is a command line tool for converting virtual machines (VMs) from one format to another. It accepts either a VM definition file (such as VMware vmx format) or a directory containing a VM. By default, a new VM definition file, and converted disk images, will be placed in a new output directory.

If an output directory is specified, it will be created if necessary, and the output VM definition placed within the new directory, along with any disk images, as needed.

If an output VM definition file is specified, it will be created alongside any disks in the same directory.

Options  Any of the following options can be omitted, in which case virt-convert will use defaults when required. An input VM definition or containing directory must be provided. By default, an output directory is generated based upon the name of the VM. The default input format is VMware vmx, and the default output format is a libvirt "image" XML definition.

  -a, --arch=arch
       Architecture of the virtual machine (i686, x86_64, ppc). Defaults to that of the host machine.

  -D, --disk-format=format
       Output disk format, or none if no conversion should be performed. format is one of:

       none
           No disks are converted or copied.

       vmdk
           VMWare VMDK format

       raw
           raw file

       vdisk
           vdisk format (see vdiskadm(1M))

  -d, --debug
       Display debugging information.

  -h, --help
       Display the help message and exit.

  -i, --input-format format
       Input format. Currently, vmx and ovf are supported.

  --noacpi
       Override the OS type and variant to disable the ACPI setting for fully virtualized guest.
Overridethe OStype and variant to disable the APIC setting for fully virtualized guest.

-o, --output-format format
Output format. Currently, the supported output formats are virt-instance and virt-image. virt-instance is the recommended format for Solaris.

-os-type=os_type
Optimize the guest configuration for a type of operating system. This will attempt to pick the most suitable ACPI and APIC settings, optimally supported mouse drivers, and generally accommodate other operating system quirks.

-os-variant=os_variant
Further optimize the guest configuration for a specific operating system variant. This parameter is optional.

-p, --paravirt
Create a paravirtualized guest image. Convert machine to a paravirtualized Xen-based image.

-q, --quiet
Avoid verbose output.

-v, --hvm
Create a fully virtualized guest image. Convert machine to a hvm/qemu–based image (this is the default if --paravirt is not specified).

Examples

CONVERTING A VMWARE VMX APPLIANCE

The following sequence of commands converts a VMware VMX appliance and imports it into Solaris xVM.

# virt-convert -o virt-instance /guests/vmx-appliance/ /guests/xvm-appliance/
# virsh define --relative-path=/guests/xvm-appliance/ /guests/xvm-appliance/appliance.xml

vdiskadm(1M), attributes(5)
Caveats  Not all conversions will result in a working guest installation. If the source OS image is configured to use SCSI disks, the use of IDE disks may cause the OS boot to fail. Some images may be configured to use the VMware drivers such as *vlance*. In the *vlance* case and in general, device emulation support may not be sufficient for all OS installations.

Name virtinfo – virtualization domain information

Synopsis virtinfo [-acdpstu]

Description The `virtinfo` utility provides virtualization information returned by `libvirt(3LIB)` about the current domain. When options are specified, symbols that represent one or more virtualization domain characteristics are written to standard output. If no options are specified, `virtinfo` shows only the virtualization domain type.

Options The `virtinfo` command supports the following options:

- `-a` Shows all information that is currently available from the system.
- `-c` Shows the network node name of the control domain. This name is identical to the string shown by running the `uname -n` command on the control domain.
- `-d` Shows the domain name for this virtual domain.
- `-p` Shows information in a parseable format.

The parseable output for Logical Domains (LDoms) has the following format:

```
VERSION 1.0
DOMAINROLE|impl=LDoms|control={true|false}|
    io={true|false}|service={true|false}|
    root={true|false}
DOMAINNAME|name=domain-name
DOMAINUUID|uuid=uuid
DOMAINCONTROL|name=control-domain-nodename
DOMAINCHASSIS|serialno=serial-no
```

- `-s` Shows the platform serial number.
- `-t` Shows the domain type.

The domain type for Logical Domains is a string of one or more of the following blank-separated values:

LDoms LVoms implementation
c control Control domain
g guest Guest domain
I/O I/O domain
s service Service domain
r root Root I/O domain

Note that the `control` and `guest` values are mutually exclusive.
-u    Shows the universally unique identifier (UUID) of the domain. See the `libuuid(3LIB)` man page.

**Exit Status**  The following exit values are returned:

0       Successful completion.

>0      An error occurred.

**Examples**  **EXAMPLE 1**  Viewing Default Information

The following example shows the default information about the domain:

```
$ virtinfo
Domain role: LDomS control I/O service root

The current domain is the control domain, which is also an
I/O domain, the service domain and a root I/O domain.
```

**EXAMPLE 2**  Viewing All Information

The following example shows all available information about the domain:

```
$ virtinfo -a
Domain role: LDomS control I/O service root
Domain name: primary
Domain UUID: 8e0d6ec5-cd55-e57f-ae9f-b4cc050999a4
Control domain: san-t2k-6
Chassis serial#: 0704RB0280
```

**EXAMPLE 3**  Viewing All Information In a Parsable Format

The following example shows all available information about the domain in a parsable format:

```
$ virtinfo -ap
VERSION 1.0
DOMAINROLE|impl=LDoms|control=true|io=true|service=true|root=true
DOMAINNAME|name=primary
DOMAINUUID|uuid=8e0d6ec5-cd55-e57f-ae9f-b4cc050999a4
DOMAINCONTROL|name=san-t2k-6
DOMAINCHASSIS|serialno=0704RB0280
```

vmstat(1M)

Name
vmstat – report virtual memory statistics

Synopsis
vmstat [-ipqsS] [-T u | d] [disks] [interval [count]]

Description
vmstat reports virtual memory statistics regarding kernel thread, virtual memory, disk, trap, and CPU activity.

On MP (multi-processor) systems, vmstat averages the number of CPUs into the output. For per-processor statistics, see mpstat(1M).

vmstat only supports statistics for certain devices. For more general system statistics, use sar(1), iostat(1M), or sar(1M).

Without options, vmstat displays a one-line summary of the virtual memory activity since the system was booted.

During execution of the kernel status command, the state of the system can change. If relevant, a state change message is included in the vmstat output, in one of the following forms:
<<device added: sd0>>
<<device removed: sd0>>
<<processors added: 1, 3>>
<<processors removed: 1, 3>>

See Oracle Solaris Administration: Common Tasks for device naming conventions for disks.

Options
The following options are supported:

- i  Report the number of interrupts per device. count and interval does not apply to the -i option.
- p  Report paging activity in details. This option will display the following, respectively:
    epi  Executable page-ins.
    epo  Executable page-outs.
    epf  Executable page-frees.
    api  Anonymous page-ins.
    apo  Anonymous page-outs.
    apf  Anonymous page-frees.
    fpi  File system page-ins.
    fpo  File system page-outs.
    fpf  File system page-frees.
When executed in a zone and if the pools facility is active, all of the above only report activity on the processors in the processor set of the zone’s pool.

- q  Suppress messages related to state changes.

- s  Display the total number of various system events since boot. count and interval does not apply to the -s option.

- S  Report on swapping rather than paging activity. This option will change two fields in vmstat’s ”paging” display: rather than the ”re” and ”mf” fields, vmstat will report ”si” (swap-ins) and ”so” (swap-outs).

- T u | d  Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See date(1).

Operands  The following operands are supported:

count  Specifies the number of times that the statistics are repeated. count does not apply to the -i and -s options.

disks  Specifies which disks are to be given priority in the output (only four disks fit on a line). Common disk names are id, sd, xd, or xy, followed by a number (for example, sd2, xd0, and so forth).

interval  Specifies the last number of seconds over which vmstat summarizes activity. This number of seconds repeats forever. interval does not apply to the -i and -s options.

Examples  EXAMPLE1  Using vmstat

The following command displays a summary of what the system is doing every five seconds.

```
example% vmstat 5
```

The fields of vmstat’s display are
Using `vmstat` (Continued)

**kthr**
Report the number of kernel threads in each of the three following states:

- **r** the number of kernel threads in run queue
- **b** the number of blocked kernel threads that are waiting for resources I/O, paging, and so forth
- **w** the number of swapped out lightweight processes (LWPs) that are waiting for processing resources to finish.

**memory**
Report on usage of virtual and real memory.

- **swap** available swap space (Kbytes)
- **free** size of the free list (Kbytes)

**page**
Report information about page faults and paging activity. The information on each of the following activities is given in units per second.

- **re** page reclaims — but see the `-S` option for how this field is modified.
- **mf** minor faults — but see the `-S` option for how this field is modified.
- **pi** kilobytes paged in
- **po** kilobytes paged out
- **fr** kilobytes freed
- **de** anticipated short-term memory shortfall (Kbytes)
- **sr** pages scanned by clock algorithm

When executed in a zone and if the pools facility is active, all of the above (except for “de”) only report activity on the processors in the processor set of the zone’s pool.

**disk**
Report the number of disk operations per second. There are slots for up to four disks, labeled with a single letter and number. The letter indicates the type of disk (`s = SCSI, i = IPI, and so forth`); the number is the logical unit number.

**faults**
Report the trap/interrupt rates (per second).

- **in** interrupts
- **sy** system calls
- **cs** CPU context switches

When executed in a zone and if the pools facility is active, all of the above only report activity on the processors in the processor set of the zone’s pool.
EXAMPLE 1 Using `vmstat` (Continued)

cpu Give a breakdown of percentage usage of CPU time. On MP systems, this is an average across all processors.
    us user time
    sy system time
    id idle time

    When executed in a zone and if the pools facility is active, all of the above only report activity on the processors in the processor set of the zone's pool.

Attributes See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

Invocation is evolving. Human readable output is unstable.

See Also `date(1), sar(1), iostat(1M), mpstat(1M), sar(1M), time(2), attributes(5)`

Notes The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.
The `vntsd` daemon is a server that supports connections to the Logical Domains (LDoms) console by using telnet(1). When a telnet session starts, `vntsd` sends telnet options to the client indicating a willingness to remotely echo characters and to suppress go ahead.

Consoles are organized into groups by the LDoms Manager. Each console group is assigned a unique group name and TCP port number. `vntsd` uses the group's port number to export access to the consoles within that group. To establish a connection with a console or console group, a user starts a telnet(1) session with the corresponding group's port number. Depending on the number of consoles within that group, `vntsd` does one of two things:

- If there is only one console in the group, `vntsd` connects a session to that LDoms console.
- If there are multiple consoles in the group, `vntsd` prompts the user to select the console to which they would like to connect, as shown in "Multiple-Console Options," below.

For each console, `vntsd` provides write access only to the first user connecting to the console. Subsequent users connecting to the console are allowed only to read from the console and wait for write access. When the first user disconnects, write privileges are transferred to the next user waiting in the queue. If a user who does not have write privileges attempts to write to a console, the `vntsd` displays the following message:

```
You do not have write access
```

A user who has no write access can acquire write access forcibly by using the `~w` special console command, described in "Special Console Commands," below.

`vntsd` can be invoked only with superuser privileges or by someone fitting the appropriate security profile.

The options for `vntsd` are divided into multiple-console options and console commands.

### Multiple-Console Options

The options listed below are supported when there are multiple LDoms consoles in a group. The syntax for the use of these options is:

```
<hostname>-vnts-<group-name>: <option>
```

For example:

```
myhost-vnts-salesgroup: h
```

The `h` option invokes help, as described below.

`h`

Display the following help text:

```
  h -- this help
  l -- list of consoles
  q -- quit
  c{id}, n{name} -- connect to console of domain {id} or domain name
```
List all consoles in the group. For example:

<table>
<thead>
<tr>
<th>DOMAIN ID</th>
<th>DOMAIN NAME</th>
<th>DOMAIN STATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>ldg1</td>
<td>online</td>
</tr>
<tr>
<td>1</td>
<td>ldg2</td>
<td>connected</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

The two domain states and their meanings are:

- **online**
  - No one is connected to the console.
- **connected**
  - At least one user is already connected to the console.

q

Disconnect from vntsd.

c[id], n[name]

Connect to specified console. Upon connection, the following message is displayed:

Connecting to console <domain-name> in group <group-name>

Press ~? for control options ...

A tilde (~) appearing as the first character of a line is an escape signal that directs vntsd to perform a special console command. The tilde-tilde (~~) sequence outputs a tilde. In conjunction with the initial tilde, vntsd accepts the following special console commands:

- ~
  - Disconnect from the console or console group.
- ~w
  - Force write access to the console.
- ~p
  - Disconnect from this console, and connect to the console that precedes this console in the list of consoles.
- ~n
  - Disconnect from this console, and connect to the console that follows this console in the list of consoles.
- ~#
  - Send break.
- ^B
  - Send alternate break.
- ~?
  - Display vntsd help, as follows:
vntsd(1M)

~# - Send break
~”B - Send alternate break
~. - Exit from this console
~w - Force write access
~n - Console next
~p - Console previous
~? - Help

Files
/usr/lib/ldoms/vntsd
   Binary executable vntsd file.
/usr/lib/ldoms/vntsd.xml
   Service management facility (smf(5)) manifest file for vntsd.

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/ldoms</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

See Also
telnet(1), svccfg(1M), usermod(1M), auth_attr(4), attributes(5), smf(5)

Notes
The vntsd is managed by the service management facility, smf(5), under the service identifier:
svc:/ldoms/vntsd

You can change the following properties using the svccfg(1M) command:

vntsd/vcc_device
   Set an instance of the virtual console concentrator (vcc) driver to which vntsd is connected.

vntsd/listen_addr
   Set the IP address to which vntsd listens, using the following syntax:
   vntsd/listen_addr:"xxx.xxx.xxx.xxx"
   ...
   where xxx.xxx.xxx.xxx is a valid IP address. The default value of this property is to listen on IP address 127.0.0.1. Users can connect to a guest console over a network if the value is set to the IP address of the control domain.

   Note – Enabling network access to a console has security implications. Any user can connect to a console and for this reason it is disabled by default.

vntsd/timeout_minutes
   Set timeout in minutes. vntsd will timeout (close) telnet connection if there is no activity (input or output) on the console. The default value is 0, which disables timeout.
vntsd/authorization

Enable the authorization checking of users and roles for the domain console or consoles that are being accessed. The default value of this property is `false` to maintain backward compatibility. To enable authorization checking, use the `svccfg(1M)` command to set the property value to `true`. While this option is enabled, vntsd listens and accepts connections on `localhost`. If the `listen_addr` property specifies an alternate IP address when this option is enabled, vntsd ignores the alternate IP address and continues to listen on `localhost`. Connections that are initiated from other hosts will also fail. Authorizations are available to access all consoles or console groups, or to access specific consoles or console groups. When the vntsd service is enabled, the following authorization is added to the authorization description database, `auth_attr(4)`:  
solaris.vntsd.consoles:::Access All LDoms Guest Consoles::

Add any fine-grained authorizations based on the name of the console group. For example, if the name of the console group to be authorized is `ldg1`, add the following entry to the `auth_attr(4)` file:

solaris.vntsd.console-ldg1:::Access Specific LDoms Guest Console::

By default, the authorization to access all consoles is assigned to the root user or role. The superuser, or user with appropriate privileges, can use the `usermod(1M)` command to assign the required authorization or authorizations to other users or roles.

The following example gives user `user1` the authorization to access all domain consoles:

```
# usermod -A "solaris.vntsd.consoles" user1
```

The following example gives user `user1` the authorization to access the console group named `ldg1`:

```
# usermod -A "solaris.vntsd.console-ldg1" user1
```
volcopy(1M)

Name
volcopy – make an image copy of file system

Synopsis
volcopy [-F FSType] [-V] [generic_options]
[-o FSType-specific_options] operands

Description
volcopy makes a literal copy of the file system. This command may not be supported for all FSTypes.

Options
The following options are supported:

-F FSType
Specify the FSType on which to operate. The FSType should either be specified here or be determinable from /etc/vfstab by matching the operands with an entry in the table. Otherwise, the default file system type specified in /etc/default/fs will be used.

-V
Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option should be used to verify and validate the command line.

generic_options
Options that are commonly supported by most FSType-specific command modules. The following options are available:

-a
Require the operator to respond “yes” or “no” instead of simply waiting ten seconds before the copy is made.

-s
(Default) Invoke the DEL if wrong verification sequence.

-o FSType-specific_options
Specify FSType-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the FSType-specific module of the command.

Operands
The following operands are supported:

operands
generally include the device and volume names and are file system specific. A detailed description of the operands can be found on the FSType-specific man pages of volcopy.

Exit Status
The following exit values are returned:

0 Successful file system copy
1 An error has occurred.
Files
/etc/vfstab list of default parameters for each file system
/etc/default/fs default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs.

LOCAL: The default partition for a command if no FSTYPE is specified.

</table>

See Also labelit(1M), vfstab(4), attributes(5) Manual pages for the FSTYPE-specific modules of volcopy.
volcopy_ufs(1M)

Name  volcopy_ufs – make an image copy of a ufs file system

Synopsis  volcopy [-F ufs] [generic_options] fsname srcdevice volname1 destdevice volname2

Description  volcopy makes a literal copy of the ufs file system using a blocksize matched to the device.

Options  The following option is supported:

generic_options  options supported by the generic volcopy command. See volcopy(1M).

Operands  The following operands are supported:

   fsname  represents the mount point (for example, root, u1, etc.) of the file system being copied.

   srcdevice or destdevice  the disk partition specified using the raw device (for example, /dev/rdsk/cld0s8, /dev/rdsk/cld1s8, etc.).

   srcdevice and volname1  the device and physical volume from which the copy of the file system is being extracted.

   destdevice and volname2  the target device and physical volume.

   fsname and volname are limited to six or fewer characters and recorded in the superblock.

   volname may be ‘−’ to use the existing volume name.

Exit Status  The following exit values are returned:

   0  Successful file system copy.

   non-zero  An error has occurred.

Files  /var/adm/filesave.log  a record of file systems/volumes copied

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  cpio(1), dd(1M), labelit(1M), volcopy(1M), attributes(5), ufs(7FS)

Notes  volcopy does not support copying to tape devices. Use dd(1M) for copying to and from tape devices.
The vrrpadm command is used to administer the VRRP (Virtual Router Redundancy Protocol) service in a system.

VRRP specifies an election protocol that dynamically assigns responsibility for a virtual router to one of the VRRP routers within a LAN. At a given moment, only one VRRP router controls the IPv4 or IPv6 virtual address(es) associated with a virtual router (known as the master), and forwards packets sent to these IP addresses. The election process provides dynamic failover of the forwarding responsibility should the master become unavailable.

Each vrrpadm subcommand operates on a VRRP router, which is identified by a name given by the administrator. VRRP routers with the same VRID and address family within a LAN comprise a virtual router, which protects a set of virtual IP addresses.

A system can have multiple VRRP routers; each belongs to a different virtual router.

Sub-commands

The following subcommands are supported. Note that all subcommands but show-router require the solaris.network.vrrp authorization. The show-router subcommand does not require special authorizations.

vrrpadm create-router -V vrid -l link -A inet | inet6
    [-p priority] [-i adv_interval] [-o flags] router_name
Create a VRRP router with a specified configuration.

    -A inet | inet6, --address_family=inet | inet6
    Address family. Either IPv4 or IPv6.

    -i adv_interval, --adv_interval=adv_interval
    The advertisement interval in milliseconds. Default is 1000 (one second). The valid
    interval range is 10-40950.

    -l link, --link=link
    The data link on which the VRRP router is configured. This determines the LAN this
    VRRP router is running in. The data-link can be a physical link, a VLAN, or an
    aggregation.
-o flags, --flags=flags
The preempt and accept modes, delimited by a comma. Values can be:

- preempt
- un_preempt
- accept
- noaccept

By default both modes are set to true.

The preempt mode controls whether an enabled higher priority backup router preempts a lower priority master router. If preempt mode is true, then the preemption is allowed; otherwise, preemption is prohibited. Note that the preempt mode must be true if the VRRP router is the owner of the virtual IP addresses.

The accept mode controls the local packet acceptance of the virtual IP addresses. If accept mode is true, the master must accept packets sent to the virtual IP addresses. If accept mode is false, the master does not accept those packets, although it does respond to ARP requests or ND Solicitations and Advertisement for those non-accepted virtual IP addresses. It also must forward packets for the router specified in this subcommand. Note that accept mode must be true if the VRRP router is the owner of the virtual IP addresses. An example of syntax for this option:

- o preempt, no_accept

-p priority, --priority=priority
The priority of the specified VRRP router used in master selection. The higher the value, the greater the possibility the router is selected as the master.

The default value is 255, which indicates the specified VRRP router is the IP Address Owner and owns all the virtual IP addresses. An IP Address Owner will respond to the packets addressed to one of the virtual IP addresses for ICMP pings, TCP connections, and so forth.

The range 1-254 is available for VRRP routers backing up a virtual router. Master selection is weighted toward the VRRP router with the higher priority.

-V vrid, --VRID=vrid
The virtual router identifier (VRID). Together with the address family, it identifies a virtual router within a LAN.

router_name
The name of a VRRP router. This name is used to identify a VRRP router in other vrrpadm subcommands.

The maximum length of a valid router name is 31 characters. Legal characters are alphanumeric (a-z, A-Z, 0-9) and the underscore ('_').

vrrpadm delete-router router_name
Delete the VRRP router identified by router_name.
vrrpadm disable-router router_name
Disable the virtual router identified by router_name. Once the router is disabled, it will stop participating in the master selection process in the virtual router.

vrrpadm enable-router router_name
Re-enable the virtual router identified by router_name that was disabled. The router will resume participating in the master selection process in the virtual router.

vrrpadm modify-router [-p priority] [-i adv_interval] [-o flags] [router_name]
Modify the configuration of the VRRP router identified by router_name. Only the priority, the advertisement interval, the preempt mode, and the accept mode can be modified.

- p priority, --priority=priority
  The new priority of this VRRP router.
- i adv_interval, --adv_interval=adv_interval
  The new advertisement interval.
- o flags, --flags=flags
  The new preempt and accept modes. Either one or both can be specified. If both are specified, they are delimited by a comma. For example:
  - o preempt,no_accept

vrrpadm show-router [-P | -x] [-p] [-o field[,...]] [router_name]
Display the information for the VRRP router identified by router_name. If no router_name is specified, display information for all the VRRP routers on the system.

By default (with no options), the following fields are displayed:

NAME
  The name of the VRRP router.

VRID
  The VRID of the VRRP router.

LINK
  The data link on which the VRRP router is created.

AF
  The address family of the VRRP router, either IPv4 or IPv6.

PRIOR
  The priority of this VRRP router used in master selection.

ADV_INTV
  The advertisement interval, in milliseconds.

STATE
  The current state of the VRRP router, INIT (Initialize), BACK (Backup), or MAST (Master).

MODE
  A set of flags associated with the VRRP router. Possible values are:
The router has been enabled.
Preempt mode is true.
Accept mode is true.
Virtual address owner.

VNIC
The VRRP VNIC created for this VRRP router.
Note that the name of the VNIC can change over time unless the router is enabled.

The `show-router` subcommand has the following options:

- `-x, --extended`
  Display additional information of the given VRRP router:

  PRIMARY IP
  The primary IP address selected by the VRRP router.

  VIRTUAL IPS
  The virtual IP addresses configured on the VRRP router.

  PRV_STAT
  The previous state of the VRRP router.

  STAT_LAST
  Time since the last state transition.

- `-P, --peer`
  Display information for the backup VRRP router. This option is meaningful only when the VRRP router is in the backup state.

  The following fields are displayed:

  NAME
  The name of the VRRP router.

  PEER
  The primary IP address of the peer VRRP router.

  P_Prio
  The priority of the peer VRRP router contained in the advertisement received from the peer.

  P_INTV
  The advertisement interval (in milliseconds) contained in advertisements received from the peer.

  P_ADV_LAST
  Time since last received advertisement from the peer.
MASTER_DOWN_INT
Time interval (in milliseconds) after which to declare Master down.

-p, --parseable
Display the VRRP router information in the machine parseable format.

-o field[,...], --output=field
A case-insensitive, comma-separated list of output fields to display. The field name must
be one of the fields listed above, or the special value all to display all fields. By default
(without -o), vrrpadm show displays all fields.

Name  vrrpd – VRRP daemon

Synopsis  /usr/lib/inet/vrrpd

svc:/network/vrrp:default

Description  vrrpd is the system daemon program that handles the administrative events for the VRRP routers. It is controlled through the service management facility (SMF) service instance:

svc:/network/vrrp:default

The daemon should not be invoked directly. It does not constitute an administrative nor a programming interface. The administrative interface for managing VRRP routers is vrrpadm(1M).

Options  The daemon has no options.

Name  vscanadm -- vscan service configuration utility

Synopsis  vscanadm set -p property=value [-p property=value]...
          vscanadm get [-p property]...
          vscanadm import -p property filename
          vscanadm export -p property filename
          vscanadm validate -p property filename
          vscanadm add-engine [-p property=value]... engine_id
          vscanadm remove-engine engine_id
          vscanadm set-engine -p property=value [-p property=value]... engine_id
          vscanadm get-engine [-p property=value]... [engine_id]
          vscanadm show
          vscanadm stats [-z]

Description  The vscanadm command sets and displays properties of the vscan service, zpool(1M), and provides scan statistics.

File system exemption from virus scanning may be configured per file system using the appropriate file system administrative command, for example zfs(1M).

Scan engines are third-party applications on external hosts that perform the actual virus scanning operation on files. Multiple scan engines can be configured for use by the vscan service. A minimum of two scan engines is recommended. File scan requests are distributed among the configured scan engines to achieve load balancing. A scan engine is identified by its engine_id. The engine_id is a user defined string of up to 64 bytes.

The vscan service properties are divided into two categories: scan engine properties, which are specific to a scan engine definition, and general properties, which apply to the service and are not scan engine-specific.

Subcommands  vscanadm recognizes the following subcommands:

vscanadm set -p property=value [-p property=value]...
Sets the values of vscan service general properties.

-p property=value  Specifies a property value

vscanadm get [-p property]...
Displays the values of vscan service general properties. If no properties are specified, all vscan service general properties are displayed.

-p property  Specifies a property value

The following properties are available for the vscanadm set and vscanadm get subcommands:
max-size

The maximum size of files that should be virus scanned. Files exceeding max-size are not scanned. The max-size-action property determines whether access should be allowed or denied to files that exceed max-size.

The value of max-size is a string with a numeric (decimal) component and an optional letter component that specifies a unit size, in the format “N[N][KMGTP][B]”.

Following the numeric component, the optional unit can be specified as either one or two characters. For example, either “K” or “KB” can be used to specify kilobytes. Unit specifiers are not case-sensitive, and must follow the numeric value immediately with no intervening whitespace.

With either no unit specifier, or a unit specifier of only “B”, the numeric value is assumed to be in bytes. The default value is 1GB.

Note that while the vscan service defines a maximum file size for scanning, scan engines also typically define their own maximum file size setting. It is recommended that max-size be set to a value less than or equal to the maximum file size for the scan engine(s).

max-size-action

Specifies whether access will be allowed or denied to files larger than max-size. Files larger than max-size are not virus scanned. Valid values are:

- allow allow access to files larger than max-size (no virus scan). This is the default value.
- deny deny access to files larger than max-size (no virus scan)

vscanadm import -p property filename

Imports the property value from the specified file. The file must contain a single line specifying the value of a single property.

vscanadm export -p property filename

Exports the property value to the specified file. The file must contain a single line specifying the value of a single property.

vscanadm validate -p property filename

Validates the property value in the specified file. The file must contain a single line specifying the value of a single property.

The following properties are available for the vscanadm import, vscanadm export, and vscanadm validate subcommands:

types

A comma-separated list of file type extension matching rules. This list defines which types of files are scanned and which should be excluded during virus
scanning. Each rule comprises the rule indicator [+|-], followed by a file type 
expression against which a file's type extension is compared. The file type 
expression is case insensitive and may include the “*” and “?” wildcards. There 
should be no whitespace between the rule indicator and the file type expression. If a 
comma is included within the file type expression, it must be escaped using a “\” 
(backslash). A file type extension does not include its preceding dot.

The rule indicator is a single character and can be one of:

+    include file type in virus scanning
-    exclude file type from virus scanning

When a file is being evaluated as a candidate for virus scanning, its file type will be 
compared with the rules defined in types. The first rule matched will be applied. If 
no match is found, the file will be virus scanned. The total length of the types string 
can not exceed 4096 bytes. The default content of the types list is “++”.

vscanadm add-engine [-p property=value]... engine_id
  Adds a new scan engine identified by engine_id. The default values are used for any scan 
  engine properties that are not specified. The hostname defaults to the engine_id.

  -p property=value    Specifies a property value

vscanadm remove-engine engine_id
  Remove scan engine identified by engine_id, removing all of its configuration property 
  values.

vscanadm set-engine -p property=value [-p property=value]... engine_id
  Creates or updates the configuration property values for the scan engine identified by 
  engine_id.

  -p property=value    Specifies a property value

vscanadm get-engine [-p property=value]... [engine_id]
  Displays the values of the specified scan engine properties for the scan engine identified by 
  engine_id. If no engine_id is specified, this subcommand displays the specified scan engine 
  property values for all configured scan engines. If no properties are specified, this 
  subcommand displays all vscan service scan engine properties.

  -p property=value    Specifies a property value

The following properties are available for the vscanadm add-engine, vscanadm 
remove-engine, vscanadm set-engine, and vscanadm get-engine subcommands:

enable            Specifies whether the scan engine is enabled or disabled. Valid values are 
                  "on" (enabled) and "off" (disabled). The default is "on" (enabled). A scan 
                  engine cannot be enabled if its host property is invalid.

host              Hostname or IPv4 format IP address of the scan engine.
port  ICAP port number of the scan engine. The numeric value ranges from 0 to 65535. The default ICAP port is 1344.

max-connection  The maximum number of concurrent connections that may be established with a scan engine. The numeric value ranges from 1 to 512. This property defaults to 8.

vscanadm show  Displays the values of all vscan service general properties and scan engine properties.

vscanadm stats [-z]  Displays or resets the following vscan service statistics:
   - number of files scanned
   - number of infected files
   - number of failed scan requests
   - scan errors (including a per scan engine error count)

   -z  Resets vscan service statistics counters to zero

Examples

**EXAMPLE 1** Setting the Maximum Size Limit
To set the maximum size limit for files to be virus scanned to 128 megabytes, enter

```
# vscanadm set -p max-size=128M
```

**EXAMPLE 2** Allowing Access to Files
To allow access to files exceeding the maximum file size, enter

```
# vscanadm set -p max-size-action=allow
```

**EXAMPLE 3** Setting File Types
To set the types so that only files of type “odt”, “exe” and “jpg” are virus scanned, enter

```
# vscanadm set -p types=+odt,+exe,+jpg,-*
```

To set the types so that all file types except “doc” are virus scanned, enter

```
# vscanadm set -p types=-doc,+*
```

**EXAMPLE 4** Displaying the File Types List
To display the file types list, enter

```
# vscanadm get -p types
```

**EXAMPLE 5** Adding the Scan Engine
To add the scan engine “my_eng” using the default values, enter

```
# vscanadm add-engine my_eng
```
EXAMPLE 6  Disabling the Scan Engine
To disable the scan engine “my_eng”, enter
# vscanadm set-engine -p enable=off my_eng

EXAMPLE 7  Displaying Scan Engine Properties
To display the properties of the scan engine “my_eng”, enter
# vscanadm get-engine my_eng

EXAMPLE 8  Removing Scan Engine
To remove the scan engine “my_eng”, enter
# vscanadm remove-engine my_eng

EXAMPLE 9  Displaying Vscan Service General and Scan Engine Properties
To display all vscan service general properties and scan engine properties, enter
# vscanadm show

Exit Status  The following exit values are returned:
0         Successful completion.
non-zero  An error occurred.

See Also  vscand(1M), zfs(1M), attributes(5), smf(5)

Notes  All users are permitted to use vscanadm to view vscan properties and statistics. To set property values or reset statistics, the following authorizations are required:
solaris.sfm.value.vscan
    change the property values or reset statistics
solaris.manage.vscan
    refresh the service to apply property value changes

To add or remove properties (add-engine, remove-engine) the following authorizations are required:
solaris.smf.modify.application    add or remove property group
solaris.manage.vscan             refresh the service to apply property value changes

All of these authorizations are included in the “VSCAN Management” profile.
vscand(1M)

Name  vscand – vscan service daemon

Synopsis  /usr/lib/vscan/vscand

Description  vscand is the daemon that handles virus scan requests from file systems on file open and close operations. A file system may support enabling and disabling of virus scanning on a per dataset basis, using that file system's administrative command, for example zfs(1M).

If the file state or scan policy (see vscanadm(1M)) requires that a file be scanned, vscand communicates with external third-party virus scanners (scan engines) using the Internet Content Adaptation Protocol (ICAP, RFC 3507) to have the file scanned.

A file is submitted to a scan engine if it has been modified since it was last scanned, or if it has not been scanned with the latest scan engine configuration (Virus definitions). The file's modified attribute and scan stamp attribute are used to store this information. Once the file is scanned, the modified attribute is cleared and the scan stamp attribute is updated.

If the file is found to contain a virus, the virus is logged in syslogd(1M), an audit record is written, and the file is quarantined (by setting its quarantine attribute). Once a file is quarantined, attempts to read, execute or rename the file will be denied by the file system. The syslogd(1M) entry and the audit record specify the name of the infected file and the violations detected in the file. Each violation is specified as "ID - threat description", where ID and threat description are defined in the X-Infection-Found-Header in ICAP RFC 3507; Extensions.

By default, vscand connects to scan engines on port 1344. The port and other service configuration parameters can be configured using vscanadm(1M).

The vscan service is disabled by default, and can be enabled using svcadm(1M).

Exit Status  The following exit values are returned:

- 0  Daemon started successfully.
- non-zero  Daemon failed to start.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

See Also  ps(1), svcs(1), logadm(1M), svcadm(1M), syslogd(1M), vscanadm(1M), zfs(1M), attributes(5), smf(5)
If a file is accessed using a protocol which does not invoke the file system open and close operations, for example NFSv3, virus scanning is not initiated on the file.

File content is transferred to the scan engines as clear text data.

Administrative actions for the vscan service, such as enabling, disabling, or requesting a restart, can be performed using svcadm(1M). The vscan service status can be queried using the svcs(1) command.

The vscan service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/filesystem/vscan
vtdaemon provides a secure switch function, by means of hotkeys, between different text virtual consoles. It runs with full privileges. See \texttt{vt(7I)} for specifications of hotkey sequences.

The service is managed using the action authorization \texttt{solaris.smf.manage.vt} which is included in the Device Security Rights Profile. The service is local only and has no inbound network ports. It is disabled in non-global zones or when the virtual console functionality is not available.

vtdaemon uses PAM for authentication.

Note that vtdaemon only locks and unlocks the text console. For graphical X sessions, it invokes the corresponding lock program (for example, \texttt{xscreensaver}), which deals with authentication and audit.

The vtdaemon service has the following SMF configuration properties:

- **hotkeys (boolean)**
  - Allows authorized users to dynamically enable or disable the VT switch by means of hotkeys. Its default value is \texttt{TRUE} (enabled).

- **secure (boolean)**
  - Allows authorized users to dynamically enable or disable the security of hotkeys. If disabled, the user can freely switch to any session without authentication. Its default value is \texttt{TRUE} (enabled).

\textbf{Attributes}

See \texttt{attributes(5)} for descriptions of the following attributes:

\begin{tabular}{|l|l|}
\hline
\textbf{ATTRIBUTE TYPE} & \textbf{ATTRIBUTE VALUE} \\
\hline
Availability & system/core-os \\
Interface Stability & Private \\
\hline
\end{tabular}

\textbf{See Also} \texttt{svcs(1)}, \texttt{svcadm(1M)}, \texttt{attributes(5)}, \texttt{smf(5)}, \texttt{vt(7I)}

\textbf{Notes}

The vtdaemon service is managed by the service management facility, \texttt{smf(5)}, under the service identifier:

\texttt{svc:/system/vtdaemon:default}

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using \texttt{svcadm(1M)}. The service's status can be queried using the \texttt{svcs(1)} command.

The vtdaemon service has the following SMF configuration properties:
wall(1M)

Name       wall – write to all users
Synopsis    
/usr/sbin/wall [-a] [-g grpname] [filename]
Description wall reads its standard input until an end-of-file. It then sends this message to all currently
logged-in users preceded by:

Broadcast Message from . . .

If filename is given, then the message is read in from that file. Normally, pseudo-terminals that
do not correspond to login sessions are ignored. Thus, when using a window system, the
message appears only on the console window. However, -a will send the message even to such
pseudo-terminals.

It is used to warn all users, typically prior to shutting down the system.

The sender must be superuser to override any protections the users may have invoked. See
mesg(1).

wall runs setgid() to the group ID tty, in order to have write permissions on other user’s
terminals. See setuid(2).

wall will detect non-printable characters before sending them to the user’s terminal. Control
characters will appear as a “^” followed by the appropriate ASCII character; characters with
the high-order bit set will appear in “meta” notation. For example, \003 is displayed as ‘^C’
and \372 as ‘M–z’.

Options   The following options are supported:

-a         Broadcast message to the console and pseudo-terminals.
-g grpname  Broadcast to the users in a specified group only, per the group database (see
group(4)).

Environment Variables If the LC_* variables (LC_CTYPE, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) are not
set in the environment, the operational behavior of wall for each corresponding locale
category is determined by the value of the LANG environment variable. See environ(5). If
LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If
none of the above variables are set in the environment, the ”C” (U.S. style) locale determines
how wall behaves.

Files   /dev/tty*

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>
See Also  msg(1), write(1), setuid(2), attributes(5), environ(5)

Notes  wall displays "Cannot send to . . ." when the open on a user's tty file fails.
### wanboot_keygen(1M)

**Name**
wanboot_keygen – create and display client and server keys for WAN booting

**Synopsis**
/usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d, cid= client_ID,type=3des
/usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d, cid= client_ID,type=aes
/usr/lib/inet/wanboot/keygen -m
/usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d, cid= client_ID,type=sha1
/usr/lib/inet/wanboot/keygen -d -m
/usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d, cid= client_ID,type=keytype

**Description**
The keygen utility has three purposes:

- Using the `-c` flag, to generate and store per-client 3DES/AES encryption keys, avoiding any DES weak keys.
- Using the `-m` flag, to generate and store a “master” HMAC SHA-1 key for WAN install, and to derive from the master key per-client HMAC SHA-1 hashing keys, in a manner described in RFC 3118, Appendix A.
- Using the `-d` flag along with either the `-c` or `-m` flag to indicate the key repository, to display a key of type specified by `keytype`, which must be one of 3des, aes, or sha1.

The net and cid arguments are used to identify a specific client. Both arguments are optional. If the `cid` option is not provided, the key being created or displayed will have a per-network scope. If the `net` option is not provided, then the key will have a global scope. Default net and code values are used to derive an HMAC SHA-1 key if the values are not provided by the user.

**Options**
The following options are supported:
- `-c` Generate and store per-client 3DES/AES encryption keys, avoiding any DES weak keys. Also generates and stores per-client HMAC SHA-1 keys. Used in conjunction with `-o`.
- `-d` Display a key of type specified by `keytype`, which must be one of 3des, aes, or sha1. Use `-d` with `-m` or with `-c` and `-o`.
- `-m` Generate and store a “master” HMAC SHA-1 key for WAN install.
- `-o` Specifies the WANboot client and/or `keytype`.

**Examples**

**EXAMPLE 1** Generate a Master HMAC SHA-1 Key

```bash
# keygen -m
```

**EXAMPLE 2** Generate and Then Display a Client-Specific Master HMAC SHA-1 Key

```bash
# keygen -c -o net=172.16.174.0, cid=010003BA0E6A36, type=sha1
# keygen -d -c -o net=172.16.174.0, cid=010003BA0E6A36, type=sha1
```
EXAMPLE 3 Generate and Display a 3DES Key with a Per-Network Scope

# keygen -c -o net=172.16.174.0,type=3des
# keygen -d -o net=172.16.174.0,type=3des

Exit Status 0 Successful operation.
>0 An error occurred.

wanboot_keymgmt(1M)

Name  wanboot_keymgmt – insert and extract keys

Synopsis  
/usr/lib/inet/wanboot/keymgmt -i -k key_file -s keystore -o type=keytype
/usr/lib/inet/wanboot/keymgmt -x -f outfile -s keystore -o type=keytype

Description  The keymgmt utility has two purposes:
- To take a raw key, stored in key_file, and insert it in the repository specified by keystore.
- To extract a key of a specified type from the repository specified by keystore, depositing it in outfile.

outfile will be created if it does not already exist. The type of key being added or extracted is specified by keytype and may have one of four values: 3des, aes, rsa, or sha1 (the last used by HMAC SHA-1). When extracting a key, the first key with an OID matching the supplied type is used.

Arguments  The following arguments are supported:
- -i Used in conjunction with -k to insert a raw key in keystore.
- -f outfile Used to specify a file to receive an extracted key.
- -k key_file Used in conjunction with -i to specify the file in which a raw key is stored. This key will be inserted in keystore.
- -o type=keytype Specifies the type of key being inserted or extracted. Must be one of 3des, aes, rsa, or sha1.
- -s keystore Specifies a repository in which a key will be inserted or from which a key will be extracted.
- -x Used in conjunction with -f to extract a key of a specified type and deposit it in outfile.

Exit Status  0 Successful operation.
>0 An error occurred.

ITU-T Recommendation X.208
The `p12split` utility extracts a certificate and private key from the repository specified by `p12file`, depositing the certificate in `out_cert` and the key in `out_key`. If supplied, the `-l` option specifies the value for the `LocalKeyId` that will be used in the new certificate and key files. `p12split` can optionally extract a trust certificate into the `out_trust` file if the `-t` option is specified. Use the `-v` option to get a verbose description of the split displayed to standard output.

**Options**
The following arguments and options are supported:

- `-c out_cert` Specifies a repository that receives a extracted certificate.
- `-i p12file` Specifies a repository from which a certificate and private key is extracted.
- `-k out_key` Specifies a repository that receives a extracted private key.
- `-l id` Specifies the value for the `LocalKeyId` that will be used in the new certificate and key files.
- `-t out_trust` Specifies a file for receiving an extracted trust certificate.
- `-v` Displays a verbose description of the split to stdout.

**Exit Status**

- `0` Successful operation.
- `>0` An error occurred.

wanbootutil – manage keys and certificates for WAN booting

**Synopsis**
wanbootutil [keygen] [option_specific_arguments]
wanbootutil [keymgmt] [option_specific_arguments]
wanbootutil [p12split] [option_specific_arguments]

**Description**
The `wanbootutil` command creates and manages WANboot encryption and hashing keys and manipulates PKCS#12 files for use by WAN boot.

`wanbootutil` has three subcommands, each covered in a separate man page:
- **wanboot_keygen**(1M) Generates encryption and hashing keys.
- **wanboot_keymgmt**(1M) Inserts and extracts keys from WAN boot key repositories.
- **wanboot_p12split**(1M) Splits a PKCS#12 file into separate certificate and key files for use by WAN boot.

**Options**
The options are supported for `wanbootutil` are the use of `keygen`, `keymgmt`, or `p12split`. The options for these subcommands are described in their respective man pages.

**Examples**
**EXAMPLE 1** Generate a 3DES Client Key
```bash
# wanbootutil keygen -c -o net=172.16.174.0,cid=010003BA0E6A36,type=3des
```

**EXAMPLE 2** Insert an RSA Private Client Key
```bash
wanbootutil keymgmt -i -k keyfile \\
-s /etc/netboot/172.16.174.0/010003BA0E6A36/keystore -o type=rsa
```

**EXAMPLE 3** Split a PKCS#12 File into Certificate and Key Components
```bash
# wanbootutil p12split -i p12file -c out_cert -k out_key
```

**Exit Status**

- **0** Successful operation.
- **non-zero** An error occurred. Writes an appropriate error message to standard error.

The `wbemadmin` utility starts Sun WBEM User Manager, a graphical user interface that enables you to add and delete authorized WBEM users and to set their access privileges. Use this application to manage access to groups of managed resources, such as disks and installed software, in the Solaris operating environment.

The `wbemadmin` utility allows you to perform the following tasks:

**Manage user access rights**
Use the `wbemadmin` utility to add, delete, or modify an individual user's access rights to a namespace on a WBEM-enabled system.

**Manage namespace access rights**
Use the `wbemadmin` utility to add, delete, or modify access rights for all users to a namespace.

The Sun WBEM User Manager displays a Login dialog box. You must log in as root or a user with write access to the `root\security` namespace to grant access rights to users. By default, Solaris users have guest privileges, which grants them read access to the default namespaces.

Managed resources are described using a standard information model called Common Information Model (CIM). A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects can be shared by any WBEM-enabled system, device, or application. CIM objects are grouped into meaningful collections called schema. One or more schemas can be stored in directory-like structures called namespaces.

All programming operations are performed within a namespace. Two namespaces are created by default during installation:

- `root\cimv2` — Contains the default CIM classes that represent objects on your system.
- `root\security` — Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.

When a WBEM client application connects to the CIM Object Manager in a particular namespace, all subsequent operations occur within that namespace. When you connect to a namespace, you can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace.

When a WBEM client application accesses CIM data, the WBEM system validates the user's login information on the current host. By default, a validated WBEM user is granted read access to the Common Information Model (CIM) Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.

### Name
`wbemadmin – start Sun WBEM User Manager`

### Synopsis
`/usr/sadm/bin/wbemadmin`

### Description
The `wbemadmin` utility starts Sun WBEM User Manager, a graphical user interface that enables you to add and delete authorized WBEM users and to set their access privileges. Use this application to manage access to groups of managed resources, such as disks and installed software, in the Solaris operating environment.

The `wbemadmin` utility allows you to perform the following tasks:

- **Manage user access rights**: Use the `wbemadmin` utility to add, delete, or modify an individual user's access rights to a namespace on a WBEM-enabled system.
- **Manage namespace access rights**: Use the `wbemadmin` utility to add, delete, or modify access rights for all users to a namespace.

The Sun WBEM User Manager displays a Login dialog box. You must log in as root or a user with write access to the `root\security` namespace to grant access rights to users. By default, Solaris users have guest privileges, which grants them read access to the default namespaces.

Managed resources are described using a standard information model called Common Information Model (CIM). A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects can be shared by any WBEM-enabled system, device, or application. CIM objects are grouped into meaningful collections called schema. One or more schemas can be stored in directory-like structures called namespaces.

All programming operations are performed within a namespace. Two namespaces are created by default during installation:

- `root\cimv2` — Contains the default CIM classes that represent objects on your system.
- `root\security` — Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.

When a WBEM client application connects to the CIM Object Manager in a particular namespace, all subsequent operations occur within that namespace. When you connect to a namespace, you can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace.

When a WBEM client application accesses CIM data, the WBEM system validates the user's login information on the current host. By default, a validated WBEM user is granted read access to the Common Information Model (CIM) Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.
You can set access privileges on individual namespaces or for a user-namespace combination. When you add a user and select a namespace, by default the user is granted read access to CIM objects in the selected namespace. An effective way to combine user and namespace access rights is to first restrict access to a namespace. Then grant individual users read, read and write, or write access to that namespace.

You cannot set access rights on individual managed objects. However you can set access rights for all managed objects in a namespace as well as on a per-user basis.

If you log in to the root account, you can set the following types of access to CIM objects:
- Read Only — Allows read-only access to CIM Schema objects. Users with this privilege can retrieve instances and classes, but cannot create, delete, or modify CIM objects.
- Read/Write — Allows full read, write, and delete access to all CIM classes and instances.
- Write — Allows write and delete, but not read access to all CIM classes and instances.
- None — Allows no access to CIM classes and instances.

Context help is displayed in the left side of the wbemadmin dialog boxes. When you click on a field, the help content changes to describe the selected field. No context help is available on the main User Manager window.

The wbemadmin security administration tool updates the following Java classes in the root\security namespace:
- Solaris_UserAcl — Updated when access rights are granted or changed for a user.
- Solaris_namespaceAcl — Updated when access rights are granted or changed for a namespace.

Usage The wbemadmin utility is not the tool for a distributed environment. It is used for local administration on the machine on which the CIM Object Manager is running.

Exit Status The wbemadmin utility terminates with exit status 0.

Warning The root\security namespace stores access privileges. If you grant other users access to the root\security namespace, those users can grant themselves or other users rights to all other namespaces.

wbemconfig – convert a JavaSpaces datastore to the newer Reliable Log datastore format

**Synopsis**
/usr/sadm/lib/wbem/wbemconfig convert

**Description**
A Reliable Log directory is created that contains the converted data. This directory is named /var/sadm/wbem/logr.

The convert argument is the only supported option of this command. You should only run this command after stopping WBEM (CIM Object Manager) with the `init.wbem stop` command. Otherwise your data may be corrupted.

This command successfully converts any proprietary custom MOFs you have created in the datastore, but not any CIM or Solaris MOFs you have modified. These will be destroyed. To recompile any modified CIM or Solaris MOFs into the new datastore, run the `mofcomp` command on the MOF files containing the class definitions.

Because the `wbemconfig convert` command invokes the JVM (Java Virtual Machine) to perform conversion of the JavaSpaces datastore, you must be running the same version of the JVM as when the original JavaSpaces storage was created. After the `wbemconfig convert` command is completed, you can change to any version of the JVM you want.

To see what version of the JVM you are running, issue the `java -version` command.

**Options**
The following options are supported:

- convert: Convert a JavaSpaces datastore to the newer Reliable Log datastore format.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>

`init.wbem(1M), wbemadmin(1M), wbemlogviewer(1M), mofcomp(1M), attributes(5)`
The `wbemlogviewer` utility starts the WBEM Log Viewer graphical user interface, which enables administrators to view and maintain log records created by WBEM clients and providers. The WBEM Log Viewer displays a Login dialog box. You must log in as root or a user with write access to the `root\cimv2` namespace to view and maintain log files. Namespaces are described in `wbemadmin(1M)`.

Log events can have three severity levels.

- Errors
- Warnings
- Informational

The WBEM log file is created in the `/var/sadm/wbem/log` directory, with the name `wbem_log`. The first time the log file is backed up, it is renamed `wbem_log.1`, and a new `wbem_log` file is created. Each succeeding time the `wbem_log` file is backed up, the file extension number of each backup log file is increased by 1, and the oldest backup log file is removed if the limit, which in turn is specified in the log service settings, on the number of logfiles is exceeded. Older backup files have higher file extension numbers than more recent backup files.

The log file is renamed with a `.1` file extension and saved when one of the following two conditions occur:

- The current file reaches the specified file size limit.
- A WBEM client application uses the `clearLog()` method in the `Solaris_LogService` class to clear the current log file.
- A WBEM client application uses the `clearLog()` method in the `Solaris_LogService` class to clear the current log file.
- A user chooses `Action->Back Up Now` in the Log Viewer application.

Help is displayed in the left panel of each dialog box. Context help is not displayed in the main Log Viewer window.

**Usage**

The WBEM Log Viewer is not the tool for a distributed environment. It is used for local administration.

The WBEM Log Viewer allows you to perform the following tasks:

- View the logs
- Set properties of log files
- Back up a log file

Click `Action->Log File Settings` to specify log file parameters and the log file directory.

Click `Action->Back Up Now` to back up and close the current log file and start a new log file.
Open historical log files
Click Action->Open Log File to open a backed-up log file.

Delete an old log file
Open the file and then click Action->Delete Log File. You can only delete backed-up log files.

View log record details
Double-click a log entry or click View->Log Entry Details to display the details of a log record.

Sort the logs
Click View->Sort By to sort displayed entries. You can also click any column heading to sort the list. By default, the log entries are displayed in reverse chronological order (new logs first).

**Exit Status**
The `wbemlogviewer` utility terminates with exit status 0.

**Files**
`/var/sadm/wbem/log/wbem_log` WBEM log file

wcadmin(1M)

Name
wcadmin – manage the configuration of the Sun Java Web Console

Synopsis
/usr/sbin/wcadmin subcommand options
/usr/sbin/wcadmin [-h] --help
/usr/sbin/wcadmin [-V] --version

Description
wcadmin is a Command Line Interface (CLI) — based tool for managing the configuration of
the Sun Java Web Console.

Subcommands
The following subcommands are supported:

add
The wcadmin add subcommand adds a new shared jar file, a new JAAS login
module, or a new shared service property to the console configuration. An
optional identifier may be specified; if omitted, the identifier is derived from the
resource name. The resource is added when the console is next started.

The format of the add subcommand is:

add -l -a appname [-n id] jarpath
add -m -a appname [-n id] -b behavior -s service [-o name=value] classname
add -p -a appname name=value [... name=value]

deploy
The wcadmin deploy subcommand deploys the specified web application into
the console's web server instance. Applications are deployed directly from their
installation directories.

The format of the deploy subcommand is:

deploy [-D] -a appname -x context app_path

disable
The wcadmin disable subcommand disables access to the specified web
application in the console's web server instance.

The format of the disable subcommand is:

disable -x context

enable
The wcadmin enable subcommand enables access to the specified web
application in the console's web server instance.

The format of the enable subcommand is:

enable -x context

list
The wcadmin list subcommand lists the resources currently configured for the
console; including deployed web applications, shared jar files, login modules,
and shared service properties. If no option is specified, all resources are listed.
The format of the `list` subcommand is:

```
list [-a] [-d] [-l] [-m] [-p]
```

**password**

The `wcadmin password` subcommand manages the administrator and security keystore passwords for the console. Keystore passwords should not be changed while the console is running.

The format of the `password` subcommand is:

```
password [-a] [-k] [-t]
```

```
password -f password_file
```

**reload**

The `wcadmin reload` subcommand unloads the specified web application from the console's web server instance and reloads the application from its original installation directory.

The format of the `reload` subcommand is:

```
reload -x context
```

**remove**

The `wcadmin remove` subcommand removes a shared jar file, a login module, or a shared service property from the console configuration. The resource may be specified by its identifier or by its full jarpath or classname. The resource is removed when the console is next started.

The format of the `remove` subcommand is:

```
remove -l -a appname [-n id] jarpath
```

```
remove -m -a appname [-n id] classname
```

```
remove -p -a appname property [...] 
```

**undeploy**

The `wcadmin undeploy` subcommand undeploys the specified web application from the console's web server instance.

The format of the `undeploy` subcommand is:

```
undeploy [-D] -a appname -x context
```

**Options**

The following options are supported:

```
-h | -help | -?           Display runtime help.
-V | --version           Display console version information.
-D | --defer             When used with the deploy and undeploy subcommands, defers the deployment or undeployment until the next console restart.
```
The operation is deferred by simply adding or removing the corresponding resource registration notification file. If defer is not specified, a runtime deployment or undeployment is performed, so that the application becomes available or unavailable in the running console. If the console instance is not currently running, the operation is automatically deferred.

- `a | --adminpassword` Specify that the administrator password should be changed, when used with password subcommand. You are prompted for a new password, which must be 8 to 32 characters.

- `a | --application` Specify the application name, when used with subcommands other than password subcommand.

- `d | --detail` Specify that configuration details of each resource should be displayed.

- `f` Specify the fully qualified path name to a file containing one or more password property values. See the description of the password_file argument.

- `k | --keypassword` Specify that the keystore password should be changed. You are prompted for a new password, which must be 8 to 32 characters.

- `l | --library` Specify that the resource is a shared jar file.

- `m | --module` Specify that the resource is a JAAS login module.

- `n | --name` Specify the short-hand identifier name for the resource. If omitted, the identifier name is derived from the full resource name.

- `o | --option` Specify the name and value of a login module option property, separated by the equals character.

- `p | --property` Specify that the resource is one or more shared service properties.

- `s | --service` Specify the name of the JAAS login service definition. If omitted, the default console login service definition is assumed.

- `t | --trustpassword` Specify that the truststore password should be changed. You are prompted for a new password, which must be 8 to 32 characters.

- `x | --context` Specify the web application context path name under which the application is deployed.

**Arguments**

- `app_path` The fully qualified file system path to the web application installation directory.

- `appname` The application name. The name must be unique among all web applications registered with the console. It is also used as the name of the subdirectory under the console's pre-registration directory which contains
all the resource registration notification files for that application. Typically, the application package name, plugin identifier, or context path name is specified for the application name.

behavior The JAAS login module control flag behavior. Must be one of “optional”, “required”, “requisite”, or “sufficient”.

classname The fully qualified Java package class name of the JAAS login module. The specified class must be included in a shared jar file added to the console.

context The web application context path name under which the application is deployed. With the .reg suffix, the context forms the file name of the registration notification file for that application.

id The short-hand identifier name for a jar file or login module resource to be added or removed. The identifier name must be unique among the resources shared for a given application name. With the .reg suffix, it forms the file name of the registration notification file for that resource.

jarpath The fully qualified file system path to the jar file resource. When the resource is added to the console, its path is included in the classpath of the console’s shared class loader.

option The JAAS login module option property name.

property The shared service property name.

password_file The fully qualified path to a password text file that contains the new administrator, keystore, and truststore passwords in property file format. The administrator password is specified using the “adminpassword” property. The keystore password is specified using the “keypassword” property. The truststore password is specified using the “trustpasswd” property. At least one password property must be contained in the password file.

value The login module option or shared service property value. If the value contains white space, it must be quoted.

Examples The following command adds a jar file to be shared in the console:

wcadmin add -l -a myapp_1.0 -n wbem /usr/sadm/lib/wbem.jar

The following command deploys a new web application:

wcadmin deploy -a myapp_1.0 -x myapp /opt/SUNWmyapp/myapp

The following command reloads an existing web application:

wcadmin reload -x myapp

The following command undeploys a web application at the next server restart:
wcadmin undeploy -D -a myapp_1.0 -x myapp

The following command lists all the deployed web applications in the console. If the status field is "running", the web application is available. If the status field is "stopped", the web application is disabled and is not available. If all web applications are "stopped", this typically indicates the console web server instance is not running.

wcadmin list -a

The following command removes a shared jar file:

wcadmin remove -l -a myapp_1.0 -n wbem

The following command changes passwords that are specified in a file:

wcadmin password -f /home/mydir/console-passwords

Exit Status The following exit values are returned:

0  Subcommand succeeded without error
1  Usage error: missing or malformed arguments
2  Fatal error: subcommand failed with one or more errors

whodo(1M)

Name  whodo – who is doing what

Synopsis  /usr/sbin/whodo [-h] [-l] [user]

Description  The whodo command produces formatted and dated output from information in the /var/adm/utmpx and /proc/pid files.

The display is headed by the date, time, and machine name. For each user logged in, device name, user-ID and login time is shown, followed by a list of active processes associated with the user-ID. The list includes the device name, process-ID, CPU minutes and seconds used, and process name.

If user is specified, output is restricted to all sessions pertaining to that user.

Options  The following options are supported:

- h  Suppress the heading.
- l  Produce a long form of output. The fields displayed are: the user’s login name, the name of the tty the user is on, the time of day the user logged in (in hours:minutes), the idle time — that is, the time since the user last typed anything (in hours:minutes), the CPU time used by all processes and their children on that terminal (in minutes:seconds), the CPU time used by the currently active processes (in minutes:seconds), and the name and arguments of the current process.

Examples  EXAMPLE 1  Using the whodo Command

The command:

example% whodo

produces a display like this:

Tue Mar 12 15:48:03 1985
bailey
  tty09  mcn   8:51
  tty09  28158  0:29 sh

  tty52  bdr   15:23
  tty52  21688  0:05 sh
  tty52  22788  0:01 whodo
  tty52  22017  0:03 vi
  tty52  22549  0:01 sh

  xt162  lee   10:20
  tty08  6748  0:01 layers
  xt162  6751  0:01 sh
  xt163  6761  0:05 sh
  tty08  6536  0:05 sh
Environment Variables

If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of tar(1) for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how who does.

LC_CTYPE
  Determines how who does characters. When LC_CTYPE is set to a valid value, who can display and handle text and filenames containing valid characters for that locale. The who command can display and handle Extended Unix code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. who can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES
  Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

LC_TIME
  Determines how who does date and time formats. In the "C" locale, date and time handling follow the U.S. rules.

Exit Status
The following exit values are returned:

  0     Successful completion.
  non-zero     An error occurred.

Files
/etc/passwd     System password file
/var/adm/utmpx  User access and administration information
/proc/pid       Contains PID

The `wpad` daemon provides common client functionality for the WiFi Protected Access (WPA) versions 1 and 2, as defined by IEEE802.11i standard. WPA was created by the WiFi Alliance, an industry trade group. WPA implements the majority of the IEEE 802.11i standard, and was intended as an intermediate measure to take the place of Wired Equivalent Privacy (WEP) while 802.11i was prepared. WPA2 implements the full standard.

`wpad` provides the following WPA/IEEE 802.11i features:

- WPA-PSK ("WPA-Personal")
- Key management for CCMP, TKIP, WEP104, WEP40

Stop and start the `wpad` daemon using `dladm(1M)`. Use:

```
# dladm connect-wifi
```
...to start the `wpad` daemon. Use:

```
# dladm disconnect-wifi
```
...to stop the daemon.

The following options are supported:

- `-i interface`
  Specify a WiFi Link interface to start the `wpad` daemon.

- `-k pre_shared_key_name`
  Specify the pre-shared key used for the WiFi Link.

### Examples

#### EXAMPLE 1
Starting the `wpad` Daemon on Specific WiFi Link

To create the WPA key `psk`, enter the following command:

```
# dladm create-secobj -c wpa psk
```
To use key `psk` to connect to ESSID `wlan` on link `ath0`, enter the following command:

```
# dladm connect-wifi -k psk -e wlan ath0
```

#### EXAMPLE 2
Stopping the `wpad` Daemon on Specific WiFi Link

To stop the daemon on the link `ath0`, enter:

```
# dladm disconnect-wifi ath0
```

### Attributes
See `attributes(5)` for descriptions of the following attributes:
<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

</tbody>
</table>

The `wpad` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/wpa:
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcadm(1M)` command.

See Also `svcs(1), dladm(1M), svcadm(1M), attributes(5), smf(5)`

Notes The `wpad` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/wpa:
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcadm(1M)` command.
The `wracct` utility allows the administrator to invoke the extended accounting system, if active, to write intermediate records representing the resource usage of a selected set of processes or tasks. For tasks, a `record_type` option is also supported, allowing the administrator to request the writing of:

- an interval record, which reflects task usage since a previous interval record (or since task creation if there is no interval record), or
- a partial record, which reflects usage since task creation.

The following options are supported:

- `-i id_list` Select the IDs of the tasks or processes to write records for. Specify `id_list` as a comma- or space-separated list of IDs, presented as a single argument. For some shells, this requires appropriate quoting of the argument.
- `-t record_type` Select type of record to write for the selected task or process. For tasks, `record_type` can be `partial` or `interval`. `partial` is the default type, and the only type available for process records.

The following operands are supported:

- `process` Treat the given ID as a process ID for the purposes of constructing and writing an extended accounting record.
- `task` Treat the given ID as a task ID for the purposes of constructing and writing an extended accounting record.

**Examples**

**EXAMPLE 1** Writing a Partial Record

Write a partial record for all active `sendmail` processes.

```
# /usr/bin/wracct -i "pgrep sendmail" process
```

**EXAMPLE 2** Writing an Interval Record

Write an interval record for the task with ID 182.

```
# /usr/bin/wracct -t interval -i 182 task
```

**Exit Status** The following exit values are returned:

- 0  Successful completion.
- 1  An error occurred.
- 2  Invalid command line options were specified.
Pertinent components of extended accounting facility are not active.

**Files**  
/var/adm/exacct/task  Extended accounting task files.  
/var/adm/exacct/proc  Extended accounting data files.

acctadm(1M), attributes(5)
The `wusbadm` command provides a command line interface to administer wireless USB hosts and devices, including listing hosts and devices information, associating the host with the device, removing host or device information from the system, and enabling or disabling hosts.

Before connecting a wireless USB device to a host for the first time, a user needs to set up the association information between them by running the `wusbadm associate` subcommand. Following this, the user can connect or disconnect the device by simply turning on or off the device radio (perhaps a button on the device, depending on the manufacturer). The device radio's turning on and off are analogous to the hotplugging of wired USB devices.

The association information created by the `associate` subcommand is maintained in the non-volatile memory of the device and the host. On the host, it can be removed by the `remove-dev` or `remove-host` subcommands. On the device, it can be overwritten by another association. For a device is associated with multiple hosts, the way that the device prioritizes or updates its multiple records of association depends on the manufacturer.

Each `wusbadm` subcommand operates on one of the following objects:

### host-id
A two-digit number (in the range from 01 to 99) that uniquely identifies a wireless USB host on a system. It is generated when the `wusb` service (see NOTES section) is successfully enabled and finds the host instance for the first time. The number is maintained until removed by `remove-host` subcommand.

### dev-id
A five-digit number that uniquely identifies a wireless USB device associated with a wireless USB host. The first two digits are the host-id of the wireless USB host with which the device is associated. The last three-digit number (in the range from 001 to 999) is used to differentiate devices associated with the same host. In the five-digit number, the first two digits and the last three are separated by a dot.

`dev-id` is generated during the device association process. It is maintained for the device until removed by the `remove-dev` subcommand or until updated by another association between the same host and device.
Sub-commands

The following subcommands are supported. Except for the `list` subcommand, each subcommand displays subcommand-specific usage information if you run it without any options or operands.

```
list [-h | -d] [-o field[,...]]
```

List wireless USB hosts and devices on a system, displaying the ID, state, and type for all hosts and devices. By default, `list` will list all hosts and devices and all fields. Each host and its devices will be displayed as a group. This subcommand supports the following options.

```
-o field[,...], --output=field[,...]
```

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all` to display all fields. By default (without `-o`), `list` displays all fields.

**ID**

The `host-id` or `dev-id`.

**TYPE**

The `host` or `device` types.

For `host`, the types include `whci` (on-board host) and `hwa` (hot-pluggable host).

For `device`, the types include `kbd`, `mouse`, `storage`, `printer`, `dwa` (wireless USB hub), `audio`, `video`, and so forth.

**STATE**

There are the following states for the host:

- **enabled**
  
  The host is ready to work or is already working, including performing association, connecting devices, performing data communication, and so forth.

- **disabled**
  
  The host is not ready to work with any devices and no devices are connected to the host. It might be stopped by a `disable-host` subcommand, or the host might not be available because it is physically unplugged or because of a driver detach.

- **disconnected**
  
  The host is not attached to the system. An `hwa` device is in this state after it is unplugged from the USB port on the system.

There are the following states for the device:

- **connected**
  
  The device is connected with a host and ready to be opened, or it is already opened and working. By default, the device tries to get into this state after the association is complete and its radio is turned on.
The device is not connected to a host or not ready to be opened yet. The device might be in this state because its radio is out of range, power is off, hardware problems, and so forth.

-h, --host
List the wireless USB hosts only.

-d, --device
List the wireless USB devices only.

associate [-h host-id] [[-c [-f]] | -n] [-o]
Designate the host to start an association process. Association is the initial step before a wireless USB device can be connected with a wireless USB host.

There are two association models:

Cable association
A user connects the device and host with a USB cable first, and then run this subcommand to designate the host to setup the association information with the device. After the association is in effect, the cable is no longer needed in the subsequent connections between the same host and the device.

Numeric association
A user turns on the device radio and runs this subcommand to designate the host to talk to the device. A short number is then displayed on both host and device. The user compares the values of the numbers and confirms on both the host and the device.

Following a successful association, the associated USB host and device are able to proceed with the wireless connection process. By default, the association information will be kept both on the host and the device until it is removed or overwritten.

If there are multiple devices available for association, this subcommand will list all of them, enabling a user to choose among them. This subcommand has the following options.

-h host-id, --host host-id
Specify the host for which the association will be done. If this option is not specified, this subcommand lists all enabled hosts for users to choose.

-c, --cable
Start the cable association process. A user plugs the wireless USB device to the host and runs the associate subcommand with this option.

-n, --numeric
Start the numeric association process. This subcommand prompts the user to compare the number displayed on the host and the device.

If neither of the preceding two association model options (-n or -c) is specified, this subcommand prompts the user to specify one of the following association model options.
-f, --force
Start the cable association process. A user plugs the wireless USB device to the host and runs the associate subcommand with this option.

-o, --onetime
Indicate that this association is for a one-time connection. That is, after the association, if the device is connected and then disconnected, the association information for this device will be removed from the host system. A user would need to perform another association for the next connection.

`remove-dev` [[-d dev-id] | [-h host-id]] [-f]
Remove the association information of the wireless USB device from the system. After the removal, the device cannot be connected with the host until the user runs the associate subcommand again, for the host and device. This subcommand has the following options.

- d, --device=dev-id
Remove the association information of the wireless USB device specified by dev-id.

- h host-id, --host=host-id
Remove the association information of all the wireless USB devices associated with the host specified by host-id.

- f, --force
Perform the removal without asking for confirmation. If the device is being connected with the host, then this subcommand will force it to disconnect.

`remove-host` [-h host-id] [-f]
Remove the host information from the system, including host-id and the association information of all the devices associated with the host. This subcommand is used most often for removing the temporarily used hot-pluggable wireless USB host, for example, a hwa dongle. The host can be brought back by being re-enumerated, for example, physically hot-plugging a hwa dongle. The host-id will then be updated and no device association information can be restored. It is not recommended to remove a on-board host. This subcommand has the following options.

- h host-id, --host=host-id
Specifies the host-id to be removed.

- f, --force
Perform the removal without asking for confirmation. If there are one or more devices connected with the host, then force them to disconnect.

`enable-host` [-h host-id]
Take the host to the enabled state. By default, the host is in the enabled state. This subcommand has the following option.

- h host-id, --host=host-id
Specifies the host-id to be enabled.
disable-host [-h host-id] [-f]

Take the host to the disabled state. The host-id and all the association information of the
giving host are maintained. Issuing an enable-host subcommand brings the host back to the
disabled state. This subcommand has the following options.

-h host-id, --host=host-id
  Specifies the host-id to be disabled.

-f, --force
  Perform the disable operation without asking for confirmation. If there are one or more
devices connected with the host, this option forces them to disconnect.

Examples

**EXAMPLE 1** Listing All Hosts and Devices

The following command lists all wireless USB hosts and devices.

```
# wusbadm list
```

<table>
<thead>
<tr>
<th>host-id</th>
<th>state</th>
<th>device</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>enabled</td>
<td>hwa</td>
</tr>
<tr>
<td>01.001</td>
<td>connected</td>
<td>mouse</td>
</tr>
<tr>
<td>01.002</td>
<td>connected</td>
<td>kbd</td>
</tr>
<tr>
<td>02</td>
<td>enabled</td>
<td>whci</td>
</tr>
<tr>
<td>02.001</td>
<td>connected</td>
<td>printer</td>
</tr>
<tr>
<td>02.002</td>
<td>disconnected</td>
<td>storage</td>
</tr>
<tr>
<td>03</td>
<td>disabled</td>
<td>hwa</td>
</tr>
<tr>
<td>03.001</td>
<td>disconnected</td>
<td>storage</td>
</tr>
<tr>
<td>03.002</td>
<td>disconnected</td>
<td>dwa</td>
</tr>
</tbody>
</table>

**EXAMPLE 2** Associating to a Device Using Cable

The following command associates a device to a specific host (host-id 01), using the cable
association approach.

```
# wusbadm associate -h 01 -c
```

Associate a device with host (01) via cable.

Continue (yes/no)?

**EXAMPLE 3** Removing a Device's Association

The following command removes a device’s association information from the host system.

```
# wusbadm remove-dev -d 01.002
```

Remove the information of device (01.002) from system.

This device can not be connected with the host until it is associated
again. Continue (yes/no)?

**EXAMPLE 4** Removing Associations for All Devices

The following command removes the association information for all devices associated with a
specific host.

```
# wusbadm remove-dev -h 02
```

Remove the information of all the devices associated with host (02)
EXAMPLE 4 Removing Associations for All Devices  (Continued)

from the system.
All the devices associated with the host cannot be connected with it
until they are associated again. Continue (yes/no)?

Exit Status The following exit values are returned:

0  Successful operation.
1  Error: the operation failed. For example, a device failed to associate with a host.
2  Usage error.

Attributes See attributes(5) for descriptions of the following attributes:

Notes The wusb (wireless USB administration) service is managed by the service management
facility, smf(5), under the service identifier:

svc:/system/wusb:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can
be performed using svcadm(1M). The service's status can be queried using the svcs(1)
command.

The wusb service is implemented by the wusbd daemon, a private interface. As with the wusb
service, the daemon is started by the SMF. Specify the daemon with the service instance:

svc:/system/wusbd:default

The wusbd daemon should not be invoked directly.
ypbind – NIS binder process

Synopsis /usr/lib/netsvc/yp/ypbind [-broadcast | -ypset | -ypsetme]

Description NIS provides a simple network lookup service consisting of databases and processes. The databases are stored at the machine that runs an NIS server process. The programmatic interface to NIS is described in ypclnt(3NSL). Administrative tools are described in ypinit(1M), ypwhich(1), and ypset(1M). Tools to see the contents of NIS maps are described in ypcat(1), and ypmatch(1).

ypbind is a daemon process that is activated at system startup time from the svc:/network/nis/client:default service. By default, it is invoked as ypbind -broadcast. ypbind runs on all client machines that are set up to use NIS. The function of ypbind is to remember information that lets all NIS client processes on a node communicate with some NIS server process. ypbind must run on every machine which has NIS client processes. The NIS server may or may not be running on the same node, but must be running somewhere on the network.

The SMF service svc:/network/nis/client has the following properties in the config property group:

config.use_broadcast
config.use_ypsetme

The information ypbind remembers is called a binding — the association of a domain name with a NIS server. The process of binding is driven by client requests. As a request for an unbound domain comes in, if started with the -broadcast option, the ypbind process broadcasts on the net trying to find an NIS server, that is, a ypserv process serving the domain with a name the same as (case sensitive) the name of the domain in the client request. Since the binding is established by broadcasting, there must be at least one NIS server on the net. If started without the -broadcast option, ypbind process steps through the list of NIS servers that was created by ypinit -c for the requested domain. There must be an NIS server process on at least one of the hosts in the NIS servers file. It is recommended that you list each of these NIS servers by name and numeric IP address in /etc/hosts. Though the practice is not recommended, NIS allows you to list servers by numeric address only, bypassing /etc/hosts. In such a configuration, ypwhich(1) returns a numeric address instead of a name.

Once a domain is bound by ypbind, that same binding is given to every client process on the node. The ypbind process on the local node or a remote node may be queried for the binding of a particular domain by using the ypwhich(1) command.

If ypbind is unable to speak to the NIS server process it is bound to, it marks the domain as unbound, tells the client process that the domain is unbound, and tries to bind the domain once again. Requests received for an unbound domain will wait until the requested domain is bound. In general, a bound domain is marked as unbound when the node running the NIS server crashes or gets overloaded. In such a case, ypbind will try to bind to another NIS server using the process described above. ypbind also accepts requests to set its binding for a
particular domain. The request is usually generated by the `ypset(1M)` command. In order for `ypset` to work, `ypbind` must have been invoked with flags `-ypset` or `-ypsetme`.

NIS configuration and activation is managed in Location profiles (refer to `netcfg(1M)` for more information about location profiles). These profiles are either fixed, meaning the network configuration is being managed in the traditional way, or reactive, meaning the network configuration is being managed automatically, reacting to changes in the network environment according to policy rules specified in the profiles.

When a fixed location (there can currently be only one, the Default Fixed location) is active, changes made to the SMF repository will be applied to the location when it is disabled, and thus will be restored if that location is later re-enabled.

When a reactive location is active, changes should not be applied directly to the SMF repository; these changes will not be preserved in the location profile, and will thus be lost if the location is disabled, or if the system's network configuration, as managed by `svc:/network/physical:default` and `svc:/network/location:default`, is refreshed or restarted. Changes should instead be applied to the location itself, using the `netcfg(1M)` command; this will save the change to the location profile repository, and will also apply it to the SMF repository (if the change is made to the currently active location).

The presence or absence of `nis` in the `nameservices` property of a location profile will determine whether or not `svc:/network/nis/client:default` is enabled. The `nis-nameservice-servers` property may be empty, indicating that `-broadcast` should be enabled, or it may contain the list of servers to which the client may bind.

### Options

**-broadcast**

Send a broadcast datagram using UDP/IP that requests the information needed to bind to a specific NIS server. This option is analogous to `ypbind` with no options in earlier Sun releases and is recommended for ease of use.

Enabling the SMF property `config.use_broadcast` enables `-broadcast`.

**-ypset**

Allow users from any remote machine to change the binding by means of the `ypset` command. By default, no one can change the binding. This option is insecure.

Enabling the SMF property `config.use_ypset` enables `-ypset`.

**-ypsetme**

Only allow root on the local machine to change the binding to a desired server by means of the `ypset` command. `ypbind` can verify the caller is indeed a root user by accepting such requests only on the loopback transport. By default, no external process can change the binding.

Enabling the SMF property `config.use_ypsetme` enables `-ypsetme`. 
ypbind(1M)

**Files**
/var/yp/binding/ypdomain/ypservers
List the servers to which the NIS client is allowed to bind.

/etc/inet/hosts
File in which it is recommended that NIS servers be listed.

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/network/nis</td>
</tr>
</tbody>
</table>

**See Also**
svcs(1), ypcat(1), ypmatch(1), ypwhich(1), ifconfig(1M), netcfg(1M), svcadm(1M),
ypinit(1M), ypset(1M), ypclnt(3NSL), hosts(4), ypfiles(4), attributes(5), smf(5)

**Notes**

ypbind supports multiple domains. The ypbind process can maintain bindings to several domains and their servers, the default domain is the one specified by the `domainname(1M)` command at startup time.

The `-broadcast` option works only on the UDP transport. It is insecure since it trusts "any" machine on the net that responds to the broadcast request and poses itself as an NIS server.

The ypbind service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/nis/client:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service’s status can be queried using the `svcs(1)` command.
ypinit(1M)

Name
ypinit – set up NIS client

Synopsis
/usr/sbin/ypinit [-c] [-m] [-s master_server]

Description
ypinit can be used to set up an NIS client system. You must be the superuser to run this command. This script need not be used at all if ypbind(1M) is started with the -broadcast option (it is invoked with this option from the svc:/network/nis/client:default service).

Normally, ypinit is run only once after installing the system. It may be run whenever a new NIS server is added to the network or an existing one is decommissioned.

ypinit prompts for a list of NIS servers to bind the client to; this list should be ordered from the closest to the furthest server. It is recommended that you list each of these NIS servers by name and numeric IP address in /etc/hosts. Though the practice is not recommended, NIS allows you to list servers by numeric address only, bypassing /etc/hosts. In such a configuration, ypwhich(1) returns a numeric address instead of a name.

ypinit stores the list of servers to which a client can bind in the file /var/yp/binding/domain/ypservers. This file is used by ypbind when run without the -broadcast option.

Interaction with Location Profiles
NIS client configuration is managed in Location profiles (refer to netcfg(1M) for more information about location profiles). These profiles are either fixed, meaning the network configuration is being managed in the traditional way, or reactive, meaning the network configuration is being managed automatically, reacting to changes in the network environment according to policy rules specified in the profiles.

When a fixed location (there can currently be only one, the DefaultFixed location) is active, changes made to the SMF repository will be applied to the location when it is disabled, and thus will be restored if that location is later re-enabled.

When a reactive location is active, changes should not be applied directly to the SMF repository; these changes will not be preserved in the location profile, and will thus be lost if the location is disabled, or if the system's network configuration, as managed by svc:/network/physical:default and svc:/network/location:default, is refreshed or restarted. Changes should instead be applied to the location itself, using the netcfg(1M) command; this will save the change to the location profile repository, and will also apply it to the SMF repository (if the change is made to the currently active location).

NIS client configuration is stored in the default-domain and nis-nameservice-servers properties of a location profile.

Options
- c
  Set up a ypc client system.

- m
  Build a master ypserver data base.
-s master_server
Slave database. master_server must be the same master configured in the YP maps and
returned by the ypwhich -m command.

Files
/etc/hosts
File in which it is recommended that NIS servers be listed.

/var/yp/binding/domain/ypservers
Lists the servers to which the NIS client is allowed to bind.

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/network/nis</td>
</tr>
</tbody>
</table>

See Also
svcs(1), ypwhich(1), netcfg(1M), svcadm(1M), ypbind(1M), sysinfo(2), hosts(4),
attributes(5), smf(5)

Notes
The NIS client service is managed by the service management facility, smf(5), under the
service identifier:

svc:/network/nis/client:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can
be performed using svcadm(1M). The service's status can be queried using the svcs(1)
command.

Bugs
ypinit sets up the list of NIS servers only for the current domain on the system when it is run,
that is, the domain returned by the SI_RPC_DOMAIN command to sysinfo(2). Care should be
taken to ensure that this is the same as the desired domain for NIS client processes.
**Synopsis**
```
cd /var/yp ; make [map]
```

**Description**
The file called `Makefile` in `/var/yp` is used by `make(1S)` to build the Network Information Service (NIS) database. With no arguments, `make` creates `dbm` databases for any NIS maps that are out-of-date, and then executes `yppush(1M)` to notify slave databases that there has been a change.

If you supply a `map` on the command line, `make` will update that map only. Typing `make passwd` will create and `yppush` the password database (assuming it is out of date). Likewise, `make ipnodes` and `make networks` will create and `yppush` the `ipnodes` and `networks` files, `${INETDIR}/ipnodes` and `${DIR}/networks`.

There are four special variables used by `make`: `DIR`, which gives the directory of the source files; `NOPUSH`, which when non-null inhibits doing a `yppush` of the new database files; `INETDIR`, which gives the directory of the `ipnodes` source file; and `DOM`, which is used to construct a domain other than the master’s default domain. The default for `DIR` is `/etc`, and the default for `INETDIR` is `/etc/inet`. The default for `NOPUSH` is the null string.

Refer to `ypfiles(4)` and `ypserv(1M)` for an overview of the NIS service.

If a NIS to LDAP (N2L) configuration file, `/var/yp/NISLDAPmapping`, is present, the NIS server components run in N2L mode. In N2L mode, the server components use a new set of map files with an LDAP-prefix, based on the LDAP DIT. In N2L mode, authoritative NIS information is obtained from the DIT. The NIS source files and `ypmake` have no role, and they should not be used. If `ypmake` is accidentally run, then the server components will detect this, and will log a warning message. For additional information, see `ypfiles(4)`.

**Files**
- `/var/yp` Directory containing NIS configuration files.
- `/etc/inet/hosts` System hosts file.
- `/etc` Default directory for source files.

Notes

The NIS makefile is only used when running the `ypserv(1M)` server to provide NIS services. See `ypfiles(4)` for more details.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same. Only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.
ypmap2src – convert NIS maps to NIS source files

Synopsis
/usr/lib/netsvc/yp/ypmap2src [-t]
   [-c custom-map-name]... [-d domain] -o output-directory
   [ source-file]...

Description
Use the ypmap2src utility to convert standard NIS maps to approximations of the equivalent NIS source files. This utility functions like the reverse of ypmake(1M).

The primary use for ypmap2src is to convert from a NIS server that uses the NIS to LDAP(N2L) transition mechanism, which does not use NIS source files, to traditional NIS, where source files are required. The ypmap2src utility is also used by NIS administrators who wish to discover the contents of NIS maps for which the sources are not available.

Generally, this operation is not necessary. More often, administrators will switch from traditional NIS to N2L in anticipation of the eventual transition to LDAP naming. When this switch is made, authoritative information is moved into the LDAP DIT, and the NIS sources have no further role. N2L supports NIS clients until such time as they can be converted to LDAP, and the NIS service suspended.

The ypmap2src utility does not guarantee that the files that are generated are identical to the original NIS source files. Some information might have been thrown away by ypmake and cannot be recovered. N2L also might have updated the maps to reflect changes made by LDAP clients. It is essential that the sources generated are checked to confirm no problems have occurred.

Per entry comment fields, from existing source files, are not merged into source files generated by ypmap2src. If a user wishes N2L to maintain comment information, then the NISLDAP mapping configuration file should be modified so that the comment fields are mapped into LDAP. This will ensure that the comments are visible to native LDAP clients and present in the N2L map files.

When ypmap2src is run, it will take up-to-date comments from the map file and insert them into the NIS source file generated.

Handling Custom Maps
ypmap2src only knows about the standard NIS maps and standard source to map conversion. If an advanced user has changed these, that is, the user has modified the NIS makefile, the equivalent changes must also be made to the ypmap2src script.

Options
ypmap2src supports the following options:

- c
  Specifies that custom-map-name should be converted to a source file by running makedbm -u on it. This is a short cut so that simple custom maps can be handled without editing ypmap2src.

- d domain-name
  Specifies the domain to convert. The domain-name can be a fully qualified file path, such as /var/yp/a.b.c, or just a domain name, a.b.c. In the latter case, ypmap2tosrc looks in /var/yp for the domain directory.
ypmap2src(1M)

-o dest
Specifies the destination directory for the converted files. A directory other than /etc should be specified. The maps generated are copied to the correct location, /etc, /etc/security or other source directory, as appropriate.

-t
Specifies that traditional NIS maps, without N2L’s LDAP_ prefix, should be converted. By default, maps with the LDAP_ prefix are converted.

Operands
ypmap2src supports the following operands:

source-file
Lists the standard source files to convert. If this option is not given, then all the standard source files, plus any custom files specified by the -c option, are converted.

Oracle Solaris Administration: Naming and Directory Services
**Name**  yppoll – return current version of a NIS map at a NIS server host

**Synopsis**  
```
/usr/sbin/yppoll [-d ypdomain] [-h host] mapname
```

**Description**  
The `yppoll` command asks a `ypserv()` process what the order number is, and which host is the master NIS server for the named map.

**Options**  
- `-d ypdomain`  Use `ypdomain` instead of the default domain.
- `-h host`  Ask the `ypserv` process at `host` about the map parameters. If `host` is not specified, the NIS server for the local host is used. That is, the default host is the one returned by `ypwhich(1)`.

`ypwhich(1), ypfiles(4), attributes(5)`
**Synopsis**

```
```

**Description**

`yppush` copies a new version of a Network Information Service (NIS) map from the master NIS server to the slave NIS servers. It is normally run only on the master NIS server by the `Makefile` in `/var/yp` after the master databases are changed. It first constructs a list of NIS server hosts by reading the NIS `ypservers` map within the `domain`. Keys within the `ypservers` map are the ASCII names of the machines on which the NIS servers run.

A “transfer map” request is sent to the NIS server at each host, along with the information needed by the transfer agent (the program that actually moves the map) to call back the `yppush`. When the attempt has completed (successfully or not), and the transfer agent has sent `yppush` a status message, the results can be printed to `stdout`. Messages are also printed when a transfer is not possible, for instance, when the request message is undeliverable, or when the timeout period on responses has expired.

Refer to `ypfiles(4)` and `ypserv(1M)` for an overview of the NIS service.

**Options**

The following options are supported:

- `-d domain` Specifies a `domain`.
- `-h host` Propagates only to the named `host`.
- `-p #parallel-xfrs` Allows the specified number of map transfers to occur in parallel.
- `-v` Verbose. This prints messages when each server is called, and for each response. If this flag is omitted, only error messages are printed.

**Files**

`/var/yp` Directory where NIS configuration files reside.

`/var/yp/domain/ypservers` Map containing list of NIS servers to bind to when running in server mode.

**Notes**

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.
Bugs  In the current implementation (version 2 NIS protocol), the transfer agent is `ypxfr(1M)`, which is started by the `ypserv` program. If `yppush` detects that it is speaking to a version 1 NIS protocol server, it uses the older protocol, sending a version 1 `YPROC_GET` request and issues a message to that effect. Unfortunately, there is no way of knowing if or when the map transfer is performed for version 1 servers. `yppush` prints a message saying that an “old-style” message has been sent. The system administrator should later check to see that the transfer has actually taken place.
ypserv, ypxfrd – NIS server and binder processes

**Synopsis**

```
/usr/lib/netsvc/yp/ypserv [-dv] [-i | -I] [-r | -R]
/usr/lib/netsvc/yp/ypxfrd
```

**Description**

The Network Information Service (NIS) provides a simple network lookup service consisting of databases and processes. The databases are ndbm files in a directory tree rooted at /var/yp. See `ndbm(3C)`. These files are described in `ypfiles(4)`. The processes are

```
/usr/lib/netsvc/yp/ypserv, the NIS database lookup server, and
/usr/lib/netsvc/yp/ypbind, the NIS binder.
```

The programmatic interface to the NIS service is described in `ypclnt(3NSL)`. Administrative tools are described in `yppoll(1M)`, `yppush(1M)`, `ypset(1M)`, `ypxf(1M)`, and `ypwhich(1)`. Tools to see the contents of NIS maps are described in `ypcat(1)` and `ypmatch(1)`. Database generation and maintenance tools are described in `ypinit(1M)`, `ypmake(1M)`, and `makedbm(1M)`.

The `ypserv` utility is a daemon process typically activated at system startup from `svc:/network/nis/server:default`. Alternatively, you can, as the root user, start NIS services using `ypstart(1M)` from the command-line. `ypserv` runs only on NIS server machines with a complete NIS database. You can halt all NIS services using the `ypstop(1M)` command.

The `ypserv` daemon’s primary function is to look up information in its local database of NIS maps.

The operations performed by `ypserv` are defined for the implementor by the *YP Protocol Specification*, and for the programmer by the header file `<rpcsvc/yp_prot.h>`.

Communication to and from `ypserv` is by means of RPC calls. Lookup functions are described in `ypclnt(3NSL)`, and are supplied as C-callable functions in the `libnsl(3LIB)` library. There are four lookup functions, all of which are performed on a specified map within some NIS domain: `yp_match(3NSL)`, `yp_first(3NSL)`, `yp_next(3NSL)`, and `yp_all(3NSL)`. The `yp_match` operation takes a key, and returns the associated value. The `yp_first` operation returns the first key-value pair from the map, and `yp_next` can be used to enumerate the remainder. `yp_all` ships the entire map to the requester as the response to a single RPC request.

The SMF service `svc:/network/nis/server` manages the configuration of the `ypserv` daemon.

A number of special keys in the DBM files can alter the way in which `ypserv` operates. The keys of interest are:
YP_INTERDOMAIN  The presence of this key causes ypser\v to forward to a DNS server host lookups that cannot be satisfied by the DBM files.

YP_SECURE  This key causes ypser\v to answer only questions coming from clients on reserved ports.

YP_MULTI_hostname  This is a special key in the form, \texttt{YP_MULTI\_hostname addr1,...,addrN}. A client looking for \texttt{hostname} receives the closest address.

Two other functions supply information about the map, rather than map entries: \texttt{yp\_order(3NSL)} and \texttt{yp\_master(3NSL)}. In fact, both order number and master name exist in the map as key-value pairs, but the server will not return either through the normal lookup functions. If you examine the map with \texttt{makedbm(1M)}, however, they are visible. Other functions are used within the NIS service subsystem itself, and are not of general interest to NIS clients. These functions include \texttt{do\_you\_serve\_this\_domain?}, \texttt{transfer\_map}, and \texttt{reinitialize\_internal\_state}.

On start up, ypser\v checks for the existence of the NIS to LDAP (N2L) configuration file \texttt{/var/yp/NI\_LDAP\_mapping}. If it is present then a master server starts in N2L mode. If the file is not present it starts in "traditional" (non N2L) mode. Slave servers always start in traditional mode.

In N2L mode, a new set of map files, with an LDAP prefix, are generated, based on the contents of the LDAP DIT. The old map files, NIS source files and \texttt{ypmake(1M)} are not used.

It is possible that ypmake(1M) can be accidentally run in N2L mode. If it occurs, the old style map files are overwritten. That the map files are overwritten is harmless. However, any resulting yppush(1M) operation will push information based on the DIT rather than the source files. The user may not expect information based on the DIT. ypser\v keeps track of the last modification date of the old style map files. If the map files have been updated, a warning is logged that suggests that the user call yppush directly instead of ypmake.

If a server attempts to run in N2L mode and a LDAP server cannot be contacted, it behaves as follows:

1. When ypser\v is started, a warning will be logged.
2. When a NIS read access is made and the TTL entry has expired, a warning is logged. Information that is returned from the cache has not been updated.
3. When a NIS write access is made, a warning is logged. The cache will not be updated, and a NIS failure will be returned.

If ypfrd is running in N2L mode and is asked to transfer a map, ypfrd first checks whether the map is out of date. If the map is out of date, ypfrd initiates an update from the DIT. ypfrd cannot wait for the update to complete. If ypfrd waited, the client end ypfr
operation could time out. To prevent ypfrd from timing out, the existing map is transferred from the cache. The most up to date map will be transferred on subsequent ypfrd operations.

Options

`ypserv -d` The NIS service should go to the DNS for more host information. This requires the existence of a correct `/etc/resolv.conf` file pointing to a DNS server. This option turns on DNS forwarding regardless of whether or not the `YP_INTERDOMAIN` flag is set in the hosts maps. See `makedbm(1M)`. In the absence of an `/etc/resolv.conf` file, `ypserv` complains, but ignores the `-d` option.

If enabled, the property `group/property config.service_dns` tells `ypserv` to enable the `-d` option.

`-i` If in N2L mode, initialize the NIS related parts of the DIT based on the current, non `LDAP_` prefixed, map files. The `LDAP_` prefixed maps are not created or updated. If you require that `LDAP_` prefixed maps be updated or created, then use the `-ir` option.

The `-i` option does not attempt to create any NIS domain or container objects. If any NIS domain or container objects have not already been created, then errors will occur, as entries are written to nonexistent containers.

`-I` Identical to `-i`, except that any missing domain and container objects are created.

`-r` If in N2L mode, then refresh the `LDAP_` prefixed map files based on the contents of the DIT.

`-ir` If both `-i` and `-r` are specified in N2L mode, then the DIT will first be initialized from the current non `LDAP_` prefixed map files. A new set of `LDAP_` prefixed maps will then be generated from the contents of the DIT. A new set of `LDAP_` prefixed maps is required when moving from traditional NIS to N2L mode NIS.

`-Ir` Identical to `-ir`, except that any missing domain and container objects are created.

`-v` Operate in the verbose mode, printing diagnostic messages to stderr.

When run with the `-i`, `-r`, `-I`, `-ir` or `-Ir` options, the `ypserv` command runs in the foreground and exits once map initialization has been completed. Once the `ypserv` command exits, the user knows the maps are ready and can restart `ypserv` and the other yp daemons by running `ypstart(1M)`.

If there is a requirement to initialize the DIT from the NIS source files, which may have been modified since the maps were last remade, run `ypmake` before running `ypserv -i` or `ypserv -ir`. `ypmake` regenerated old style NIS maps. Then `ypserv -ir` dumps them into the DIT. When the `-ir` option is used, the `LDAP_` prefixed maps are also generated or updated. Since these maps will be more recent than the old style maps, `ypmake` will not be reported as erroneous when it is run.
Definesthehostsandnetworksthatare
grantedaccesstoinformationintheserved
domain. It is read at startup time by both
ypserv and ypxfrd.

/var/yp/ypserv.log
If the /var/yp/ypserv.log file exists when
ypserv starts up, log information is written to
it when error conditions arise.

/var/yp/binding/domainname/ypservers
Lists the NIS server hosts that
ypbind can
bind to.

Notes
ypserv supports multiple domains. The ypserv process determines the domains it serves by
looking for directories of the same name in the directory /var/yp. It replies to all broadcasts
requesting yp service for that domain.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The
functionality of the two remains the same; only the name has changed. The name Yellow
Pages is a registered trademark in the United Kingdom of British Telecommunications PLC,
and must not be used without permission.

NIS uses ndbm() files to store maps. Therefore, it is subject to the 1024 byte limitations
described in the USAGE and NOTES sections of the ndbm(3C) man page.

The NIS server service is managed by the service management facility, smf(5), under the
service identifier:
svc:/network/nis/server:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can
be performed using svcadm(1M). The service's status can be queried using the svc(1)
command.
ypserv_resolv is an auxiliary process that provides DNS forwarding service for NIS hosts requests to ypserve that is running in the NIS compatibility mode. It is generally started by invoking ypserve(1M) with the -d option. Although it is not recommended, ypserve_resolv can also be started independently with the options shown below.

This command requires that the /etc/resolv.conf file be setup for communication with a DNS nameserver. The dig(1M) utility can be used to verify communication with a DNS nameserver. See resolv.conf(4) and dig(1M).

Options
- F Run in foreground.
- C fd Use fd for service xprt.
- v Verbose. Send output to the syslog daemon.
- V Verbose. Send output to stdout.
- t xx Use transport xx.
- p yy Use transient program# yy.

ypset – point ypbind at a particular server

**Synopsis**

```
/usr/sbin/ypset [-d ypdomain] [-h host] server
```

**Description**

In order to run `ypset`, `ypbind` must be initiated with the `-ypset` or `-ypsetme` options. See `ypbind(1M)`. `ypset` tells `ypbind` to get NIS services for the specified `ypdomain` from the `ypserv` process running on `server`. If `server` is down, or is not running `ypserv`, this might not be discovered until an NIS client process tries to obtain a binding for the domain. At this point, the binding set by `ypset` is tested by `ypbind`. If the binding is invalid, `ypbind` attempts to rebind for the same domain.

`ypset` is useful for binding a client node that is not on a broadcast net, or is on a broadcast net that is not running an NIS server host. It is also useful for debugging NIS client applications, for instance, where an NIS map exists only at a single NIS server host.

Where several hosts on the local net are supplying NIS services, `ypbind` can rebind to another host, even while you attempt to find out if the `ypset` operation succeeded. For example, if you enter the `ypset` command below, you might get the subsequent response from `ypwhich`:

```
example% ypset host1
example% ypwhich
host2
```

The sequence shown above is a function of the NIS subsystem's attempt to load-balance among the available NIS servers, and occurs when `host1` does not respond to `ypbind` because it is not running `ypserv` (or is overloaded), and `host2`, running `ypserv`, obtains the binding.

`server` indicates which NIS server to bind to, and must be specified as a name or an IP address. This works only if the node has a current valid binding for the domain in question and `ypbind` has been set to allow use of `ypset`. In most cases, `server` should be specified as an IP address.

`ypset` tries to bind over a connectionless transport. The NIS library call, `yp_all()`, uses connection-oriented transport and derives the NIS server's address based on the connectionless address supplied by `ypset`.

Refer to `ypfiles(4)` for an overview of the NIS name service.

**Options**

- `-d ypdomain` Use `ypdomain`, instead of the default domain.
- `-h host` Set `ypbind`'s binding on `host`, instead of locally. Specify `host` as a name.

*Oracle Solaris Administration: Common Tasks*

**Notes**  The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two services remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.
ypxfr(1M)

Name  ypxfr, ypxfr_1perday, ypxfr_1perhour, ypxfr_2perday – transfer NIS map from a NIS server to host

Synopsis  /usr/lib/netsvc/yp/ypxfr [-c] [-f] [-C tid prog server]
           [-d ypdomain] [-h host] [-s ypdomain] mapname

Description  The ypxfr command moves an NIS map in the default domain for the local host to the local host by making use of normal NIS services. It creates a temporary map in the directory /var/yp/ypdomain (this directory must already exist; ypdomain is the default domain for the local host), fills it by enumerating the map's entries, fetches the map parameters (master and order number), and loads them. It then deletes any old versions of the map and moves the temporary map to the real name.

If run interactively, ypxfr writes its output to the terminal. However, if it is started without a controlling terminal, and if the log file /var/yp/ypxfr.log exists, it appends all its output to that file. Since ypxfr is most often run from the privileged user's crontab file, or by ypserv, the log file can retain a record of what was attempted, and what the results were.

For consistency between servers, ypxfr should be run periodically for every map in the NIS database. Different maps change at different rates: a map might not change for months at a time, for instance, and can therefore be checked only once a day. Some maps might change several times per day. In such a case, you might want to check hourly for updates. A crontab(1) entry can be used to automatically perform periodic updates. Rather than having a separate crontab entry for each map, you can group commands to update several maps in a shell script. Examples (mnemonically named) are in /usr/sbin/yp: ypxfr_1perday, ypxfr_2perday, and ypxfr_1perhour.

Refer to ypfiles(4) for an overview of the NIS name service.

Options  -c  Do not send a “Clear current map” request to the local ypserv process. Use this flag if ypserv is not running locally at the time you are running ypxfr. Otherwise, ypxfr complains that it cannot communicate with the local ypserv, and the transfer fails.

-f  Force the transfer to occur even if the version at the master is not more recent than the local version.

-C tid prog server  This option is for use only by ypserv. When ypserv starts ypxfr, it specifies that ypxfr should call back a yppush process at the host server, registered as program number prog, and waiting for a response to transaction tid.

-d ypdomain  Specify a domain other than the default domain.

-h host  Get the map from host, regardless of the master. If host is not specified, ypxfr asks the NIS service for the name of the master, and tries to get the map from there. host must be a valid host name.
Specify a source domain from which to transfer a map that should be the same across domains.

Files
/var/yp/ypxfr.log Log file
/usr/lib/netsvc/yp/ypxfr_1perday Script to run one transfer per day, for use with cron(1M)

zdb – ZFS debugger

**Description**

The `zdb` command is used by support engineers to diagnose failures and gather statistics. Since the ZFS file system is always consistent on disk and is self-repairing, `zdb` should only be run under the direction by a support engineer.

If no arguments are specified, `zdb` performs basic consistency checks on the pool and associated datasets, and report any problems detected.

Any options supported by this command are internal to Sun and subject to change at any time.

**Exit Status**

The following exit values are returned:

- **0**: The pool is consistent.
- **1**: An error was detected.
- **2**: Invalid command line options were specified.

**Name**
zdump – time zone dumper

**Synopsis**
zdump [ --version ] [ -v ] [ -c ] [ loyear, hiyear ] [ zonename ] ...

**Description**
The zdump command prints the current time for each time zone (zonename) listed on the command line. Specify zonename as the name of the time zone database file relative to /usr/share/lib/zoneinfo.

Specifying an invalid time zone (zonename) to zdump does not return an error, rather zdump uses UTC. This is consistent with the behavior of the library calls; zdump reflects the same behavior of the time routines in libc. See ctime(3C) and mktime(3C).

**Options**
The following options are supported:

- `--version` Outputs version information and exits.
- `-v` Displays the entire contents of the time zone database file for zonename. Prints the time at the lowest possible time value; the time one day after the lowest possible time value; the times both one second before and exactly at each time at which the rules for computing local time change; the time at the highest possible time value; and the time at one day less than the highest possible time value. See mktime(3C) and ctime(3C) for information regarding time value (time_t). Each line of output ends with `isdst=1` if the given time is Daylight Saving Time, or `isdst=0` otherwise.
- `-c` [ loyear, hiyear ] Cuts off the verbose output near the start of the given year(s). By default, the program cuts off verbose output near the start of the years -500 and 2500.

**Exit Status**
The following exit values are returned:

0 Successful completion.
1 An error occurred.

**Files**
/usr/share/lib/zoneinfo Standard zone information directory

Description
The zfs command configures ZFS datasets within a ZFS storage pool, as described in zpool(1M). A dataset is identified by a unique path within the ZFS namespace. For example:

pool/(filesystem, volume, snapshot)

where the maximum length of a dataset name is MAXNAMELEN (256 bytes).

A dataset can be one of the following:

file system
A ZFS dataset of type filesystem can be mounted within the standard system namespace and behaves like other file systems. While ZFS file systems are designed to be POSIX compliant, known issues exist that prevent compliance in some cases. Applications that depend on standards conformance might fail due to nonstandard behavior when checking free file system space.

volume
A logical volume exported as a raw or block device. This type of dataset should only be used under special circumstances. File systems are typically used in most environments.

snapshot
A read-only version of a file system or volume at a given point in time. It is specified as filesystem@name or volume@name.

ZFS File System Hierarchy
A ZFS storage pool is a logical collection of devices that provide space for datasets. A storage pool is also the root of the ZFS file system hierarchy.

The root of the pool can be accessed as a file system, such as mounting and unmounting, taking snapshots, and setting properties. The physical storage characteristics, however, are managed by the zpool(1M) command.

See zpool(1M) for more information on creating and administering pools.

Snapshots
A snapshot is a read-only copy of a file system or volume. Snapshots can be created extremely quickly, and initially consume no additional space within the pool. As data within the active dataset changes, the snapshot consumes more data than would otherwise be shared with the active dataset.

Snapshots can have arbitrary names. Snapshots of volumes can be cloned or rolled back, but cannot be accessed independently.

File system snapshots can be accessed under the .zfs/snapshot directory in the root of the file system. Snapshots are automatically mounted on demand and may be unmounted at regular intervals. The visibility of the .zfs directory can be controlled by the snapdir property.
Clones

A clone is a writable volume or file system whose initial contents are the same as another dataset. As with snapshots, creating a clone is nearly instantaneous, and initially consumes no additional space.

Clones can only be created from a snapshot. When a snapshot is cloned, it creates an implicit dependency between the parent and child. Even though the clone is created somewhere else in the dataset hierarchy, the original snapshot cannot be destroyed as long as a clone exists. The origin property exposes this dependency, and the destroy command lists any such dependencies, if they exist.

The clone parent-child dependency relationship can be reversed by using the promote subcommand. This causes the "origin" file system to become a clone of the specified file system, which makes it possible to destroy the file system that the clone was created from.

Mount Points

Creating a ZFS file system is a simple operation, so the number of file systems per system is likely to be numerous. To cope with this, ZFS automatically manages mounting and unmounting file systems without the need to edit the /etc/vfstab file. All automatically managed file systems are mounted by ZFS at boot time.

By default, file systems are mounted under /path, where path is the name of the file system in the ZFS namespace. Directories are created and destroyed as needed.

A file system can also have a mount point set in the mountpoint property. This directory is created as needed, and ZFS automatically mounts the file system when the zfs mount -a command is invoked (without editing /etc/vfstab). The mountpoint property can be inherited, so if pool/home has a mount point of /export/stuff, then pool/home/user automatically inherits a mount point of /export/stuff/user.

A file system can be mounted temporarily at a location other than the file system’s persistent mount point by specifying the -o mountpoint=value option to the zfs mount command. This is only permitted for file systems with non-legacy mount points.

A file system mountpoint property of none prevents the file system from being mounted.

If needed, ZFS file systems can also be managed with traditional tools (mount, umount, /etc/vfstab). If a file system’s mount point is set to legacy, ZFS makes no attempt to manage the file system, and the administrator is responsible for mounting and unmounting the file system.

Zones

The physical properties of an added file system are controlled by the global administrator. However, the zone administrator can create, modify, or destroy files within the added file system, depending on how the file system is mounted.

A dataset can also be delegated to a non-global zone by using the zonecfg add dataset subcommand. You cannot delegate a dataset to one zone and the children of the same dataset to another zone. The zone administrator can change properties of the dataset or any of its children. However, the quota property is controlled by the global administrator.
A ZFS volume can be added as a device to a non-global zone by using the `zonecfg add device` subcommand. However, its physical properties can be modified only by the global administrator.

For more information about `zonecfg` syntax, see `zonecfg(1M)`.

After a dataset is delegated to a non-global zone, the zoned property is automatically set. A zoned file system can only be mounted in the global zone by using a temporary `mountpoint` property (see “Temporary Mount Point Properties”).

The global administrator can forcibly clear the zoned property, though this should be done with extreme care. The global administrator should verify that all the mount points are acceptable before clearing the property.

**Deduplication**

Deduplication is the process of removing redundant data at the block-level, reducing the total amount of data stored. Deduplication is pool-wide; each dataset can opt in or out using its own `dedup` property. If a file system has the `dedup` property enabled, duplicate data blocks are removed synchronously on write. The result is that only unique data are stored and common components are shared among files in all datasets in the pool that have `dedup` enabled.

**Encryption**

For a full description of ZFS encryption and the ZFS encryption syntax, see `zfs_encrypt(1M)`.

**Native Properties**

Properties are divided into two types, native properties and user-defined (or *user*) properties. Native properties either provide internal statistics or control ZFS behavior. In addition, native properties are either editable or read-only. User properties have no effect on ZFS behavior, but you can use them to annotate datasets in a way that is meaningful in your environment. For more information about user properties, see the “User Properties” section, below.

Every dataset has a set of properties that provide statistics about the dataset as well as control various behaviors. Properties are inherited from the parent unless overridden by the child. Some properties apply only to certain types of datasets (file systems, volumes, or snapshots).

The values of numeric properties can be specified using human-readable suffixes (for example, k, KB, M, Gb, and so forth, up to Z for zettabyte). The following are all valid (and equal) specifications:

`1536M`, `1.5g`, `1.50GB`

The values of non-numeric properties are case-sensitive and must be lowercase, except for the `mountpoint` property.

The following native properties consist of read-only statistics about the dataset. These properties can be neither set, nor inherited. Native properties apply to all dataset types unless otherwise noted.
available
The amount of space available to the dataset and all its children, assuming that there is no
other activity in the pool. Because space is shared within a pool, availability can be limited
by any number of factors, including physical pool size, quotas, reservations, or other
datasets within the pool.

This property can also be referred to by its shortened column name, avail.

compressratio
The compression ratio achieved for this dataset, expressed as a multiplier. Compression
can be turned on by running: zfs set compression=on dataset. The default value is off.

creation
The time this dataset was created.

defer_destroy
This property is on if the snapshot has been marked for deferred destroy by using the zfs
destroy -d command. Otherwise, the property is off.

keychangedate
For more information, see zfs_encrypt(1M).

keystatus
For more information, see zfs_encrypt(1M).

mounted
For file systems, indicates whether the file system is currently mounted. This property can
be either yes or no.

origin
For cloned file systems or volumes, the snapshot from which the clone was created. The
origin cannot be destroyed (even with the -r or -f options) so long as a clone exists.

referenced
The amount of data that is accessible by this dataset, which may or may not be shared with
other datasets in the pool. When a snapshot or clone is created, it initially references the
same amount of space as the file system or snapshot it was created from, since its contents
are identical.

This property can also be referred to by its shortened column name, refer.

rekeydate
For more information, see zfs_encrypt(1M).

type
The type of dataset: filesystem, volume, or snapshot.

used
The amount of space consumed by this dataset and all its descendents. This is the value that
is checked against this dataset’s quota and reservation. The space used does not include this
dataset’s reservation, but does take into account refreservation (through
usedbyrefreservation) and the reservations of any descendent datasets (through usedbychildren). The amount of space that a dataset consumes from its parent, as well as the amount of space that are freed if this dataset is recursively destroyed, is the greater of its space used and its reservation.

When snapshots (see the "Snapshots" section) are created, their space is initially shared between the snapshot and the file system, and possibly with previous snapshots. As the file system changes, space that was previously shared becomes unique to the snapshot, and counted in the snapshot’s space used. Additionally, deleting snapshots can increase the amount of space unique to (and used by) other snapshots.

The amount of space used, available, or referenced does not take into account pending changes. Pending changes are generally accounted for within a few seconds. Committing a change to a disk using fsync(3C) or O_SYNC does not necessarily guarantee that the space usage information is updated immediately.

The usedby* properties decompose the used properties into the various reasons that space is used. Specifically, used = usedbychildren + usedbydataset + usedbyrefreservation +, usedbysnapshots. These properties are only available for datasets created on pools that are version 13 or higher.

usedbychildren
The amount of space used by children of this dataset, which would be freed if all the dataset’s children were destroyed.

usedbydataset
The amount of space used by this dataset itself, which would be freed if the dataset was destroyed (after first removing any refreservation and destroying any necessary snapshots or descendents).

usedbyrefreservation
The amount of space used by a refreservation set on this dataset, which would be freed if the refreservation was removed.

Space accounted for by this property represents potential consumption by future writes, reserved in advance to prevent write allocation failures in this dataset. This can include unwritten data, space currently shared with snapshots, and compression savings for volumes (which may be lost when replaced with less compressible data). When allocations for later writes increase usedbydataset or usedbysnapshots, usedbyrefreservation will decrease accordingly.

usedbysnapshots
The amount of space consumed by snapshots of this dataset. In particular, it is the amount of space that would be freed if all of this dataset's snapshots were destroyed. Note that this is not simply the sum of the snapshots’ used properties because space can be shared by multiple snapshots.
userused@

The amount of space consumed by the specified user in this dataset. Space is charged to the
owner of each file, as displayed by `ls -l`. The amount of space charged is displayed by `du`
and `ls -s`. See the `zfs userspace` subcommand for more information.

Unprivileged users can access only their own space usage. The root user, or a user who has
been granted the userused privilege with `zfs allow`, can access everyone's usage.

The `userused@...` properties are not displayed by `zfs get all`. The user's name must be
 appended after the `@` symbol, using one of the following forms:

- POSIX name (for example, `joe`)
- POSIX numeric ID (for example, `789`)
- SID name (for example, `joe.smith@mydomain`)
- SID numeric ID (for example, `S-1-123-456-789`)

userrefs

This property is set to the number of user holds on this snapshot. User holds are set by
using the `zfs hold` command.

groupused@

The amount of space consumed by the specified group in this dataset. Space is charged to
the group of each file, as displayed by `ls -l`. See the `userused@user` property for more
information.

Unprivileged users can only access their own groups' space usage. The root user, or a user
who has been granted the groupused privilege with `zfs allow`, can access all groups' usage.

volblocksize=blocksize

For volumes, specifies the block size of the volume. The `blocksize` cannot be changed once
the volume has been written, so it should be set at volume creation time. The default
`blocksize` for volumes is 8 KB. Any power of 2 from 512 bytes to 1 MB is valid.

This property can also be referred to by its shortened column name, `volblock`.

The following native properties can be used to change the behavior of a ZFS dataset.

aclmode=discard | mask | passthrough

Controls how an ACL is modified during `chmod(2)`. A file system with an aclmode property
of discard (the default) deletes all ACL entries that do not represent the mode of the file.
An aclmode property of mask reduces user or group permissions. The permissions are
reduced so that they are no greater than the group permission bits, unless it is a user entry
that has the same UID as the owner of the file or directory. In this case, the ACL
permissions are reduced so that they are no greater than owner permission bits. mask also
preserves the ACL across mode changes (without an explicit ACL set [by means of
`chmod(1)`] between the mode changes). A file system with an aclmode property of
passthrough indicates that no changes will be made to the ACL other than generating the
necessary ACL entries to represent the new mode of the file or directory.
aclinherit=discard | noallow | restricted | passthrough | passthrough-x

Controls how ACL entries are inherited when files and directories are created. A file system with an aclinherit property of discard does not inherit any ACL entries. A file system with an aclinherit property value of noallow only inherits inheritable ACL entries that specify "deny" permissions. The property value restricted (the default) removes the write_acl and write_owner permissions when the ACL entry is inherited. A file system with an aclinherit property value of passthrough inherits all inheritable ACL entries without any modifications made to the ACL entries when they are inherited. A file system with an aclinherit property value of passthrough-x has the same meaning as passthrough, except that all ACEs inherit the execute permission only if the file creation mode also requests the execute bit.

When the property value is set to passthrough, files are created with a mode determined by the inheritable ACEs. If no inheritable ACEs exist that affect the mode, then the mode is set in accordance to the requested mode from the application.

atime=on | off

Controls whether the access time for files is updated when they are read. Turning this property off avoids producing write traffic when reading files and can result in significant performance gains, though it might confuse mailers and other similar utilities. The default value is on.

canmount=on | off | noauto

If this property is set to off, the file system cannot be mounted, and is ignored by zfs mount -a. Setting this property to off is similar to setting the mountpoint property to none, except that the dataset still has a normal mountpoint property, which can be inherited. Setting this property to off allows datasets to be used solely as a mechanism to inherit properties. One example of setting canmount=off is to have two datasets with the same mountpoint, so that the children of both datasets appear in the same directory, but might have different inherited characteristics.

When the noauto option is set, a dataset can only be mounted and unmounted explicitly. The dataset is not mounted automatically when the dataset is created or imported, nor is it mounted by the zfs mount -a command or unmounted by the zfs unmount -a command.

This property is not inherited.

checksum=on | off | fletcher2, | fletcher4 | sha256 | sha256+mac

Controls the checksum used to verify data integrity. The default value is on, which automatically selects an appropriate algorithm (currently, fletcher4, but this may change in future releases). The value off disables integrity checking on user data. Disabling checksums is NOT a recommended practice.

Changing this property affects only newly-written data.
The value of sha256+mac is only available when encryption is enabled. The checksum property becomes readonly when encryption is enabled, and then is always set to sha256+mac.

compression=on | off | lzjb | gzip | gzip-N | zle

Controls the compression algorithm used for this dataset. The lzjb compression algorithm is optimized for performance while providing decent data compression. Setting compression to on uses the lzjb compression algorithm. The gzip compression algorithm uses the same compression as the gzip(1) command. You can specify the gzip level by using the value gzip-N where N is an integer from 1 (fastest) to 9 (best compression ratio). Currently, gzip is equivalent to gzip-6 (which is also the default for gzip(1)).

This property can also be referred to by its shortened column name compress. Changing this property affects only newly-written data.

copies=1 | 2 | 3

Controls the number of copies of data stored for this dataset. These copies are in addition to any redundancy provided by the pool, for example, mirroring or RAID-Z. The copies are stored on different disks, if possible. The space used by multiple copies is charged to the associated file and dataset, changing the used property and counting against quotas and reservations.

Changing this property only affects newly-written data. Therefore, set this property at file system creation time by using the -o copies=N option.

When encryption is enabled on a dataset, copies can be set to a maximum of 2.

dedup=on | off | verify | sha256 | verify

Controls whether deduplication is in effect for a dataset. The default value is off. The default checksum used for deduplication is sha256 (subject to change). When dedup is enabled, the dedup checksum algorithm overrides the checksum property. Setting the value to verify is equivalent to specifying sha256, verify.

If the property is set to verify, then, whenever two blocks have the same signature, ZFS will do a byte-for-byte comparison with the existing block to ensure that the contents are identical.

devices=on | off

Controls whether device nodes can be opened on this file system. The default value is on.

exec=on | off

Controls whether processes can be executed from within this file system. The default value is on.

logbias = latency | throughput

Controls how ZFS optimizes synchronous requests for this dataset. If logbias is set to latency, ZFS uses the pool's separate log devices, if any, to handle the requests at low latency. If logbias is set to throughput, ZFS does not use the pool's separate log devices.
Instead, ZFS optimizes synchronous operations for global pool throughput and efficient use of resources. The default value is `latency`.

`mlslabel=label|none`

See the `multilevel` property for a description of the behavior of the `mlslabel` property on multilevel file systems. The following `mlslabel` description applies to non-multilevel file systems.

The `mlslabel` property is a sensitivity label that determines if a dataset can be mounted in a zone on a system with Trusted Extensions enabled. If the labeled dataset matches the labeled zone, the dataset can be mounted and accessed from the labeled zone.

When the `mlslabel` property is not set, the default value is `none`. Setting the `mlslabel` property to `none` is equivalent to removing the property.

The `mlslabel` property can be modified only when Trusted Extensions is enabled and only with appropriate privilege. Rights to modify it cannot be delegated. When changing a label to a higher label or setting the initial dataset label, the `{PRIV_FILE_UPGRADE_SL}` privilege is required. When changing a label to a lower label or the default (none), the `{PRIV_FILE_DOWNGRADE_SL}` privilege is required. Changing the dataset to labels other than the default can be done only when the dataset is not mounted. When a dataset with the default label is mounted into a labeled zone, the mount operation automatically sets the `mlslabel` property to the label of that zone.

When Trusted Extensions is not enabled, only datasets with the default label (`none`) can be mounted.

`mountpoint=path|none|legacy`

Controls the mount point used for this file system. See the “Mount Points” section for more information on how this property is used.

When the `mountpoint` property is changed for a file system, the file system and any children that inherit the mount point are unmounted. If the new value is `legacy`, then they remain unmounted. Otherwise, they are automatically remounted in the new location if the property was previously `legacy` or `none`, or if they were mounted before the property was changed. In addition, any shared file systems are unshared and shared in the new location.

`nbmand=on|off`

For more information, see `zfs_share(1M)`.

`primarycache=all|none|metadata`

Controls what is cached in the primary cache (ARC). If this property is set to `all`, then both user data and metadata is cached. If this property is set to `none`, then neither user data nor metadata is cached. If this property is set to `metadata`, then only metadata is cached. The default value is `all`. 

---

zfs(1M)
**quota=size|none**

Limits the amount of space a dataset and its descendents can consume. This property enforces a hard limit on the amount of space used. This includes all space consumed by descendents, including file systems and snapshots. Setting a quota on a descendent of a dataset that already has a quota does not override the ancestor's quota, but rather imposes an additional limit.

Quotas cannot be set on volumes, as the `volsize` property acts as an implicit quota.

**sync=standard|always|disabled**

Determines the degree to which file system transactions are synchronized. This property can be set when a dataset is created, or dynamically, and will take effect immediately. This property can have one of the following settings:

- **standard**
  The default option. Synchronous file system transactions are written to the intent log and then all devices written are flushed to ensure the data is stable (that is, not cached by device controllers).

- **always**
  Each file system transaction is written and flushed to stable storage. This value has a significant performance penalty but might be appropriate for troubleshooting synchronous file system transactions.

- **disabled**
  Synchronous requests are disabled. File system transactions commit to stable storage only on the next DMU transaction group commit, which might be after many seconds. This setting gives the highest performance. However, it is very dangerous as ZFS would be ignoring the synchronous transaction demands of applications such as databases or NFS. Furthermore, when this setting is in effect for the currently active root or `/var` filesystem, out-of-spec behavior, application data loss, and increased vulnerability to replay attacks can result. Administrators should only use this option only when these risks are understood.

**userquota@user=size|none**

Limits the amount of space consumed by the specified user. Similar to the `refquota` property, the `userquota` space calculation does not include space that is used by descendents datasets, such as snapshots and clones. User space consumption is identified by the `userspace@user` property.

Enforcement of user quotas may be delayed by several seconds. This delay means that a user might exceed her quota before the system notices that she is over quota. The system would then begin to refuse additional writes with the `EDQUOT` error message. See the `zfs userspace` subcommand for more information.

Unprivileged users can only access their own groups’ space usage. The root user, or a user who has been granted the `userquota` privilege with `zfs allow`, can get and set everyone’s quota.
This property is not available on volumes, on file systems before version 4, or on pools before version 15. The userquota@... properties are not displayed by zfs get all. The user’s name must be appended after the @ symbol, using one of the following forms:

- **POSIX name** (for example, joe)
- **POSIX numeric ID** (for example, 789)
- **SID name** (for example, joe.smith@mydomain)
- **SID numeric ID** (for example, S-1-123-456-789)

**groupquota@group=size | none**

Limits the amount of space consumed by the specified group. Group space consumption is identified by the userquota@user property.

Unprivileged users can access only their own groups’ space usage. The root user, or a user who has been granted the groupquota privilege with zfs allow, can get and set all groups’ quotas.

**readonly=on | off**

Controls whether this dataset can be modified. The default value is off.

This property can also be referred to by its shortened column name, rdonly.

**recordsize=size**

Specifies a suggested block size for files in the file system. This property is designed solely for use with database workloads that access files in fixed-size records. ZFS automatically tunes block sizes according to internal algorithms optimized for typical access patterns.

For databases that create very large files but access them in small random chunks, these algorithms may be suboptimal. Specifying a recordsize greater than or equal to the record size of the database can result in significant performance gains. Use of this property for general purpose file systems is strongly discouraged, and may adversely affect performance.

The default recordsize is 128 KB. The size specified must be a power of two greater than or equal to 512 and less than or equal to 1 MB.

Changing the file system’s recordsize affects only files created afterward; existing files and received data are unaffected.

This property can also be referred to by its shortened column name, recsize.

**refquota=size | none**

Limits the amount of space a dataset can consume. This property enforces a hard limit on the amount of space used. This hard limit does not include space used by descendents, including file systems and snapshots.

**refreservation=size | none**

The minimum amount of space guaranteed to a dataset, not including its descendents. When the usedbydataset space is below this value, the dataset is treated as if it were taking up the amount of space specified by refreservation. The usedbyrefreservation figure...
represents this extra space, adding to the total used space charged to the dataset, and in turn consuming from the parent datasets' usage, quotas, and reservations. This protects the dataset from overcommitment of pool resources, by ensuring that space for future writes is reserved in advance.

Space shared with snapshots can later be replaced with new data, and the snapshot represents a commitment to keep both copies. If `refreservation` is set, `usedbyrefreservation` must be increased to the full size of `refreservation` when taking a new snapshot, accounting for this commitment. If there is insufficient space available to the dataset for this increase, snapshot creation will be denied.

This property can also be referred to by its shortened column name, `refreserv`.

`reservation=size|none`

The minimum amount of space guaranteed to a dataset and its descendents. When the amount of space used is below this value, the dataset is treated as if it were taking up the amount of space specified by its reservation. Reservations are accounted for in the parent datasets' space used, and count against the parent datasets' quotas and reservations.

This property can also be referred to by its shortened column name, `reserv`.

`rstchown=on|off`

Indicates whether the file system restricts users from giving away their files by means of `chown(1)` or the `chown(2)` system call. The default is to restrict `chown`. When `rstchown` is off then `chown` will act as if the user has the PRIV_FILE_CHOWN_SELF privilege.

`secondarycache=all|none|metadata`

Controls what is cached in the secondary cache (L2ARC). If this property is set to `all`, then both user data and metadata is cached. If this property is set to `none`, then neither user data nor metadata is cached. If this property is set to `metadata`, then only metadata is cached. The default value is `all`.

`setuid=on|off`

Controls whether the set-UID bit is respected for the file system. The default value is `on`.

`shadow=URI|none`

Identifies a ZFS file system as a `shadow` of the file system described by the `URI`. Data is migrated to a shadow file system with this property set from the file system identified by the `URI`. The file system to be migrated must be read-only for a complete migration.

Access to a directory that is not yet migrated in the shadow file system is blocked until the entire directory is migrated. Access to a file that is not yet migrated in the shadow file system causes only a portion of the file being accessed to be migrated. Multiple processes can migrate different portions of a file at the same time.

Two forms of `URI` are accepted, one for migrating a local file system to another file system on the same physical system, and one for remotely migrating a file system from an NFS server. The forms are:
If `shadowd(1M)` is still running when the migration is complete, the file system is automatically remounted with the shadow property set to `none`. Or, when the migration is complete, you can manually set the shadow property to `none`.

```
sharenfs=on|off
For more information, see `zfs_share(1M)`.
```

```
sharesmb=on|off
For more information, see `zfs_share(1M)`.
```

```
snapdir=hidden|visible
Controls whether the `.zfs` directory is hidden or visible in the root of the file system as discussed in the “Snapshots” section. The default value is `hidden`.
```

```
version=1|2|current
The on-disk version of this file system, which is independent of the pool version. This property can only be set to later supported versions. See the `zfs upgrade` command.
```

```
volsize=size
Specifies the logical size of the volume. By default, creating a volume establishes a reservation that is a somewhat larger than the actual logical volume size, to account for ZFS metadata overhead. Any changes to `volsize` are reflected in an equivalent change to the reservation. The `volsize` can only be set to a multiple of `voltblocksize`, and cannot be zero.

The reservation is set on the volume to prevent unexpected behavior for consumers. Without the reservation, the volume could run out of space, resulting in undefined behavior or data corruption, depending on how the volume is used. These effects can also occur when the volume size is changed while it is in use (particularly when shrinking the size). Extreme care should be used when adjusting the volume size. Though not recommended, a sparse volume (also known as thin provisioning) can be created by specifying the `-s` option to the `zfs create -V` command. A sparse volume is a volume where the reservation is less then the volume size. Consequently, writes to a sparse volume can fail with ENOSPC when the pool is low on space. For a sparse volume, changes to `volsize` are not reflected in the reservation.
```

```
vscan=on|off
For more information, see `zfs_share(1M)`.
```

```
xattr=on|off
Controls whether extended attributes are enabled for this file system. The default value is on.
```

```
zoned=on|off
Controls whether the dataset is managed from a non-global zone. See the “Zones” section for more information. The default value is off.
```

file://path
nfs://host/path
The following properties cannot be changed after the file system is created and, therefore, should be set when the file system is created. If the properties are not set with the `zfs create` or `zpool create` commands, these properties are inherited from the parent dataset. If the parent dataset lacks these properties due to having been created prior to these features being supported, the new file system will have the default values for these properties.

**casesensitivity** = sensitive | insensitive | mixed
   For more information, see `zfs_share(1M)`.

**normalization = none | formC | formD | formKC | formKD**
   For more information, see `zfs_share(1M)`.

**utf8only = on | off**
   For more information, see `zfs_share(1M)`.

**encryption = off | on | aes-128-ccm | aes-192-ccm | aes-256-ccm | aes-128-gcm | aes-192-gcm | aes-256-gcm**
   For more information, see `zfs_encrypt(1M)`.

**multilevel = on | off**
   This property can only be used on a system with Trusted Extensions enabled. The default value is off.

Objects in a multilevel file system are individually labeled with an explicit sensitivity label attribute that is automatically generated. Objects can be relabeled in place by changing this label attribute, by using the `setlabel(1)` or `setflabel(3TSOL)` interfaces.

Zone datasets, system root datasets, and other datasets containing packaged Solaris code should not be multilevel.

There are differences in the `mlslabel` property on multilevel file systems. The `mlslabel` value defines the highest possible label that objects in the file system can have. Attempts to create a file at (or relabel a file to) a label higher than the `mlslabel` are disallowed. Mount policy based on `mlslabel` does not apply to multilevel file systems.

For multilevel file systems, the `mlslabel` property can be set explicitly during file system creation, otherwise a default `mlslabel` property of `ADMIN_HIGH` will be automatically created. After creating a multilevel file system, the `mlslabel` can be changed, but it cannot be changed to a lower label, nor be removed, nor set to `none`.

The following property must be specified at creation time and can modified by using special commands:

**keysource = raw | hex | passphrase | prompt | file**
   For more information, see `zfs_encrypt(1M)`.
When a file system is mounted, either through the legacy `mount(1M)` command or the `zfs mount` command, its mount options are set according to its properties. The correlation between properties and mount options is as follows:

<table>
<thead>
<tr>
<th>PROPERTY</th>
<th>MOUNT OPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>devices</td>
<td>devices/nodes/ces</td>
</tr>
<tr>
<td>mountpoint</td>
<td>mountpoint</td>
</tr>
<tr>
<td>exec</td>
<td>exec/noexec</td>
</tr>
<tr>
<td>readonly</td>
<td>ro/rw</td>
</tr>
<tr>
<td>setuid</td>
<td>setuid/nosetuid</td>
</tr>
<tr>
<td>xattr</td>
<td>xattr/noxattr</td>
</tr>
<tr>
<td>rståchown</td>
<td>rståchown/norståchown</td>
</tr>
</tbody>
</table>

In addition, these options can be set on a per-mount basis using the `-o` option, without affecting the property that is stored on disk. The values specified on the command line override the values stored in the dataset. The `-nosuid` option is an alias for `nodevices`, `nosetuid`. These properties are reported as temporary by the `zfs get` command. For properties other than `mountpoint`, if the properties are changed while the dataset is mounted, the new setting overrides any temporary settings. The `mountpoint` property cannot be changed while a temporary `mountpoint` property is in effect (that is, while the dataset is mounted at a temporary location).

User properties have no effect on ZFS behavior, but applications or administrators can use them to annotate datasets (file systems, volumes, and snapshots).

User property names must contain a colon (`:`) character to distinguish them from native properties. They may contain lowercase letters, numbers, and the following punctuation characters: colon (`:`), dash (`-`), period (`.`), and underscore (`_`). The expected convention is that the property name is divided into two portions such as `module:property`, but this namespace is not enforced by ZFS. User property names can be at most 256 characters, and cannot begin with a dash (`-`).

When making programmatic use of user properties, it is strongly suggested to use a reversed DNS domain name for the `module` component of property names to reduce the chance that two independently-developed packages use the same property name for different purposes. In the Oracle Solaris release, the `com.oracle` user property is reserved for `beadm` command and library.

The values of user properties are arbitrary strings, are always inherited, and are never validated. All of the commands that operate on properties (`zfs list`, `zfs get`, and so forth) can be used to manipulate both native properties and user properties. Use the `zfs inherit` command to clear a user property. If the property is not defined in any parent dataset, it is removed entirely. Property values are limited to 1024 characters.
During an initial installation, a swap device and dump device are created on ZFS volumes in the ZFS root pool. Separate ZFS volumes must be used for the swap area and dump devices. Do not swap to a file on a ZFS file system. A ZFS swap file configuration is not supported.

You can encrypt a ZFS volume used as a swap device by specifying the encryption property for that device and specifying the encrypted option in `vfstab(4)`. For more information about the encryption property, see `zfs_encrypt.1m`.

If you need to change your swap area or dump device after the system is installed or upgraded, use the `swap(1M)` and `dumpadm(1M)` commands. If you need to change the size of your swap area or dump device, see the Oracle Solaris 11.1 Administration: ZFS File Systems

**Subcommands**

All subcommands that modify state are logged persistently to the pool in their original form.

- `zfs ?`
  - Displays a help message.

- `zfs help command | help | property property-name | permission`
  - Displays `zfs` command usage information. You can display help for a specific command, property, or delegated permission. If you display help for a specific command or property, the command syntax or property value is displayed. Using `zfs help` without any arguments displays a complete list of `zfs` commands.

- `zfs help -l properties`
  - Displays `zfs` property information, including whether the property value is editable and inheritable, and their possible values.

- `zfs allow filesystem | volume`
- `zfs allow [-ldug] everyone|user|group[,...] perm[@setname[,...]] filesystem| volume`
- `zfs allow [-ld] -e perm[@setname[,...]] filesystem| volume`
- `zfs allow -c perm[@setname[,...]] filesystem|volume`
- `zfs allow -s @setname perm[@setname[,...]] filesystem|volume`

  For a full description of the `zfs allow` syntax and examples, see `zfs_allow(1M)`.

- `zfs clone [-p] [-K] [-o property=value] ... snapshot filesystem|volume`
  - Creates a clone of the given snapshot. See the “Clones” section for details. The target dataset can be located anywhere in the ZFS hierarchy, and is created as the same type as the original.

  - `-p`
    - Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the `mountpoint` property inherited from their parent. If the target file system or volume already exists, the operation completes successfully.

  - `-o property=value`
    - Sets the specified property; see `zfs create` for details.
For information, see `zfs_encrypt(1M)`.

```plaintext
zfs create [-p] [-o property=value] ... filesystem
```

Creates a new ZFS file system. The file system is automatically mounted according to the `mountpoint` property inherited from the parent.

- `-p`

Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the `mountpoint` property inherited from their parent. Any property specified on the command line using the `-o` option is ignored. If the target filesystem already exists, the operation completes successfully.

- `-o property=value`

Sets the specified property as if the command `property=value` was invoked at the same time the dataset was created. Any editable ZFS property can also be set at creation time. Multiple `-o` options can be specified. An error results if the same property is specified in multiple `-o` options.

```plaintext
zfs create [-ps] [-b blocksize] [-o property=value] ... -V size volume
```

Creates a volume of the given size. The volume is exported as a block device in `/dev/zvol/{dsk, rdsk}/path`, where `path` is the name of the volume in the ZFS namespace. The size represents the logical size as exported by the device. By default, a reservation of equal size is created.

`size` is automatically rounded up to the nearest 128 KB to ensure that the volume has an integral number of blocks regardless of `blocksize`.

- `-p`

Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the `mountpoint` property inherited from their parent. Any property specified on the command line using the `-o` option is ignored. If the target filesystem already exists, the operation completes successfully.

- `-s`

Creates a sparse volume with no reservation. See `volsize` in the Native Properties section for more information about sparse volumes.

- `-o property=value`

Sets the specified property as if the `property=value` command was invoked at the same time the dataset was created. Any editable ZFS property can also be set at creation time. Multiple `-o` options can be specified. An error results if the same property is specified in multiple `-o` options.

- `-b blocksize`

Equivalent to `-o volblocksize=blocksize`. If this option is specified in conjunction with `-o volblocksize`, the resulting behavior is undefined.
zfs destroy [-rRf] filesystem | volume
Destroys the given dataset. By default, the command unshares any file systems that are currently shared, unmounts any file systems that are currently mounted, and refuses to destroy a dataset that has active dependents (children or clones).

- r
Recursively destroy all children.

- R
Recursively destroy all dependents, including cloned file systems outside the target hierarchy.

- f
Force an unmount of any file systems using the unmount -f command. This option has no effect on non-file systems or unmounted file systems.

Extreme care should be taken when applying either the - r or the - f options, as they can destroy large portions of a pool and cause unexpected behavior for mounted file systems in use.

zfs destroy [-rRd] snapshot
The given snapshot is destroyed immediately if and only if the zfs destroy command without the - d option would have destroyed it. Such immediate destruction would occur, for example, if the snapshot had no clones and the user-initiated reference count were zero.

If the snapshot does not qualify for immediate destruction, it is marked for deferred deletion. In this state, it exists as a usable, visible snapshot until both of the preconditions listed above are met, at which point it is destroyed.

- d
Defer snapshot deletion.

- r
Destroy (or mark for deferred deletion) all snapshots with this name in descendent file systems.

- R
Recursively destroy all dependents.

zfs destroy [share]
The specified file system share is destroyed.

zfs diff [-FHte] [-o field] ... snapshot [snapshot | filesystem]
zfs diff -E [-FHT] [-o field] ... snapshot | filesystem
Gives a high-level description of the differences between a snapshot and a descendent dataset. The descendent can be either a snapshot of the dataset or the current dataset.

If a single snapshot is specified, then differences between that snapshot and the current dataset are given.
For each file that has undergone a change between the original snapshot and the descendent, the type of change is described along with the name of the file. In the case of a rename, both the old and new names are shown. Whitespace characters, backslash characters, and other non-printable or non-7-bit ASCII characters found in file names are displayed as a backslash character followed by the three-digit octal representation of the byte value.

If the -t option is specified, the first column of output from the command is the file’s st_ctim value. For deleted files, this is the final st_ctim in the earlier snapshot.

The type of change follows any timestamp displayed, and is described with a single character:

+ Indicates the file was added in the later dataset.
- Indicates the file was removed in the later dataset.
M Indicates the file was modified in the later dataset.
R Indicates the file was renamed in the later dataset.

If the -F option is specified, the next column of output is a single character describing the type of the file. The mappings are:

F Regular file
/ Directory
B Block device
> Door
| FIFO
@ Symbolic link
P Event portal
= Socket

If the modification involved a change in the link count of a non-directory file, the change is expressed as a delta within parentheses on the modification line. If the file was renamed, the old name is separated from the new with the string ->
.

If the -H option is selected, easier-to-parse output is produced. Fields are separated by a single tab, and no arrow string (->) is placed between the old and new names of a rename. No guarantees are made on the spacing between fields of non -H output.

If the -e option is selected, then all files added or modified between the two snapshots are enumerated and no deleted files are displayed. The change type always reports as + regardless of the type of modification.
If the -E option is selected, then differences are given as if from an empty snapshot to the specified snapshot or dataset.

If the -o field option is selected then only selected fields are displayed. Each line starts with the standard fields requested by the -F and -t options, followed by the fields requested in successive -o options. As with the -H option, all fields are separated by a single tab. The allowable field names include:

- **object**: The number printed by `ls -i` for the file
- **parent**: The number printed by `ls -i` for enclosing directory of the file
- **size**: The file size as displayed by `ls -s`
- **links**: The number of links to the file
- **linkscchange**: The change in the number of links to the file
- **name**: The name of the file
- **oldname**: The name of the file before the rename, or – (hyphen) if the file was not renamed
- **user**: The owner name of the file as displayed by `ls`
- **group**: The group name of the file as displayed by `ls`
- **ctime**: Timestamp when the file’s metadata was last modified
- **mtime**: Timestamp when the file was last modified
- **atime**: Timestamp when a file was last accessed
- **crtime**: Timestamp when a file was created

You must be granted the **diff** permission with `zfs allow` to use this subcommand, unless you already have the {PRIV_SYS_CONFIG} or {PRIV_SYS_MOUNT} privilege.

```
zfs get [-rHpe] [-d max] [-o all | field[,...] [-s source[,...]] all | property[,...] filesystem|volume|snapshot|share ...
zfs(1M) System Administration Commands-Part3 2619
```

Displays properties for the given datasets. If no datasets are specified, then the command displays properties for all datasets on the system. For each property, the following columns are displayed:

- **name**: Dataset name
- **property**: Property name
- **value**: Property value
- **source**: Property source. Can either be local, default, temporary, inherited, or none (-).

All columns except the RECEIVED column are displayed by default; specify particular or all columns, using the -o option. This command takes a comma-separated list of properties as described in the “Native Properties” and “User Properties” sections.
The special value `all` can be used to display all properties that apply to the given dataset’s type (filesystem, volume, or snapshot).

- `r`
  Recursively display properties for any children.

- `H`
  Display output in a form more easily parsed by scripts. Any headers are omitted, and fields are explicitly separated by a single tab instead of an arbitrary amount of space.

- `p`
  Displays numbers in parseable (exact) values.

- `e`
  Expands property sublists to any depth.

- `d max`
  Recursively displays any children of the dataset, limiting the recursion to `depth`. A depth of 1 will display only the dataset and its direct children.

- `o field`
  Set of fields to display. One or more of:

  - `name,property,value,received,source`

  Present multiple fields as a comma-separated list. The default value is:

  - `name,property,value,received,source`

  The keyword `all` specifies all sources.

- `s source`
  A comma-separated list of sources to display. Those properties coming from a source other than those in this list are ignored. Each source must be one of the following:

  - `local,default,inherited,temporary,received,none`

  The default value is all sources.

`zfs groupspace [-hniHp] [-o field[,...]] [-sS field[,...]] [-t type[,...]] filesystem | snapshot`

Displays space consumed by, and quotas on, each group in the specified filesystem or snapshot. This subcommand is identical to `zfs userspace`, except that the default types to display are `-t posixgroup,smbgroup`.

- `zfs hold [-r] tag snapshot ...`
  Adds a single reference, named with the `tag` argument, to the specified snapshot or snapshots. Each snapshot has its own tag namespace, and tags must be unique within that space.

  If a hold exists on a snapshot, attempts to destroy that snapshot by using the `zfs destroy` command return `EBUSY`. 
specifies that a hold with the given tag is applied recursively to the snapshots of all
descendent file systems.

zfs holds [-r] snapshot ...
   Lists all existing user references for the given snapshot or snapshots.
   -r
      Lists the holds that are set on the named descendent snapshots, in addition to listing the
      holds on the named snapshot.

zfs inherit [-rS] property filesystem|volume|snapshot|share ...
   Clears the specified property, causing it to be inherited from an ancestor. If no ancestor has
   the property set, then the default value is used. See the “Properties” section for a listing of
   default values, and details on which properties can be inherited.
   -r
      Recursively inherits the given property for all children.
   -S
      Reverts to the received property value, if any. If the property does not have a received
      value, the behavior of zfs inherit -S is the same as zfs inherit without -S. If the
      property does have a received value, zfs inherit masks the received value with the
      inherited value until zfs inherit -S reverts to the received value.

zfs key -l [-a | [-r] filesystem|volume]
zfs key -u [-f] [-a | [-r] filesystem|volume
zfs key -c [-o keysource=value] [-a | [-r] filesystem|volume}
zfs key -K [-a | [-r] filesystem|volume}
   For a full description of the zfs key syntax and examples, see zfs_encrypt(1M).

zfs list [-rH] [-d max] [-o property[...]] [-t type[...]] [-s property ] ... [-S property ] ...
   Lists the property information for the given datasets in tabular form. If specified, you can
   list property information by the absolute pathname or the relative pathname. By default, all
   file systems and volumes are displayed. Snapshots are displayed if the listsnaps property
   is on. The default is off. The following fields are displayed: name, used, available,
   referenced, mountpoint.
   -H
      Used for scripting mode. Do not print headers and separate fields by a single tab instead
      of arbitrary white space.
   -r
      Recursively displays any children of the dataset on the command line.
   -d depth
      Recursively displays any children of the dataset, limiting the recursion to maximum
      depth. A depth of 1 will display only the dataset and its direct children.
-o property
A comma-separated list of properties to display. The property must be:

- One of the properties described in the “Native Properties” section
- A user property
- The value name to display the dataset name
- The value space to display space usage properties on file systems and volumes. This is a shortcut for specifying
  -o name, avail, used, usedsnap, usedds, usedrefreserv, usedchild
  -t filesystem, volume syntax.

-s property
A property for sorting the output by column in ascending order based on the value of the property. The property must be one of the properties described in the “Properties” section, or the special value name to sort by the dataset name. Multiple properties can be specified at one time using multiple -s property options. Multiple -s options are evaluated from left to right in decreasing order of importance.

The following is a list of sorting criteria:

- Numeric types sort in numeric order.
- String types sort in alphabetical order.
- Types inappropriate for a row sort that row to the literal bottom, regardless of the specified ordering.
- If no sorting options are specified the existing behavior of zfs list is preserved.

-S property
Same as the -s option, but sorts by property in descending order.

-t type
A comma-separated list of types to display, where type is one of filesystem, snapshot, volume, or all. For example, specifying -t snapshot displays only snapshots. The following aliases can be used in place of the type specifiers: fs (filesystem), snap (snapshot), and vol (volume).

zfs mount
Displays all ZFS file systems currently mounted.

zfs mount [-vOS] [-o options] -a | filesystem
Mounts ZFS file systems. Invoked automatically as part of the boot process.

-0 options
An optional, comma-separated list of mount options to use temporarily for the duration of the mount. See the “Temporary Mount Point Properties” section for details.

-0
Perform an overlay mount. See mount(1M) for more information.
Report mount progress.

Mount all available ZFS file systems. Invoked automatically as part of the boot process.

Mount the specified file system.

A `zfs mount` operation for an encrypted dataset might prompt you for a key, depending on the `keysource` property value. This might occur, for example, if the `keysource` locator is set to `prompt`.

Promotes a clone file system to no longer be dependent on its `origin` snapshot. This makes it possible to destroy the file system that the clone was created from. The clone parent-child dependency relationship is reversed, so that the origin file system becomes a clone of the specified file system.

The snapshot that was cloned, and any snapshots previous to this snapshot, are now owned by the promoted clone. The space they use moves from the origin file system to the promoted clone, so enough space must be available to accommodate these snapshots. No new space is consumed by this operation, but the space accounting is adjusted. The promoted clone must not have any conflicting snapshot names of its own. The `rename` subcommand can be used to rename any conflicting snapshots.

Creates a snapshot whose contents are as specified in the stream provided on standard input. If a full stream is received, then a new file system is created as well. Streams are created using the `zfs send` subcommand, which by default creates a full stream. `zfs recv` can be used as an alias for `zfs receive`.

If an incremental stream is received, then the destination file system must already exist, and its most recent snapshot must match the incremental stream’s source. For ZFS volumes, the destination device link is destroyed and recreated, which means the volume cannot be accessed during the receive operation.

When a snapshot replication package stream that is generated by using the `zfs send -R` command is received, any snapshots that do not exist on the sending location are destroyed by using the `zfs destroy -d` command. If `property=value` or `-x property` is specified, it applies to the effective value of the property throughout the entire subtree of replicated datasets. Effective property values may be set or inherited, depending on the property and whether the dataset is the topmost in the replicated subtree. Received properties are retained in spite of being overridden and may be restored with `zfs inherit -rS` or `zfs send -Rb`. 
The name of the snapshot (and file system, if a full stream is received) that this subcommand creates depends on the argument type and the -d or -e option.

If the argument is a snapshot name, the specified snapshot is created. If the argument is a file system or volume name, a snapshot with the same name as the sent snapshot is created within the specified filesystem or volume. If the -d or -e option is specified, the snapshot name is determined by appending the sent snapshot’s name to the specified filesystem. If the -d option is specified, all but the pool name of the sent snapshot path is appended (for example, b/c@1 appended from sent snapshot a/b/c@1), and if the -e option is specified, only the tail of the sent snapshot path is appended (for example, c@1 appended from sent snapshot a/b/c@1). In the case of -d, any file systems needed to replicate the path of the sent snapshot are created within the specified file system.

-d

Uses all but the first element of the sent snapshot path (all but the pool name) to determine the name of the new snapshot as described in the paragraph above.

-e

Uses the last element of the sent snapshot path to determine the name of the new snapshot as described in the paragraph above.

-F

Forces a rollback of the file system to the most recent snapshot before performing the receive operation. If receiving an incremental replication stream (for example, one generated by zfs send -R -[iI]), destroy snapshots and file systems that do not exist on the sending side.

-n

Do not actually receive the stream. This can be useful in conjunction with the -v option to verify the name the receive operation would use.

-o property=value

Sets the specified property as if the command property=value is invoked at the same time the received dataset is created from the non-incremental send stream or updated from the incremental send stream. Any editable ZFS property can also be set at receive time. Set-once properties bound to the received data, such as normalization and casesensitivity, cannot be set at receive time even when the datasets are newly created by zfs receive. Multiple -o options can be specified. An error results if the same property is specified in multiple -o or -x options.

-u

File system that is associated with the received stream is not mounted.

-v

Print verbose information about the stream and the time required to perform the receive operation.
-x property
   Ensures that the effective value of the specified property after the receive is unaffected
   by the value of that property in the send stream (if any), as if the property had been
   excluded from the send stream. If the specified property is not present in the send
   stream, this option does nothing. If a received property needs to be overridden, the
   effective value can be set or inherited, depending on the property. In the case of an
   incremental update, -x leaves any existing local setting or explicit inheritance
   unchanged (since the received property is already overridden). All -o restrictions apply
   equally to -x.

zfs release [-r] tag snapshot...
   Removes a single reference, named with the tag argument, from the specified snapshot or
   snapshots. The tag must already exist for each snapshot.

   If a hold exists on a snapshot, attempts to destroy that snapshot by using the zfs destroy
   command return EBUSY.

   -r
      Recursively releases a hold with the given tag on the snapshots of all descendent file
      systems.

zfs rename filesystem|volume|snapshot filesystem|volume|snapshot
zfs rename [-p] filesystem|volume filesystem|volume
   Renames the given dataset. The new target can be located anywhere in the ZFS hierarchy,
   with the exception of snapshots. Snapshots can only be renamed within the parent file
   system or volume. When renaming a snapshot, the parent file system of the snapshot does
   not need to be specified as part of the second argument. Renamed file systems can inherit
   new mount points, in which case they are unmouted and remounted at the new mount
   point.

   -p
      Creates all the nonexistent parent datasets. Datasets created in this manner are
      automatically mounted according to the mountpoint property inherited from their
      parent.

zfs rename -r snapshot snapshot
   Recursively renames the snapshots of all descendent datasets. Snapshots are the only
   dataset that can be renamed recursively.

zfs rename share share
   Renames the specified share to a new share name.

zfs rollback [-rRf] snapshot
   Rolls back the given dataset to a previous snapshot. When a dataset is rolled back, all data
   that has changed since the snapshot is discarded, and the dataset reverts to the state at the
time of the snapshot. By default, the command refuses to roll back to a snapshot other than the most recent one. In order to do so, all intermediate snapshots must be destroyed by specifying the -r option.

The -rR options do not recursively destroy the child snapshots of a recursive snapshot. Only the top-level recursive snapshot is destroyed by either of these options. To completely roll back a recursive snapshot, you must rollback the individual child snapshots.

- r
  Recursively destroys any snapshots more recent than the one specified.

- R
  Recursively destroys any more recent snapshots, as well as any clones of those snapshots.

- f
  Used with the -R option to force an unmount of any clone file systems that are to be destroyed.

zfs send [-DRbpv] [-iI] snapshot
zfs send -r [-Dbpv] [-i snapshot] snapshot

Creates a stream representation of the second snapshot, which is written to standard output. The output can be redirected to a file or to a different system (for example, using ssh(1)). By default, a full stream is generated.

- b
  Sends only received property values whether or not they are overridden by local settings, but only if the dataset has ever been received. Use this option when you want ZFS receive to restore received properties backed up on the sent dataset and to avoid sending local settings that may have nothing to do with the source dataset, but only with how the data is backed up.

- c
  Creates a self-contained stream. A self-contained stream is one that is not dependent on any datasets not included in the stream package. Valid only with the -r option. If used with the -i option, the stream will be dependent on the snapshot specified as an argument to the that option.

See the “ZFS Streams” section of the ZFS Administration Guide for details.

- D
  Performs dedup processing on the stream. Deduplicated streams cannot be received on systems that do not support the stream deduplication feature.

See the “ZFS Streams” section of the ZFS Administration Guide to understand how a replication stream package differs from a recursive stream package.
-i snapshot
Generates an incremental stream from the first snapshot to the second snapshot. The incremental source (the first snapshot) can be specified as the last component of the snapshot name (for example, the part after the @), and it is assumed to be from the same file system as the second snapshot.

If the destination is a clone, the source may be the origin snapshot, which must be fully specified (for example, pool/fs@origin, not just @origin).

-I snapshot
Generates a stream package that sends all intermediary snapshots from the first snapshot to the second snapshot. For example, -I @a fs@d is similar to -i @a fs@b; -i @b fs@c; -i @c fs@d. The incremental source snapshot may be specified as with the -i option.

-R
Generates a replication stream package that replicates the specified file system, and all descendent file systems, up to the named snapshot. When received, all properties, snapshots, descendent file systems, and clones are preserved.

If the -i or -I flags are used in conjunction with the -R flag, an incremental replication stream is generated. The current values of properties, and current snapshot and file system names are set when the stream is received. If the -F flag is specified when this stream is received, snapshots and file systems that do not exist on the sending side are destroyed.

-r
Generates a recursive stream package. A recursive stream package contains a series of full and/or incremental streams. When received, all properties and descendent file systems are preserved. Unlike with the replication stream packages generated with the -R flag, intermediate snapshots are not preserved unless the intermediate snapshot is the origin of a clone that is included in the stream.

If the -i option is used in conjunction with the -r option, an incremental recursive stream is generated. The current values of properties as well as current snapshot and file system names are set when the stream is received. If the -F option is specified when this stream is received, snapshots and file systems that do not exist on the sending side are destroyed. The -I option cannot be used in conjunction with the -r option.

When combined with the -c option, a self-contained recursive stream package is created. If both the -c and -i options are used, file systems and volumes that do not have the snapshot specified with the -i option are sent as self-contained streams.

See the “ZFS Streams” section of the ZFS Administration Guide to understand how a recursive stream package differs from a replication stream package.

-p
Sends properties.
-v
Displays verbose information about the stream package generated.

The format of the stream is committed. You will be able to receive your streams on future versions of ZFS.

**zfs set [-r] property=value filesystem|volume|snapshot ...**
Sets the property to the given value for each dataset. Only some properties can be edited. See the “Properties” section for more information on what properties can be set and acceptable values. Numeric values can be specified as exact values, or in a human-readable form with a suffix of B, K, M, G, T, P, E, Z (for bytes, kilobytes, megabytes, gigabytes, terabytes, petabytes, exabytes, or zettabytes, respectively). User properties can be set on snapshots. For more information, see the “User Properties” section.

- r
Recursively apply the effective value of the setting throughout the subtree of child datasets. The effective value may be set or inherited, depending on the property. Use the `zfs help -l properties` command to review whether a property is settable or inheritable.

**zfs share [-u] -o property=value ... filesystem%share**
**zfs share filesystem|mountpoint|filesystem%share**
**zfs share -a | filesystem**
For a full description of `zfs share` syntax and examples and setting the share nfs or share.smb property, see `zfs_share(1M)`.

**zfs snapshot [-r] [-o property=value] ... filesystem@snapshotname|volume@snapshotname**
Creates a snapshot with the given name. All previous modifications by successful system calls to the file system are part of the snapshot. `zfs snap` can be used as an alias for `zfs snapshot`. See the “Snapshots” section for details.

- r
Recursively creates snapshots of all descendent datasets. Snapshots are taken atomically, so that all recursive snapshots correspond to the same moment in time.

- o property=value
Sets the specified property; see `zfs create` for details.

**zfs unallow [-rldug] everyone|user|group[,...] [perm[@setname[, ...]]] filesystem|volume**
**zfs unallow [-rld] -e [perm[@setname[, ...]]] filesystem|volume**
**zfs unallow [-r] -c [perm[@setname[, ...]]] filesystem|volume**
**zfs unallow [-r] -s @setname [perm[@setname[, ...]]] filesystem|volume**
For a full description of the `zfs unallow` syntax and examples, see `zfs_allow(1M)`.

**zfs unmount [-f] -a | filesystem|mountpoint**
Unmounts currently mounted ZFS file systems. Invoked automatically as part of the shutdown process.
-f
  Forcefully unmount the file system, even if it is currently in use.

-a
  Unmounts all available ZFS file systems. Invoked automatically as part of the boot
  process.

filesystem|mountpoint
  Unmounts the specified file system. The command can also be given a path to a ZFS file
  system mount point on the system.

For an encrypted dataset, the key is not unloaded when the file system is unmounted. To
unload the key, see zfs key.

zfs unshare filesystem|mountpoint|filesystem%share
zfs unshare -a | -r filesystem
  For a full description of zfs unshare syntax and examples, see zfs_share(1M).

zfs upgrade
  Identifies a file system version, which determines available file system features in the
  currently running software release. You can continue to use older file system versions, but
  some features might not be available. A file system can be upgraded by using the zfs
  upgrade -a command. You will not be able to access a file system of a later version on a
  system that runs an earlier software version.

zfs upgrade [-v]
  Displays ZFS file system versions that are supported by the current software. The current
  ZFS file system versions and all previously supported versions are displayed, along with an
  explanation of the features provided with each version.

zfs upgrade [-r] [-V version] [-a | filesystem]
  Upgrades file systems to a new, on-disk version. Upgrading a file system means that it will
  no longer be accessible on a system running an older software version. A zfs send stream
  that is generated from a new file system snapshot cannot be accessed on a system that runs
  an older software version.

  In general, the file system version is independent of the pool version. See zpool(1M) for
  information on the zpool upgrade command.

  In some cases, the file system version and the pool version are interrelated and the pool
  version must be upgraded before the file system version can be upgraded.

-a
  Upgrades all file systems on all imported pools.

filesystem
  Upgrades the specified file system.

-r
  Upgrades the specified file system and all descendent file systems.
-V version
Upgrades to the specified version. If the -V flag is not specified, this command upgrades to the most recent version. This option can only be used to increase the version number, and only up to the most recent version supported by this software.

zfs userspace [-hnHp] [-o field[,...] [-sS field]] [-t type[,...]] filesystem | snapshot
Displays space consumed by, and quotas on, each user in the specified filesystem or snapshot. This corresponds to the userused@user and userquota@user properties.

-\n
Displays syntax help message and exit.

-n
Prints numeric ID instead of user/group name.

-H
Does not print headers, use tab-delimited output.

-p
Uses exact (parseable) numeric output.

-o field[,...]
Displays only the specified fields from the following set, type, name, used, quota. The default is to display all fields.

-s field
Sorts output by this field. The s and S flags may be specified multiple times to sort first by one field, then by another. The default is -s type -s name.

-S field
Sorts by this field in reverse order. See -s.

-t type[,...]
Prints only the specified types from the following set, all, posixuser, smbuser, posixgroup, smbgroup.

The default is -t posixuser, smbuser
The default can be changed to include group types.

-i
Translates SID to POSIX ID. The POSIX ID may be ephemeral if no mapping exists. Normal POSIX interfaces (for example, stat(2), ls -l) perform this translation, so the -i option allows the output from zfs userspace to be compared directly with those utilities. However, -i may lead to confusion if some files were created by an SMB user before a SMB-to-POSIX name mapping was established. In such a case, some files are owned by the SMB entity and some by the POSIX entity. However, the -i option will report that the POSIX entity has the total usage and quota for both.
Examples

**EXAMPLE 1**  Creating a ZFS File System Hierarchy

The following commands create a file system named `pool/home` and a file system named `pool/home/bob`. The mount point `/export/home` is set for the parent file system, and is automatically inherited by the child file system.

```bash
# zfs create pool/home
# zfs set mountpoint=/export/home pool/home
# zfs create pool/home/bob
```

**EXAMPLE 2**  Creating a ZFS Snapshot

The following command creates a snapshot named `yesterday`. This snapshot is mounted on demand in the `.zfs/snapshot` directory at the root of the `pool/home/bob` file system.

```bash
# zfs snapshot pool/home/bob@yesterday
```

**EXAMPLE 3**  Creating and Destroying Multiple Snapshots

The following command creates snapshots named `yesterday` of `pool/home` and all of its descendent file systems. Each snapshot is mounted on demand in the `.zfs/snapshot` directory at the root of its file system. The second command destroys the newly created snapshots.

```bash
# zfs snapshot -r pool/home@yesterday
# zfs destroy -r pool/home@yesterday
```

**EXAMPLE 4**  Disabling and Enabling File System Compression

The following command disables the `compression` property for all file systems under `pool/home`. The next command explicitly enables compression for `pool/home/anne`.

```bash
# zfs set compression=off pool/home
# zfs set compression=on pool/home/anne
```

**EXAMPLE 5**  Listing ZFS Datasets

The following command lists all active file systems and volumes in the system. Snapshots are displayed if the `list snaps` property is on. The default is off. See `zpool(1M)` for more information on pool properties.

```bash
# zfs list

NAME    USED  AVAIL  REFER MOUNTPOINT
pool     450K  457G   18K  /pool
pool/home 315K  457G   21K  /export/home
pool/home/anne 18K  457G   18K /export/home/anne
pool/home/bob  276K  457G  276K /export/home/bob
```

**EXAMPLE 6**  Setting a Quota on a ZFS File System

The following command sets a quota of 30 GB for `pool/home/bob`.

```bash
# zfs set quota=30G pool/home/bob
```
The following command lists all properties for pool/home/bob.

```
# zfs get all pool/home/bob
```

EXAMPLE 7  Listing ZFS Properties  (Continued)

pool/home/bob usedbychildren 0 -
pool/home/bob usedbydataset 31K -
pool/home/bob usedbyrefreservation 0 -
pool/home/bob usedbysnapshots 0 -
pool/home/bob utf8only off -
pool/home/bob version 6 -
pool/home/bob vscan off default
pool/home/bob xattr on default
pool/home/bob zoned off default

The following command gets a single property value.

# zfs get -H -o value compression pool/home/bob

The following command lists all properties with local settings for pool/home/bob.

# zfs get -r -s local -o name,property,value all pool/home/bob

<table>
<thead>
<tr>
<th>NAME</th>
<th>PROPERTY</th>
<th>VALUE</th>
</tr>

</tbody>
</table>

EXAMPLE 8  Rolling Back a ZFS File System

The following command reverts the contents of pool/home/anne to the snapshot named yesterday, deleting all intermediate snapshots.

# zfs rollback -r pool/home/anne@yesterday

EXAMPLE 9  Creating a ZFS Clone

The following command creates a writable file system whose initial contents are the same as pool/home/bob@yesterday.

# zfs clone pool/home/bob@yesterday pool/clone

EXAMPLE 10  Promoting a ZFS Clone

The following commands illustrate how to test out changes to a file system, and then replace the original file system with the changed one, using clones, clone promotion, and renaming:

# zfs create pool/project/production
  populate /pool/project/production with data
# zfs snapshot pool/project/production@today
# zfs clone pool/project/production@today pool/project/beta
make changes to /pool/project/beta and test them
# zfs promote pool/project/beta
# zfs rename pool/project/production pool/project/legacy
# zfs rename pool/project/beta pool/project/production
EXAMPLE 10  Promoting a ZFS Clone (Continued)

once the legacy version is no longer needed, it can be destroyed
# zfs destroy pool/project/legacy

EXAMPLE 11  Inheriting ZFS Properties

The following command causes pool/home/bob and pool/home/anne to inherit the checksum property from their parent.
# zfs inherit checksum pool/home/bob pool/home/anne

EXAMPLE 12  Remotely Replicating ZFS Data

The following commands send a full stream and then an incremental stream to a remote machine, restoring them into poolB/received/fs@aa and poolB/received/fs@b, respectively. poolB must contain the file system poolB/received, and must not initially contain poolB/received/fs.
# zfs send pool/fs@a | \  
   ssh host zfs receive poolB/received/fs@a
# zfs send -i a pool/fs@b | ssh host \
   zfs receive poolB/received/fs

The above syntax assumes that ssdh has been configured to allow remote root access.

EXAMPLE 13  Using the zfs receive -d Option

The following command sends a full stream of poolA/fsA/fsB@snap to a remote machine, receiving it into poolB/received/fsA/fsB@snap. The fsA/fsB@snap portion of the received snapshot's name is determined from the name of the sent snapshot. poolB must contain the file system poolB/received. If poolB/received/fsA does not exist, it is created as an empty file system.
# zfs send poolA/fsA/fsB@snap | \  
   ssh host zfs receive -d poolB/received

EXAMPLE 14  Setting User Properties

The following example sets the user-defined com.example:department property for a dataset.
# zfs set com.example:department=12345 tank/accounting

EXAMPLE 15  Performing a Rolling Snapshot

The following example shows how to maintain a history of snapshots with a consistent naming scheme. To keep a week's worth of snapshots, the user destroys the oldest snapshot, renames the remaining snapshots, and then creates a new snapshot, as follows:
# zfs destroy -r pool/users@7daysago
# zfs rename -r pool/users@6daysago @7daysago
# zfs rename -r pool/users@5daysago @6daysago
### EXAMPLE 15  Performing a Rolling Snapshot  (Continued)

```plaintext
# zfs rename -r pool/users@4daysago @5daysago
# zfs rename -r pool/users@3daysago @4daysago
# zfs rename -r pool/users@2daysago @3daysago
# zfs rename -r pool/users@yesterday @2daysago
# zfs rename -r pool/users@today @yesterday
# zfs snapshot -r pool/users@today
```

### EXAMPLE 16  Displaying ZFS Snapshot Differences

The following example is output of the `zfs diff -F` and `-t` options specified:

```plaintext
# zfs diff -Ft myfiles@snap1
1269962501.206726811 M / /myfiles/
1269962444.207369955 M F /myfiles/link_to_me (+1)
1269962499.207519034 R /myfiles/renamed_me -> /myfiles/renamed
1269962431.813566720 - F /myfiles/delete_me
1269962518.666905544 + F /myfiles/new_file
1269962501.393099817 + | /myfiles/new_pipe
```

#### Exit Status

The following exit values are returned:

- **0**
  - Successful completion.

- **1**
  - An error occurred.

- **2**
  - Invalid command line options were specified.

#### Attributes

See `attributes(5)` for descriptions of the following attributes:

Notes  A file described as modified by the `diff` subcommand might have been modified in multiple ways. Any action that causes a change in the `st_ctim` (see `stat(2)`) is a basis for reporting a modification.
Name  zfs_allow – delegates ZFS file system administration permission to non-privileged users

Synopsis  zfs help subcommand | help | property property-name | permission
          zfs help -l properties
          zfs allow filesystem|volume
          zfs allow [-ldug] everyone|user|group[,...] perm[@setname[,...]]
                   filesystem|volume
          zfs allow [-ld] -e perm[@setname[,...]] filesystem|volume
          zfs allow -c perm[@setname[,...]] filesystem|volume
          zfs allow -s @setname perm[@setname[,...]] filesystem|volume
          zfs unallow [-rldug] everyone|user|group[,...] [perm[@setname[,...]]]
                    filesystem|volume
          zfs unallow [-rld] -e [perm[@setname[,...]]] filesystem|volume
          zfs unallow [-r] -c [perm[@setname[...]]] filesystem|volume
          zfs unallow [-r] -s @setname [perm[@setname[,...]]] filesystem|volume

Description  The zfs allow command can be used to delegate permissions to non-privileged users for administering ZFS file systems in a ZFS storage pool, as described in zpool(1M). You can use the zfs unallow command to revoke administrative permissions.

Permissions are generally the ability to use a ZFS subcommand or change a ZFS property. The following permissions are available:

# zfs help permissions
The following delegated permissions are supported:

<table>

</table>
ability in the new parent

rollback subcommand Allows rolling back datasets to previously-taken snapshots
send subcommand Allows sending of snapshots
share subcommand Allows sharing file systems over NFS or SMB protocols
snapshot subcommand Allows taking of snapshots
groupquota other Allows accessing any groupquota@... property
groupused other Allows reading any groupused@... property
key other Allows load/unload of dataset key
keychange other Allows key change operations
userprop other Allows changing any user property
userquota other Allows accessing any userquota@... property
userused other Allows reading any userused@... property

The following properties can have delegated permissions applied:

aclinherit aclmode atime canmount
casesensitivity checksum compression copies
dedup devices encryption exec
keysource logbias mountpoint multilevel
nbmand normalization primarycache quota
readonly recordsize refquota refreservation
reservation rsizehidden secondarycache setuid
shadow sharernfs sharesmb snapdir
sync utf8only version volblocksize
volsize vscan xattr zoned

Subcommands

All subcommands that modify state are logged persistently to the pool in their original form.

zfs ?
Displays a help message.

zfs help command | help | property property-name | permission
Displays zfs command usage information. You can display help for a specific command, property, or delegated permission. If you display help for a specific command or property, the command syntax or property value is displayed. Using zfs help without any arguments displays a complete list of zfs commands.

zfs help -l properties
Displays zfs property information, including whether the property value is editable and inheritable, and their possible values.

zfs allow filesystem | volume
Displays permissions that have been delegated on the specified filesystem or volume. See the other forms of zfs allow for more information.

zfs allow [-ldug] everyone|user|group[...].perm[@setname[...]] filesystem|volume
zfs allow [-ld] -e perm[@setname[...]] filesystem | volume
Delegates ZFS administration permission for the file systems to non-privileged users.
[-ug] everyone|user|group[,...]
Specifies to whom the permissions are delegated. Multiple entities can be specified as a comma-separated list. If neither of the -ug options are specified, then the argument is interpreted preferentially as the keyword everyone, then as a user name, and lastly as a group name. To specify a user or group named "everyone", use the -u or -g options. To specify a group with the same name as a user, use the -g options.

[-e] perm[@setname][,...]
Specifies that the permissions be delegated to everyone. Multiple permissions may be specified as a comma-separated list. Permission names are the same as ZFS subcommand and property names. See the property list below. Property set names, which begin with an at sign (@), may be specified. See the -s form below for details.

[-ld] filesystem|volume
Specifies where the permissions are delegated. If neither of the -ld options are specified, or both are, then the permissions are allowed for the file system or volume, and all of its descendents. If only the -l option is used, then is allowed "locally" only for the specified file system. If only the -d option is used, then is allowed only for the descendent file systems.

zfs allow -c perm[@setname][,...] filesystem|volume
Sets "create time" permissions. These permissions are granted (locally) to the creator of any newly-created descendant file system.

zfs allow -s @setname perm[@setname][,...] filesystem|volume
Defines or adds permissions to a permission set. The set can be used by other zfs allow commands for the specified file system and its descendents. Sets are evaluated dynamically, so changes to a set are immediately reflected. Permission sets follow the same naming restrictions as ZFS file systems, but the name must begin with an "at sign" (@), and can be no more than 64 characters long.

zfs unallow [-rldug] everyone|user|group[,...] [perm[@setname][,...]] filesystem|volume
zfs unallow [-rld] -e [perm[@setname][,...]] filesystem|volume
zfs unallow [-r] -c [perm[@setname][,...]] filesystem|volume
Removes permissions that were granted with the zfs allow command. No permissions are explicitly denied, so other permissions granted are still in effect. For example, if the permission is granted by an ancestor. If no permissions are specified, then all permissions for the specified user, group, or everyone are removed. Specifying everyone (or using the -e option) only removes the permissions that were granted to everyone, not all permissions for every user and group. See the zfs allow command for a description of the -ldugec options.

- r
Recursively remove the permissions from this file system and all descendents.

zfs unallow [-r] -s @setname [perm[@setname][,...]] filesystem|volume
Removes permissions from a permission set. If no permissions are specified, then all permissions are removed, thus removing the set entirely.

**Examples**

**EXAMPLE 1**  Delegating ZFS Administration Permissions on a ZFS Dataset

The following example shows how to set permissions so that user anne can create, destroy, mount, and take snapshots on pool/home/anne. The permissions on pool/home/anne are also displayed.

```bash
# zfs allow anne create,destroy,mount,snapshot pool/home/anne
# zfs allow pool/home/anne
```

Local+Descendent permissions:

```
user anne create,destroy,mount,snapshot
```

Because the pool/home/anne mount point permission is set to 755 by default, user anne will be unable to mount filesystems under pool/home/anne. Set an ACL similar to the following syntax to provide mount point access:

```bash
# chmod A+user:anne:add_subdirectory:allow /pool/home/anne
```

**EXAMPLE 2**  Delegating Create Time Permissions on a ZFS Dataset

The following example shows how to grant anyone in the group staff to create file systems in pool/home. This syntax also allows staff members to destroy their own file systems, but not destroy anyone else’s file system. The permissions on pool/home are also displayed.

```bash
# zfs allow staff create,mount pool/home
# zfs allow -c destroy pool/home
# zfs allow pool/home
```

Create time permissions:

```
destroy
```

Local+Descendent permissions:

```
group staff create,mount
```

**EXAMPLE 3**  Defining and Granting a Permission Set on a ZFS Dataset

The following example shows how to define and grant a permission set on the pool/home file system. The permissions on pool/home are also displayed.

```bash
# zfs allow -s @pset create,destroy,snapshot,mount pool/home
# zfs allow staff @pset pool/home
# zfs allow pool/home
```

Permission sets:

```
@pset create,destroy,mount,snapshot
```

Create time permissions:

```
destroy
```

Local+Descendent permissions:

```
group staff @pset,create,mount
```
EXAMPLE 4  Delegating Property Permissions on a ZFS Dataset

The following example shows to grant the ability to set quotas and reservations on the tank/users file system. The permissions on tank/users are also displayed.

```
# zfs allow mark quota,reservation tank/users
# zfs allow tank/users
---- Permissions on tank/users ---------------------------------------
Local+Descendent permissions:
  user mark quota,reservation
mark% zfs set quota=10G tank/users/tim
mark% zfs get quota tank/users/tim
NAME PROPERTY VALUE SOURCE
  tank/users/tim quota 10G local
```

EXAMPLE 5  Removing ZFS Delegated Permissions on a ZFS Dataset

The following example shows how to remove the snapshot permission from the @pset permission set for the staff group on the pool/home file system. The permissions on pool/home are also displayed.

```
# zfs unallow -s @pset snapshot pool/home
# zfs allow pool/home
---- Permissions on pool/home ----------------------------------------
Permission sets:
  @pset create,destroy,mount
Create time permissions:
  destroy
Local+Descendent permissions:
  group staff @pset,create,mount
```

**Exit Status**  The following exit values are returned:

0  
  Successful completion.

1  
  An error occurred.

2  
  Invalid command line options were specified.

**Attributes**  See attributes(5) for descriptions of the following attributes:

**Name**
zfs_encrypt – encrypting ZFS file systems

**Synopsis**
zfs [-?]

zfs help subcommand | help | property property-name | permission
zfs help -l properties
zfs create -o encryption=on [-o keysource=raw | hex | passphrase,prompt | file://|pkcs11:|https://] ... dataset
zfs clone [-p] [-K] [-o property=value] ... snapshot filesystem|volume
zfs get [-r]-d depth|[-Hp][-o all | field[,...]] [-s source[,...]]
all | property[,...] filesystem|volume|snapshot ...
zfs key -l | {-a | [-r] filesystem|volume}
zfs key -u [-f] {-a | [-r] filesystem|volume}
zfs key -c [-o keysource=value] {-a | [-r] filesystem|volume}
zfs key -K {-a | [-r] filesystem|volume}
zfs mount
zfs mount [-vO] [-o options] -a | filesystem
zfs unmount [-f] -a | filesystem|mountpoint

**Description**
The `zfs create -o encryption` command encrypts a newly created ZFS dataset within a ZFS storage pool, as described in `zpool(1M)`.

Encryption

Encryption is the process in which data is encoded for privacy and a key is needed by the data owner to access the encoded data. You can set an encryption policy when a ZFS dataset is created, but the policy cannot be changed. See the encryption and keysource property descriptions in the “Native Properties” section for details.

Dataset encryption is inherited permanently and cannot be removed during dataset cloning. When receiving a replicated dataset stream, the destination dataset must have encryption enabled if encryption is desired. Otherwise, the data is stored as clear text. A fully replicated stream of an encrypted dataset results in an encrypted dataset but under a newly generated key. The stream itself is not encrypted.

Native ZFS Encryption Properties

The following native properties related to ZFS encryption consist of read-only statistics about the dataset. These properties cannot be set nor inherited. Native properties apply to all dataset types unless otherwise noted. For a full description and list of ZFS native properties, see `zfs(1M)`.

`keychangedate`

The date of the last wrapping key change from a `zfs key -c` operation on a given dataset. If no key change operation has been performed, `keychangedate` is the same as the creation date.
keystatus
Identifies the encryption key status for the dataset. The availability of a dataset’s key is indicated by showing the status of available or unavailable. For datasets that do not have encryption enabled, none is displayed.

mounted
For file systems, indicates whether the file system is currently mounted. This property can be either yes or no.

rekeydate
The date of the last data encryption key change from a zfs key -K or zfs clone -K operation on this dataset. If no rekey operation has been performed, rekeydate is the same as creation date.

The following properties cannot be changed after the file system is created and, therefore, should be set when the file system is created. If the properties are not set with the zfs create or zpool create commands, these properties are inherited from the parent dataset. If the parent dataset lacks these properties due to having been created prior to these features being supported, the new file system will have the default values for these properties.

encryption=off | on | aes-128-ccm | aes-192-ccm | aes-256-ccm | aes-128-gcm | aes-192-gcm | aes-256-gcm
Defines the encryption algorithm and key length that is used for the encrypted dataset. The on value is equal to aes -128 -ccm. The default value is off. When encryption is set to a value other than off, the checksum property is set to sha256+mac and becomes readonly.

You must grant the checksum, encryption, and keysource permissions to delegate the encryption property.

The following properties must be specified at creation time and can modified by using special commands:

keysource=raw | hex | passphrase.prompt | file:// | pkcs11: | https://
Defines the format and location of the key that wraps the dataset keys. The key must be present when the dataset is created, mounted, or loaded by using the zfs key -l command.

The keysource property accepts two values: format determines how the key is presented; locator identifies where the key is coming from.

format accepts three values:
- raw: the raw key bytes
- hex: a hexadecimal key string
- passphrase: a character string that generates a key

locator accepts two values:
- prompt: You are prompted for a key or a passphrase when the dataset is created or mounted
- file:///filename: the key or a passphrase file location in a file system
- pkcs11: A URI describing the location of a key or a passphrase in a PKCS#11 token
- https://location: The key or a passphrase file location on a secure server. Transporting key information in the clear using this method is not recommended. A GET on the URL returns just the key value or the passphrase, according to what was requested in the format part of the keysource.

When using an https:// locator for the keysource, the certificate that the server presents must be one that is trusted by libcurl and OpenSSL. Add your own trust anchor or self signed certificate to the certificate store in /etc/openssl/certs. Place the PEM format certificate into the /etc/certs/CA directory and run the svcadm refresh ca-certificates command.

See “Examples” for examples of creating a key by using the https:// locator.

To change the wrapping key value or the key, you must run the zfs key -c command. If only the key location needs to changed, for example, a filename change, then use the zfs set command with the keysource property. Note that no checking is performed by ZFS when only the key location is changed with the zfs set command, such as whether the new location has a valid wrapping key.

If keysource is not specified and not inherited, then the default keysource is set to passphrase,prompt for a dataset that has encryption on and is set to none for a dataset that has encryption off.

**Subcommands**

All subcommands that modify state are logged persistently to the pool in their original form.

zfs ?  
Displays a help message.

zfs help command | help | property property-name | permission  
Displays zfs command usage information. You can display help for a specific command, property, or delegated permission. If you display help for a specific command or property, the command syntax or property value is displayed. Using zfs help without any arguments displays a complete list of zfs commands.

zfs help -l properties  
Displays zfs property information, including whether the property value is editable and inheritable, and their possible values.

zfs create [-p] [-o encryption=on] [-o keysource=raw | hex | passphrase,prompt] [file://]pkcs11://https:// ...filesystem  
Creates a new ZFS file system with encryption enabled, which uses aes-128-ccm. See the encryption property description for a list of supported encryption algorithms.

-p  
Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their
parent. Any property specified on the command line using the -o option is ignored. If the target filesystem already exists, the operation completes successfully.

- o encryption=value
   Sets the encryption property to value. Multiple -o options can be specified. An error results if the same property is specified in multiple -o options.

zfs clone [-p ] [-K ] [-o property=value] ... snapshot filesystem|volume
   Creates a clone of the given snapshot. See the "Clones" section for details. The target dataset can be located anywhere in the ZFS hierarchy, and is created as the same type as the original.

- p
   Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their parent. If the target filesystem or volume already exists, the operation completes successfully.

- o property=value
   Sets the specified property; see zfs create for details.

- K
   Creates a new data encryption key in the keychain for this dataset. Data written in the clone uses the new data encryption key, which is distinct from its original snapshot.

zfs set keysource=value filesystem|volume] ... 
   Sets the keysource property to the given value for each dataset. You can only change the keysource location. If you want to change the wrapping key value, use the zfs key -c command.

- r
   Recursively apply the effective value of the setting throughout the subtree of child datasets. The effective value may be set or inherited, depending on the property.

zfs get encryption | keysource | keystatus | rekeydate filesystem|volume] ... 
   Displays properties for the given datasets.

- r
   Recursively display properties for the given datasets.

- d depth
   Recursively display any descendent datasets, limiting the recursion to depth. A depth of 1 will display only the dataset and its direct children.

- H
   Display output in a form more easily parsed by scripts. Any headers are omitted, and fields are explicitly separated by a single tab instead of an arbitrary amount of space.
zfs key -l [ -a | [ -r ] filesystem|volume]

Loads the encryption key for a dataset and any datasets that inherit the key. The key that is provided with this command is not the actual key that is used to encrypt the dataset. It is a wrapping key for the set of data encryption keys for the dataset.

- l

Loads the wrapping key to unlock the encrypted dataset and datasets that inherit the key. This command loads the key based on what is defined by the dataset's keysource property.

During a pool import, a key load operation is performed when a dataset is mounted. During boot, if the wrapping key is available and the keysource is not set to prompt, the key load operation is performed.

- a

Apply to all datasets in all pools on the system.

- r

Apply the operation recursively to all datasets below the named filesystem or volume.

zfs key -u [ -f ] [ -a | [ -r ] filesystem|volume]

Unloads the encryption key for a dataset and any datasets that inherit the key.

- u

Unmounts the dataset and then attempts to unload the wrapping key for an encrypted dataset and datasets that inherit the key. If successful, the dataset is not accessible and is unmounted.

- f

Attempts to force unmount the dataset before attempting to unload the key. If not specified, a normal unmount is attempted.

- a

Apply to all datasets in all pools on the system.

- r

Apply the operation recursively to all datasets below the named filesystem or volume.

zfs key -c [ -o keysource=value ] [ -a | [ -r ] filesystem|volume]

Changes the wrapping key. If the new key has a different format or locator, the keysource property must be included as part of the command. Only the keysource property can be changed as part of the zfs key -c command.

- c

Changes the wrapping key for the key of an encrypted dataset and the datasets that inherit it. The existing key must already have been loaded before the key change operation can occur. ZFS does not prompt you for the existing passphrase.
-o property=value  
Property to be changed as part of the key change operation. The keysource property is the only option that can be changed as part of a key change operation.

You must have permission to change the keysource properties.

-a  
Apply to all datasets in all pools on the system.

-r  
Apply the operation recursively to all datasets below the named file system or volume.

zfs key -K {-a [ -r ] filesystem|volume}  
Creates a new data encryption key. The new data encryption key is wrapped by the same wrapping key as any existing data encryption keys for this dataset.

-K  
Creates a new data encryption key for this dataset. Data written after this operation will use the new data encryption key.

-a  
Apply to all datasets in all pools on the system.

-r  
Apply the operation recursively to all datasets below the named file system or volume.

zfs mount  
zfs mount [-vO] [-o options] -a | filesystem  
Mounts ZFS file systems. Invoked automatically as part of the boot process. For a full description of zfs mount syntax, see zfs(1M).

filesystem
Mount the specified filesystem.

A zfs mount operation of an encrypted dataset might prompt you for a key, depending on the keysource property value. This might occur, for example, if the keysource locator is set to prompt.

zfs unmount [-f] -a | filesystem|mountpoint
Unmounts currently mounted ZFS file systems. Invoked automatically as part of the shutdown process. For a full description of zfs unmount syntax, see zfs(1M).

filesystem|mountpoint
Unmount the specified filesystem. The command can also be given a path to a ZFS file system mount point on the system.

For an encrypted dataset, the key is not unloaded when the file system is unmounted. To unload the key, see zfs key.
Creating an Encrypted Dataset

The following example shows how to create an encrypted dataset by using a passphrase prompt, which is the default value of the keysource property. This example assumes that the tank/home dataset is not encrypted.

```
# zfs create -o encryption=on tank/home/bob
Enter passphrase for 'tank/home/bob': **********
Enter again: **********
```

In the following example, the `pktool(1)` command is used to generate a raw key to a file. Next, an encrypted dataset (tank/home/anne) is created with the `aes-256-ccm` algorithm and the raw key file that was generated by `pktool`.

```
# pktool genkey keystore=file outkey=/media/stick/mykey \
keytype=aes keylen=256
# zfs create -o encryption=aes-256-ccm \
-o keysource=raw,file:///rmdisk/stick/mykey tank/home/anne
```

This example shows how to create an encrypted ZFS file system that retrieves the passphrase that is stored at an `https` location.

```
# zfs create -o encryption=on \
-o keysource=passphrase,https://keys.example.com/keys/42 tank/home/fs1
```

This example shows how to generate a raw key in a PKCS#11 token. Then, an encrypted dataset is created with the raw PKCS#11 key that was generated from `pktool`.

```
# pktool genkey keystore=pkcs11 keytype=aes keylen=128 label=fs2
Enter PIN for Sun Software PKCS#11 softtoken: xxxxx
# zfs create -o encryption=on -o keysource=raw,pkcs11:object=fs2 \
tank/home/fs2
Enter PKCS#11 token PIN for 'tank/home/fs2': xxxxx
```

This example shows how to generate a raw key in a KMS token. Then, an encrypted dataset is created with the raw KMS key that was generated from `pktool`.

```
# pktool genkey keystore=pkcs11 keytype=aes keylen=256 token=KMS \nlabel=fs3
Enter PIN for KMS: xxxxx
# zfs create -o encryption=aes-256-ccm \
-o keysource="raw,pkcs11:token=KMS;object=fs3" tank/home/fs3
Enter 'KMS' PKCS#11 token PIN for 'tank/home/fs3': xxxxx
```

Creating an Encrypted Dataset with a Different Encryption Algorithm

In this example, any tank/home datasets inherit the keysource properties, but the tank/home/bob dataset is created by using a different encryption algorithm.

```
# zpool create tank ....
# zfs create -o encryption=on tank/home
# zfs get keystatus tank/home
```
EXAMPLE 2  Creating an Encrypted Dataset with a Different Encryption Algorithm

<table>
<thead>
<tr>
<th>NAME</th>
<th>PROPERTY</th>
<th>VALUE</th>
<th>SOURCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank/home</td>
<td>keystatus</td>
<td>available</td>
<td>-</td>
</tr>
</tbody>
</table>

```
# zfs create -o encryption=aes-256-ccm tank/home/bob
```

EXAMPLE 3  Inheriting Encryption and Keysource Properties

In this example, all of the `tank/home` datasets inherit the encryption and keysource properties.

```
# zpool create -O encryption=on -o keysource=raw,file:///... tank ...
# zfs create tank/home
```

EXAMPLE 4  Changing an Encrypted Dataset's Wrapping Key and Keysource

This example shows how to change a dataset's wrapping key to a new key defined by the dataset's keysource property.

```
# zfs create -o encryption=aes-256-ccm -o keysource=raw,file:///etc/keyfile \
  tank/home/rory
# zfs get keysource tank/home/rory
```

```
<table>
<thead>
<tr>
<th>NAME</th>
<th>PROPERTY</th>
<th>VALUE</th>
<th>SOURCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank/home/rory</td>
<td>keysource</td>
<td>raw,file:///etc/keyfile</td>
<td>local</td>
</tr>
</tbody>
</table>
```

```
# zfs key -c -o keysource=passphrase,prompt tank/home/rory
Enter passphrase for 'tank/home/rory/': **********
Enter again: **********
```

```
# zfs get keychangedate tank/home/rory
```

```
<table>
<thead>
<tr>
<th>NAME</th>
<th>PROPERTY</th>
<th>VALUE</th>
<th>SOURCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank/home/rory</td>
<td>keychangedate</td>
<td>Thu Jun 28 14:32 2012</td>
<td>local</td>
</tr>
</tbody>
</table>
```

The following example shows how to change the http location of dataset's wrapping key.

```
# zfs get keysource tank/home/bob
```

```
<table>
<thead>
<tr>
<th>NAME</th>
<th>PROPERTY</th>
<th>VALUE</th>
<th>SOURCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank/home/bob</td>
<td>keysource</td>
<td>passphrase,prompt</td>
<td>local</td>
</tr>
</tbody>
</table>
```

```
# zfs set keysource=passphrase,https://internal.example.com/keys/bob/zfs \
  tank/home/bob
```

You must have the delegated key and keychange permissions to change the keysource property.

EXAMPLE 5  Rekeying the Dataset's Encryption Key

This example shows how to change a dataset's encryption key, which is neither visible nor managed by you or an administrator. The dataset's encryption key is wrapped (encrypted) by the key specified in the keysource property.
EXAMPLE 5  Rekeying the Dataset's Encryption Key  (Continued)

# zfs key -K tank/project42
# zfs get rekeydate,creation tank/project42

You must have the delegated keychange permission to perform a key change operation.

EXAMPLE 6  Customizing the Encrypted Dataset's Wrapping Key

The following examples illustrate that the wrapping key size does not have to match the key size specified for the encryption property.

# zfs create -o encryption=aes-128-gcm -o keysource=raw,file:///k256 \   /tank/home/amy

In the above example, the encryption key size is 128 and the wrapping key size is 256.

# zfs create -o encryption=aes-256-gcm -o keysource=raw,file:///k192 \   /tank/home/rose

In the above example, the encryption key size is 256 and the wrapping key size is 192.

Exit Status  The following exit values are returned:

0  Successful completion.

1  An error occurred.

2  Invalid command line options were specified.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/file-system/zfs</td>

For information about using other ZFS features, see zfs_allow(1M), zfs_share(1M), zfs(1M), and the Oracle Solaris 11.1 Administration: ZFS File Systems.
You can create an NFS share or an SMB share of a ZFS file system by setting share.nfs or share.smb property. You can also use the `zfs share` and `zfs unshare` commands to publish or unpublish a ZFS share.

A file system can be shared by setting or inheriting the share.nfs=on or share.smb=on property value. For example:

```bash
# zfs set share.nfs=on tank/home
# zfs set share.smb=on tank/data
```

The above simple syntax creates and publishes the file system shares automatically. This method is referred to as an automatic share. For more information, see the EXAMPLES section.

The automatic share is read-only and inherits all of its properties from the parent file system. This method allows sharing to be enabled by inheritance alone, if needed, without having to create a share for each descendent file system. The published share name, share.name, of an automatic share is generated from the dataset mount point.

For example, the share.name of tank/home is `tank_home`.

A file system’s automatic share name displays as `filesystem%`. For example, `tank/home%`.

You can also create and publish a share by using the `zfs share` command as follows:

```bash
# zfs share -o share.smb=on sandbox/myfs%myshare
```
The above syntax creates and publishes a named share, which provides more flexibility when you need to share subdirectories within a file system over NFS or SMB protocols. For more information, see the EXAMPLES section.

The `list shares` pool property is used to determine whether share information is displayed when using the `zfs list` command. For more information, see `zpool(1M)`.

File system properties are divided into two types, native properties and user-defined (or user) properties. Native properties either display information or control ZFS behavior. In addition, native properties are either editable or read-only.

Properties are inherited from the parent unless overridden by the child. Some properties apply only to certain types of datasets (file systems, volumes, or snapshots).

The following native properties can be used to change the behavior of a ZFS file system and are generally used when a file system is shared.

- **nbmand=on|off**
  - Controls whether the file system should be mounted with nbmand (Non Blocking mandatory locks). This is used for SMB clients. Changes to this property only take effect when the file system is unmounted and remounted. See `mount(1M)` for more information on nbmand mounts.

- **readonly=on|off**
  - Controls whether this dataset can be modified. The default value is `off`.

  This property can also be referred to by its shortened column name, `rdonly`.

- **share.nfs=on|off**
  - Controls whether a ZFS dataset is created and published as an NFS share. You can also publish and unpublish an named NFS share of a ZFS dataset by using the `zfs share` and `zfs unshare` commands. Both methods of publishing an NFS share require that the NFS share properties are already set. For information about setting NFS share properties, see the `zfs set` command syntax below.

  When the `share.nfs` property is changed, the file system share and any children inheriting the property are re-published with any new options that have been set with the `zfs set` command only if the property was previously `off`, or if the shares were published before the property was changed. If the new property value is `off`, the file system shares are unpublished.

- **share.smb=on|off**
  - Controls whether a ZFS dataset is created and published as an SMB share. You can also publish and unpublish an named SMB share of a ZFS dataset by using the `zfs share` and `zfs unshare` commands. Both methods of publishing an SMB share require that the SMB share properties are also set. For information about setting SMB share properties, see the `zfs set` command syntax below.
When SMB shares are created, the SMB share name appears as an entry in the `.zfs/shares` directory. You can use the `ls` or `chmod` command to display the share-level ACLs on the entries in this directory.

When the property is changed from off to on, any shares that inherit the property are re-shared with their current options. When the property is set to off, the shares that inherit the property are unshared.

```
vsCan=on | off
```

Controls whether regular files should be scanned for viruses when a file is opened and closed. In addition to enabling this property, the virus scan service must also be enabled for virus scanning to occur. The default value is off.

The following properties cannot be changed after the file system is created and, therefore, should be set when the file system is created. If the properties are not set with the `zfs create` or `zpool create` commands, these properties are inherited from the parent dataset. If the parent dataset lacks these properties due to having been created prior to these features being supported, the new file system will have the default values for these properties.

```
casesensitivity=sensitive | insensitive | mixed
```

Indicates whether the file name matching algorithm used by the file system should be case-sensitive, case-insensitive, or allow a combination of both styles of matching. The default value for the `casesensitivity` property is `mixed`. Traditionally, UNIX and POSIX file systems have case-sensitive file names.

The `mixed` value for the `casesensitivity` property indicates that the file system can support requests for both case-sensitive and case-insensitive matching behavior. Currently, case-insensitive matching behavior on a file system that supports mixed behavior is limited to the Solaris SMB server product. For more information about the `mixed` value behavior, see the *Oracle Solaris 11.1 Administration: ZFS File Systems*.

```
normalization = none | formC | formD | formKC | formKD
```

Indicates whether the file system should perform a unicode normalization of file names whenever two file names are compared, and which normalization algorithm should be used. File names are always stored unmodified, names are normalized as part of any comparison process. If this property is set to a legal value other than none, and the `utf8only` property was left unspecified, the `utf8only` property is automatically set to on. The default value of the `normalization` property is `none`. This property cannot be changed after the file system is created.

```
utf8only=on | off
```

Indicates whether the file system should reject file names that include characters that are not present in the UTF-8 character code set. If this property is explicitly set to off, the normalization property must either not be explicitly set or be set to none. The default value for the `utf8only` property is off. This property cannot be changed after the file system is created.
In addition to native properties and user properties, you can also designate properties that control the way a file system is shared. The following set of share-related properties fall into 3 categories: global properties that apply to both NFS and SMB sharing, NFS-specific properties, and SMB-specific properties.

Global share properties are mostly read-only with a few exceptions. The following global share properties apply to either a NFS or SMB share or on the shared or to be shared file system:

### TABLE 1 Global Share Property Descriptions

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Inheritable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>share.desc</code></td>
<td>Editable property that provides a user-defined description and can be set on the file system or a share. The default value is no description.</td>
<td>Yes</td>
<td>string</td>
</tr>
<tr>
<td><code>share.fs</code></td>
<td>Read-only property that identifies the file system name for a share.</td>
<td>No</td>
<td>filesystem</td>
</tr>
<tr>
<td><code>share.name</code></td>
<td>Read-only property that identifies the share name for a share.</td>
<td>No</td>
<td>share-name</td>
</tr>
<tr>
<td><code>share.noauto</code></td>
<td>Editable property that disables automatic sharing and can only be set on the file system to be shared only.</td>
<td>No</td>
<td>on or off</td>
</tr>
<tr>
<td><code>share.path</code></td>
<td>Editable property that sets the share path on a share.</td>
<td>No</td>
<td>mountpoint-relative-path</td>
</tr>
<tr>
<td><code>share.point</code></td>
<td>Read-only property that identifies the absolute path of an existing share that is derived from the current value of the <code>share.path</code> property relative to the dataset mount point.</td>
<td>No</td>
<td>path</td>
</tr>
<tr>
<td><code>share.protocols</code></td>
<td>Read-only property that identifies the protocols established for the file system or the share.</td>
<td>No</td>
<td>protocol-list</td>
</tr>
<tr>
<td><code>share.state</code></td>
<td>Read-only property that identifies the current state of the share.</td>
<td>No</td>
<td>unshared, shared, or failed</td>
</tr>
</tbody>
</table>

The following share properties are specific to the NFS protocol. All NFS share specific properties are editable and inheritable. The default value for most of these properties is off unless stated otherwise.

The following are the NFS share property descriptions.

**share.nfs**

Determines whether a file system is shared over the NFS protocol. Value: on or off
share.nfs.aclok
Determines NFSv2 client access control so that when this property is set on the server, maximum access is given to all clients. If this property is not set, minimum access is given to all clients. Value: on or off

share.nfs.aclfab
Determines whether ACL permissions are fabricated. Value: on or off

share.nfs.anon
Sets UID to the effective user ID of unknown users. By default, unknown users are given the effective UID nobody. If UID is set to -1, access is denied. Value: uid

share.nfs.charset.euc-cn
Sets NFS character encoding to euc-cn (Chinese). Value: access-list

share.nfs.charset.euc-jpms
Sets NFS character encoding to euc-jpms (MicroSoft-compatible Japanese). Value: access-list

share.nfs.charset.euc-kr
Sets NFS character encoding to euc-kr (Korean). Value: access-list

share.nfs.charset.euc-tw
Sets NFS character encoding to euc-tw (Taiwanese). Value: access-list

share.nfs.charset.iso8859-1
Sets NFS character encoding to ISO 8859-1 (Latin 1). Value: access-list

share.nfs.charset.iso8859-2
Sets NFS character encoding to ISO 8859-2 (Latin 2). Value: access-list

share.nfs.charset.iso8859-5
Sets NFS character encoding to ISO 8859-5 (Latin/Cyrillic). Value: access-list

share.nfs.charset.iso8859-6
Sets NFS character encoding to ISO 8859-6 (Arabic). Value: access-list

share.nfs.charset.iso8859-7
Sets NFS character encoding to ISO 8859-7 (Greek). Value: access-list

share.nfs.charset.iso8859-8
Sets NFS character encoding to ISO 8859-8 (Hebrew). Value: access-list

share.nfs.charset.iso8859-9
Sets NFS character encoding to ISO 8859-9 (Turkish). Value: access-list

share.nfs.charset.iso8859-13
Sets NFS character encoding to ISO 8859-13 (Baltic). Value: access-list

share.nfs.charset.iso8859-15
Sets NFS character encoding to ISO 8859-15 (Western European). Value: access-list
share.nfs.charset.koi8-r
Sets NFS character encoding to ISO KOI8-R (Russian/Cyrillic). Value: access-list

share.nfs.cksum
Not yet implemented. Value: string

share.nfs.index
Determines whether a file is loaded rather than a directory listing that contains this file when the directory is referenced by an NFS URL. Value: filename

share.nfs.log
Enables NFSv2 or NFSv3 server logging for the specified file system. The tag is defined in the /etc/nfs/nfslog.conf file. If no tag is specified, the default values associated with the global tag in the /etc/nfs/nfslog.conf file is used. Value: tag

share.nfs.nosub
Prevents NFSv2 or NFSv3 clients from mounting subdirectories of shared directories. Value: on or off

share.nfs.nosuid
Prevents the NFS client from creating files with setuid or setgid permissions. If enabled, the NFS server silently ignores any attempt to enable the setuid or setgid permissions. Value: on or off

share.nfs.public
Changes the location of the public file handle from root to the shared directory for NFS-enabled browsers and clients. Value: on or off

share.nfs.sec
Sets the default security mode to SYS. The SYS security mode uses AUTH_SYS authentication, which means the user’s UID and GID are passed in clear text on the network, unauthenticated by the NFS server. Value: security-mode-list

share.nfs.sec.default.none
Sets the default security mode to none for access-list. Value: access-list

share.nfs.sec.default.ro
Sets the default security mode to read-only access for access-list. Value: access-list

share.nfs.sec.default.root
Sets the default security mode to root access for access-list. By default, no system has root access. Value: access-list

share.nfs.sec.default.root_mapping
Sets the default security mode to root access to a specific UID. By default, no user has root access. Value: UID

share.nfs.sec.default.rw
Sets the default security mode to read-write access for access-list. Value: access-list
share.nfs.sec.default.window
Sets a maximum life time in seconds for the requestor’s credential that the NFS server allows for the default security mode. The default value is 30000 seconds (8.3 hours). Value: seconds

share.nfs.sec.dh.none
Sets the Diffie Helman (dh) security mode to none for access-list. Value: access-list

share.nfs.sec.dh.ro
Sets the dh security mode to read-only access for access-list. Value: access-list.

share.nfs.sec.dh.root
Sets the dh security mode to root access for access-list. By default, no system has root access. Value: access-list.

share.nfs.sec.dh.root_mapping
Sets the dh security mode to root access to a specific UID. By default, no user has root access. Value: UID

share.nfs.sec.dh.rw
Sets the default security mode to read-write access for access-list. Value: access-list

share.nfs.sec.dh.window
Sets a maximum life time in seconds for the requestor’s credential that the NFS server allows for the dh security mode. The default value is 30000 seconds (8.3 hours). Value: seconds

share.nfs.sec.krb5.none
Sets the Kerberos V5 (krb5) security mode to none for access-list. Value: access-list

share.nfs.sec.krb5.ro
Sets the krb5 security mode to read-only access for access-list. Value: access-list

share.nfs.sec.krb5.root
Sets the krb5 security mode to root access for access-list. By default, no system has root access. Value: access-list

share.nfs.sec.krb5.root_mapping
Sets the krb5 security mode to root access to a specific UID. By default, no user has root access. Value: UID

share.nfs.sec.krb5.rw
Sets the krb5 security mode to read-write access for access-list. Value: access-list

share.nfs.sec.krb5.window
This property is not implemented for the krb5 security mode. Value: N/A

share.nfs.sec.krb5i.none
Sets the Kerberos V5 (krb5i) security mode to none. Value: access-list

share.nfs.sec.krb5i.ro
Sets the krb5i security mode to read-only access for access-list. Value: access-list
share.nfs.sec.krb5i.root
Sets the krb5i security mode to root access for access-list. By default, no system has root access. Value: access-list

share.nfs.sec.krb5i.root_mapping
Sets the krb5i security mode to root access to a specific UID. By default, no user has root access. Value: UID

share.nfs.sec.krb5i.rw
Sets the krb5i security mode to read-write access for access-list. Value: access-list

share.nfs.sec.krb5i.window
This property is not available for the krb5i security mode. Value: N/A

share.nfs.sec.krb5p.none
Sets the Kerberos V5 (krb5i) security mode to none for access-list. Value: access-list

share.nfs.sec.krb5p.ro
Sets the krb5p security mode to read-only access for access-list. Value: access-list

share.nfs.sec.krb5p.root
Sets the krb5p security mode to root access for access-list. By default, no system has root access. Value: access-list

share.nfs.sec.krb5p.root_mapping
Sets the krb5p security mode to root access to a specific UID. By default, no user has root access. Value: UID

share.nfs.sec.krb5p.rw
Sets the krb5i security mode to read-write access for access-list. Value: access-list

share.nfs.sec.krb5p.window
This property is not implemented for the krb5p security mode. Value: N/A

share.nfs.sec.none.none
Sets the security mode to none for access-list. Value: access-list

share.nfs.sec.none.ro
Sets the security mode to read-only access for access-list. Value: access-list.

share.nfs.sec.none.root
Sets the security mode to root access for access-list. By default, no system has root access. Value: access-list

share.nfs.sec.none.root_mapping
Sets the security mode to root access to a specific UID. By default, no user has root access. Value: UID

share.nfs.sec.none.rw
Sets the security mode to read-write access for access-list. Value: access-list
share.nfs.sec.none.window  
This property is not implemented. Value: seconds

share.nfs.sec.sys.none  
Sets the SYS security mode to none for access-list. Value: access-list

share.nfs.sec.sys.ro  
Sets the SYS security mode to read-only access for access-list. Value: access-list

share.nfs.sec.sys.root  
Sets the SYS security mode to root access for access-list. By default, no system has root access. Value: access-list

share.nfs.sec.sys.root_mapping  
Sets the security mode to root access to a specific UID. By default, no user has root access. Value: UID

share.nfs.sec.sys rw  
Sets the security mode to read-write access for access-list. Value: access-list

share.nfs.sec.sys.window  
This property is not implemented for the SYS security mode. Value: seconds

The following share properties are specific to the SMB protocol. All SMB share specific properties are editable and inheritable.

**TABLE 2** SMB Share Property Descriptions

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>share.smb</td>
<td>Determines whether a file system is shared over the SMB protocol. The default value is off.</td>
<td>on or off</td>
</tr>
<tr>
<td>share.smb.ad-container</td>
<td>Enables SMB share to be published in an AD container. The default value is off.</td>
<td>string</td>
</tr>
<tr>
<td>share.smb.abe</td>
<td>Enables Access-Based Enumeration (abe) support. The default is off.</td>
<td>share-name</td>
</tr>
<tr>
<td>share.smb.csc</td>
<td>Enables client side caching support. The default value is disabled.</td>
<td>disabled, manual, auto, or vdo</td>
</tr>
<tr>
<td>share.smb.catia</td>
<td>Enables CATIA translation support. The default value is off.</td>
<td>on or off</td>
</tr>
<tr>
<td>share.smb.dfsroot</td>
<td>Enables a DFS root support. The default value is off.</td>
<td>on or off</td>
</tr>
<tr>
<td>share.smb.guestok</td>
<td>Enables guest access. The default value is off.</td>
<td>on or off</td>
</tr>
</tbody>
</table>
Subcommands

All subcommands that modify state are logged persistently to the pool in their original form.

zfs

Displays a help message.

zfs help command | help | property property-name | permission

Displays zfs command usage information. You can display help for a specific command, property, or delegated permission. If you display help for a specific command or property, the command syntax or property value is displayed. Using zfs help without any arguments displays a complete list of zfs commands.

zfs help -l properties

Displays zfs property information, including whether the property value is editable and inheritable, and their possible values.

zfs create [-p] [-o share.nfs=on | share.smb=on -o ... filesystem

Creates a new ZFS file system. The file system is automatically mounted according to the mountpoint property inherited from the parent.

-o property=value

Sets the specified property as if the command zfs set property=value was invoked at the same time the dataset was created. Any editable ZFS property can also be set at creation time. Multiple -o options can be specified. An error results if the same property is specified in multiple -o options.

zfs destroy [share]

The specified file system share is destroyed.

zfs get [-r] [-d depth] [-Hp] [-o all | field[,...] [-s source[,...]] all | property[,...] dataset|dataset%namedshare ...

Displays properties for the given datasets. If no datasets are specified, then the command displays properties for all datasets on the system. For each property, the following columns are displayed:

  name      Dataset name
  property  Property name
  value     Property value

TABLE 2  SMB Share Property Descriptions  (Continued)

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>share.smb.ro</td>
<td>Sets the SMB share to read-only. You can specify on, off, or list of names (access-list). The default value is off.</td>
<td>access-list</td>
</tr>
<tr>
<td>share.smb.rw</td>
<td>Sets the SMB share to read-write. You can specify on, off, or list of names (access-list). The default value is on.</td>
<td>access-list</td>
</tr>
<tr>
<td>share.smb.none</td>
<td>Sets the SMB share to off for the specified users in the access-list.</td>
<td>access-list</td>
</tr>
</tbody>
</table>
source Property source. Can either be local, default, temporary, inherited, or none (-).

All columns except the RECEIVED column are displayed by default; specify particular or all columns, using the -o option. This command takes a comma-separated list of properties as described in the “Native Properties” and “User Properties” sections.

The special value all can be used to display all properties that apply to the given dataset’s type (filesystem, volume, or snapshot).

- r
  Recursively display properties for any children.

- d depth
  Recursively display any children of the dataset, limiting the recursion to depth. A depth of 1 will display only the dataset and its direct children.

- H
  Display output in a form more easily parsed by scripts. Any headers are omitted, and fields are explicitly separated by a single tab instead of an arbitrary amount of space.

- o field
  Set of fields to display. One or more of:
  name, property, value, received, source

  Present multiple fields as a comma-separated list. The default value is:
  name, property, value, source

  The keyword all specifies all sources.

- s source
  A comma-separated list of sources to display. Those properties coming from a source other than those in this list are ignored. Each source must be one of the following:
  local, default, inherited, temporary, received, none

  The default value is all sources.

- p
  Display numbers in parseable (exact) values.

zfs get share [filesystem]
Displays all defined shares or the defined shares for a specified file system.

zfs set share.nfs=on | share.smb=on [desc=description], filesystem | filesystem%share
Defines an NFS or SMB file sharing properties for a ZFS dataset by setting the share.nfs or share.smb property to on.

zfs set [-r] property=value filesystem|volume|snapshot|share ...
Sets the property to the given value for each file system or file system share. Only some properties can be edited. See the section for more information on what properties can be
set and acceptable values. For more information, see NFS Share Property Descriptions section or the SMB Share Property Descriptions section.

- "r
   Recursively applies the effective value of the setting throughout the subtree of child datasets. The effective value may be set or inherited, depending on the property.

zfs share [-u] -o property=value ... filesystem%share
zfs share filesystem|mountpoint|filesystem%share
zfs share -a -r | filesystem

Creates and publishes an NFS or SMB share of a ZFS dataset according to the share properties values.

Sharing a dataset with the NFS or SMB protocol means that the dataset data is available over the network. ZFS datasets that have the share.nfs or share.smb property set are automatically shared when a system is booted.

- "u
   Creates a share without immediately sharing it.

- "o property=value
   Shares the ZFS file system with the specified share property value.

- "a
   Shares all ZFS file systems according to their share property values and to the settings of the share.nfs and share.smb properties.

- "r
   Applies the share operation recursively to all file systems and shares below the specified file system.

filesystem | filesystem%share
Shares the specified file system or named file system share.

zfs unshare filesystem|mountpoint|filesystem%share
zfs unshare -a | -r | filesystem

Unshares all ZFS datasets that have the share.nfs or share.smb property set.

- "a
   Unshare all shared ZFS file systems. Invoked automatically as part of the boot process.

- "r
   Applies the unshare operation recursively to all file systems and shares below the specified file system.

filesystem|mountpoint|filesystem%share
Unshare the specified file system. The command can also be given a path to a ZFS file system shared on the system.
The following examples show how to share ZFS file systems in different ways.

A ZFS file system can be shared when it is created. For example:

```
# zfs create -o share.nfs=on tank/workspace
```

You can also apply a share property.

```
# zfs set share.nfs.nosuid=on tank/workspace
```

Confirm that the file system is shared. For example:

```
# grep workspace /etc/dfs/sharetab
/tank/workspace tank_workspace nfs nosuid,sec=sys,rw
```

A descendent file system is automatically shared. For example:

```
# zfs create tank/workspace/fs1
```

A file system can be shared after it is created. For example:

```
# zfs set share.smb=on tank/data
```

**EXAMPLE 2  Creating a More Complex SMB Share of ZFS File System**

The following example shows how to create an SMB that uses ABE (access-enabled enumeration) to determine which users can see files for which they have access. A share called %shareabe is created with the share.smb.abe property set to on. A new share called %sharenoabe is created on the same file system with share.smb.abe set to off.

```
# zfs share -o share.smb=on -o share.smb.abe=on tank/users/files%shareabe
# zfs share -o share.smb=off tank/users/files%sharenoabe
```

To allow specific users to see all files in the sharenoabe share and other users to see only files for which they have access in the shareabe share, you would need to modify the share permissions that are accessible in /tank/users/files/.zfs/shares directory.

**EXAMPLE 3  Adding or Changing Share Properties on a ZFS File System**

You can share a file system over both NFS and SMB protocols. For example:

```
# zfs set share.nfs=on tank/data
# zfs set share.smb=on tank/data
```

You can further add or change share properties. For example:

```
# zfs set share.nfs.ro=on tank/data
```

**EXAMPLE 4  Displaying NFS or SMB Share Information**

Display NFS or SMB share information.
EXAMPLE 4  Displaying NFS or SMB Share Information  (Continued)

Confirm that descendant filesystems are shared when the parent filesystem is shared. For example:

```
# zfs get -r share.nfs tank/workspace
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>PROPERTY</th>
<th>VALUE</th>
<th>SOURCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank/workspace</td>
<td>share.nfs</td>
<td>on</td>
<td>local</td>
</tr>
<tr>
<td>tank/workspace%</td>
<td>share.nfs</td>
<td>on</td>
<td>inherited from tank/workspace</td>
</tr>
<tr>
<td>tank/workspace/fs1</td>
<td>share.nfs</td>
<td>on</td>
<td>inherited from tank/workspace</td>
</tr>
<tr>
<td>tank/workspace/fs1%</td>
<td>share.nfs</td>
<td>on</td>
<td>inherited from tank/workspace</td>
</tr>
</tbody>
</table>

Exit Status The following exit values are returned:

0  Successful completion.
1  An error occurred.
2  Invalid command line options were specified.

zfs(1M), and the Oracle Solaris 11.1 Administration: ZFS File Systems.
Name  zic – time zone compiler

          [-p posixrules] [-y yearistype] [filename]...

Description  zic reads text from the file(s) named on the command line and creates the time conversion information files specified in this input. If a filename is ‘−’, the standard input is read.

Input lines are made up of fields. Fields are separated by any number of white space characters. Leading and trailing white space on input lines is ignored. A pound sign (#) indicates a comment that extends to the end of the line. White space characters and pound signs can be enclosed within double quotes (" ") if they are to be used as part of a field. Any line that is blank (after comment stripping) is ignored. Non-blank lines are expected to be of one of three types: rule lines, zone lines, or link lines.

Rule  A rule line has the form:

For example:

    Rule  NAME  FROM  TO  TYPE  IN  ON  AT  SAVE  LETTER/S

The fields that make up a rule line are:

Rule  USA  1969  1973  -  Apr  lastSun  2:00  1:00  D

NAME  Gives the (arbitrary) name of the set of rules this rule is part of.

FROM  Gives the first year in which the rule applies. The word minimum (or an abbreviation) means the minimum year with a representable time value. The word maximum (or an abbreviation) means the maximum year with a representable time value.

TO  Gives the final year in which the rule applies. In addition to minimum and maximum (as above), the word only (or an abbreviation) can be used to repeat the value of the FROM field.

TYPE  Gives the type of year in which the rule applies. If TYPE is:

    ‘−’  The rule applies in all years between FROM and TO, inclusive.
    uspres  The rule applies in U.S. Presidential election years.
    nonpres  The rule applies in years other than U.S. Presidential election years.
    even  The rule applies to even-numbered years.
    odd  The rule applies to odd-numbered years.

If TYPE is something else, then zic will attempt to execute the command

yearistype year type
to check the type of a year: an exit status of 0 means that the year is of the given type; an exit status of 1 means that the year is not of the given type. The year is type command is not currently provided in the Solaris environment.

IN  Names the month in which the rule takes effect. Month names can be abbreviated.

ON  Gives the day on which the rule takes effect. Recognized forms include:

      5       the fifth day of the month
      lastSun  The last Sunday in the month
      lastMon  The last Monday in the month
      Sun>50   First Sunday on or after the eighth
      Sun<25   Last Sunday on or before the 25th

Names of days of the week can be abbreviated or spelled out in full. Note: There cannot be spaces within the ON field.

AT  Gives the time of day at which the rule takes effect. Recognized forms include:

      2       Time in hours
      2:00    Time in hours and minutes
      15:00   24-hour format time (for times after noon)
      1:28:14 Time in hours, minutes, and seconds, where hour 0 is midnight at the start of the day and hour 24 is midnight at the end of the day.

Any of these forms can be followed by the letter w if the given time is local "wall clock" time; s if the given time is local "standard" time; or u (or g or z) if the given time is universal time. In the absence of an indicator, wall clock time is assumed.

SAVE  Gives the amount of time to be added to local standard time when the rule is in effect. This field has the same format as the AT field (without the w and s suffixes).

LETTER/S  Gives the “variable part” (for example, the “S” or “D” in “EST” or “EDT” of time zone abbreviations to be used when this rule is in effect. If this field is ‘−’, the variable part is null.

Zone  A zone line has the form:

Zone  NAME  GMTOFF  RULES/SAVE  FORMAT  [UNTIL]

For example:
The fields that make up a zone line are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>The name of the time zone. This is the name used in creating the time conversion information file for the zone.</td>
</tr>
<tr>
<td>GMTOFF</td>
<td>The amount of time to add to UTC to get standard time in this zone. This field has the same format as the AT and SAVE fields of rule lines; begin the field with a minus sign to subtract time from UTC.</td>
</tr>
<tr>
<td>RULES/SAVE</td>
<td>The name of the rule(s) that apply in the time zone or, alternately, an amount of time to add to local standard time. If this field is ‘−’, then standard time always applies in the time zone.</td>
</tr>
<tr>
<td>FORMAT</td>
<td>The format for time zone abbreviations in this time zone. The pair of characters %s is used to show where the &quot;variable part&quot; of the time zone abbreviation goes. Alternately, a slash (/) separates standard and daylight abbreviations.</td>
</tr>
<tr>
<td>UNTIL</td>
<td>The time at which the UTC offset or the rule(s) change for a location. It is specified as a year, a month, a day, and a time of day. The time of day has the same format as the AT field of rule lines. If this is specified, the time zone information is generated from the given UTC offset and rule change until the time specified.</td>
</tr>
</tbody>
</table>

The month, day, and time of day have the same format as the IN, ON, and AT columns of a rule; trailing columns can be omitted, and default to the earliest possible value for the missing columns.

The next line must be a "continuation" line. This line has the same form as a zone line except that the string "Zone" and the name are omitted. The continuation line places information starting at the time specified as the UNTIL field in the previous line in the file used by the previous line. Continuation lines can contain an UNTIL field, just as zone lines do, indicating that the next line is a further continuation.

Link A link line has the form:

```
Link LINK-FROM LINK-TO
```

For example:

```
Link Europe/Istanbul Asia/Istanbul
```

The LINK-FROM field should appear as the NAME field in some zone line; the LINK-TO field is used as an alternate name for that zone.
Except for continuation lines, lines can appear in any order in the input.

**Options**

- `-v` Outputs version information and exits.
- `-d directory` Creates time conversion information files in the directory `directory` rather than in the standard directory `/usr/share/lib/zoneinfo`.
  
  The `-d` and `-l` options are mutually exclusive.
- `-l localtime` Uses the given time zone as local time `localtime`. `zic` acts as if the file contained a link line of the form:
  
  Link `localtime` `localtime`
  
  The `-d` and `-l` options are mutually exclusive.
- `-p posixrules` Uses the rules of the given time zone `posixrules` when handling POSIX-format time zone environment variables. `zic` acts as if the input contained a link line of the form:
  
  Link `posixrules` `posixrules`
  
  This option is not used by `ctime(3C)` and `mktime(3C)` in the Solaris environment.
- `-s` Limits time values stored in output files to values that are the same whether they are taken to be signed or unsigned. You can use this option to generate SVVS-compatible files.

  This option is obsolete and may be removed in a future release.
- `-y yearistype` Uses the given command `yearistype` rather than `yearistype` when checking year types (see Rules under DESCRIPTION).

**Operands**

- `filename` A file containing input lines that specify the time conversion information files to be created. If a `filename` is `−−`, the standard input is read.

**Files**

- `/usr/share/lib/zoneinfo` Standard directory used for created files
- `/usr/share/lib/zoneinfo/src` Directory containing source files

**Attributes**

See `attributes(5)` for descriptions of the following attributes:
* The -s option is obsolete.

See Also  `time(1), zdump(1M), ctime(3C), mktime(3C), attributes(5)`

Notes  For areas with more than two types of local time, you might need to use local standard time in the AT field of the earliest transition time's rule to ensure that the earliest transition time recorded in the compiled file is correct.

If the current `timezone` file is edited and compiled using the "zic" command, the changes will only be reflected in any new processes that are running. The most accurate way to reflect the changes for the whole system would be a reboot.
The zoneadm utility is used to administer system zones. A zone is an application container that is maintained by the operating system runtime.

Except for simple listing and help functions, only a user operating in the global system zone can use zoneadm, and it must be executed with an effective user ID of root. In addition, the user must be authorized to execute specific subcommands.

zoneadm checks for authorization strings that optionally include the specified zonename as a suffix, preceded by the slash character. When omitted, the authorization matches any zone.

Subcommands that only provide information, for example, help or list, do not require any authorizations. All other subcommands require the authorization solaris.zone.manage/zonename.

Once a process has been placed in a zone other than zone 0, neither that process nor any of its children can change zones.

Options

The following options are supported:

- **-R root**
  Specify an alternate root (boot environment). This option can only be used in conjunction with the "list" and "mark" subcommands.

- **-u uuid-match**
  Unique identifier for a zone, as assigned by libuuid(3LIB). If this option is present and the argument is a non-empty string, then the zone matching the UUID is selected instead of the one named by the -z option, if such a zone is present.

- **-z zonename**
  String identifier for a zone.

Subcommands

Subcommands which can result in destructive actions or loss of work have a -F flag to force the action. If input is from a terminal device, the user is prompted if such a command is given without the -F flag; otherwise, if such a command is given without the -F flag, the action is disallowed, with a diagnostic message written to standard error. If a zone installation or uninstallation is interrupted, the zone is left in the incomplete state. Use uninstall to reset such a zone back to the configured state.
The following subcommands are supported:

```
attach [-u] [-F] [-x extended_options] [-n path] [brand-specific options]
```

The `attach` subcommand takes a zone that has been detached from one system and attaches the zone onto a new system. Therefore, it is advised (though not required) that the `detach` subcommand should be run before the “attach” takes place. Once you have the new zone in the configured state, use the `attach` subcommand to set up the zone root instead of installing the zone as a new zone.

The `attach` subcommand is also used to transition a zone from the unavailable state to the installed state. If the `attach` subcommand is unable to perform such a transition, the zone will remain in the unavailable state.

The `-F` option can be used to force the zone into the “installed” state with no validation. This option should be used with care since it can leave the zone in an unsupported state if it was moved from a source system to a target system that is unable to properly host the zone. The `-n` option can be used to perform a “dry run” of the `attach` subcommand. It uses the output of the “`detach -n`” subcommand as input and is useful to identify any conflicting issues, such as the network device being incompatible, and can also determine whether the host is capable of supporting the zone. The path can be “`-`”, to read the input from standard input.

The zone’s brand may include additional options that govern how the zone will be attached. See `brands(5)` for specific brand information.

Use the following command to attach a zone:

```
# zoneadm -z my-zone attach
```

Use the following command to attach and update a zone:

```
# zoneadm -z my-zone attach -u
```

In the absence of `-n` (as above), the source zone must be halted before this subcommand can be used.

```
-n path
```

Read the zone manifest and verify that the target machine has the correct configuration to host the zone without actually performing an attach. The zone on the target system does not have to be configured on the new host before doing a trial-run attach.

```
-u
```

Update the attached zone.

```
-x force-zpool-import
```

Specify this option to forcibly reuse existing zpool resources that may appear to be in-use.
-x force-zpool-create
-x force-zpool-create-all
Specify -x with force-zpool-create-all to forcibly create all zpool resources.

Use -x with force-zpool-create, with the syntax:
-x force-zpool-create=zpoolname{,zpoolname,zpoolname,...}
...to limit this option to a specific set of zpool resources. To name a root zpool resource, use rpool. For a zpool resource, use the name specified in the corresponding zone config name property.

These options are only available for archive-based attach usage. See brands(5) for the information which brands support archive-based attach.

boot [-w|--w] [-W|--W] [-- boot_options]
Boot (or activate) the specified zones.

The boot subcommand has the following mutually exclusive options:

- w
  Boots the zone with a writable root, effectively overriding the file-mac-profile setting in the zone's configuration. This option is in effect for this boot-cycle only: a subsequent reboot will boot the zone with a file-mac-profile in effect again.

- W
  Boots the zone in transient r/w mode; when the zone completes self-assembly, the zone will reboot in read-only mode. Has no effect non-read only root zones.

The following boot_options are supported:

- i altinit
  Select an alternative executable to be the primordial Process. altinit is a valid path to an executable. The default primordial process is init(1M).

- m smf_options
  The smf_options include two categories of options to control booting behavior of the service management facility: recovery options and messages options.

  Message options determine the type and amount of messages that smf(5) displays during boot. Service options determine the services which are used to boot the system. See kernel(1M) for a listing of the -m suboptions.

- s
  Boots only to milestone svc:/milestone/single-user:default. This milestone is equivalent to init level s. See svc.startd(1M) and init(1M).

close [-m copy] [-s zfs_snapshot] [-x extended_options] [brand-specific options] source_zone
Install a zone by copying an existing installed zone. This subcommand is an alternative way to install the zone.
-m copy
    Force the clone to be a copy, even if a “ZFS clone” is possible.
    
    Note, this is the default (and only supported) clone method for zones that have a
    rootzpool resource configured.

-s zfs_snapshot
    Specify the name of a ZFS snapshot to use as the source of the clone. The snapshot
    must be a snapshot of the source zone taken from a previous “zoneadm clone” installation.

-x force-zpool-import
    Specify the -x option with force-zpool-import to forcibly reuse existing zpool
    resources that may appear to be in use.

-x force-zpool-create
-x force-zpool-create-all
    Specify the -x option with force-zpool-create-all to forcibly create all zpool
    resources.
    
    Use -x with force-zpool-create, with the syntax:
    -x force-zpool-create=zpoolname{,zpoolname,zpoolname,...}
    ...to limit this option to a specific set of zpool resources. To name a rootzpool zpool
    resource, use rpool. For a zpool resource, use the name specified in the corresponding
    zone config name property.
    
    The source zone must be halted before this subcommand can be used.

detach [-F | -n]
    Detach the specified zone. Detaching a zone is the first step in moving a zone from one
    system to another. The full procedure to migrate a zone is that the zone is detached, the
    zonepath directory is moved to the new host, and then the zone is attached on the new host.
    Once the zone is detached, it is left in the configured state. If you try to install or clone to a
    configured zone that has been detached, you will receive an error message and the install
    or clone subcommand will not be allowed to proceed. The -n option can be used to
    perform a “dry run” of the detach subcommand. This generates the information needed
    for running the “attach -n” subcommand, which is useful to identify any conflicting
    issues, such as the network device being incompatible or if the host is capable of supporting
    the zone. The information is sent to standard output and can be saved to a file or piped to
    the “attach -n” subcommand. The -F option can be used to forcefully detach the zone
    without performing verification checks on the existing zonepath.
    
    Use the following command to detach a zone:
    
    # zoneadm -z my-zone detach
    
    Unless the -n option is used, the source zone must be halted before this subcommand can
    be used.
-F
Forcefully detach the zone without performing verification checks on the zone's storage. This option is typically used if the storage for the zone path is no longer accessible to this host. Such a scenario is normally encountered when the zone's storage has been failed over to an alternate host, either manually or as part of a cluster.

-n
Generate a zone manifest on a running zone without actually detaching the zone. The state of the zone on the originating system is not changed. The zone manifest is sent to stdout. The global administrator can direct this output to a file or pipe it to a remote command to be immediately validated on the target host.

halt
Halt the specified zones. halt bypasses running the shutdown scripts inside the zone. It also removes run time resources of the zone.

See also the shutdown subcommand, below.

help [subcommand]
Display general help. If you specify subcommand, displays help on subcommand.

install [-x extended_options] [brand-specific options]
Install the specified zone on the system. This subcommand automatically attempts to verify first. It refuses to install if the verify step fails. See the verify subcommand.

-x force-zpool-import
Specify the -x option with force-zpool-import to forcibly reuse existing zpool resources that may appear to be in use.

-x force-zpool-create
-x force-zpool-create-all
Specify the -x option with force-zpool-create-all to forcibly create all zpool resources.

Use -x with force-zpool-create, with the syntax:

-x force-zpool-create=zpoolname{,zpoolname,zpoolname,...}

...to limit this option to a specific set of zpool resources. To name a root zpool resource, use rpool. For a zpool resource, use the name specified in the corresponding zone config name property.

The zone's brand may include additional options that govern how the software will be installed in the zone. See brands(5) for specific brand information.

list [list_options]
Display the name of the current zones, or the specified zone if indicated.

By default, all running zones are listed. If you use this subcommand with the zoneadm -z zonename option, it lists only the specified zone, regardless of its state. In this case, the -i and -c options are disallowed.
If neither the -i or -c options are given, all running zones are listed.

The following list_options are supported:

- **c**
  Display all configured zones. This option overrides the -i option.

- **i**
  Expand the display to all installed zones.

- **p**
  Request machine parsable output. The output format is a list of lines, one per zone, with colon-delimited fields. These fields are:

  If the zonepath contains embedded colons, they can be escaped by a backslash ("\:"), which is parsable by using the shell read(1) function with the environmental variable IFS. The uuid value is assigned by libuuid(3LIB) when the zone is installed, and is useful for identifying the same zone when present (or renamed) on alternate boot environments. Any software that parses the output of the “zoneadm list -p” command must be able to handle any fields that may be added in the future.

  The -v and -p options are mutually exclusive. If neither -v nor -p is used, just the zone name is listed.

- **v**
  Display verbose information, including zone name, id, current state, root directory, brand type, ip-type, and options.

  The -v and -p options are mutually exclusive. If neither -v nor -p is used, just the zone name is listed.

**mark state**

Change the state of a zone. Only a subset of the zone states are supported, as described below.

**incomplete**

Change the state of an installed zone to incomplete. This command can be useful in cases where administrative changes on the system have rendered a zone permanently unusable or inconsistent. This change cannot be undone, except by uninstalling the zone.

**unavailable**

Change the state of an installed zone to unavailable. This command can be useful in cases where administrative changes or failures on the system have rendered a zone temporarily unusable. This change can be undone with the attach subcommand.
**move new_zonepath**

Move the `zonepath` to `new_zonepath`. The zone must be halted before this subcommand can be used. The `new_zonepath` must be a local file system and normal restrictions for `zonepath` apply.

Note, for zones configured with a rootzpool resource only the `zonepath` will be renamed but the zone itself will not move out of its containing zpool.

**ready**

Prepares a zone for running applications but does not start any user processes in the zone.

**reboot [- -- boot_options]**

Restart the zone. This is equivalent to a `halt boot` sequence (shutdown scripts are not run).

See the boot subcommand for supported boot options.

**shutdown [-r [- -- boot_options]]**

Cleanly shut down the zone (equivalent to running `/usr/sbin/init 0` in the zone). The `shutdown` subcommand waits until the zone is successfully shut down; a `zoneadm halt` can be used to forcibly halt the zone, if the shutdown process takes a long time.

If `-r` is specified, reboot the zone. See the boot subcommand for supported boot options.

**uninstall [-F] [-x extended_options]**

Uninstall the specified zone from the system. Use this command with caution. It removes all of the files under the `zonepath` of the zone in question. You can use the `-F` flag to force the action.

- `-x force-zpool-destroy`
- `-x force-zpool-destroy-all`

The `-x` option with `force-zpool-destroy-all` option can be used to destroy all zpools.

Use `-x` with `force-zpool-destroy`, with the syntax:

```bash
-x force-zpool-destroy=zpoolname(zpoolname,zpoolname,...)
```

...to limit this option to a specific set of zpool resources. To name a rootzpool zpool resource, use `rpool`. For a zpool resource, use the name specified in the corresponding zone config name property.

**verify**

Check to make sure the configuration of the specified zone can safely be installed on the machine. Following is a breakdown of the checks by resource/property type:

**zonepath**

`zonepath` and its parent directory exist and are owned by root with appropriate modes. The appropriate modes are that `zonepath` is 700, its parent is not group or world-writable and so forth. `zonepath` is not over an NFS mount. A sub-directory of the `zonepath` named “root” does not exist.
If `zonepath` does not exist, the `verify` does not fail, but merely warns that a subsequent install will attempt to create it with proper permissions. A `verify` subsequent to that might fail should anything go wrong.

`zonepath` cannot be a symbolic link.

`fs`

Any `fs` resources have their `type` value checked. An error is reported if the value is one of `proc`, `mntfs`, `autofs`, or `nfs` or the filesystem does not have an associated mount binary at `/usr/lib/fs/<fstype>/mount`.

It is an error for the directory to be a relative path.

It is an error for the path specified by `raw` to be a relative path or if there is no `fsck` binary for a given filesystem type at `/usr/lib/fs/<fstype>/fsck`. It is also an error if a corresponding `fsck` binary exists but a `raw` path is not specified.

`net`

All physical network interfaces exist. All network address resources are one of:

- a valid IPv4 address, optionally followed by "/" and a prefix length;
- a valid IPv6 address, which must be followed by "/" and a prefix length;
- a host name which resolves to an IPv4 address.

Note that hostnames that resolve to IPv6 addresses are not supported.

The physical interface name is the network interface name.

A zone can be configured to be either exclusive-IP or shared-IP. For a shared-IP zone, both the physical and address properties must be set. For an exclusive-IP zone, the physical property must be set and the address property cannot be set.

`anet`

It verifies that the lower-link, over which the VNIC will be automatically created, exists.

`rctl`

It also verifies that any defined resource control values are valid on the current machine. This means that the privilege level is privileged, the limit is lower than the currently defined system value, and that the defined action agrees with the actions that are valid for the given resource control.

`rootzpool, zpool`

All `zpool`s configured are online on the system for a zone in the installed state.

For a zone in configured state, it verifies that none of the configured `zpool` resources are already online on the system.
Examples  
EXAMPLE 1 Using the -m Option  
The following command illustrates the use of the -m option.

```
# zoneadm boot -- -m verbose
```

EXAMPLE 2 Using the -i Option  
The following command illustrates the use of the -i option.

```
# zoneadm boot -- -i /usr/sbin/init
```

EXAMPLE 3 Using the -s Option  
The following command illustrates the use of the -s option.

```
# zoneadm boot -- -s
```

Exit Status  
The following exit values are returned:

<table>
<thead>
<tr>
<th>Exit Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful completion.</td>
</tr>
<tr>
<td>1</td>
<td>An error occurred.</td>
</tr>
<tr>
<td>2</td>
<td>Invalid usage.</td>
</tr>
</tbody>
</table>

Notes  
The zones(5) service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/zones:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

For the first boot after a read-only zone is installed or upgraded, or when the zone is booted with -w/-W, the write-only protection is disabled. Care must be taken that the zone is otherwise protected.
zoneadm(1M)

**Name**
zoneadm – zone administration daemon

**Synopsis**
/usr/lib/zones/zoneadm

**Description**
zoneadm is a system daemon that is started when the system needs to manage a particular zone. Because each instance of the zoneadm daemon manages a particular zone, it is not unexpected to see multiple zoneadm daemons running.

This daemon is started automatically by the zone management software and should not be invoked directly. The daemon shuts down automatically when no longer in use. It does not constitute a programming interface, but is classified as a private interface.

Addresses configured by zoneadm on behalf of shared-ip zones are assigned automatically generated `ipadm(1M)` address object names prefixed with the string zoneadm. For example, in the following output, the address 10.2.2.1/24, configured on the net0 interface, was configured by zoneadm with an automatically generated address object name of net0/zoneadm.v4.

```
# ipadm show-addr

**Notes**
The `zones(5)` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/zones:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
**zonecfg** utility creates, modifies, and lists the configuration of a zone. The creation and modification functions are only available to authorized users and require that the process is executed with an effective user ID of root. Otherwise it runs in read-only mode.

A zone's configuration consists of a number of resources and properties.

To simplify the user interface, **zonecfg** uses the concept of a scope. The default scope is global.

The following synopsis of the **zonecfg** command is for interactive usage:

```
zonecfg -z zonename subcommand
```

Parameters changed through **zonecfg** do not affect a running zone. The zone must be rebooted for the changes to take effect.

In addition to creating and modifying a zone, the **zonecfg** utility can also be used to persistently specify the resource management settings for the global zone.

In the following text, “rctl” is used as an abbreviation for “resource control”. See `resource_controls(5)`.

Every zone is configured with an associated brand. The brand determines the user-level environment used within the zone, as well as various behaviors for the zone when it is installed, boots, or is shutdown. Once a zone has been installed the brand cannot be changed. The default brand is determined by the installed distribution in the global zone. Some brands do not support all of the **zonecfg** properties and resources. See the brand-specific man page for more details on each brand. For an overview of brands, see the `brands(5)` man page.

The following resource types are supported:

- **attr**
  Generic attribute.

- **capped-cpu**
  Limits for CPU usage.

- **capped-memory**
  Limits for physical, swap, and locked memory.

- **dataset**
  ZFS dataset.
dedicated-cpu
Subset of the system's processors dedicated to this zone while it is running.

device
Device.

fs
file-system

net
Network interface.

anet
Automatic network interface.

admin
Delegated administrator.

rctl
Resource control.

rootzpool
Dedicated ZFS zpool for zone installation.

zpool
ZFS zpool delegated to the zone.

Previous releases of Solaris offered the notion of sparse root zones. This functionality was
intimately associated with the SVr4 packaging system and intended to save disk space and
reduce administrative effort.

The new packaging system, IPS, provides more flexibility when choosing which packages to
install in a zone. This, along with advances in file system technology (notable among which is
ZFS deduplication), means that it was most sensible to remove sparse root zones. The benefits
of sparse root zones are provided for all zones by means of the combination of IPS packaging
and file system advances.

Each resource type has one or more properties. There are also some global properties, that is,
properties of the configuration as a whole, rather than of some particular resource.

The following properties are supported:

(global)
zonename

(global)
zonepath

(global)
autoboot
(global)
    bootargs

(global)
    pool

(global)
    limitpriv

(global)
    brand

(global)
    cpu-shares

(global)
    hostid

(global)
    max-lwps

(global)
    max-msg-ids

(global)
    max-processes

(global)
    max-sem-ids

(global)
    max-shm-ids

(global)
    max-shm-memory

(global)
    scheduling-class

(global)
    fs-allowed

(global)
    file-mac-profile

fs
    dir, special, raw, type, options

net
    address, allowed-address, configure-allowed-address, physical, defrouter

anet

    configure-allowed-address, defrouter, mac-address, mac-slot, mac-prefix, mtu,
maxbw, priority, vlan-id, vlsi-typeid, vlsi-vers, vlsi-mgrid, rxfanout, rxrings, 
trxrings, link-protection, allowed-dhcp-cids, pkey, linkmode, etsbw-lcl, cos

device
  match, allow-partition, allow-raw-io

rctl
  name, value

attr
  name, type, value

dataset
  name, alias

dedicated-cpu
  ncpus, importance

capped-memory
  physical, swap, locked

capped-cpu
  ncpus

admin
  user, auths

rootzpool
  storage

zpool
  storage, name

As for the property values that are paired with these names, they are either simple, complex, or
lists. The type allowed is property-specific. Simple values are strings, optionally enclosed
within quotation marks. Complex values have the syntax:

\(<\text{name}=\langle\text{value}\rangle, \langle\text{name}=\langle\text{value}\rangle, \ldots\)\)

where each \(<\text{value}\) is simple, and the \(<\text{name}\) strings are unique within a given property.
Lists have the syntax:

\([\langle\text{value}\rangle, \ldots]\)

where each \(<\text{value}\) is either simple or complex. A list of a single value (either simple or
complex) is equivalent to specifying that value without the list syntax. That is, “foo” is
equivalent to “[foo]”. A list can be empty (denoted by “[]”).

In interpreting property values, zonecfg accepts regular expressions as specified in
\fnmatch(5)\). See EXAMPLES.

The property types are described as follows:
global: zonename
  The name of the zone.

global: zonepath
  Path to zone's file system.

global: autoboot
  Boolean indicating that a zone should be booted automatically at system boot. Note that if
  the zones service is disabled, the zone will not autoboot, regardless of the setting of this
  property. You enable the zones service with a svcadm command, such as:

  # svcadm enable svc:/system/zones:default

  Replace enable with disable to disable the zones service. See svcadm(1M).

global: bootargs
  Arguments (options) to be passed to the zone bootup, unless options are supplied to the
  "zoneadm boot" command, in which case those take precedence. The valid arguments are
  described in zoneadm(1M).

global: pool
  Name of the resource pool that this zone must be bound to when booted. This property is
  incompatible with the dedicated-cpu resource.

global: limitpriv
  The maximum set of privileges any process in this zone can obtain. The property should
  consist of a comma-separated privilege set specification as described in
  priv_str_to_set(3C). Privileges can be excluded from the resulting set by preceding their
  names with a dash (-) or an exclamation point (!). The special privilege string "zone" is not
  supported in this context. If the special string "default" occurs as the first token in the
  property, it expands into a safe set of privileges that preserve the resource and security
  isolation described in zones(5). A missing or empty property is equivalent to this same set
  of safe privileges.

  The system administrator must take extreme care when configuring privileges for a zone.
  Some privileges cannot be excluded through this mechanism as they are required in order
  to boot a zone. In addition, there are certain privileges which cannot be given to a zone as
  doing so would allow processes inside a zone to unduly affect processes in other zones.
  zoneadm(1M) indicates when an invalid privilege has been added or removed from a zone’s
  privilege set when an attempt is made to either "boot" or "ready" the zone.

  See privileges(5) for a description of privileges. The command “ppriv -l” (see
  ppriv(1)) produces a list of all Solaris privileges. You can specify privileges as they are
  displayed by ppriv. In privileges(5), privileges are listed in the form
  PRIV_privilege_name. For example, the privilege sys_time, as you would specify it in this
  property, is listed in privileges(5) as PRIV_SYS_TIME.

global: brand
  The zone's brand type.
global: ip-type
A zone can either have its own exclusive instance of IP (the default) or share the IP instance with the global zone. In the default zone template, SYSdefault, ip-type is set to exclusive. In the also-supplied SYSdefault-shared-ip template, ip-type is set to shared.

This property takes the values exclusive and shared.

global: hostid
A zone can emulate a 32-bit host identifier to ease system consolidation. A zone's hostid property is empty by default, meaning that the zone does not emulate a host identifier. Zone host identifiers must be hexadecimal values between 0 and FFFFFFFE. A 0x or 0X prefix is optional. Both uppercase and lowercase hexadecimal digits are acceptable.

global: fs-allowed
A comma-separated list of additional filesystems that can be mounted within the zone; for example, ufs, pcfs. By default, only hsfs(7FS) and network filesystems can be mounted.

This property does not apply to file systems mounted into the zone by means of add fs or add dataset.

Caution – Allowing filesystem mounts other than the default might allow the zone administrator to compromise the system with a bogus filesystem image and is not supported.

global: file-mac-profile
Define which parts of the filesystem are exempted from the read-only policy, that is, which parts of the filesystem the zone is allowed to write to.

There are currently four supported values for this property: none, strict, fixed-configuration, and flexible-configuration.

none makes the zone exactly the same as a normal, r/w zone. strict allows no exceptions to the read-only policy. fixed-configuration allows the zone to write to files in and below /var, except directories containing configuration files:

```
/var/ld
/var/lib/postrun
/var/pkg
/var/spool/cron,
/var/spool/postrun
/var/svc/manifest
/var/svc/profiles
```

flexible-configuration is equal to fixed-configuration, but allows writing to files in /etc in addition.

global: fs: dir, special, raw, type, options
Values needed to determine how, where, and so forth to mount file systems. See mount(1M), mount(2), fsck(1M), and vfstab(4).
net: address, allowed-address, configure-allowed-address, physical, defrouter

The net resource represents the assignment of a physical network resource to a zone. The resource must exist in the global zone prior to the assignment.

The network address and physical interface name of the network interface. The network address is one of:

- a valid IPv4 address, optionally followed by "/" and a prefix length;
- a valid IPv6 address, which must be followed by "/" and a prefix length;
- a host name which resolves to an IPv4 address.

Note that host names that resolve to IPv6 addresses are not supported.

The physical interface name is the network interface name.

The value for the optional default router is specified similarly to the network address except that it must not be followed by a / (slash) and a network prefix length. To enable correct use of the defrouter functionality, the zones that use the property must be on a different subnet from the subnet on which the global zone resides. Also, each zone (or set of zones) that uses a different defrouter setting must be on a different subnet.

A zone can be configured to be either exclusive-IP or shared-IP. For a shared-IP zone, you must set both the physical and address properties; setting the default router is optional. The interface specified in the physical property must be plumbed in the global zone prior to booting the non-global zone. However, if the interface is not used by the global zone, it should be configured down in the global zone, and the default router for the interface should be specified here. The allowed-address property cannot be set for a shared-IP zone.

For an exclusive-IP zone, the physical property must be set and the address property must not be set. Optionally, the set of IP addresses that the exclusive-IP zone can use might be constrained by specifying the allowed-address property. If allowed-address has not been specified, then the exclusive-IP zone can use any IP address on the associated physical interface for the net resource. Otherwise, when allowed-address is specified, the exclusive-IP zone cannot use IP addresses that are not in the allowed-address list for the physical address. If configure-allowed-address is set to true, the addresses specified by allowed-address are automatically configured on the interface each time the zone boots. When it is set to false, the allowed-address will not be configured on zone boot. By default, configure-allowed-address is set to true when an allowed-address is specified. In addition, when the allowed-address list has been populated, the defrouter property can also be optionally specified. However, if the defrouter value is specified and configure-allowed-address is set to false, the defrouter value will be ignored and an appropriate warning message will be shown. The interface specified for the physical property must not be in use in the global zone. If an allowed-address and default router are specified by means of zonecfg, these will be applied to the interface when it is enabled by means of ipadm(1M) in the non-global, exclusive-IP zone, typically during zone boot. The non-global exclusive-IP zone will not be able to apply any other addresses to that
interface, nor will it be able to transmit packets with a different source address for the
specified IP version. A default router set up by means of zonecfg cannot be persistently
deleted from within the non-global exclusive-IP zone using the -p flag with route(1M).

Note that a single datalink cannot be shared among multiple exclusive-IP zones.

The anet resource represents the automatic creation of a network resource for an
exclusive-IP zone. When zonecfg creates a zone using the default SYSdefault template, an
anet resource with the following properties is automatically included in the zone
configuration:

```
linkname=net0
lower-link=auto
mac-address=random
link-protection=mac-nospoof
```

When such a zone boots, a temporary VNIC or IPoIB datalink is automatically created for
the zone. The VNIC or the IPoIB datalink is deleted when the zone halts.

The supported properties are described below. All these properties are optional. Only the
global zone is allowed to modify the automatically created VNIC or IPoIB datalink or its
properties. If a property set in zonecfg cannot be assigned to the VNIC or IPoIB datalink at
its creation time, the zone will fail to boot.

**linkname**

Specify a name for the automatically created VNIC or IPoIB datalink. By default, this
property will be automatically set to the first available name (for the zone) of the form
netN, where N is a non-negative integer. For example: net0, net1, and so on. The info
subcommand displays the automatically selected `linkname`.

Multiple zones, including the global zone, can have links with the same name at the
same time.

**lower-link**

Specify the link over which the VNIC or IPoIB will be created. This property has a
default value of auto for Ethernet links. If pkey is specified, lower-link must be
specified with a valid IPoIB phys class datalink. The administrator may explicitly specify
a value upon adding an anet resource. The link can be any link accepted as an argument
to dladm create-vnic's -l option or to dladm create-part's -l option (see
dladm(1M)). If this property is set to a `linkname` (other than auto) and that link does not
exist, then the zone will fail to boot. When set to auto, the `zoneadm(1M)` daemon will
automatically choose the link over which the VNIC will be created each time the zone
boots. All IPoIB datalinks will be skipped when selecting the default lower-link for creating the VNIC automatically during boot. A link will be chosen using the following heuristic:

1. A link aggregation that has a link state of up.
2. Of the physical Ethernet links that have a link state of up, the one with the alphabetically smallest link name.
3. If none is up, the datalink named net0 is used if it exists.

If none of the above can be satisfied, the zone will fail to boot.

allowed-address
See the description of the allowed-address property for exclusive-IP zones in the net resource.

auto-mac-address
Holds the value of the randomly generated MAC address when the mac-address property (see below) is set to random or auto, so that the zone reacquires the same address on a persistent basis. To reset the randomly generated address, an administrator needs to clear this property.

configure-allowed-address
See the description of the configure-allowed-address property for exclusive-IP zones in the net resource.

cos
The 802.1p priority associated with the datalink. See dladm(1M) for details on this property.

defrouter
See the description of the defrouter property for exclusive-IP zones in the net resource.

etsbw-lcl
Indicates the ETS bandwidth on the TX side. See dladm(1M) for details on this property.

mac-address
Set the VNIC's MAC address based on the specified value or keyword. If the value is not a keyword, it is interpreted as a unicast MAC address. This property is not supported on IPoIB datalinks. The supported keywords are:

- **factory**: Assign a factory MAC address to the VNIC. When a factory MAC address is requested, the mac-slot property can be used to specify the MAC address slot identifier. Otherwise, the next available factory MAC address will be used.

- **random**: Assign a random MAC address to the VNIC. Use the mac-prefix property to specify a prefix. Otherwise, a default prefix consisting of a valid IEEE OUI with the local bit set will be used. This is the default value.
- auto: Try to use a factory MAC address first. If none is available, assign a random MAC address.

If a random MAC address is selected, then the address generated will be preserved across zone boots and zone detach/attach. This will allow zones to retain their DHCP leases by maintaining stable client IDs, and otherwise take advantage of other benefits of having stable MAC addresses.

**mac-prefix**

Specify the MAC address prefix if a random MAC address is requested. Otherwise this property is ignored. This property is not valid over IPoIB datalinks.

**mac-slot**

Specify the MAC address slot identifier if the factory MAC address is requested. Otherwise this property is ignored. This property is not valid over IPoIB datalinks.

**mtu**

The maximum transmission unit of the VNIC in bytes. See `mtu` property in `dladm(1M)`.

**maxbw**

Specify the full duplex bandwidth for the VNIC. See `maxbw` property in `dladm(1M)`. By default, the VNIC will use the `maxbw` set on the `lower-link` and if none is set then there is no bandwidth limit.

**priority**

Specify the relative priority for the VNIC. See the `priority` property in `dladm(1M)` for supported values and default.

**vlan-id**

Enable VLAN tagging for this VNIC and specify a id for the VLAN tag. There is no default value which means if this property is not set then the VNIC does not participate in any VLAN. This property is not supported on IPoIB datalinks.

**vsi-typeid**

Specify the VSI Type ID associated with a VNIC. See description in `dladm(1M)`.

**vsi-vers**

Specify the VSI Version associated with a VNIC. See description in `dladm(1M)`.

**vsi-mgrid**

Specify the VSI Manager ID associated with a VNIC. See description in `dladm(1M)`.

**rxfanout**

Specify the number of receive-side fanout threads. See description in `dladm(1M)`.

**rxrings**

Specify the receive rings for the VNIC. See `rxrings` property in `dladm(1M)` for supported values and default.
txrings
Specify the transmit rings for the VNIC. See txrings property in dladm(1M) for supported values and default.

link-protection
Enables one or more types of link protection using comma-separated values. See the protection property in dladm(1M) for supported values. It has a default value of mac-nospoof.

Note that adding ip-nospoof to this property will have no effect unless allowed-address is also set. Setting allowed-address will implicitly add ip-nospoof to the set of link-protection, and clearing allowed-address will remove it.

allowed-dhcp-cids
Setting this property will enable dhcp-nospoof on the VNIC. See dladm(1M) for details.

pkey
Specifies the InfiniBand Partition key value in hexadecimal. pkey is always treated as hexadecimal, whether it has the 0x prefix or not. This property is only valid for IPoIB datalinks.

linkmode
Sets the link transport service type on an IB partition datalink. The default value is cm. This property is valid only for IPoIB datalinks. Valid values are:

  cm
  Connected Mode. This mode uses a default MTU of 65520 and supports a maximum MTU of 65535 bytes. If Connected Mode is not available for a remote node, Unreliable Datagram mode will automatically be used instead.

  ud
  Unreliable Datagram Mode. This mode uses a default MTU of 2044 and supports a maximum MTU of 4092 bytes.

device: match, allow-partition, allow-raw-io
Device name to match. This can be a pattern to match or an absolute pathname. Note that device resources and aliased datasets can have namespace conflicts in /dev/zvol. See dev(7FS).

Both allow-partition and allow-raw-io can be set to true or false, and default to false. See NOTES.

Note – In general, adding devices to a zone can compromise the security of the system; see NOTES.

rctl: name, value
The name and priv/limit/action triple of a resource control. See prctl(1) and rctladm(1M). The preferred way to set rctl values is to use the global property name associated with a specific rctl.
attr: name, type, value
   The name, type and value of a generic attribute. The type must be one of int, uint,
   boolean or string, and the value must be of that type. uint means unsigned, that is, a
   non-negative integer.

dataset: name, alias
   The name of a ZFS dataset to be accessed from within the zone. See zfs(1M). Each dataset
   is aliased such that it appears as a virtual ZFS pool in the zone. The alias is the name of this
   virtual pool. See zpool(1M) for name restrictions that apply to ZFS pool names and as a
   result also apply to dataset alias values. The alias rpool is reserved from the zone’s rpool
dataset. Note that aliased datasets and device resources can have namespace conflicts in
   /dev/zvol. See dev(7FS).

global: cpu-shares
   The number of Fair Share Scheduler (FSS) shares to allocate to this zone. This property is
   incompatible with the dedicated-cpu resource. This property is the preferred way to set
   the zone.cpu-shares rctl.

global: max-lwps
   The maximum number of LWP s simultaneously available to this zone. This property is the
   preferred way to set the zone.max-lwps rctl.

global: max-msg-ids
   The maximum number of message queue IDs allowed for this zone. This property is the
   preferred way to set the zone.max-msg-ids rctl.

global: max-processes
   The maximum number of process table slots simultaneously available to this zone. This
   property is the preferred way to set the zone.max-processes rctl. Setting this property will
   implicitly set the value of the max-lwps property to 10 times the number of process slots
   unless the max-lwps property has been set explicitly.

global: max-sem-ids
   The maximum number of semaphore IDs allowed for this zone. This property is the
   preferred way to set the zone.max-sem-ids rctl.

global: max-shm-ids
   The maximum number of shared memory IDs allowed for this zone. This property is the
   preferred way to set the zone.max-shm-ids rctl.

global: max-shm-memory
   The maximum amount of shared memory allowed for this zone. This property is the
   preferred way to set the zone.max-shm-memory rctl. A scale (K, M, G, T) can be applied to
   the value for this number (for example, 1M is one megabyte).

global: scheduling-class
   Specifies the scheduling class used for processes running in a zone. When this property is
   not specified, the scheduling class is established as follows:
   ■ If the cpu-shares property or equivalent rctl is set, the scheduling class FSS is used.
If neither cpu-shares nor the equivalent rctl is set and the zone’s pool property references a pool that has a default scheduling class, that class is used.

- Under any other conditions, the system default scheduling class is used.

dedicated-cpu: ncpus, importance
The number of CPUs that should be assigned for this zone's exclusive use. The zone will create a pool and processor set when it boots. See pooladm(1M) and poolcfg(1M) for more information on resource pools. The ncpu property can specify a single value or a range (for example, 1-4) of processors. The importance property is optional; if set, it will specify the pset.importance value for use by poold(1M). If this resource is used, there must be enough free processors to allocate to this zone when it boots or the zone will not boot. The processors assigned to this zone will not be available for the use of the global zone or other zones. This resource is incompatible with both the pool and cpu-shares properties. Only a single instance of this resource can be added to the zone.

capped-memory: physical, swap, locked
The caps on the memory that can be used by this zone. A scale (K, M, G, T) can be applied to the value for each of these numbers (for example, 1M is one megabyte). Each of these properties is optional but at least one property must be set when adding this resource. Only a single instance of this resource can be added to the zone. The physical property sets the max-rss for this zone. This will be enforced by rcapd(1M) running in the global zone. The swap property is the preferred way to set the zone.max-swap rctl. The locked property is the preferred way to set the zone.max-locked-memory rctl.

capped-cpu: ncpus
Sets a limit on the amount of CPU time that can be used by a zone. The unit used translates to the percentage of a single CPU that can be used by all user threads in a zone, expressed as a fraction (for example, .75) or a mixed number (whole number and fraction, for example, 1.25). An ncpu value of 1 means 100% of a CPU, a value of 1.25 means 125%, .75 mean 75%, and so forth. When projects within a capped zone have their own caps, the minimum value takes precedence.

The capped-cpu property is an alias for zone.cpu-cap resource control and is related to the zone.cpu-cap resource control. See resource_controls(5).

admin: user, auths
Delegates zone administrative authorizations to the specified user or role. The user must correspond to a valid local account. The allowed values for auths are:

- login
  Allows authenticated use of zlogin(1) into this zone.

- manage
  Allows normal management of the configured zone.

- copyfrom
  Allows the use of the specified zone as a source from which to clone a new zone.
rootzpool:storage
Defines one or more storage resources to be used exclusively for a dedicated zpool containing the zone installation. The allowed values for storage are defined in `suri(5)`.

zpool: storage, name
Defines one or more storage resources to be used exclusively for a zpool delegated to the zone. The allowed values for storage are defined in `suri(5)`. The allowed values for name are defined in `zpool(1M)`. The name `rpool` is not permitted.

</table>

To further specify things, the breakdown of the complex property “value” of the “rctl” resource type, it consists of three name/value pairs, the names being “priv”, “limit” and “action”, each of which takes a simple value. The “name” property of an “attr” resource is syntactically restricted in a fashion similar but not identical to zone names: it must begin with an alphanumeric, and can contain alphanumerics plus the hyphen (-), underscore (_), and dot (.) characters. Attribute names beginning with “zone” are reserved for use by the system. Finally, the “autoboot” global property must have a value of “true” or “false”. 
Using the kernel statistics (\texttt{kstat(3KSTAT)}) module \texttt{caps}, the system maintains information for all capped projects and zones. You can access this information by reading kernel statistics (\texttt{kstat(3KSTAT)}), specifying \texttt{caps} as the \texttt{kstat} module name. The following command displays kernel statistics for all active CPU caps:

\texttt{# kstat caps::'/cpucaps'/}

A \texttt{kstat(1M)} command running in a zone displays only CPU caps relevant for that zone and for projects in that zone. See EXAMPLES.

The following are cap-related arguments for use with \texttt{kstat(1M)}:

- \texttt{caps}
  - The \texttt{kstat} module.
- \texttt{project_caps} or \texttt{zone_caps}
  - \texttt{kstat} class, for use with the \texttt{kstat -c} option.
- \texttt{cpucaps_project_id} or \texttt{cpucaps_zone_id}
  - \texttt{kstat} name, for use with the \texttt{kstat -n} option. \texttt{id} is the project or zone identifier.

The following fields are displayed in response to a \texttt{kstat(1M)} command requesting statistics for all CPU caps.

- \texttt{module}
  - In this usage of \texttt{kstat}, this field will have the value \texttt{caps}.
- \texttt{name}
  - As described above, \texttt{cpucaps_project_id} or \texttt{cpucaps_zone_id}
- \texttt{above_sec}
  - Total time, in seconds, spent above the cap.
- \texttt{below_sec}
  - Total time, in seconds, spent below the cap.
- \texttt{maxusage}
  - Maximum observed CPU usage.
- \texttt{nwait}
  - Number of threads on cap wait queue.
- \texttt{usage}
  - Current aggregated CPU usage for all threads belonging to a capped project or zone, in terms of a percentage of a single CPU.
- \texttt{value}
  - The cap value, in terms of a percentage of a single CPU.
- \texttt{zonename}
  - Name of the zone for which statistics are displayed.
Options
The following options are supported:

- `-f command_file`
  Specify the name of `zonecfg` command file. `command_file` is a text file of `zonecfg` subcommands, one per line.

- `-z zonename`
  Specify the name of a zone. Zone names are case sensitive. Zone names must begin with an alphanumeric character and can contain alphanumeric characters, the underscore (`_`) the hyphen (`-`), and the dot (`.`). The name `global` and all names beginning with `SYS` are reserved and cannot be used.

Subcommands
You can use the `add` and `select` subcommands to select a specific resource, at which point the scope changes to that resource. The `end` and `cancel` subcommands are used to complete the resource specification, at which time the scope is reverted back to global. Certain subcommands, such as `add`, `remove` and `set`, have different semantics in each scope.

`zonecfg` supports a semicolon-separated list of subcommands. For example:

```
# zonecfg -z myzone "add net; set physical=myvnic; end"
```

Subcommands which can result in destructive actions or loss of work have an `-F` option to force the action. If input is from a terminal device, the user is prompted when appropriate if such a command is given without the `-F` option otherwise, if such a command is given without the `-F` option, the action is disallowed, with a diagnostic message written to standard error.

The following subcommands are supported:

- `add resource-type` (global scope)
- `add property-name property-value` (resource scope)

In the global scope, begin the specification for a given resource type. The scope is changed to that resource type.

In the resource scope, add a property of the given name with the given value. The syntax for property values varies with different property types. In general, it is a simple value or a list of simple values enclosed in square brackets, separated by commas (`[foo, bar, baz]`). See `PROPERTIES`.

- `cancel`

  End the resource specification and reset scope to global. Abandons any partially specified resources. `cancel` is only applicable in the resource scope.

- `clear property-name`

  Clear the value for the property.

- `commit`

  Commit the current configuration from memory to stable storage. The configuration must be committed to be used by `zoneadm`. Until the in-memory configuration is committed,
you can remove changes with the `revert` subcommand. The `commit` operation is attempted automatically upon completion of a `zonecfg` session. Since a configuration must be correct to be committed, this operation automatically does a verify.

```
create [-F] [-a path | -b | -t template]
  Create an in-memory configuration for the specified zone. Use `create` to begin to configure a new zone. See `commit` for saving this to stable storage.

  If you are overwriting an existing configuration, specify the `-F` option to force the action. Specify the `-t template` option to create a configuration identical to `template`, where `template` is the name of a configured zone.

  `create` uses a default template of `SYSdefault`. The default template can be changed on a system-wide basis using the `default_template` SMF property of the `svc:/system/zones:default` service. An administrator can override the default for this zone using `-t` (with a specific template) or `-b` (to use a blank template).

  Use the `-a path` option to facilitate configuring a detached zone on a new host. The `path` parameter is the `zonepath` location of a detached zone that has been moved on to this new host. Once the detached zone is configured, it should be installed using the "zoneadm attach" command (see `zoneadm(1M)`). All validation of the new zone happens during the `attach` process, not during zone configuration.

  Use the `-b` option to create a blank configuration. Without arguments, `create` applies the Oracle Sun default settings.
```

delete [-F]
Delete the specified configuration from memory and stable storage. This action is instantaneous, no commit is necessary. A deleted configuration cannot be reverted.

```
end
End the resource specification. This subcommand is only applicable in the resource scope. `zonecfg` checks to make sure the current resource is completely specified. If so, it is added to the in-memory configuration (see `commit` for saving this to stable storage) and the scope reverts to global. If the specification is incomplete, it issues an appropriate error message.
```

export [-f output-file]
Print configuration to standard output. Use the `-f` option to print the configuration to `output-file`. This option produces output in a form suitable for use in a command file.

```
help [usage] [subcommand] [syntax] [command-name]
Print general help or help about given topic.
```

```
info zonename | zonepath | autoboot | brand | pool | limitpriv
info [resource-type [property-name=property-value]*]
Display information about the current configuration. If `resource-type` is specified, displays only information about resources of the relevant type. If any `property-name` value pairs are
specified, displays only information about resources meeting the given criteria. In the resource scope, any arguments are ignored, and info displays information about the resource which is currently being added or modified.

**remove resource-type {property-name=property-value} (global scope)**

In the global scope, removes the specified resource. The { } syntax means 0 or more of whatever is inside the square braces. If you want only to remove a single instance of the resource, you must specify enough property name-value pairs for the resource to be uniquely identified. If no property name-value pairs are specified, all instances will be removed. If there is more than one pair is specified, a confirmation is required, unless you use the -F option.

**select resource-type {property-name=property-value}**

Select the resource of the given type which matches the given property-name property-value pair criteria, for modification. This subcommand is applicable only in the global scope. The scope is changed to that resource type. The { } syntax means 1 or more of whatever is inside the curly braces. You must specify enough property-name property-value pairs for the resource to be uniquely identified.

**set property-name=property-value**

Set a given property name to the given value. Some properties (for example, zonename and zonepath) are global while others are resource-specific. This subcommand is applicable in both the global and resource scopes.

**verify [-v]**

Verify the current configuration for correctness:

- All resources have all of their required properties specified.
- A zonepath is specified.

If the -v option is specified, warnings will be issued if there is a potential for devices specified in device resources to conflict with and hide ZFS volumes created within aliased datasets. See dev(7FS).

**revert [-F]**

Revert the configuration back to the last committed state. The -F option can be used to force the action.

**exit [-F]**

Exit the zonecfg session. A commit is automatically attempted if needed. You can also use an EOF character to exit zonecfg. The -F option can be used to force the action.

**Examples**

**EXAMPLE 1** Creating the Environment for a New Zone

In the following example, zonecfg creates the environment for a new zone. /usr/local is loopback mounted from the global zone into /opt/local. /opt/sfw is loopback mounted from the global zone, a VNIC over nxge0 is added to the zone with three IP addresses, and a limit on the number of fair-share scheduler (FSS) CPU shares for a zone is set using the rctl
EXAMPLE 1  Creating the Environment for a New Zone  (Continued)

resource type. The example also shows how to select a given resource for modification; in this
case, by selecting the anet resource that is automatically created by zonecfg.

e.example#  zonecfg -z myzone3
my-zone3: No such zone configured
Use 'create' to begin configuring a new zone.
zonecfg:myzone3>  create
zonecfg:myzone3>  set zonepath=/export/home/my-zone3
zonecfg:myzone3>  set autoboot=true
zonecfg:myzone3>  add fs
zonecfg:myzone3:fs>  set dir=/opt/local
zonecfg:myzone3:fs>  set special=/usr/local
zonecfg:myzone3:fs>  set type=lofs
zonecfg:myzone3:fs>  add options [ro,nodevices]
zonecfg:myzone3:fs>  end
zonecfg:myzone3>  add fs
zonecfg:myzone3:fs>  set dir=/mnt
zonecfg:myzone3:fs>  set special=/dev/dsk/c0t0d0s7
zonecfg:myzone3:fs>  set raw=/dev/rdsk/c0t0d0s7
zonecfg:myzone3:fs>  set type=ufs
zonecfg:myzone3:fs>  end
zonecfg:myzone3>  add fs
zonecfg:myzone3:fs>  set dir=/opt/sfw
zonecfg:myzone3:fs>  set special=/opt/sfw
zonecfg:myzone3:fs>  set type=lofs
zonecfg:myzone3:fs>  add options [ro,nodevices]
zonecfg:myzone3:fs>  end
zonecfg:myzone3>  select anet linkname=net0
zonecfg:myzone3:anet>  set lower-link=nxge0
zonecfg:myzone3:anet>  set allowed-address="192.168.0.1/24,192.168.1.2/24,192.168.2.3/24"
zonecfg:myzone3:anet>  end
zonecfg:myzone3>  set cpu-shares=5
zonecfg:myzone3>  add capped-memory
zonecfg:my-zone3:capped-memory>  set physical=50m
zonecfg:my-zone3:capped-memory>  set swap=100m
zonecfg:my-zone3:capped-memory>  end
zonecfg:myzone3>  exit

EXAMPLE 2  Creating an Exclusive-IP Zone

The following example creates a zone that is assigned a VNIC named net0. The link over
which the VNIC is created is automatically determined. The IP addresses and routing are
configured inside the new zone using ipadm(1M).

e.example#  zonecfg -z excl
zonecfg:excl>  create
EXAMPLE 2  Creating an Exclusive-IP Zone  (Continued)

zonecfg:excl> set zonepath=/export/zones/excl
zonecfg:excl> exit

EXAMPLE 3  Creating a Shared-IP Zone

The following example creates a zone that shares an IP stack with the global zone, and is assigned a single IP address and default router.

```
example# zonecfg -z shared
zonecfg:shared> create -b
zonecfg:shared> set zonepath=/export/zones/shared
zonecfg:shared> set ip-type=shared
zonecfg:shared> add net
zonecfg:shared:net> set physical=nge0
zonecfg:shared:net> set address=192.168.0.3/24
zonecfg:shared:net> set defrouter=192.168.0.1
zonecfg:shared:net> end
zonecfg:shared> exit
```

EXAMPLE 4  Associating a Zone with a Resource Pool

The following example shows how to associate an existing zone with an existing resource pool:

```
example# zonecfg -z myzone
zonecfg:myzone> set pool=mypool
zonecfg:myzone> exit
```

For more information about resource pools, see pooladm(1M) and poolcfg(1M).

EXAMPLE 5  Changing the Name of a Zone

The following example shows how to change the name of an existing zone:

```
example# zonecfg -z myzone
zonecfg:myzone> set zonename=myzone2
zonecfg:myzone2> exit
```

EXAMPLE 6  Changing the Privilege Set of a Zone

The following example shows how to change the set of privileges an existing zone's processes will be limited to the next time the zone is booted. In this particular case, the privilege set will be the standard safe set of privileges a zone normally has along with the privilege to change the system date and time:

```
example# zonecfg -z myzone
zonecfg:myzone> set limitpriv="default,sys_time"
zonecfg:myzone2> exit
```
EXAMPLE 7  Setting the zone.cpu-shares Property for the Global Zone

The following command sets the zone.cpu-shares property for the global zone:

```
example# zonecfg -z global
zonecfg:global> set cpu-shares=5
zonecfg:global> exit
```

EXAMPLE 8  Using Pattern Matching

The following commands illustrate zonecfg support for pattern matching. In the zone flexlm, enter:

```
zonecfg:flexlm> add device
zonecfg:flexlm:device> set match="/dev/cua/a00[2-5]"
zonecfg:flexlm:device> end
```

In the global zone, enter:

```
global# ls /dev/cua
a  a000  a001  a002  a003  a004  a005  a006  a007  b
```

In the zone flexlm, enter:

```
flexlm# ls /dev/cua
a002  a003  a004  a005
```

EXAMPLE 9  Setting a Cap for a Zone to Three CPUs

The following sequence uses the zonecfg command to set the CPU cap for a zone to three CPUs.

```
zonecfg:myzone> add capped-cpu
zonecfg:myzone>capped-cpu> set ncpus=3
zonecfg:myzone>capped-cpu>capped-cpu> end
```

The preceding sequence, which uses the capped-cpu property, is equivalent to the following sequence, which makes use of the zone.cpu-cap resource control.

```
zonecfg:myzone> add rctl
zonecfg:myzone:rctl> set name=zone.cpu-cap
zonecfg:myzone:rctl> add value (priv=privileged,limit=300,action=none)
zonecfg:myzone:rctl> end
```

EXAMPLE 10  Using kstat to Monitor CPU Caps

The following command displays information about all CPU caps.

```
# kstat -n /cpucaps/
module: caps                      instance: 0
  name: cpucaps_project_0          class: project_caps
           above_sec          0
           below_sec          2157
```

```
EXAMPLE 10 Using kstat to Monitor CPU Caps (Continued)

  usage 7
  value 100
  zonename test_001

EXAMPLE 11 Displaying CPU Caps for a Specific Zone or Project

Using the kstat -c and -i options, you can display CPU caps for a specific zone or project, as below. The first command produces a display for a specific project, the second for the same project within zone 1.

# kstat -c project_caps
# kstat -c project_caps -i 1

EXAMPLE 12 Delegating Zone Administrative Rights

The following example shows how to assign administrative rights for the current zone to a role.

example# zonecfg -z myzone
zonecfg:myzone> add admin
zonecfg:myzone:admin> set user=zadmin
zonecfg:myzone:admin> set auths=login,manage
zonecfg:myzone:admin> end
zonecfg:myzone> commit

The result of executing these commands would be an updated entry in the RBAC user_attr(4) database, similar to the following:

zadmin:::type=role;
auths=solaris.zone.login/myzone,solaris.zone.manage/myzone;
Zone Management

EXAMPLE 13 Creating an Exclusive-IP Zone with Non-Default Properties

The following example creates a zone with an automatically created VNIC over mylink0 with the given MAC address, maximum bandwidth of 100 Mbps, high priority, dedicated hardware rings for RX side, no dedicated hardware rings for the TX side (that is, software-based) and with a VLAN id 2.
EXAMPLE 13    Creating an Exclusive-IP Zone with Non-Default Properties

    (Continued)

    example# zonecfg -z excl
    excl: No such zone configured
    Use 'create' to begin configuring a new zone
    zonecfg:excl> create -b
    zonecfg:excl> set zonepath=/export/ zones/excl
    zonecfg:excl> add anet
    zonecfg:excl:anet> set linkname=mynic0
    zonecfg:excl:anet> set lower-link=mylink0
    zonecfg:excl:anet> set mac-address=8:0:20:fe:4e:b8
    zonecfg:excl:anet> set maxbw=100M
    zonecfg:excl:anet> set priority=high
    zonecfg:excl:anet> set vlan-id=2
    zonecfg:excl:anet> set rxrings=hw
    zonecfg:excl:anet> set txrings=sw
    zonecfg:excl:anet> end
    zonecfg:excl> exit

EXAMPLE 14    Creating a Read-Only Zone

    The following example creates a new zone that has its root filesystem protected against
    modifications by the zone. Files in /var are writable by virtue of the fixed-configuration
    profile that is applied.

    example# zonecfg -z rozone
    rozone: No such zone configured
    Use 'create' to begin configuring a new zone
    zonecfg:rozone> create
    zonecfg:rozone> set brand=solaris
    zonecfg:rozone> set zonepath=/export/ zones/rozone
    zonecfg:rozone> set autoboot=true
    zonecfg:rozone> set file-mac-profile=fixed-configuration
    zonecfg:rozone> set ip-type=exclusive
    zonecfg:rozone> add net
    zonecfg:rozone:net> set physical=vnic0
    zonecfg:rozone:net> end
    zonecfg:rozone> exit

EXAMPLE 15    Creating an Exclusive-IP Zone with an IB Partition

    The following example creates a zone with default properties. The zone will automatically
    create a IPoIB datalink when the zone boots and delete the datalink when the zone halts.

    example# zonecfg -z excl
    excl: No such zone configured
    Use 'create' to begin configuring a new zone
    zonecfg:excl> create
    zonecfg:excl> set zonepath=/export/ zones/excl
EXAMPLE 15  Creating an Exclusive-IP Zone with an IB Partition  (Continued)

zonecfg:excl> set ip-type=exclusive
zonecfg:excl> add anet
zonecfg:excl> set linkname=part0
zonecfg:excl> set lower-link=net4
zonecfg:excl> set pkey=ffff
zonecfg:excl:anet> end
zonecfg:excl> exit

EXAMPLE 16  Creating a Zone Installed into a Dedicated Storage Resource and zpool

The following example creates a new zone with a zpool resource comprised of one storage resource containing the entire zone installation. The zpool will be automatically created or a pre-created zpool will be imported during zone installation. The name will be zoss_rpool.

eexample# zonecfg -z zoss
zoss: No such zone configured
Use 'create' to begin configuring a new zone
zonecfg:zoss> create
zonecfg:zoss> set zonepath=/zoss
zonecfg:zoss> add rootzpool
zonecfg:zoss:rootzpool> add storage iscsi://127.0.0.1/luname.naa.6001\44f03d70c80000004ea57da1001
zonecfg:zoss:rootzpool> end
zonecfg:zoss> exit

EXAMPLE 17  Creating a Zone with a Delegated zpool Resource

The following example creates a new zone with a zpool resource delegated to the zone comprised of two storage resources. The zpool will be automatically created or a pre-created zpool will be imported during zone installation. The name will be zoss_mypool.

eexample# zonecfg -z zoss
zoss: No such zone configured
Use 'create' to begin configuring a new zone
zonecfg:zoss> create
zonecfg:zoss> set zonepath=/zoss
zonecfg:zoss> add zpool
zonecfg:zoss:zpool> set name=mypool
zonecfg:zoss:zpool> add storage dev:/dev/dsk/c0t1d0
zonecfg:zoss:zpool> add storage dev:/dev/dsk/c1t1d0
zonecfg:zoss:zpool> end
zonecfg:zoss> exit

Exit Status  The following exit values are returned:

0  Successful completion.
An error occurred.

Invalid usage.

Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management

Notes All character data used by zonecfg must be in US-ASCII encoding.

Adding a device to a zone, in general, can allow the zone to adversely affect the security and stability of the system, as not all devices have been audited for secure use inside a zone.

Storage devices using the sd or ssd target driver (this can be checked using prtconf -D /dev/dsk/c2t40d3, for example) can be safely delegated to a zone. This will allow a zone admin to label and partition such devices.

In order to allow disk labelling by means of format(1M), an entire disk/LUN should be delegated to a zone, and the allow-partition property set. For example:

```
zonectfg:myzone> add device
zonectfg:myzone> set match=/dev/*dsk/c2t40d3*
zonectfg:myzone> set allow-partition=true
zonectfg:myzone> end
```

While it is not recommended, it is also possible to delegate just a single slice (for example, match=/dev/dsk/c2t40d3s0) of a disk. In order for this to be safe, the allow-partition property must not be true, and the slice or partition must not overlap the disk header of disk labels (these are located within the first two or last two blocks of the partition or disk).

Raw access to storage devices can be enabled by setting the allow-raw-io property to true. This is unsafe, as it allows raw SCSI commands (see uscsi(7I)) to be performed by zone processes.
Inside a zone, device-in-use checking does not work, as the /devices/ tree it relies upon is not present. A future project might address this limitation.
zonep2vchk – check a global zone’s configuration for physical to virtual migration into non-global zone

Synopsis

zonep2vchk [-V] [-T release] [-c]
zonep2vchk [-T release] [-P] [-b] [ -s path[,path...] ] [-S file]
[ -r {time}(h|m|s} ] [ -x ] [ -e execname[,execname...] ]
[-E file]

Description

The zonep2vchk utility is used to evaluate a global zone’s configuration before the process of physical-to-virtual (p2v) migration into a non-global zone.

The p2v process involves archiving a global zone (source), and then installing a non-global zone (target) using that archive. See the install -a documentation in the solaris(5) and solaris10(5) man pages.

zonep2vchk serves two functions. First, it can be used to report issues on the source which might prevent a successful p2v migration. Second, it can output a template zonecfg, which can be used to assist in configuring the non-global zone target.

zonep2vchk can be executed on a Solaris 10 or later global zone. To execute on Solaris 10, copy the zonep2vchk utility to the Solaris 10 source global zone.

Security

The zonep2vchk utility must be run with an effective user id of zero. It interrogates the configuration state of a variety of Solaris subsystems.

Options

The following options are supported:

-V
    Display the command version and exit.

-T release
    Specify the target release. The defaults are:

    Global Zone          Default Target
    Solaris 10           S10
    Solaris 11           S11

    Any configuration files generated by zonep2vchk will be applicable to the target release. See -c below.

When run on Solaris 10, a target release of S11 can be specified, which will check for p2v into a Solaris 10 Branded zone.

When the target is S10, it is assumed that a shared stack will be used. Any issues that will require an exclusive IP stack will be reported.

When the target is S11, it is assumed that an exclusive IP stack will be used.
If a particular feature in use by the global zone requires a particular patch/update level of the target to function, this information will be printed in the zonep2vchk output.

-P
Generate machine-parseable output. See the section "Parseable Output Format" below.

-c
Display a template zone configuration on stdout in the form of zonecfg(1M) export output. This configuration will contain resource limits and network configuration based on the source host's physical resources and networking configuration.

-b
Perform basic checks. This will check the global zone for issues that could prevent a successful p2v. This is the default behavior if none of -b, -c, -s, -S, -r, -x are specified.

-r[time] (h|m|s)
Perform runtime checks for the specified duration. This will analyze the currently executing processes in the global zone, and report issues that could prevent successful execution inside a non-global zone. Issues reported reflect actions made by the processes during the time in which zonep2vchk was executing.

-x
Perform runtime checks (as with -r) until SIGINT is received, such as is delivered by Ctr rl -c from most shells.

-e execname[,execname...]
When performing runtime analysis (-r, -x), limit inspected programs to those matching the specified list of execnames. The execname is the name of process, as returned by ps -o comm. It is not necessary for named processes to exist when zonep2vchk is invoked. Any matching processes created while zonep2vchk is running will be inspected.

-E file
Similar to -e, but reads the list of execnames from file, one per line.

-s path[,path...]
Perform static binary analysis on the files or directories specified. This will inspect ELF binaries for system and library calls that might affect function inside a zone. Directories will be recursed, and non-ELF files will be ignored.

-S file
Similar to -s, but reads the path list from file, one per line.

Parseable Output Format
zonep2vchk will output a single line of parseable output for each issue detected. The line format is:

category:issue:field1: [field2: . . . ]

Each field is delimited by a colon (:). Colon characters escaped with a backslash (\:) should not be treated as field delimiters.
Multiple instances of the same issue can be reported, each with fields describing the particular instance of the issue.

Below the existing categories and issues are defined. Future versions of zonep2vchk might include additional categories and issues. Existing issues might have new fields added after the existing fields for existing issues.

**header Category**

The header category lists information about the source, target, and zonep2vchk version. The issues in this category are:

**version**

The version of the zonep2vchk command.

*Field1:* The version of the zonep2vchk command.

**source**

Information about the source system.

*Field1:* The nodename of the source system.

*Field2:* The /etc/release version of the source system.

*Field3:* The kernel version of the source system.

*Field4:* The platform of the source system.

**target**

Information about the specified target of the p2v check.

*Field1:* The Solaris version of the target.

*Field2:* The brand type that would be used on the target.

*Field3:* The ip-type of the expected zone on the target.

**footer Category**

The footer category lists final summary information. The issues in this category are:

**issues**

A summary of the number of issues found.

*Field1:* The number of issues detected.

**incompatible Category**

The incompatible category represents issues that will not function in a non-global zone. The issues in this category are:

**etcsystem**

An /etc/system tunable exists. These tunables do not function inside a zone. The /etc/system tunable can be transferred to the target global zone, but it will affect the entire system, including all zones and the global zone. If there is an alternate tunable that can be configured from within the zone, this tunable is described.

*Field1:* The /etc/system tunable setting.
Field 2:
One of:

- noalternate: There is no alternate tunable from within a non-global zone.
- obsolete: The tunable is obsolete on the target. It no longer serves any function.
- replaced: The tunable has been replaced on the target. The replacement is configured in the global zone, and described by fields 3 and 4.
- alternate: An alternate tunable exists. This tunable can be configured from within a non-global zone. The tunable is described by fields 3 and 4.
- noinfo: zonep2vchk is not knowledgeable of the tunable. Tunable likely has no alternate inside a zone.

Field 3:
Type of alternate/replacement tunable.

Field 4:
Description of alternate/replacement tunable.

Field 1:
The name of the non-active boot environment.

be
More than one boot environment exists. Only the active boot environment will be transferable to the non-global zone.

Field 1: mobileip
The mobile IP agent, which does not function in a zone, is configured. See `mipagent(1M)` for details.

nfs (S10 sources only)
The system is sharing a filesystem by means of NFS. Native zones on Solaris 10 and Solaris 11 zones on Solaris 11 cannot share by means of NFS.

Field 1: Path of file system being shared.

smb
The system is sharing a filesystem by means of in-kernel smb/cifs. Zones cannot share filesystems by means of SMB.

Field 1: Path of file system being shared.

pkg
A package delivering software known not to work in a zone is installed.

Field 1: Name of the package.

iscsi-target
The system is exporting an iSCSI target. Zones cannot export iSCSI targets.
Field1: Name of the iSCSI target.

fcoe-target
The system has configured an FCOE target. Zones cannot configure FCOE targets.
Field1: Ethernet device used.
Field2: WWN of the FCOE target.

fc-target
The system has configured an Fiberchannel target. Zones cannot configure Fiberchannel targets.
Field1: WWN of the Fiberchannel target.

npiv
The system has configured a virtual NPIV HBA. Zones cannot configure virtual HBAs.
Field1: Physical WWN hosting the virtual HBA.
Field2: Virtual WWN.

scsi
The system has configured an SCSI block device. Zones cannot configure scsi block devices.
Field1: Object configured as a SCSI device.

svcnotallowed
A service is enabled that will not function in a zone.
Field1: Name of the service.

resourcepool
A Solaris resource pool is configured. Zones cannot configure resource pools.
Field1: Name of the pool.

pset
A processor set is configured. Zones cannot configure processor sets.
Field1: Processor set ID.
Field2: List of CPU IDs in the processor set.

zones
Zones are configured. A zone cannot host zones. Any zones will not exist in the target non-global zone after p2v. Zones can be migrated separately using the detach/attach features in zoneadm(1M).
Field1: Name of the zone.
Field2: State of the zone.
lofi (Solaris 10 targets only)
A lofi device is configured. A zone cannot configure lofi devices.

Field1: Name of the lofi device.
Field2: Path of the file backing the device.

syscall (generated by -s and -f)
A binary makes a system or library call that cannot be made from a zone.

Field1: Name of the the binary file.
Field2: Name of the system or library call.

syscallargs (generated by -s and -f)
A binary makes a system or library call that cannot be made from a zone if called with
certain arguments.

Field1: Name of the system or library call.

See regular output (no -P) for details on disallowed arguments.

lib (generated by -s and -f)
A binary links with a library that cannot be used inside a zone.

Field1: Name of the binary file.
Field2: Name of the disallowed library.

privnotallowed (generated by -r and -x)
A privilege is used by a process that cannot be added to a zone.

Field1: Name of the process.
Field2: Name of the privilege.

devennotallowed (generated by -r and -x)
A device is opened by a process that cannot be added to a zone.

Field1: Name of the process.
Field2: Name of the device.

configuration Category
The configuration category represents issues that will require a configuration setting to
allow the issue to function inside the non-global zone. This could be a zonecfg(1M)
configuration setting, a configuration change in the global zone, or both.

The issues in this category are:

datalink
A datalink feature is configured that cannot be configured from within a zone. The datalink
feature must be configured in the global zone, and if necessary, delegated to the zone using
zonecfg add anet (Solaris 11 only) or zonecfg add net.
**Field1:** Name of the datalink feature. One of:
- **aggr** Aggregation.
- **ibiface** Infiniband interface.
- **ibpart** Infiniband partition.
- **vnic** Virtual NIC.
- **etherstub** Ethernet stub.
- **bridge** A bridge instance.
- **secobj** A wireless WPA or WEB security object.

**Field2:** Datalink object name.

**dhcp-server** (Solaris 10 targets only)
The host is a DHCP server. To provide DHCP service, a zone must have `ip-type=exclusive`, or have the privilege `net_rawaccess` and the device `/dev/ip`. Note that this will allow a shared stack zone to read and write raw IP packets on the network, similar to an exclusive stack zone or global zone.

**Field1:** FMRI of the DHCP server service.

**ntp-client**
An NTP client service is enabled. This service updates the system clock. Since all zones share the same system clock, this service is disabled automatically during `p2v`. If it is desired that the zone update the system clock on the target host, the zone will need the privilege `sys_time`, and the service will need to be enabled inside the zone after `p2v`.

**Field1:** FMRI of the client service.

**driverconf**
A networking device contains configuration settings in its `.conf` file. Zones cannot configure drivers. The driver must be configured in the global zone. Some network driver settings might be configurable using `dladm(1M)` instead of editing a driver configuration file.

**Field1:** Path of the configuration file.

**ifname** (Solaris 10 targets only)
an existing configuration file will be impacted by the change of a network device name. For example, an `/etc/hostname.bge0` file will be impacted if the network device given to the target non-global zone is not `bge0`.

**Field1:** Path of the impacted file.

**iscsi-initiator**
The system is accessing an iSCSI target as a client. Zones cannot access iSCSI targets. The global zone must be the iSCSI initiator. The device can then be added to the zone using `zonedcfg add device`. 
Field1: iSCSI target being accessed.

fcoe-initiator
The system has an FCOE initiator configured. A zone cannot configure an FCOE initiator. The global zone must configure the FCOE initiator, and make the SCSI target devices available to the zone using `zonecfg add fs` or `zonecfg add device`.

Field1: Ethernet network device.
Field2: WWN of the initiator.

fc-initiator
The system has an HBA Fiberchannel port online. A zone cannot access a Fiberchannel target. The target must be accessed from the global zone and made available to the zone.

Field1: Fiberchannel HBA port WWN.

linkprop
Datalink properties are configured. A zone cannot configure datalink properties. They must be configured from the global zone.

Field1: Name of the datalink.
Field2: Property name
Field3: Property value.

ndd
Tunables that cannot be configured by a zone have been configured using `ndd`. These tunables must be configured from the global zone.

Field1: File or script setting the tunable.
Field2: Driver being tuned.
Field3: Tunable parameter.

dynaddr
One or more dynamically assigned IP addresses are configured on a network interface. These addresses are not supported with shared-IP zones. These IP addresses could change as a result of MAC address changes. You may need to modify this system's address information on the DHCP server and on the DNS, LDAP, or NIS name servers.

Field1 can be one of:

dhcp
Configured DHCP address. In this case, Field2 is the name of the interface configured for DHCP.

v6autoconf
IPv6 stateless address configuration is enabled. In this case, Field2 is the name of the interface with IPv6 auto configuration.
rar (Solaris 10 source only) Reverse ARP assigned address is enabled. In this case, 
Field2 is the name of the interface with reverse ARP enabled.

pat ch (Solaris 10 source with Solaris 11+ target only) 
A patch is required before p2v into a non-global zone.

Field1: The patch required.

phys (Solaris 10 targets only) 
A physical interface exists on the source system that will have to be replaced with a 
dedicated physical or VLAN interface on the destination system if migrating to an 
exclusive-IP zone.

Field1: Name of the interface on the source system.

sched 
The system is configured with a default scheduling class. The default scheduling class of a 
non-global zone can be configured using the zonecfg set scheduler property. This will 
be provided in the -c output.

Field1: The configured default scheduling class.

sharedip (Solaris 10 targets only) 
If migrating to a shared-IP zone, the following networking features will need to be 
configured from the global zone on behalf of the zone.

Field1 can be one of:

ipmpgroup An IPMP group is configured. If IPMP is required, it must be 
configured from the global zone. In this case, Field2 is the IPMP group name.

vni A virtual network interface is configured. These must be configured 
from the global zone. In this case, Field2 is the VNI interface name.

v4forwarding v6forwarding IP forwarding (v4 or v6) is configured on an interface. In this case, 
Field2 is the interface with IP forwarding configured.

staticroute Static routes are configured. Static routes must be configured from the 
global zone.

excl u se only (Solaris 10 targets only) 
A networking feature is configured that is not supported for use with shared-IP zones. The 
feature will work without modification in exclusive-IP zones.

Field1:

iptun A IPv4, IPv6, or 6to4 tunnel interface has been plumbed.

Field2: Name of the tunnel interface.
A networking feature is configured that is not supported in an exclusive-IP zone. When migrating to a shared-IP zone, the feature must be configured in the global zone to support communication.

**Field1:**

- **cgtp**  
  A Carrier Grade Transport Protocol interface has been plumbed.

**Field2:**  
Name of the CGTP interface.

A networking feature requires its underlying device be allocated to the zone with the `zonecfg(1M) add device` command. This feature is not supported with shared-IP zones.

**Field1:**

- **ppp**  
  Point-to-Point Protocol (PPP). PPP configuration files exist under `/etc/ppp`. The underlying device that needs to be allocated to the zone is either a serial port or, in the case of pppoe, an Ethernet physical or VNIC interface.

**svcexlip** (Solaris 10 targets only)  
A service is enabled that will require an exclusive-IP zone.

**Field1:**  
Name of the service FMRI.

**svcpriv**  
A service is enabled that will require additional privileges be added to the zone using the `zonecfg(1M) limitpriv` property.

**Field1:**  
FMRI of the service.

**Field2:**  
List of the privileges required by the service.

**svm**  
A Solaris Volume Manager metadevice is configured. Metadevices must be configured in the global zone, and made available to the non-global zone using `zonecfg(1M) add device`, `add fs`, or `add dataset`.

**Field1:**  
Name of the metadevice.

**ramdisk**  
A ramdisk device is configured. A zone cannot configure ramdisk devices.

**Field1:**  
Ramdisk device path.

**vfstab**  
A filesystem mount is configured by means of `/etc/vfstab`. The filesystem must be migrated to the target global zone and made available to the non-global zone.

**Field1:**  
Device being mounted.
Field2: Mountpoint.

zpool
The system has additional zpools configured. These zpools must be migrated to the target global zone, and made available to the zone using zonecfg add dataset or zonecfg add fs.

Field1: Name of the pool.

privexcl (Solaris 10 targets only)
A process used a privilege that requires and exclusive-IP stack. See zonecfg(1M) for a description of the ip-type property.

Field1: Name of the process.
Field2: Privilege used.

devexcl (Solaris 10 targets only)
A process opened a device that requires an exclusive IP stack. See zonecfg(1M) for a description of the ip-type property.

Field1: Name of the process.
Field2: Name of the device.

privoptional
A process used a privilege that requires additional privilege be added to the target non-global zone. See zonecfg(1M) for a description of the limitpriv property.

Field1: Name of the process.
Field2: Privilege used.

devoptional
A process opened a device that is not available in a zone by default. See zonecfg(1M) for a description of the add device resource.

Field1: Name of the process.
Field2: Path of the device.

syscallpriv (generated by -s and -f)
A binary makes a system or library call that might require additional privilege be added to the target non-global zone. See zonecfg(1M) for a description of the limitpriv property. See the non-parseable output for details concerning the system or library call.

Field1: Path of the binary
Field2: Name of the system call.
A binary makes a system or library call that might require an exclusive-ip stack. See `zonecfg(1M)` for a description of the ip-type property. See the non-parseable output for details concerning the system or library call.

**Field1**: Path of the binary

**Field2**: Name of the system call.

### Examples

**EXAMPLE 1**  Performing Static Binary Analysis

The following command performs static analysis on all ELF binaries in two application directory trees:

```
# zonep2vchk -s /opt/myapplication,/usr/local
```

**EXAMPLE 2**  Generating a Template for the Target Zone

The following command will generate a template zone configuration for Solaris 11 when run on a Solaris 10 global zone.

```
# zonep2vchk T S11 -c
```

**EXAMPLE 3**  Analyzing Running Applications for a Period

The following command will analyze the process named `myapplication` for one hour and report any activity that might not function in a zone.

```
# zonep2vchk -s 1h -e myapplication
```

**EXAMPLE 4**  Performing Basic Checks

The following command will analyze the global zone for configuration and Solaris features in use that might not function in a zone. Each discovered issue will be reported as a single line of parseable output.

```
# zonep2vchk -bP
```

### Exit Status

The following exit values are returned:

- **0**
  - Successful completion, no issues detected.

- **1**
  - An internal error occurred.

- **2**
  - Invalid usage.

- **3**
  - One or more issues were detected.

Notes

The static (-s and -f) checks make use of the elfdump(1) utility, which is delivered by the following package:

Solaris 11  developer/base-developer-utilities
Solaris 10  SUNWbtool

The runtime (-r) checks make use of the dtrace(1M) utility, which is delivered by the following package:

Solaris 11  system/dtrace
Solaris 10  SUNWdtrace
zonestatd – zones monitoring daemon

/usr/lib/zones/zonestatd

zonestatd is a system daemon that is started during system boot. It monitors the utilization of system resources by zones, as well as zone and system configuration information such as psrset psets, pool psets, and resource control settings.

This daemon is started automatically by the zone management software and should not be invoked directly. It does not constitute a programming interface; it is classified as a private interface.

Security
The zonestat service in the global zone must be online for the zonestat service in each non-global zone (NGZ) to function properly. The zonestat service in each NGZ does not directly read system configuration and utilization data, but rather reads from the zonestat service on the global zone.

Attributes
See attributes(5) for descriptions of the following attributes:

prctl(1), svcs(1), zonestat(1), acctadm(1M), pooladm(1M), poolcfg(1M), rcapadm(1M), svcadm(1M), attributes(5), smf(5), zones(5)

Notes
The zonestat service is managed by the service management facility, smf(5), under the service identifier:

csvc:/system/zones-monitoring:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

The zonestat service has the following SMF configuration property:

cfg/sample_interval

This property sets the zonestatd sample interval. This is the interval used by the zones monitoring daemon, zonestatd to sample resource utilization. This is also the interval used to determine configuration changes such as processor set changes, resource control changes, and zone state changes.

The default interval is 5 seconds.
The `zonestat` service makes use of extended accounting facility. If not already enabled, it enables the tracking of process accounting resources, and configures a process accounting file. The `zonestat` service will roll the process accounting log at its configured interval (see `zonestat(1)`).

If extended process accounting is enabled externally, the `zonestat` service will use the process accounting log as configured. It will not roll the accounting log, but will operate correctly if the accounting log is rolled externally.

**Description**
The `zpool` command configures ZFS storage pools. A storage pool is a collection of devices that provides physical storage and data replication for ZFS datasets.

All datasets within a storage pool share the same space. See `zfs(1M)` for information on managing datasets.

**Virtual Devices (vdevs)**
A *virtual device* describes a single device or a collection of devices organized according to certain performance and fault characteristics. The following virtual devices are supported:

- **disk**
  A block device, typically located under `/dev/dsk`. ZFS can use individual slices or partitions, though the recommended mode of operation is to use whole disks. A disk can be specified by a full path, or it can be a shorthand name (the relative portion of the path under `/dev/dsk`). A whole disk can be specified by omitting the slice or partition designation. Alternatively, whole disks can be specified using the `/dev/chassis/.../disk` path that describes the disk's current location. When given a whole disk, ZFS automatically labels the disk, if necessary.

- **file**
  A regular file. The use of files as a backing store is strongly discouraged. It is designed primarily for experimental purposes, as the fault tolerance of a file is only as good as the file system of which it is a part. A file must be specified by a full path.

- **mirror**
  A mirror of two or more devices. Data is replicated in an identical fashion across all components of a mirror. A mirror with $N$ disks of size $X$ can hold $X$ bytes and can withstand $(N-1)$ devices failing before data integrity is compromised.

- **raidz**
- **raidz1**
- **raidz2**
- **raidz3**
  A variation on RAID-5 that allows for better distribution of parity and eliminates the “RAID-5 write hole” (in which data and parity become inconsistent after a power loss). Data and parity is striped across all disks within a raidz group.

  A raidz group can have single-, double-, or triple parity, meaning that the raidz group can sustain one, two, or three failures, respectively, without losing any data. The raidz1 vdev type specifies a single-parity raidz group; the raidz2 vdev type specifies a double-parity raidz group; and the raidz3 vdev type specifies a triple-parity raidz group. The raidz vdev type is an alias for raidz1.
A raidz group with \( N \) disks of size \( X \) with \( P \) parity disks can hold approximately \((N-P)*X\) bytes and can withstand \( P \) device(s) failing before data integrity is compromised. The minimum number of devices in a raidz group is one more than the number of parity disks. The recommended number is between 3 and 9 to help increase performance.

**spare**

A special pseudo-vdev which keeps track of available hot spares for a pool. For more information, see the “Hot Spares” section.

**log**

A separate-intent log device. If more than one log device is specified, then writes are load-balanced between devices. Log devices can be mirrored. However, raidz vdev types are not supported for the intent log. For more information, see the “Intent Log” section.

**cache**

A device used to cache storage pool data. A cache device cannot be configured as a mirror or raidz group. For more information, see the “Cache Devices” section.

Virtual devices cannot be nested, so a mirror or raidz virtual device can only contain files or disks. Mirrors of mirrors (or other combinations) are not allowed.

A pool can have any number of virtual devices at the top of the configuration (known as root vdevs). Data is dynamically distributed across all top-level devices to balance data among devices. As new virtual devices are added, ZFS automatically places data on the newly available devices.

Virtual devices are specified one at a time on the command line, separated by whitespace. The keywords mirror and raidz are used to distinguish where a group ends and another begins. For example, the following creates two root vdevs, each a mirror of two disks:

```bash
# zpool create mypool mirror c0t0d0 c0t1d0 mirror c1t0d0 c1t1d0
```

Alternatively, the following command could be used:

```bash
# zpool create tank \n  mirror \n  /dev/chassis/RACK29.U01-04/DISK_00/disk \n  /dev/chassis/RACK29.U05-08/DISK_00/disk \n  mirror \n  /dev/chassis/RACK29.U01-04/DISK_01/disk \n  /dev/chassis/RACK29.U05-08/DISK_01/disk
```

ZFS supports a rich set of mechanisms for handling device failure and data corruption. All metadata and data is checksummed, and ZFS automatically repairs bad data from a good copy when corruption is detected.

In order to take advantage of these features, a pool must make use of some form of redundancy, using either mirrored or raidz groups. While ZFS supports running in a non-redundant configuration, where each root vdev is simply a disk or file, this is strongly discouraged. A single case of bit corruption can render some or all of your data unavailable.
A pool's health status is described by one of four states:

DEGRADED
A pool with one or more failed devices, but the data is still available due to a redundant configuration.

ONLINE
A pool that has all devices operating normally.

SUSPENDED
A pool that is waiting for device connectivity to be restored. A suspended pool remains in the wait state until the device issue is resolved.

UNAVAIL
A pool with corrupted metadata, or one or more unavailable devices and insufficient replicas to continue functioning.

The health of the top-level vdev, such as mirror or raidz device, is potentially impacted by the state of its associated vdevs, or component devices. A top-level vdev or component device is in one of the following states:

DEGRADED
One or more top-level vdevs is in the degraded state because one or more component devices are offline. Sufficient replicas exist to continue functioning.

One or more component devices is in the degraded or faulted state, but sufficient replicas exist to continue functioning. The underlying conditions are as follows:

- The number of checksum errors exceeds acceptable levels and the device is degraded as an indication that something may be wrong. ZFS continues to use the device as necessary.
- The number of I/O errors exceeds acceptable levels. The device could not be marked as faulted because there are insufficient replicas to continue functioning.

OFFLINE
The device was explicitly taken offline by the `zpool offline` command.

ONLINE
The device is online and functioning.

REMOVED
The device was physically removed while the system was running. Device removal detection is hardware-dependent and may not be supported on all platforms.

UNAVAIL
The device could not be opened. If a pool is imported when a device was unavailable, then the device will be identified by a unique identifier instead of its path since the path was never correct in the first place.
If a device is removed and later reattached to the system, ZFS attempts to put the device online automatically. Device attach detection is hardware-dependent and might not be supported on all platforms.

**Hot Spares**

ZFS allows devices to be associated with pools as *hot spares*. These devices are not actively used in the pool, but when an active device fails, it is automatically replaced by a hot spare. To create a pool with hot spares, specify a spare vdev with any number of devices. For example,

```
# zpool create pool mirror c0d0 c1d0 spare c2d0 c3d0
```

Spares can be added with the `zpool add` command and removed with the `zpool remove` command. Once a spare replacement is initiated, a new spare vdev is created within the configuration that will remain there until the original device is replaced. At this point, the hot spare becomes available again if another device fails.

An in-progress spare replacement can be cancelled by detaching the hot spare. If the original faulted device is detached, then the hot spare assumes its place in the configuration, and is removed from the spare list of all active pools.

If the original failed device is physically replaced, brought back online, or the errors are cleared, either through an FMA event or by using the `zpool online` or `zpool clear` commands, and the state of the original device becomes healthy, the INUSE spare device will become AVAIL again.

Spares cannot replace log devices.

**Intent Log**

The ZFS Intent Log (ZIL) satisfies POSIX requirements for synchronous transactions. For instance, databases often require their transactions to be on stable storage devices when returning from a system call. NFS and other applications can also use `fsync()` to ensure data stability. By default, the intent log is allocated from blocks within the main pool. However, it might be possible to get better performance using separate intent log devices such as NVRAM or a dedicated disk. For example:

```
# zpool create pool c0d0 c1d0 log c2d0
```

Multiple log devices can also be specified, and they can be mirrored. See the EXAMPLES section for an example of mirroring multiple log devices.

Log devices can be added, replaced, attached, detached, and imported, and exported as part of the larger pool. Mirrored log devices can be removed by specifying the top-level mirror for the log.

**Cache Devices**

Devices can be added to a storage pool as *cache devices*. These devices provide an additional layer of caching between main memory and disk. For read-heavy workloads, where the working set size is much larger than what can be cached in main memory, using cache devices allow much more of this working set to be served from low latency media. Using cache devices provides the greatest performance improvement for random read workloads of mostly static content.
To create a pool with cache devices, specify a cache `vdev` with any number of devices. For example:

```
# zpool create pool c0d0 c1d0 cache c2d0 c3d0
```

Cache devices cannot be mirrored or part of a raidz configuration. If a read error is encountered on a cache device, that read I/O is reissued to the original storage pool device, which might be part of a mirrored or raidz configuration.

The content of the cache devices is considered volatile, as is the case with other system caches.

### Processes

Each imported pool has an associated process, named `zpool-poolname`. The threads in this process are the pool’s I/O processing threads, which handle the compression, checksumming, and other tasks for all I/O associated with the pool. This process exists to provide visibility into the CPU utilization of the system’s storage pools. The existence of this process is an unstable interface.

### Properties

Each pool has several properties associated with it. Some properties are read-only statistics while others are configurable and change the behavior of the pool. The following are read-only properties:

- **allocated**
  
  Amount of storage space within the pool that has been physically allocated. This property can also be referred to by its shortened column name, `alloc`.

- **capacity**
  
  Percentage of pool space used. This property can also be referred to by its shortened column name, `cap`.

- **dedupratio**
  
  The deduplication ratio specified for a pool, expressed as a multiplier. This value is expressed as a single decimal number. For example, a `dedupratio` value of 1.76 indicates that 1.76 units of data were stored but only 1 unit of disk space was actually consumed. This property can also be referred to by its shortened column name, `dedup`.

  Deduplication can be enabled as follows:

  ```
  # zfs set dedup=on pool/dataset
  ```

  The default value is `off`.

  See `zfs(1M)` for a description of the deduplication feature.

- **free**
  
  Number of blocks within the pool that are not allocated.

- **guid**
  
  A unique identifier for the pool.

- **health**
  
  The current health of the pool. Health can be `ONLINE`, `DEGRADED`, `UNAVAIL`, or `SUSPENDED`.

---

To create a pool with cache devices, specify a cache `vdev` with any number of devices. For example:

```
# zpool create pool c0d0 c1d0 cache c2d0 c3d0
```

Cache devices cannot be mirrored or part of a raidz configuration. If a read error is encountered on a cache device, that read I/O is reissued to the original storage pool device, which might be part of a mirrored or raidz configuration.

The content of the cache devices is considered volatile, as is the case with other system caches.

**Processes**

Each imported pool has an associated process, named `zpool-poolname`. The threads in this process are the pool’s I/O processing threads, which handle the compression, checksumming, and other tasks for all I/O associated with the pool. This process exists to provide visibility into the CPU utilization of the system’s storage pools. The existence of this process is an unstable interface.

**Properties**

Each pool has several properties associated with it. Some properties are read-only statistics while others are configurable and change the behavior of the pool. The following are read-only properties:

- **allocated**
  
  Amount of storage space within the pool that has been physically allocated. This property can also be referred to by its shortened column name, `alloc`.

- **capacity**
  
  Percentage of pool space used. This property can also be referred to by its shortened column name, `cap`.

- **dedupratio**
  
  The deduplication ratio specified for a pool, expressed as a multiplier. This value is expressed as a single decimal number. For example, a `dedupratio` value of 1.76 indicates that 1.76 units of data were stored but only 1 unit of disk space was actually consumed. This property can also be referred to by its shortened column name, `dedup`.

  Deduplication can be enabled as follows:

  ```
  # zfs set dedup=on pool/dataset
  ```

  The default value is `off`.

  See `zfs(1M)` for a description of the deduplication feature.

- **free**
  
  Number of blocks within the pool that are not allocated.

- **guid**
  
  A unique identifier for the pool.

- **health**
  
  The current health of the pool. Health can be `ONLINE`, `DEGRADED`, `UNAVAIL`, or `SUSPENDED`. 
size
Total size of the storage pool.

These space usage properties report actual physical space available to the storage pool. The physical space can be different from the total amount of space that any contained datasets can actually use. The amount of space used in a raidz configuration depends on the characteristics of the data being written. In addition, ZFS reserves some space for internal accounting that the `zfs(1M)` command takes into account, but the `zpool` command does not. For non-full pools of a reasonable size, these effects should be invisible. For small pools, or pools that are close to being completely full, these discrepancies may become more noticeable.

The following property can be set at creation time and import time:

**altroot**
Alternate root directory. If set, this directory is prepended to any mount points within the pool. This can be used when examining an unknown pool where the mount points cannot be trusted, or in an alternate boot environment, where the typical paths are not valid.

**altroot** is not a persistent property. It is valid only while the system is up. Setting **altroot** defaults to using `cachefile=none`, though this may be overridden using an explicit setting.

The following property can be set at import time:

**readonly**=on | off
Controls whether the pool can be modified. When enabled, any synchronous data that exists only in the intent log is not accessible until the pool is imported in read-write mode.

Importing a pool in read-only mode has the following limitations:

- Attempts to set additional pool properties during the import are ignored.
- All file system mounts are converted to include the `read-only (ro)` mount option.

A pool that has been imported in read-only mode can be restored to read-write mode by exporting and importing the pool.

The following properties can be set at creation time and import time, and later changed with the `zpool set` command:

**autoexpand**=on | off
Controls automatic pool expansion when the underlying LUN is grown. If set to on, the pool will be resized according to the size of the expanded device. If the device is part of a mirror or raidz then all devices within that mirror/raidz group must be expanded before the new space is made available to the pool. The default behavior is off. This property can also be referred to by its shortened column name, expand.

**autoreplace**=on | off
Controls automatic device replacement. If set to off, device replacement must be initiated by the administrator by using the `zpool replace` command. If set to on, any new device, found in the same physical location as a device that previously belonged to the pool, is
automatically formatted and replaced. The default behavior is off. This property can also
be referred to by its shortened column name, replace.

*bootfs* = `pool/dataset`
Identifies the default bootable dataset for the root pool. This property is expected to be set
mainly by the installation and upgrade programs.

*cachefile* = `path` | `none`
Controls the location of where the pool configuration is cached. Discovering all pools on
system startup requires a cached copy of the configuration data that is stored on the root
file system. All pools in this cache are automatically imported when the system boots. Some
environments, such as install and clustering, need to cache this information in a different
location so that pools are not automatically imported. Setting this property caches the pool
configuration in a different location that can later be imported with `zpool import -c`. Setting
it to the special value `none` creates a temporary pool that is never cached, and the
special value `''` (empty string) uses the default location.

Multiple pools can share the same cache file. Because the kernel destroys and recreates this
file when pools are added and removed, care should be taken when attempting to access
this file. When the last pool using a cache file is exported or destroyed, the file is removed.

*dedupditto* = `number`
Sets a threshold for number of copies. If the reference count for a deduplicated block goes
above this threshold, another ditto copy of the block is stored automatically. The default
value is 0.

*delegation* = `on` | `off`
Controls whether a non-privileged user is granted access based on the dataset permissions
defined on the dataset. The default value is on. See `zfs(1M)` for more information on ZFS
delegated administration.

*failmode* = `wait` | `continue` | `panic`
Controls the system behavior in the event of catastrophic pool failure. This condition is
typically a result of a loss of connectivity to the underlying storage device(s) or a failure of
all devices within the pool. The behavior of such an event is determined as follows:

*wait*
Blocks all I/O access to the pool until the device connectivity is recovered and the errors
are cleared. A pool remains in the wait state until the device issue is resolved. This is the
default behavior.

*continue*
Returns EIO to any new write I/O requests but allows reads to any of the remaining
healthy devices. Any write requests that have yet to be committed to disk would be
blocked.

*panic*
Prints out a message to the console and generates a system crash dump.
\texttt{listshares=on | off}

Controls whether share information in this pool is displayed with the \texttt{zfs list} command. The default value is \texttt{off}.

\texttt{listsnaps=on | off}

Controls whether information about snapshots associated with this pool is output when \texttt{zfs list} is run without the \texttt{-t} option. The default value is \texttt{off}.

\texttt{version=version}

The current on-disk version of the pool. This can be increased, but never decreased. The preferred method of updating pools is with the \texttt{zpool upgrade} command, though this property can be used when a specific version is needed for backwards compatibility. This property can be any number between 1 and the current version reported by \texttt{zpool upgrade -v}.

All subcommands that modify state are logged persistently to the pool in their original form.

The \texttt{zpool} command provides subcommands to create and destroy storage pools, add capacity to storage pools, and provide information about the storage pools. The following subcommands are supported:

\texttt{zpool -?}

Displays a help message.

\texttt{zpool help command | help | property property-name}

Displays \texttt{zpool} command usage. You can display help for a specific command or property. If you display help for a specific command or property, the command syntax or available property values are displayed. Using \texttt{zpool help} without any arguments displays a complete list of \texttt{zpool} commands.

\texttt{zpool help -l properties}

Displays \texttt{zpool} property information, including whether the property value is editable and their possible values. If you display help for a specific subcommand or property, the command syntax or property value is displayed. Using \texttt{zpool help} without any arguments displays a complete list of \texttt{zpool} subcommands.

\texttt{zpool add [-f] [-n [-l]] pool vdev ...}

Adds the specified virtual devices to the given pool. The \texttt{vdev} specification is described in the "Virtual Devices" section. The behavior of the \texttt{-f} option, and the device checks performed are described in the \texttt{zpool create} subcommand.

\texttt{-f}

Forces use of vdevs, even if they appear in use or specify a conflicting replication level. Not all devices can be overridden in this manner.

\texttt{-n}

Displays the configuration that would be used without actually adding the vdevs. The actual pool creation can still fail due to insufficient privileges or device sharing.
If possible, have -n display the configuration in current /dev/chassis location form.

Do not add a disk that is currently configured as a quorum device to a ZFS storage pool. After a disk is in the pool, that disk can then be configured as a quorum device.

zpool attach [-f] pool device new_device
Attaches new_device to an existing zpool device. The existing device cannot be part of a raidz configuration. If device is not currently part of a mirrored configuration, device automatically transforms into a two-way mirror of device and new_device. If device is part of a two-way mirror, attaching new_device creates a three-way mirror, and so on. In either case, new_device begins to resilver immediately.

-f
Forces use of new_device, even if its appears to be in use. Not all devices can be overridden in this manner.

zpool clear [-F] [nF [-f]] pool [device]...
Clears device errors in a pool. If no arguments are specified, all device errors within the pool are cleared. If one or more devices is specified, only those errors associated with the specified device or devices are cleared.

-F
Initiates recovery mode for an unopenable pool. Attempts to discard the last few transactions in the pool to return it to an openable state. Not all damaged pools can be recovered by using this option. If successful, the data from the discarded transactions is irretrievably lost.

-n
Used in combination with the -F flag. Check whether discarding transactions would make the pool openable, but do not actually discard any transactions.

-f
This is a special pool recovery option that can be used if the fmadm acquit or fmadm repair commands fail to clear a pool’s faults. If the system reboots, FMA replays the pool faults so you will need to resolve the FMA faults after the pool is recovered.

zpool create [-f] [-n [-l]] [-B] [-o property=value] ... [-o file-system-property=value] ... [-m mountpoint] [-R root] pool vdev...
Creates a new storage pool containing the virtual devices specified on the command line. The pool name must begin with a letter, and can contain alphanumeric characters, as well as underscore (_), dash (-), colon (:), space (), and period (.). The pool names mirror, raidz, spare, and log are reserved, as are names beginning with the pattern c[0-9]. The vdev specification is described in the "Virtual Devices" section.

The command verifies that each device specified is accessible and not currently in use by another subsystem. There are some uses, such as being currently mounted, or specified as the dedicated dump device, that prevents a device from ever being used by ZFS. Other uses, such as having a preexisting UFS file system, can be overridden with the -f option.
The command also checks that the replication strategy for the pool is consistent. An attempt to combine redundant and non-redundant storage in a single pool, or to mix disks and files, results in an error unless -f is specified. The use of differently sized devices within a single raidz or mirror group is also flagged as an error unless -f is specified.

Unless the -R option is specified, the default mount point is /pool. The mount point must not exist or must be empty, or else the root dataset cannot be mounted. This can be overridden with the -m option.

-B
When operating on a whole disk device, creates the boot partition, if one is required to boot from EFI (GPT) labeled disks on the platform. The -B option has no effect on devices that are not whole disks.

-f
Forces use of vdevs, even if they appear in use or specify a conflicting replication level. Not all devices can be overridden in this manner.

-l
If possible, have -n display the configuration in current /dev/chassis location form.

-n
Displays the configuration that would be used without actually creating the pool. The actual pool creation can still fail due to insufficient privileges or if a device is currently in use.

-o property=value [-o property=value] ...
Sets the given pool properties. See the "Properties" section for a list of valid properties that can be set.

-O file-system-property=value
[-O file-system-property=value] ...
Sets the given properties for the pool's top-level file system. See the "Properties" section of zfs(1M) for a list of valid properties that can be set.

-R root
Equivalent to -o cachefile=none,altroot=root.

-m mountpoint
Sets the mount point for the pool's top-level file system. The default mount point is /pool or altroot/pool if altroot is specified. The mount point must be an absolute path, legacy, or none. For more information on dataset mount points, see zfs(1M).

zpool destroy [-f] pool
Destroys the given pool, freeing up any devices for other use. This command tries to unmount any active datasets before destroying the pool.

-f
Forces any active datasets contained within the pool to be unmounted.
zpool detach pool device
Detaches a device or a spare from a mirrored storage pool. A spare can also be detached from a RAID-Z storage pool if an existing device was physically replaced. Or, you can detach an existing device in a RAID-Z storage pool if it was replaced by a spare. The operation is refused if there are no other valid replicas of the data.

zpool export [-f] pool ...
Exports the given pools from the system. All devices are marked as exported, but are still considered in use by other subsystems. The devices can be moved between systems (even those of different endianness) and imported as long as a sufficient number of devices are present.

Before exporting the pool, all datasets within the pool are unmounted.

For pools to be portable, you must give the zpool command whole disks, not just slices, so that ZFS can label the disks with portable EFI labels. Otherwise, disk drivers on platforms of different endianness will not recognize the disks.

- f
Forcefully unmount all datasets, using the unmount - f command.

This command will forcefully export the pool.

zpool get all [property[,...] pool ...
Retrieves the given list of properties (or all properties if all is used) for the specified storage pool(s). These properties are displayed with the following fields:

<table>
<thead>
<tr>
<th>name</th>
<th>Name of storage pool</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>Property name</td>
</tr>
<tr>
<td>value</td>
<td>Property value</td>
</tr>
<tr>
<td>source</td>
<td>Property source, either 'default' or 'local'.</td>
</tr>
</tbody>
</table>

See the “Properties” section for more information on the available pool properties.

zpool history [-il] [pool] ...
Displays the command history of the specified pools or all pools if no pool is specified.

- i
Displays internally logged ZFS events in addition to user initiated events.

- l
Displays log records in long format, which in addition to standard format includes, the user name, the hostname, and the zone in which the operation was performed.

zpool import [-d path ...] [-D] zpool import [-d path ...] [-c cachefile] [-F [-n]]pool | id
Lists pools available to import. If the -d option is not specified, this command searches for devices in /dev/dsk. The -d option can be specified multiple times, and all directories and device paths are searched. If the device appears to be part of an exported pool, this command displays a summary of the pool with the name of the pool, a numeric identifier,
as well as the vdev layout and current health of the device for each device or file. Pools that were previously destroyed with the zpool destroy command, are not listed unless the -D option is specified.

The numeric identifier is unique, and can be used instead of the pool name when multiple exported pools of the same name are available.

-c cachefile
reads configuration from the given cachefile that was created with the “cachefile” pool property. This cachefile is used instead of searching for devices.

-d path
Searches for devices or files in path, where path where path can be a directory or a device path. The -d option can be specified multiple times.

-D
Lists destroyed pools only.

zpool import [-o mntopts] [ -o property=value ] ... [-d path ...] [ -c cachefile ] [ -D ] [-f] [-m] [-N] [-R root] [-F [-n [-l]]] -a
Imports all pools found in the search directories or device paths. Identical to the previous command, except that all pools with a sufficient number of devices available are imported. Pools that were previously destroyed with the zpool destroy command, are not imported unless the -D option is specified.

-o mntopts
Comma-separated list of mount options to use when mounting datasets within the pool. See zfs(1M) for a description of dataset properties and mount options.

-o property=value
Sets the specified property on the imported pool. See the “Properties” section for more information on the available pool properties.

-c cachefile
Reads configuration from the given cachefile that was created with the “cachefile” pool property. This cachefile is used instead of searching for devices.

-d path
Searches for devices or files in path. The -d option can be specified multiple times. This option is incompatible with the -c option.

-D
Imports destroyed pools only. The -f option is also required.

-f
Forces import, even if the pool appears to be potentially active.

-F
Recovery mode for a non-importable pool. Attempt to return the pool to an importable state by discarding the last few transactions. Not all damaged pools can be recovered by
using this option. If successful, the data from the discarded transactions is irretrievably
lost. This option is ignored if the pool is importable or already imported.

- a
  Searches for and imports all pools found.

- m
  Allows a pool to import when a log device is missing.

- R root
  Sets the cachefile property to none and the altroot property to root.

- N
  Imports the pool without mounting any file systems.

- n
  Used with the - F recovery option. Determines whether a non-importable pool can be
  made importable again, but does not actually perform the pool recovery. For more
details about pool recovery mode, see the - F option, above.

- l
  If possible, have - n display information in current / dev / chasis location form.

Imports a specific pool. A pool can be identified by its name or the numeric identifier. If
newpool is specified, the pool is imported using the persistent name newpool. Otherwise, it
is imported with the same name as its exported name. Do not import a root pool with a new
name. Otherwise, the system might not boot.

If a device is removed from a system without running zpool export first, the device
appears as potentially active. It cannot be determined if this was a failed export, or whether
the device is really in use from another host. To import a pool in this state, the - f option is
required.

- o mntopts
  Comma-separated list of mount options to use when mounting datasets within the pool.
  See zfs(1M) for a description of dataset properties and mount options.

- o property=value
  Sets the specified property on the imported pool. See the ”Properties” section for more
  information on the available pool properties.

- c cachefile
  Reads configuration from the given cachefile that was created with the cachefile
  pool property. This cachefile is used instead of searching for devices.

- d path
  Searches for devices or files in path. The - d option can be specified multiple times. This
  option is incompatible with the - c option.
-D
Imports destroyed pool. The -f option is also required.

-f
Forces import, even if the pool appears to be potentially active.

-F
Recovery mode for a non-importable pool. Attempt to return the pool to an importable state by discarding the last few transactions. Not all damaged pools can be recovered by using this option. If successful, the data from the discarded transactions is irretrievably lost. This option is ignored if the pool is importable or already imported.

-R root
Sets the cachefile property to none and the altroot property to root.

-N
Imports the pool without mounting any file systems.

-n
Used with the -F recovery option. Determines whether a non-importable pool can be made importable again, but does not actually perform the pool recovery. For more details about pool recovery mode, see the -F option, above.

-l
If possible, have -n display information in current /dev/chassis location form.

-m
Allows a pool to import when a log device is missing.

zpool iostat [-T d|u | -v [-l]] [pool] ... [interval[count]]
Displays I/O statistics for the given pools. When given an interval, the statistics are printed every interval seconds until Ctrl-C is pressed. If no pools are specified, statistics for every pool in the system is shown. If count is specified, the command exits after count reports are printed.

-T d|u
Display a time stamp.
Specify d for standard date format. See date(1). Specify u for a printed representation of the internal representation of time. See time(2).

-v
Verbose statistics. Reports usage statistics for individual vdevs within the pool, in addition to the pool-wide statistics.

-l
If possible, have -v display vdev statistics in current /dev/chassis location form.

zpool list [-H] [-o props[...]] [-T d|u] [pool] ...
Lists the given pools along with a health status and space usage. When given no arguments, all pools in the system are listed.
When given an interval, the status and space usage are displayed every *interval* seconds until Ctrl-C is entered. If *count* is specified, the command exits after *count* reports are displayed.

- **H**  
  Scripted mode. Do not display headers, and separate fields by a single tab instead of arbitrary space.

- **o props**  
  Comma-separated list of properties to display. See the "Properties" section for a list of valid properties. The default list is name, size, allocated, free, capacity, health, altroot.

- **T d|u**  
  Display a time stamp.
  
  Specify d for standard date format. See *date*(1). Specify u for a printed representation of the internal representation of time. See *time*(2).

**zpool offline [-t] pool device ...**  
Takes the specified physical device offline. While the *device* is offline, no attempt is made to read or write to the device.

This command is not applicable to spares or cache devices.

- **t**  
  Temporary. Upon reboot, the specified physical device reverts to its previous state.

**zpool online [-e] pool device ...**  
Brings the specified physical device online.

This command is not applicable to spares or cache devices.

- **e**  
  Expand the device to use all available space. If the device is part of a mirror or raidz then all devices must be expanded before the new space will become available to the pool.

**zpool remove pool device ...**  
Removes the specified device from the pool. This command currently only supports removing hot spares, cache, and log devices. A mirrored log device can be removed by specifying the top-level mirror for the log. Non-log devices that are part of a mirrored configuration can be removed using the *zpool detach* command. Non-redundant and raidz devices cannot be removed from a pool.

**zpool replace [-f] pool old_device [new_device]**  
Replaces *old_device* with *new_device*. This is equivalent to attaching *new_device*, waiting for it to resilver, and then detaching *old_device*. 
The size of `new_device` must be greater than or equal to the minimum size of all the devices in a mirror or raidz configuration.

`new_device` is required if the pool is not redundant. If `new_device` is not specified, it defaults to `old_device`. This form of replacement is useful after an existing disk has failed and has been physically replaced. In this case, the new disk may have the same `/dev/dsk` path as the old device, even though it is actually a different disk. ZFS recognizes this.

In `zpool status` output, the `old_device` is shown under the word `replacing` with the string `/old` appended to it. Once the resilver completes, both the `replacing` and the `old_device` are automatically removed. If the new device fails before the resilver completes and a third device is installed in its place, then both failed devices will show up with `/old` appended, and the resilver starts over again. After the resilver completes, both `/old` devices are removed along with the word `replacing`.

- `f` Forces use of `new_device`, even if it appears to be in use. Not all devices can be overridden in this manner.

`zpool scrub [-s] pool ...`

Begins a scrub. The scrub examines all data in the specified pools to verify that it checksums correctly. For replicated (mirror or raidz) devices, ZFS automatically repairs any damage discovered during the scrub. The `zpool status` command reports the progress of the scrub and summarizes the results of the scrub upon completion.

Scrubbing and resilvering are very similar operations. The difference is that resilvering only examines data that ZFS knows to be out of date (for example, when attaching a new device to a mirror or replacing an existing device), whereas scrubbing examines all data to discover silent errors due to hardware faults or disk failure.

Because scrubbing and resilvering are I/O-intensive operations, ZFS allows only one at a time. If a scrub is already in progress, a subsequent `zpool scrub` returns an error, with the advice to use `zpool scrub -s` to cancel the current scrub. If a resilver is in progress, ZFS does not allow a scrub to be started until the resilver completes.

- `s` Stop scrubbing.

`zpool set property=value pool`

Sets the given property on the specified pool. See the "Properties" section for more information on what properties can be set and acceptable values.

`zpool split [-n [-l]] [-R alroot] [-o mntopts] [-o property=value] pool newpool [device ...]`

Splits off one disk from each mirrored top-level vdev in a pool and creates a new pool from the split-off disks. The original pool must be made up of one or more mirrors and must not be in the process of resilvering. The `split` subcommand chooses the last device in each mirror vdev unless overridden by a device specification on the command line.
When using a *device* argument, `split` includes the specified device(s) in a new pool and, should any devices remain unspecified, assigns the last device in each mirror vdev to that pool, as it does normally. If you are uncertain about the outcome of a `split` command, use the `-n` ("dry-run") option to ensure your command will have the effect you intend.

- `-n` Displays the configuration that would be created without actually splitting the pool. The actual pool split could still fail due to insufficient privileges or device status.

- `-l` If possible, have `-n` display the configuration in current `/dev/chassis` location form.

- `-R altroot` Automatically import the newly created pool after splitting, using the specified `altroot` parameter for the new pool’s alternate root. See the `altroot` description in the "Properties" section, above.

- `-o mountopts` Comma-separated list of mount options to use when mounting datasets within the pool. See `zfs(1M)` for a description of dataset properties and mount options. Valid only in conjunction with the `-R` option.

- `-o property=value` Sets the specified property on the new pool. See the "Properties" section, above, for more information on the available pool properties.

`zpool status [-l] [-v] [-x] [-T [d][u]] [pool] ... [interval][count]`

Displays the detailed health status for the given pools. If no pool is specified, then the status of each pool in the system is displayed. For more information on pool and device health, see the "Device Failure and Recovery" section.

When given an interval, the status and space usage are displayed every `interval` seconds until Ctrl-C is entered. If `count` is specified, the command exits after `count` reports are displayed.

If a scrub or resilver is in progress, this command reports the percentage done and the estimated time to completion. Both of these are only approximate, because the amount of data in the pool and the other workloads on the system can change.

- `-l` If possible, display vdev status in current `/dev/chassis` location form.

- `-x` Display status only for pools that are exhibiting errors or are otherwise unavailable.

- `-v` Displays verbose data error information, printing out a complete list of all data errors since the last complete pool scrub.
zpool upgrade
Identifies a pool's on-disk version, which determines available pool features in the currently running software release. You can continue to use older pool versions, but some features might not be available. A pool can be upgraded by using the `zpool upgrade -a` command. You will not be able to access a pool of a later version on a system that runs an earlier software version.

zpool upgrade -v
Displays ZFS pool versions supported by the current software. The current ZFS pool versions and all previous supported versions are displayed, along with an explanation of the features provided with each version.

zpool upgrade [-V version] -a | pool ...
Upgrades the specified pool to the latest on-disk version. If this command reveals that a pool is out-of-date, the pool can subsequently be upgraded using the `zpool upgrade -a` command. A pool that is upgraded will not be accessible on a system that runs an earlier software release.

- a
Upgrades all pools.

- V version
Upgrade to the specified version, which must be higher than the current version. If the -V flag is not specified, the pool is upgraded to the most recent version.

**Examples**

**EXAMPLE 1** Creating a RAID-Z Storage Pool
The following command creates a pool with a single raidz root vdev that consists of six disks.

```
# zpool create tank raidz c0t0d0 c0t1d0 c0t2d0 c0t3d0 c0t4d0 c0t5d0
```

**EXAMPLE 2** Creating a Mirrored Storage Pool
The following command creates a pool with two mirrors, where each mirror contains two disks.

```
# zpool create tank mirror c0t0d0 c0t1d0 mirror c0t2d0 c0t3d0
```

Alternatively, whole disks can be specified using `/dev/chassis` paths describing the disk's current location.

```
# zpool create tank \\
mirror \\
/dev/chassis/RACK29.U01-04/DISK_00/disk \\
/dev/chassis/RACK29.U05-08/DISK_00/disk \\
```
Creating a Mirrored Storage Pool

(Continued)

```
mirror \
/dev/chassis/RACK29.U01-04/DISK_01/disk \ 
/dev/chassis/RACK29.U05-08/DISK_01/disk
```

Adding a Mirror to a ZFS Storage Pool

The following command adds two mirrored disks to the pool tank, assuming the pool is already made up of two-way mirrors. The additional space is immediately available to any datasets within the pool.

```
# zpool add tank mirror c1t0d0 c1t1d0
```

Listing Available ZFS Storage Pools

The following command lists all available pools on the system.

```
# zpool list
NAME SIZE ALLOC FREE CAP DEDUP HEALTH ALTROOT
pool 278G 4.19G 274G 1% 1.00x ONLINE -
rpool 278G 78.2G 200G 28% 1.00x ONLINE -
```

Listing All Properties for a Pool

The following command lists all the properties for a pool.

```
% zpool get all pool
NAME PROPERTY VALUE SOURCE
pool allocated 4.19G -
pool altroot - default
pool autexpand off default
pool autoreplace off default
pool bootfs - default
pool cachefile - default
pool capacity 1% -
pool dedupditto 0 default
pool dedupratio 1.00x -
pool delegation on default
pool failmode wait default
pool free 274G -
pool guid 1907687796174423256 -
pool health ONLINE -
pool listshares off local
pool listsnapshots off default
pool readonly off -
pool size 278G -
pool version 34 default
EXAMPLE 6  Destroying a ZFS Storage Pool
The following command destroys the pool “tank” and any datasets contained within.

```
# zpool destroy -f tank
```

EXAMPLE 7  Exporting a ZFS Storage Pool
The following command exports the devices in pool tank so that they can be relocated or later imported.

```
# zpool export tank
```

EXAMPLE 8  Importing a ZFS Storage Pool
The following command displays available pools, and then imports the pool “tank” for use on the system.

The results from this command are similar to the following:

```
# zpool import
pool: tank
  id: 7678868315469843843
state: ONLINE
action: The pool can be imported using its name or numeric identifier.
config:

  tank  ONLINE
  mirror-0  ONLINE
  c1t2d0  ONLINE
  c1t3d0  ONLINE
```

```
# zpool import tank
```

EXAMPLE 9  Upgrading All ZFS Storage Pools to the Current Version
The following command upgrades all ZFS Storage pools to the current version of the software.

```
# zpool upgrade -a
This system is currently running ZFS pool version 22.
```

All pools are formatted using this version.

EXAMPLE 10  Managing Hot Spares
The following command creates a new pool with an available hot spare:

```
# zpool create tank mirror c0t0d0 c0t1d0 spare c0t2d0
```

If one of the disks were to fail, the pool would be reduced to the degraded state. The failed device can be replaced using the following command:

```
# zpool replace tank c0t0d0 c0t3d0
```
EXAMPLE 10  Managing Hot Spares  (Continued)

After the device has been resilvered, the spare is automatically detached and is made available should another device fail. The hot spare can be permanently removed from the pool using the following command:

```
# zpool remove tank c0t2d0
```

EXAMPLE 11  Creating a ZFS Pool with Separate Mirrored Log Devices

The following command creates a ZFS storage pool consisting of two, two-way mirrors and mirrored log devices:

```
# zpool create pool mirror c0d0 c1d0 mirror c2d0 c3d0 log mirror c4d0 c5d0
```

EXAMPLE 12  Adding Cache Devices to a ZFS Pool

The following command adds two disks for use as cache devices to a ZFS storage pool:

```
# zpool add pool cache c2d0 c3d0
```

Once added, the cache devices gradually fill with content from main memory. Depending on the size of your cache devices, it could take over an hour for them to fill. Capacity and reads can be monitored using the `iostat` option as follows:

```
# zpool iostat -v pool 5
```

EXAMPLE 13  Removing a Mirrored Log Device

Given the configuration shown immediately below, the following command removes the mirrored log device `mirror-2` in the pool `tank`.

```
pool: tank
state: ONLINE
scrub: none requested
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c6t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c6t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-1</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c6t2d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c6t3d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>mirror-2</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c4t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c4t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

# zpool remove tank mirror-2
```
EXAMPLE 14   Recovering a Faulted ZFS Pool

If a pool is faulted but recoverable, a message indicating this state is provided by `zpool status` if the pool was cached (see `cachefile` above), or as part of the error output from a failed `zpool import` of the pool.

Recover a cached pool with the `zpool clear` command:

```
# zpool clear -F data
Pool data returned to its state as of Thu Jun 07 10:50:35 2012.
Discarded approximately 29 seconds of transactions.
```

If the pool configuration was not cached, use `zpool import` with the recovery mode flag:

```
# zpool import -F data
Pool data returned to its state as of Thu Jun 07 10:50:35 2012.
Discarded approximately 29 seconds of transactions.
```

EXAMPLE 15   Importing a ZFS Pool with a Missing Log Device

The following examples illustrate attempts to import a pool with a missing log device. The `-m` option is used to complete the import operation.

Additional devices are known to be part of this pool, though their exact configuration cannot be determined.

```
# zpool import tank
The devices below are missing, use '-m' to import the pool anyway:
    c5t0d0 [log]

cannot import 'tank': one or more devices is currently unavailable
```

```
# zpool import -m tank
# zpool status tank
    pool: tank
    state: DEGRADED
    status: One or more devices could not be opened. Sufficient replicas exist for
            the pool to continue functioning in a degraded state.
    action: Attach the missing device and online it using 'zpool online'.
            see: http://www.support.oracle.com/msg/ZFS-8000-2Q
    scan: none requested
    config:

        NAME  STATE     READ  WRITE  CKSUM
        tank  DEGRADED  0     0      0
              c7t0d0  ONLINE  0     0      0
    logs  1693927398582730352  UNAVAIL  0     0      0  was /dev/dsk/c5t0d0
```
EXAMPLE 15  Importing a ZFS Pool with a Missing Log Device  (Continued)

errors: No known data errors

The following example shows how to import a pool with a missing *mirrored* log device.

```
# zpool import tank
The devices below are missing, use -m? to import the pool anyway:
mirror-1 [log]
c5t0d0
c5t1d0
```

```
# zpool import -m tank
```

```
# zpool status tank
pool: tank
state: DEGRADED
status: One or more devices could not be opened. Sufficient replicas
exist for the pool to continue functioning in a degraded state.
action: Attach the missing device and online it using 'zpool online'.
see: http://www.support.oracle.com/msg/ZFS-8000-2Q
scan: none requested
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>DEGRADED</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c5t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>logs</td>
<td>UNAVAIL</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-1</td>
<td>UNAVAIL</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

insufficient replicas
46385995713041169 UNAVAIL 0 0 0 was /dev/dsk/c5t0d0
13821442324672734438 UNAVAIL 0 0 0 was /dev/dsk/c5t1d0
```

errors: No known data errors

EXAMPLE 16  Importing a Pool By a Specific Path

The following command imports the pool tank by identifying the pool's specific device paths,
/dev/dsk/c9t9d9 and /dev/dsk/c9t9d8, in this example.

```
# zpool import -d /dev/dsk/c9t9d9s0 /dev/dsk/c9t9d8s0 tank
```

An existing limitation is that even though this pool is comprised of whole disks, the command
must include the specific device's slice identifier.
Exit Status  The following exit values are returned:

0  Successful completion.
1  An error occurred.
2  Invalid command line options were specified.

<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

See Also  ps(1), zfs(1M), attributes(5), SDC(7)

Notes  Each ZFS storage pool has an associated process, zpool -poolname, visible in such tools as ps(1). A user has no interaction with these processes. See SDC(7).
Name  zstreamdump – filter data in zfs send stream

Synopsis  zstreamdump [-C] [-v]

Description  The zstreamdump utility reads from the output of the zfs send command, then displays
headers and some statistics from that output. See zfs(1M).

Options  The following options are supported:

- C
  Suppress the validation of checksums.

- v
  Verbose. Dump all headers, not only begin and end headers.

Attributes  See attributes(5) for descriptions of the following attributes:
