nsd(1M), inet(3SOCKET), getaddrinfo(3SOCKET), ipaddrsel.conf(4), attributes(5), inet6(7P)

Notes  
The ipnodes cache kept by nsd(1M) contains addresses that are ordered using the destination address ordering algorithm, which is one of the reasons why ipaddrsel is called before nsd in the boot sequence. If ipaddrsel is used to change the address selection policy after nsd has started, you should invalidate the nsd ipnodes cache by invoking the following command:

```
example# /usr/sbin/nsd -i ipnodes
```
ipadm – configure Internet Protocol network interfaces and TCP/IP tunables

## Synopsis

ipadm

- `ipadm create-ip [-t] IP-interface`
- `ipadm delete-ip IP-interface`
- `ipadm create-vni [-t] VNI-interface`
- `ipadm delete-vni VNI-interface`
- `ipadm create-impmp [-t] [-i interface,[...]] IPMP-interface`
- `ipadm delete-impmp [-f] IPMP-interface`
- `ipadm add-impmp [-t] -i interface,[...] [-i interface,[...]] IPMP-interface`
- `ipadm remove-impmp [-t] -i interface,[...] [-i interface,[...]] IPMP-interface`
- `ipadm show-if [-p] -o field[,...] [interface]`
- `ipadm disable-if -t interface`
- `ipadm enable-if -t interface`
- `ipadm set-ifprop [-t] -m protocol -p prop=value[,...] interface`
- `ipadm reset-ifprop [-t] -m protocol -p prop interface`
- `ipadm show-ifprop [-c] -o field[,...] [-p prop[,...]] [-m protocol] [interface]`
- `ipadm create-addr [-t] [-T static] -d [-a {local|remote}=addr[/prefixlen],...] addrobj | interface`
- `ipadm create-addr [-t] -T dhcp [-w seconds | forever] [-h hostname] addrobj | interface`
- `ipadm create-addr [-t] -T addrconf [-i {local|remote}=interface-id] [-p {stateful|stateless}={yes|no},...] addrobj | interface`
- `ipadm delete-addr [-r] addrobj`
- `ipadm show-addr [-p] -o field[,...] [-d] [addrobj | interface/ | interface]`
- `ipadm up-addr [-t] addrobj`
- `ipadm down-addr [-t] addrobj`
- `ipadm refresh-addr [-i] addrobj`
- `ipadm disable-addr -t addrobj`
- `ipadm enable-addr -t addrobj`
- `ipadm set-addrprop [-t] -p prop=value[,...] addrobj`
- `ipadm reset-addrprop [-t] -p prop=value[,...] addrobj`
- `ipadm show-addrprop [-c] -o field[,...] [-p prop[,...]] [addrobj | interface]`
- `ipadm set-prop [-t] -p prop=value[,...] protocol`
- `ipadm reset-prop [-t] -p prop protocol`
- `ipadm show-prop [-c] -o field[,...] [-p prop[,...]] protocol | protocol`
- `ipadm help [subcommand-name]`
The `ipadm` command provides a set of subcommands that can be used to:

manage interfaces:
- create and delete interfaces of interface classes `ip`, `ipmp`, and `vni`
- modify interface properties
- display interface configuration

manage addresses:
- create and delete addresses
- modify address properties
- display address configuration

manage TCP/IP protocol properties:
- modify TCP/IP properties
- display TCP/IP properties

Note that `ipadm` is used to manage network configuration manually. The `netadm(1M)` DefaultFixed NCP should be enabled for these manual configurations. Many of the `ipadm` subcommands are not functional if the DefaultFixed NCP is not enabled. The `ipadm` subcommands that do not function unless the DefaultFixed NCP is enabled are:

- `create-ip`, `delete-ip`, `create-vni`, `delete-vni`, `create-ipmp`, `delete-ipmp`, `add-ipmp`, `remove-ipmp`, `disable-if`, `enable-if`, `set-ifprop`, `reset-ifprop`, `create-addr`, `down-addr`, `up-addr`, `disable-addr`, `enable-addr`, `refresh-addr`, `delete-addr`, `set-addrprop`, `reset-addrprop`

The following subcommands still continue to function when the DefaultFixed NCP is not enabled:

- `show-if`, `show-ifprop`, `refresh-addr`, `show-addr`, `show-addrprop`, `set-prop`, `reset-prop`, `show-prop`

Refer to `netadm(1M)` for more information on how to list and enable NCPs.

The various operands to `ipadm` subcommands are described in the “Operands” section, which follows “Subcommands”.

The `ipadm` command with no subcommands displays a concise summary of interface and address configuration on the system. The output contains all the interfaces (ip, loopback, vni, and ipmp) configured on the system along with the addresses configured on these interfaces. See EXAMPLES, below, for more information.

### Required Authorization and Privilege

The following subcommands require `solaris.network.interface.config` authorization and `PRIV_SYS_IP_CONFIG` privilege.

- `create-ip`
- `create-addr`
- `delete-ip`
- `up-addr`
- `create-vni`
- `down-addr`
delete-vni refresh-addr
create-ipmp disable-addr
delete-ipmp enable-addr
add-ipmp set-addrprop
remove-ipmp reset-addrprop
disable-if set-prop
enable-if reset-prop
set-ifprop
reset-ifprop

In addition to the authorization and privilege specified above, the \texttt{ipadm} subcommands create-ip, create-vni, create-ipmp, and enable-if need PRIV_NET_RAWACCESS privilege.

\textbf{Sub-commands}  
The following subcommands are supported:

\texttt{create-ip [-t] IP-interface}
Create an IP interface that handles both IPv4 and IPv6 packets. The address of the IPv4 interface will be set to 0.0.0.0 and the address of the IPv6 interface will be set to ::. This subcommand, by default, causes the information to persist, so that on the next reboot this interface will be instantiated.

An interface is implicitly enabled for IPv4 and IPv6 when it is created. See the disable-if and enable-if subcommands below, to disable or enable an interface.

Note that \texttt{lo0} is a special interface, called the loopback interface. It is a virtual IP interface and is not associated with any physical hardware. It is one of the first IP interfaces to be created on the system, with IPv4 address of 127.0.0.1 and IPv6 address of ::/128.

\texttt{-t, --temporary}
Specifies that the operation is temporary and must not persist. The operation affects only the active configuration.

\texttt{delete-ip IP-interface}
Deletes the IP interface from active configuration. All addresses configured on the interface will be torn down. Further, all the persistent information related to the interface will be removed from the persistent data store and, for this reason, interface will not be instantiated upon reboot. To disable an interface from active configuration (rather than delete the interface), use the disable-if subcommand.

\texttt{create-vni [-t] VNI-interface}
Create a VNI interface that handles both IPv4 and IPv6 packets. The address of the IPv4 interface will be set to 0.0.0.0 and the address of the IPv6 interface will be set to ::. This subcommand, by default, causes the information to persist, so that on the next reboot this interface will be instantiated.

The interface is implicitly enabled for IPv4 and IPv6 when it is created. See the disable-if and enable-if subcommands below, to disable or enable an interface.
Note that vni is a special interface, in that it is a virtual interface and does not have any hardware associated with it. See vni(7d).

-t, --temporary
Specifies that the operation is temporary and must not persist. The operation affects only the active configuration.

**delete-vni VNI-interface**
Delete the VNI interface from active configuration. All addresses configured on the interface will be torn down. Further, all the persistent information related to the IP interface will be removed from the persistent data store and, for this reason, interface will not be instantiated upon reboot. To disable the interface from active configuration (rather than delete the interface), use the disable-if subcommand.

**create-ipmp [-t] [-i interface, [...] IPMP-interface**
Create a IPMP interface that handles both IPv4 and IPv6 packets. The address of the IPv4 interface will be set to 0.0.0.0 and the address of the IPv6 interface will be set to ::. This subcommand, by default, causes the information to persist, so that on the next reboot this interface will be instantiated.

The interface is implicitly enabled for IPv4 and IPv6 when it is created. See the disable-if and enable-if subcommands below, to disable or enable an IPMP interface.

-t, --temporary
Specifies that the operation is temporary and must not persist. The operation affects only the active configuration.

-i, --interface interface, [...]
A comma-separated list of interfaces to be added as underlying interfaces to the IPMP interface. The specified interfaces must exist in the active configuration to be successfully added to the IPMP group and must not be present in any other IPMP group. More than one -i option is allowed. The command returns with partial success if the IPMP interface was created but none of the given underlying interfaces were added successfully.

**delete-ipmp [-f] IPMP-interface**
Deletes the IPMP interface from active configuration. All addresses configured on the interface will be torn down. The command fails if the IPMP interface has any underlying interfaces, unless the -f option is specified. Further, all the persistent information related to the IPMP interface will be removed from the persistent data store and, for this reason, interface will not be instantiated upon reboot. To disable the interface from active configuration only (rather than delete the interface), use the disable-if subcommand.

-f, --force
If the IPMP interface has any underlying interfaces, specifying this option removes all the underlying interfaces from the group first, before deleting the IPMP interface.

**add-ipmp [-t] [-i interface, [...] [-i interface, [...]... IPMP-interface**
Adds one or more underlying IP interfaces to the given IPMP interface.
-t, --temporary
   Specifies that the operation is temporary and must not persist. The operation affects
   only the active configuration.

-i, --interface interface,[...]
   A comma-separated list of interfaces to be added as underlying interfaces to the IPMP
   interface. The specified interfaces must exist in the active configuration to be
   successfully added to the IPMP group and must not be present in any other IPMP
   group. The command returns with partial success if at least one interface was added and
   adding the remaining interfaces failed. More than one -i option is allowed.

remove-ipmp [-t] [-i interface,[...]] [-i interface,[...]] IPMP-interface
   Removes one or more underlying IP interfaces from the IPMP interface.

   -t, --temporary
   Specifies that the operation is temporary and must not persist. The operation affects
   only the active configuration.

   -i, --interface interface,[...]
   A comma-separated list of underlying interfaces to be removed from the IPMP
   interface. The specified interfaces must already be underlying interfaces for the given
   IPMP group. More than one -i option is allowed. The command returns with partial
   success if at least one interface was removed and removing the remaining interfaces
   failed.

show-if [[-p] -o field[,...]] [interface]
   Show network interface configuration information, either for all the network interfaces
   configured on the system, including the ones that are only in the persistent configuration,
   or for the specified network interface.

   -o field[,...], --output field[,...]
   A case-insensitive, comma-separated list of output fields to display. The field name must
   be one of the fields listed below, or the special value all to display all fields. For each
   network interface, the following fields can be displayed:

IFNAME
   The name of the IP interface.

CLASS
   Indicates one of the following:

   ip
   An interface that is plumbed over an underlying datalink.

   ipmp
   An IPMP interface that is created over one or more underlying IP interfaces.

   loopback
   A loopback interface.
vni
   A virtual IP interface. See vn(7d).

STATE
   Indicates one of the following for the displayed interface.

ok
   Indicates that the required resources for an interface are allocated. For some
   interfaces this also indicates that the link is up.

offline
   The interface is offline and thus cannot send or receive IP data traffic. See
   if_mpadm(1M).

failed
   Indicates that the datalink is down. If the interface is part of an IPMP group it could
   also mean that the interface has failed (that is, IFF_FAILED is set). Failed interfaces
   will not be used to send or receive IP data traffic. If this is set on a physical IP interface
   in an IPMP group, IP data traffic will continue to flow over other usable IP interfaces
   in the IPMP group. If this is set on an IPMP IP interface, the entire group has failed
   and no data traffic can be sent or received over any interfaces in that group. See
   in.ndpd(1M).

down
   Indicates that the interface is administratively down, preventing any IP packets from
   being sent or received through it.

disabled
   Indicates that the interface has been disabled from the active configuration using the
   disable-if subcommand.

ACTIVE
   Either yes or no, depending on whether the IP interface is being used by the system
   for IP data traffic.

CURRENT
   For interface objects, in active configuration, it indicates any of the following flags.

b
   interface supports broadcast

m
   interface supports multicast

p
   interface is a point-to-point link

v
   interface is a virtual interface (for example, vn(7d), loopback), that is, the physical
   interface has no underlying hardware.
s
IPMP interface is marked standby administratively. See _in.ndpd(1M)_.

l
interface is an underlying interface for an IPMP interface. See _in.ndpd(1M)_.

i
Underlying interface is inactive. See _in.ndpd(1M)_.

V
interface is a VRRP interface

a
VRRP interface is in accept mode (~_IFF_NOACCEPT_)

Z
Layer-3 protection of IP addresses for the interface has been administratively
enforced.

4
interface can handle IPv4 packets

6
interface can handle IPv6 packets

Note that b and p are mutually exclusive.

**PERSISTENT**
Specifies the configuration that will be applied when the interface object is
instantiated on reboot or re-enabled using the _enable-if_ subcommand. It can be
any or all of s, l, 4, and 6 (see above). This field is not shown by default and will be
shown only when all or persistent is specified with _-o_.

**OVER**
The underlying interface(s) over which the IPMP interface is created. This does not
apply to other interface classes.

_\-p, --parsable_
Display using a stable machine-parsable format. The _-o_ option is required with this
option. See "Parsable Output Format", below.

disable-if \-t interface
Disables the specified _interface_ by removing it from the active configuration. All the
addresses configured on the interface will be disabled. If the interface object was created
persistently to begin with, then the persistent configuration is unchanged. To re-enable this
interface, one should use _enable-if_.

_\-t, --temporary_
Specifies that the disable is temporary and changes apply only to the active
configuration.
enable-if -t interface
Enables the given interface by reading the configuration from the persistent store. All the persistent interface properties, if any, are applied and all the persistent addresses, if any, on the given interface will be enabled.

-t, --temporary
Specifies that the enable is temporary and changes apply only to the active configuration.

set-ifprop [-t] -m protocol -p prop=value[...], interface
Modifies an interface property to the value specified by the user. If the property takes multiple values then the values should be specified with a comma as the delimiter. Only one property can be specified at a time. The properties supported on an interface and the property's possible values can be retrieved using show-ifprop subcommand. Only one property at a time can be modified.

-t, --temporary
Specifies that the changes are temporary and changes apply only to the active configuration.

-m protocol, --module protocol
Identifies whether property should be applied for IPv4 or IPv6 packets.

-p prop=value[...], -prop prop=value[...]
A property to set to the specified values.

reset-ifprop [-t] -m protocol -p prop interface
Resets a property of the specified interface to its default value. If -t is not used, any persisted value of the property will be deleted. Only one property can be modified at a time.

-t, --temporary
Specifies that the resets are temporary and changes apply only to the active configuration.

-m protocol, --module protocol
Identifies whether the property being reset affects either IPv4 or IPv6 packets.

-p prop, -prop prop
A property to set to the specified values.

show-ifprop [[-c] -o field[...]] [-p prop,...] [-m protocol] [interface]
Show the current and persistent values of one or more properties, either for all the created interfaces or for the specified interface. Several properties of interest can be retrieved at one time by providing comma-separated property names to -p option. If the -p option is not specified, all available interface properties are displayed.

-o field[...], --output field[...]
A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. For each interface, the following fields can be displayed:
IFNAME
   The name of the interface.

PROPERTY
   The name of the property.

PROTO
   The name of the protocol the property belongs to. The protocols currently supported
   are IPv4 and IPv6.

PERM
   The read/write permissions of the property. The value shown will be r (read-only), w
   (write-only) or rw (read-and-write).

CURRENT
   The current value of the property. For disabled interfaces, because a value is not set, it
   will be shown as --.

PERSISTENT
   The persistent value of the property. Persistent values are the values that will be
   reapplied on reboot.

DEFAULT
   The default value of the property. If the property has no default value, -- is displayed.

POSSIBLE
   A comma-separated list of the values the property can have. If the values span a
   numeric range, min - max might be displayed as shorthand. If the possible values are
   unknown, ? is displayed or if they are unbounded, -- is displayed.

-c, -parsable
   Display using a stable machine-parsable format. The -o option is required with this
   option. See "Parsable Output Format", below.

-p prop, ..., --prop=prop
   A comma-separated list of properties to display. See the sections on interface properties
   following subcommand descriptions.

-m protocol, --module protocol
   Displays properties matching the given protocol. Valid values are ipv4 and ipv6.

For the supported list of interface properties, see "Interface Properties" below.

create -addr [-t] [ -T static] [-d] -a {local | remote}=addr[/prefixlen],... addrobj | interface
   Creates a static IPv4 or IPv6 address on an interface. The interface is either specified
   specifically as an argument or is derived from the addrobj argument. The interface on
   which the address is being created must already exist. The created static address will
   subsequently be identified by addrobj. When the command is invoked with an interface
   argument, then the command will automatically generate an addrobj for the address and
   will print the generated name to stdout.
Note – Automatically generated addrobj names have the following forms:

interface/v4  interface/v6
interface/v4a interface/v6a
interface/v4b interface/v6b
 .
 .
 .
i nterface/v4z  interface/v6z
interface/v4aa interface/v6aa
interface/v4ab interface/v4ab
 .
 .
 .

The IP address version is used in the automatic generation of names and names are made unique by increasingly appending one or more of the characters [a-z] to the v[46] prefix.

By default, a configured address will be marked up, so that it can be used as a source or destination of or for outbound and inbound packets.

All address objects are enabled when they are created. See the disable-addr and enable-addr subcommands for instructions on disabling or enabling an address object.

A persistent operation cannot be performed on a temporary object. That is, if the interface is temporarily created, then one cannot create the address object persistently.

If the interface specified in the addrobj name is an IPMP interface, a static data address is created on the IPMP interface. If the interface specified in the addrobj name is an underlying interface for an IPMP group, a static test address is created on the underlying interface.

-t, --temporary
  Specifies that the configured address is temporary and changes apply only to the active configuration.

-d, --down
  Specifies that the configured address should be marked down, that is, the address will not be used as a source or destination of IP packets.

-a [local | remote]=addr[/prefixlen]...
 --address [local | remote]=addr[/prefixlen]...

addr indicates a literal IP address or a hostname corresponding to the local or remote end-point (for point-to-point interfaces).

If a hostname is specified its numeric value is uniquely obtained using the entry in /etc/hosts. If no numeric IP address is defined in the file, then the numeric value is uniquely obtained using the resolver order specified for hosts or ipnodes in nsswitch.conf(4). If there are multiple entries for a given hostname, an error will be
Because IP addresses are created before naming services have been brought online during the boot process, it is important that any hostname used be included in `/etc/hosts`.

If the `prefixlen` is not explicitly specified in the command-line, the netmask for the address is obtained by following the search in the order listed below:

1. using the order specified for `netmasks` in `nsswitch.conf`
2. interpreting IPv4 address using Classful subnetting semantics defined in RFC 791, and interpreting IPv6 addresses using the definitions in RFC 4291.

For point-to-point interfaces, along with the address of the local end-point the address of the remote end-point must be specified (for example, `-a local=laddr,remote=raddr`). If `prefixlen` for the remote end-point is specified, an error will be returned.

Note that if the interface requires only a local address, specify it directly with the `-a` option as follows: `-a addr[/prefixlen]`. The address will automatically be considered a local address.

```
create-addr [-t] -T dhcp [-w seconds | forever] [-h hostname] addrobj | interface
```

Creates a DHCP-controlled IPv4 address on an interface. The interface is either specified specifically as an argument or is derived from the `addrobj` argument. The created IPv4 address will subsequently be identified by `addrobj`. When the `addrobj` contains an underlying interface, this command creates a test address; when it contains an IPMP interface, it creates a data address.

When the command is invoked with an interface argument, then the command will automatically generate an `addrobj` name for the address and will print the generated name to stdout.

All the address objects are enabled when they are created. See the `disable-addr` and `enable-addr` subcommands for instructions on disabling and enabling an address object.

A persistent operation cannot be performed on a temporary object. That is, if the interface is temporarily created, one cannot create the address object persistently.

If the interface specified in the `addrobj` name is an IPMP interface, the address obtained through DHCP is created as a data address on the IPMP interface.

```
-h hostname
```

Specifies the hostname to which the client would like the DHCP server to map the client’s leased IPv4 address. There is no guarantee that the DHCP server will be able to fulfill the hostname request.

```
-t, --temporary
```

Specifies that the configured address is temporary and changes apply only to the active configuration.
Specifies the amount of time, in seconds, to wait until the operation completes. If no wait interval is given, and the operation is one that cannot complete immediately, \texttt{ipadm} will, by default, wait 120 seconds for the requested operation to complete. Note that the default wait time is subject to change in future releases. The symbolic value \texttt{forever} can be used as well, with obvious meaning.

\texttt{create -addr [-t] -T addrconf [-i \{local | remote\}={interface-id}] [-p \{stateful | stateless\}={yes | no}],...]} addrobj | interface

Creates an auto-configured IPv6 address on an interface. The interface is either specified specifically as an argument or is derived from the \texttt{addrobj} argument. The created IPv6 addresses will be identified by \texttt{addrobj}. When the command is invoked with an interface argument, then the command will automatically generate an \texttt{addrobj} name for the address and will print the generated name to stdout.

The system uses the default interface ID (for the media-type Ethernet, the Interface ID is the MAC address of the interface) to generate auto-configured addresses. This behavior can be overridden using \texttt{-i} option.

By default:

- IPv6 addresses will be auto-configured based on prefixes advertised by routers as described in RFC 4862 and...
- IPv6 addresses will be auto-configured on the specified interface using the IPv6 address offered by DHCPv6 server as described in RFC 3315. (That is, \texttt{-p stateful=yes, stateless=yes} is the default option.)

All the address objects are enabled when they are created. See the \texttt{disable-addr} and \texttt{enable-addr} subcommands for instructions on disabling and enabling an address object.

A persistent operation cannot be performed on a temporary object. That is, if the interface is temporarily created, then one cannot create the address object persistently.

If the interface specified in the \texttt{addrobj} name is an IPMP interface, the addresses obtained through IPv6 autoconfiguration are created as data addresses on the IPMP interface.

\texttt{-t, --temporary}

Specifies that the configured address is temporary and changes apply only to the active configuration.

\texttt{-i \{local | remote\}={interface-id}, -i interface-id \{local | remote\}={interface-id}}

Specifies the interface ID to be used for generating auto-configured addresses.

For point-to-point interfaces, the interface id of the remote end-point can be specified (for example, \texttt{-i local=lid,remote=rid}).

Note that if the interface requires only a local interface id, specify it directly with the \texttt{-i} option as follows: \texttt{-i lid}. The interface id will automatically be considered a local interface id.
-p {stateful | stateless}={yes | no},...
- p prop {stateful | stateless}={yes | no},...

Specifies if stateful or stateless or both methods of auto-configuration should be enabled or not.

If -p stateful=no is specified, then stateful auto-configuration based on DHCPv6-specified IPv6 addresses will not be performed.

If -p stateless=no is specified, then stateless auto-configuration based on the router-advertised prefixes will not be performed.

If -p stateful=no, stateless=no is specified, then both the methods of auto-configuration will not be performed.

With the -T addrconf option, -p stateful=yes, stateless=yes is used by default.

delete-addr [-r] addrobj

Deletes all the addresses identified by addrobj on the interface specified in the addrobj. It also removes these addresses from the persistent data-store; thus, these addresses will not be instantiated on reboot.

If the address object is a DHCP-controlled address, delete-addr removes the address from the system without notifying the DHCP server, and records the current lease for later use.

-r, -r release

If the addrobj is a DHCP-controlled address, this option brings about the relinquishing of the DHCP-controlled IP addresses on the interface by notifying the server and the discarding of the current lease.

show-addr [-p] -o field[,...] [-d] [addrobj] [interface]

Show address information, either for the given addrobj or all the address objects configured on the specified interface, including the address objects that are only in the persistent configuration.

-p, -p parsable

Display using a stable machine-parsable format. The -o option is required with this option. See "Parsable Output Format", below.

-o field[,...], -o output field[,...]

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. For each interface, the following fields can be displayed:

ADDROBJ

The name of the address object.

TYPE

Type of the address object. It will be one of: from-gz, static, dhcp, or addrconf. The static, dhcp, and addrconf types correspond to the type of the address object.
specified by the -T option of create-addr. The from-gz type will only be displayed in non-global zones, and indicates that the address was configured based on the allowed-address property configured for the non-global exclusive-IP zone from the global zone.

STATE
State of the address object. This field is shown only when all is specified with -o. This indicates one of the following values:

disabled
Address is not part of the active configuration (see disable-addr and disable-if).
down
Address is administratively down (see down-addr).
duplicate
Address was found to conflict with another system’s IP address by duplicate address detection (DAD) and cannot be used until the conflict is resolved. The system will periodically rerun DAD to determine if the conflict has been resolved. Alternatively, refresh-addr can be used to immediately rerun DAD.
inaccessible
Address cannot be used because the IP interface it is configured on has failed.

ok
Address is enabled, up, and functioning properly. The system will accept IP packets destined to this address, and will originate IP packets with this address in accordance with the configured IP source address selection policy.
tentative
Address is currently undergoing duplicate address detection (for example, as part of up-addr or refresh-addr).

CURRENT
For address objects in active configuration, it indicates any of the following flags. This field is not shown by default and will be shown only when all or current is specified with -o.
d (deprecated)
Will not be used as source address for outbound packets unless either there are no other addresses available on the interface or the application has explicitly bound to this address.
p (private)
Address not advertised by the routing daemon.
t (temporary)
Temporary IPv6 address as defined in RFC 3041.
U (up)
Address is marked up for use as a source/destination of outbound/inbound packets.
u (unnumbered)
Address matches the local address of some other link in the system.

PERSISTENT
Specifies the configuration that will be applied when the address object is instantiated
on reboot or re-enabled using the enable-addr subcommand. It can be any or all of
U, p, and d (see above).

ADDR
Numeric IPv4 or IPv6 address. In the case of point-to-point interfaces, the addresses
of both the endpoints, are displayed (laddr->raddr). For an address object of type
dhcp, if the state of the address object is disabled, or if the address is 0.0.0.0 for
IPv4 or :: for IPv6, then a question mark (?) is displayed.

CID-TYPE
The type of the Client ID used by the dhcpagent(1M), if the address is being obtained
using DHCP. For IPv4, this shows the type of the DUID used in constructing the RFC
4361 Client ID. The type is one of DUID-LLT, DUID-EN, DUID-LL, other, or default.
This field is not shown in the default output. It can be shown using -d or using
cid-type or all with -o.

DUID-LLT
Type 1 RFC 3315 DUID is used in constructing CID-VALUE (for example,
1,1,63463777,0a:0b:0c:0d:0e:0f). Refer to the RFC for more details.

DUID-EN
Type 2 RFC 3315 DUID is used in constructing CID-VALUE (for example,
1,1,63463777,0a:0b:0c:0d:0e:0f). Refer to the RFC for more details.

DUID-LL
Type 3 RFC 3315 DUID is used in constructing CID-VALUE (for example,
1,1,63463777,0a:0b:0c:0d:0e:0f). Refer to the RFC for more details.

other
An RFC 3315 DUID of a Type in {0,4-65535} is used to derive the Client ID (for
example, 4,0x734633) or the CID-VALUE is a raw Client ID (for example, Sun,
0xab3146) that does not conform to RFC 3315.

default
Indicates that the RFC 3315 DUID is not being used to construct the Client ID.
Instead, Client ID is derived using the MAC address of the interface as per RFC 2132.
CID-VALUE will contain the string 0x01 followed by the MAC address hex string. This
is applicable only for IPv4.

CID-VALUE
Value of the Client ID used by the dhcpagent(1M), if the address is being obtained
using DHCP. Format used follows that of the configuration parameter CLIENT_ID in
file /etc/default/dhcpagent. Refer to the description of CLIENT_ID in
dhcpagent(1M). When the CID-TYPE is default, the CID-VALUE contains the legacy
CLIENT-ID, constructed as per RFC 2132. This field is not shown in the default output. It can be shown using -d or using cid-type or all with -o.

BEGIN
The time at which the lease began, if one is available, for the addresses obtained using DHCP. The time is displayed in the format dictated by the LC_TIME locale environment variable. For addresses not configured using DHCP or for DHCP addresses that do not have a lease yet, -- (two hyphens) will be displayed. This field is not shown in the default output. It can be shown using -d or using cid-type or all with -o.

EXPIRE
The time at which the lease expires, if one is available, for the addresses obtained using DHCP. The time is displayed in the format dictated by the LC_TIME locale environment variable. For addresses not configured using DHCP or for DHCP addresses that do not have a lease yet, -- (two hyphens) will be displayed. This field is not shown in the default output. It can be shown using -d or using cid-type or all with -o.

RENEW
The time at which the lease was last renewed for the addresses obtained using DHCP. The time is displayed in the format dictated by the LC_TIME locale environment variable. For addresses not configured using DHCP or for DHCP addresses that do not have a lease yet, -- (two hyphens) will be displayed. This field is not shown in the default output. It can be shown using -d or using cid-type or all with -o.

-d, --dhcp
Display the dhcp status fields for addresses acquired using DHCP. The fields displayed are ADDROBJ, STATE, ADDR, CID-TYPE, CID-VALUE, BEGIN, EXPIRE, and RENEW. This option displays only the human-readable output and cannot be used in conjunction with -p.

Note – In some cases you will see addresses that have a question mark (?) in the address object name. This means that those addresses were created outside the ipadm library and therefore not known to ipadm.

down-addr [-t] addr
The address identified by addr is marked down, so that it cannot be used as a source/destination of outbound/inbound packets. This command has no effect if the address object was already marked down prior to the down-addr invocation. If the address object is of type addrconf, the command returns an error.

-t, --temporary
Specifies that the configured address is temporary and changes apply only to the active configuration. This option is mandatory if the address object type is dhcp.

up-addr [-t] addr
The address identified by addr is marked up, so that it can be used as a source/destination of outbound/inbound packets. This subcommand has no effect if the
address object has been marked down by the system because it is a duplicate address, or if the address was marked up prior to the `up-addr` invocation. If the address object is of type `addrconf`, the command returns an error.

```
-t, --temporary
```
Specifies that the configured address is temporary and changes apply only to the active configuration. This option is mandatory if the address object type is `dhcp`.

```
refresh-addr [-1] addrobj
```
If the `addrobj` is of the type `static` then DAD (Duplicate Address Detection) will be restarted (if necessary) on the address identified by the address object.

If the `addrobj` is of the type `dhcp`, then the lease duration obtained on the address will be extended by the DHCP client daemon.

If the `addrobj` is of the type `addrconf` then the command returns an error.

```
-i, --inform
```
For a specified IP address, obtains network configuration parameters from DHCP without obtaining a lease on it. This is useful in situations where an IP address is obtained through mechanisms other than DHCP.

```
disable-addr -t addrobj
```
Disables the address by removing it from the active configuration. If the address object was originally created persistently, then the persistent configuration is unchanged. To re-enable this `addrobj`, one should use `enable-addr`.

```
-t, --temporary
```
Specifies that the disabling is temporary and changes apply only to the active configuration.

```
enable-addr -t addrobj
```
Enables the given `addrobj` by reading the configuration from the persistent store. All the persistent address properties are applied to the address object. This subcommand requires that the interface on which the address object is being enabled be present. If the interface itself is missing in active configuration and is present in persistent store, that is, if the interface is disabled, then the user has to run `enable-if` before invoking `enable-addr`.

```
-t, --temporary
```
Specifies that the enabling is temporary and changes apply only to the active configuration.

```
set-addrprop [-t] -p prop=value[,...] addrobj
```
Sets the value of a property on the `addrobj` specified. If the `addrobj` maps to several addresses, then property changes applies to all the addresses referenced by the `addrobj`. Only one property can be specified at a time. The properties supported on the `addrobj` and the property’s possible values can be retrieved using `show-addrprop` subcommand. If the `addrobj` is of type `addrconf`, the command returns an error.
-t, --temporary
Specifies that the changes are temporary and changes apply only to the active configuration.

-p prop=value[,...], --prop prop=value[,...]
A property to set to the specified values.

reset -addrprop [-t] -p prop addrobj
Resets the given address property to its default value. If -t is not used, any persistent value of the property will be deleted. Only one property can be modified at a time. If the addrobj is of type addrconf, the command returns an error.

-t, --temporary
Specifies that the resets are temporary and changes apply only to the active configuration.

-p prop, --prop prop
A property to be reset.

show-addrprop [ [-c] -o field[,...] [ -p prop,...] ] [addrobj]
Show the current and persistent values of one or more properties, either for all the configured address objects or for the specified addrobj. Several properties of interest can be retrieved at one time by providing comma-separated property names to -p option. If the -p option is not specified, all available properties are displayed. If the addrobj is of type addrconf, the command returns an error.

-o field[,...], --output field[,...]
A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. For each addrobj, the following fields can be displayed:

ADDROBJ
The name of the address object.

PROPERTY
The name of the property.

PERM
The read/write permissions of the property. The value shown will be r (read only), w (write only) or rw (read/write).

CURRENT
The current value of the property. For the disabled addresses, because the value is not set, the value displays as a double hyphen (--).

PERSISTENT
The persistent value of a property. Persistent values are the values that will be reapplied on reboot.
DEFAULT
The default value of the property. If the property has no default value, double hyphen
(--) is shown.

POSSIBLE
A comma-separated list of the values a property can have. If the values span a
numeric range, min - max might be shown as shorthand. If the possible values are
unknown, a question mark (?) is displayed or if they are unbounded, double hyphen
(--) will be shown.

-c, -parsable
Display using a stable machine-parsable format. The -o option is required with this
option. See “Parsable Output Format”, below.

-p prop,..., --prop=prop
A comma-separated list of properties to display. See the sections on address object
properties following subcommand descriptions.

set-prop [-t] -p prop[+|–]=value[,...] protocol
Modifies the value of a protocol property to the value specified. If the property takes
multiple values, the values should be specified with a comma as the delimiter. Only one
property can be specified at a time. By default, the value is persistent and will be reapplied
on reboot. The properties supported on a protocol and the property’s possible values can be
retrieved using the show-prop subcommand

The following protocols are supported: ip, ipv4, ipv6, icmp, tcp, udp and sctp.

Note that for some properties, it might be possible to set the value of the property both
globally, and on a per-interface basis. The per-interface value can be set using the
set-ifprop subcommand. In such cases, if the administrator chooses to customize the
per-interface value of the property to be distinct from the global value, the per-interface
value overrides the global setting for that interface.

-t, - temporary
Specifies that the changes to properties are temporary and changes apply only to the
active configuration.

-p prop[+|–]=value[,...], --prop prop[+|–]=value[,...]
A property to set to the specified values. It also provides the following "qualifiers" to
perform add and delete operations in addition to assignment.

+  Adds the given value to the current list of value(s).

-  Removes the given value from the current list of value(s).

=  Makes a new assignment and removes all the current value(s).
See EXAMPLES for more information on how to use the qualifiers.

reset-prop [-t] -p prop protocol
Resets a property of the specified protocol to the default value of the property. If -t is not used, any persistent value of the property will be deleted. Only one property can be modified at a time.

- t, - - temporary
Specifies that the resets are temporary and changes apply only to the active configuration.

- p prop, --prop prop
A property to be reset.

show-prop [[-c] -o field[...]] [-p prop[...]] protocol | protocol]
Show the current and persistent values of one or more properties, either for all supported protocols or for the specified protocol. Several properties of interest can be retrieved at a time by providing comma-separated property names to -p option. If the -p option is not specified, all available properties are displayed.

- o field[...], - - output field[...]
A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. For each protocol, the following fields can be displayed:

PROTO
The name of the protocol.

PROPERTY
The name of the property.

PERM
The read/write permissions of the property. The value shown will be r (read only), w (write only) or rw (read/write).

CURRENT
The current value of the property. For the disabled addresses, because the value is not set, the value displays as a double hyphen (--). If the value is unknown, it is displayed as a question mark (?). If the current value of the property is not in the set of listed POSSIBLE values, the keyword custom is displayed.

PERSISTENT
The persistent value of a property. Persistent values are the values that will be reapplied on reboot.

DEFAULT
The default value of the property. If the property has no default value, double hyphen (- -) is shown.
POSSIBLE
A comma-separated list of the values for the property setting to be used with the
set-prop subcommand. If the values span a numeric range, min - max might be
shown as shorthand. If the possible values are unknown, a question mark (?) is
displayed or if they are unbounded, double hyphen (- -) will be shown.

-c, --parsable
Display using a stable machine-parsable format. The -o option is required with this
option. See "Parsable Output Format", below.

-p prop,..., --prop=prop
A comma-separated list of properties to display. See the sections on protocol properties
following subcommand descriptions.

For the supported list of properties for every protocol, see “Protocol Properties” below.

help [subcommand-name]
Displays all of the supported ipadm subcommands or usage for a given subcommand. If
you display help for a specific subcommand, the command syntax is displayed, along with
an example. Using ipadm help without any argument displays all of the subcommands.

Parseable Output Format
The ipadm "show" subcommands have an -o option that displays output in a
machine-parsable format. The output format is one or more lines of colon (:) delimited fields.
The fields displayed are specific to the subcommand used and are listed under the entry for the
-o option for a given subcommand. Output includes only those fields requested by means of
the -o option, in the order requested. Note that the -o all option, which displays all the fields
for a given subcommand, cannot be used with parsable output option.

When you request multiple fields, any literal colon characters are escaped by a backslash (\)
before being output. Similarly, literal backslash characters are also escaped (\\). This escape
format is parsable by using shell read(1) functions with the environment variable set as IFS=:
Note that escaping is not done when you request only a single field.

Protocol Properties
The following protocol properties are supported:

Note – There are protocol properties, specific to a protocol, that begin with "_" (underbar).
These properties are subject to change or removal and by default, are not displayed in ipadm

cong_default (TCP, SCTP)
Specify the default congestion control algorithm used by the protocol when new
connections are created. Applications can opt to choose a different algorithm at a later
point in the connection's lifetime. Only enabled algorithms can be set as default (see
cong_enabled).

cong_enabled (TCP, SCTP)
This option can be used to enable or disable congestion control algorithms. By default, all
algorithms installed on the systems are enabled. Disabled algorithms cannot be set as
default (see cong_default) or used by applications.
Algorithms can be added or removed using the `set-prop` subcommand and the modifiers `+` and `-`.

ecn (TCP)
Explicit Congestion Control (see RFC 3168 for more information). Possible values are the same as above: `never`, `passive`, and `active`.

extra_priv_ports (TCP, SCTP, UDP)
This option define additional privileged ports outside of the 1-1023 range. Any program that attempts to bind the ports listed here must run as root. This prevents normal users from starting server processes on specific ports.

These ports can be added, removed, or assigned using the `set-prop` subcommand and the modifiers `+`, `-`, and `=`. See EXAMPLES below on usage.

forwarding (IPv4), forwarding (IPv6)
Enable/disable global IPv4 or IPv6 forwarding. All the configured interfaces will start/stop forwarding packets. Individual interfaces can override the global option using `set-ifprop`.

hostmodel (IPv4), hostmodel (IPv6)
Control send/receive behavior for IP packets on a multi-homed system. The value of `hostmodel` can be set to `strong` or `weak`, corresponding to the equivalent end-system model definitions of RFC 1122. In addition, a third value of `src-priority` is also supported. In the `src-priority hostmodel` scenario, a packet will be accepted on any interface, as long as the packet's destination IP address is configured and marked UP on one of the host's interfaces. When transmitting a packet, if multiple routes for the IP destination in the packet are available, the system will prefer routes where the IP source address in the packet is configured on the outgoing interface. If no such route is available, the system will fall back to selecting the “best” route, as with the weak ES case.

max_buf (TCP, SCTP, UDP, ICMP)
Maximum size of the send or receive socket buffer. The current value of this property limits the maximum value of `recv_buf` and `send_buf`.

recv_buf (TCP, SCTP, UDP, ICMP)
Modifies the receive or send buffer sizes for the specified protocol. The maximum value of these properties is bound by the current value of the `max_buf` property.

sack (TCP)
Selective acknowledgment (SACK) allows recipients to selectively acknowledge out-of-sequence data and is intended to increase performance for data transfers over lossy links. See RFC 2018 for information on the SACK. Possible values and meanings:

never
Will neither accept SACK nor send out SACK information.

passive
Will accept SACK but not send out.
active
Will both accept SACK and send out SACK information.

smallest_anon_port (TCP, SCTP, UDP)
largest_anon_port (TCP, SCTP, UDP)
These options define the upper and lower bounds on ephemeral ports. Ephemeral (means short-lived) ports are used when establishing outbound network connections. Note that the current value of the smallest_anon_port should be always less than or equal to the current value of largest_anon_port.

smallest_nonpriv_port (TCP, SCTP, UDP)
This option define the start of non-privileged ports. The non-privileged port range normally starts at 1024. Any program that attempts to bind a non-privileged port does not have to run as root.

ttl (IPv4), hoplimit (IPv6)
Specifies the value that will be set for ttl/hoplimit field of an IPv4 or IPv6 header. Can be used to prevent the system from reaching other systems more than N hops away where N was the value specified.

Interface Properties
The following interface properties are supported:

arp
Enables/disables the use of the Address Resolution Protocol (ARP) on an interface. ARP is used in mapping between network level addresses and link level addresses. This is currently implemented for mapping between IPv4 addresses and MAC addresses. Possible values are on or off. Default is on.

exchange_routes
Enables/disables exchanging of routing information on this interface. Possible values are on or off. Default is off.

group
Specifies the group name of the IPMP interface for which this interface is an underlying interface. If the interface is of class IPMP, this specifies the name of the IPMP group. It is a read-write property only on IPMP interfaces. For other interface classes, this property is read-only.

forwarding
Enables/disables IP forwarding on an interface. When enabled, the IP packets can be forwarded to and from the interface. Possible values are on or off. Default is off.

metric
Set the routing metric of the interface to n; if no value is specified, the default is 0. The routing metric is used by the routing protocol. Higher metrics have the effect of making a route less favorable. Metrics are counted as additional hops to the destination network or host.
Set the maximum transmission unit of the interface to \textit{n}. For many types of networks, the MTU has an upper limit, for example, 1500 for Ethernet.

Enables/disables the neighbor unreachability detection mechanism on a point-to-point physical interface. Possible values are \textit{on} or \textit{off}. Default is \textit{on}.

Specifies whether the interface is configured as a standby interface for an IPMP group. This property is not applicable to IPMP interfaces.

Specifies a physical or virtual interface to be used for source address selection. If the keyword \textit{none} is used, then any previous selection is cleared. Default is \textit{none}.

The address properties listed below are supported. Note that modifying address properties for \texttt{addrconf} address objects is not supported.

The address should no longer used as a source address in new communications, but packets addressed to this address are processed as expected. Possible values are \textit{on} or \textit{off}. Default is \textit{off}. This property is not supported on an address object of type \texttt{dhcp}.

The number of left-most contiguous bits of the address that comprise the IPv6 prefix or IPv4 netmask of the address. The remaining low-order bits define the host part of the address. When \texttt{prefixlen} is converted to a text representation of the address, the address contain 1's for the bit positions that are to be used for the network part, and 0's for the host part. The \texttt{prefixlen} must be specified as a single decimal number. This property is not supported on an address object of type \texttt{dhcp}.

Specifies that the addresses should not be advertised by the \texttt{in.routed} routing daemon. Possible values are \textit{on} or \textit{off}. Default is \textit{off}.

The hostname to which the client would like the DHCP server to map the client's leased IPv4. A hostname request is not guaranteed to be fulfilled.

Enables packets to be transmitted using the addresses referenced by the address object. This is the default behavior when the address is up. Possible values are \textit{on} or \textit{off}. Default is \textit{on}.

Specifies the zone in which all the addresses referenced by the address object should be placed. The named zone must be active in the kernel in the ready or running state. The interface is unplumbed when the zone is halted or rebooted. The zone must be configured
to be an shared-IP zone. `zonecfg(1M)` is used to assign network interface names to exclusive-IP zones. To modify the zone assignment such that it persists across reboots, please use `zonecfg(1M)`. Possible values are the list of all the zones configured on the system. Default is `global`.

**Operands** Each `ipadm` subcommand operates on one of the following objects:

- **addrobj**
  An address configured on a network interface is identified by an `addrobj`. An `addrobj` consists of two parts. The first part is the name of the network interface on which the address is configured. The second part is a user-specified string that can use any of the alphanumeric characters and can be at most 32 characters in length and must begin with a letter. The two parts of the `addrobj` are delimited by a slash (`/`). An address object always represents a unique set of addresses in a system.

  **Note** – The exception to this namespace rule is that some addresses, created externally to `ipadm`, might be created with an `addrobj` where the second part of the `addrobj` includes a prefix. In such cases, the second part of the `addrobj` will contain a prefix, a “.” (period) delimiter, and a consumer-defined string (for example, `net0/zoneadm.v4`). `ipadm` users cannot create an `addrobj` with this format because `ipadm` cannot create an `addrobj` that includes a period. It is possible, though not optimal, to use `ipadm` to further manage an `addrobj` of this type.

- **interface**
  Name of the network interface on which network address is configured. In general, the name can use any alphanumeric characters, plus the underscore (`_`) and the period (`.`), but must start with an alphabetic character and end with a number.

- **protocol**
  Name of the TCP/IP Internet protocol family for which a property is to be configured. Following protocols are supported: `ip`, `ipv4`, `ipv6`, `icmp`, `tcp`, `sctp` and `udp`.

**Examples**

**EXAMPLE 1** Using `ipadm` with No Arguments

The following command displays a concise view of the interface and address configuration on a system.

```
# ipadm

<table>
<thead>
<tr>
<th>NAME</th>
<th>CLASS/TYPE</th>
<th>STATE</th>
<th>UNDER</th>
<th>ADDR</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipm0</td>
<td>ipm</td>
<td>degraded</td>
<td>--</td>
<td>--</td>
</tr>
<tr>
<td>ipm0/v6</td>
<td>static</td>
<td>ok</td>
<td>--</td>
<td>2001:db8:1:2::4c08/128</td>
</tr>
<tr>
<td>lo0</td>
<td>loopback</td>
<td>ok</td>
<td>--</td>
<td>--</td>
</tr>
<tr>
<td>lo0/v4</td>
<td>static</td>
<td>ok</td>
<td>--</td>
<td>127.0.0.1/8</td>
</tr>
<tr>
<td>lo0/v6</td>
<td>static</td>
<td>ok</td>
<td>--</td>
<td>::/128</td>
</tr>
<tr>
<td>net0</td>
<td>ip</td>
<td>ok</td>
<td>--</td>

<td>static</td>
<td>ok</td>
<td>--</td>
<td>10.132.146.233/23</td>
</tr>
<tr>
<td>net1</td>
<td>ip</td>
<td>failed</td>
<td>ipm0</td>
<td>--</td>
</tr>
</tbody>
</table>
```
EXAMPLE 1  Using `ipadm` with No Arguments  (Continued)

```
net1/aconf  addrconf  ok  --  fe80::214:4fff:fe58:1831/10
net2        ip        ok  ipmp0  --
net2/aconf  addrconf  ok  --  fe80::214:4fff:fe58:1832/10
```

EXAMPLE 2  Creating IPv4 Static Addresses

The following command creates the address 10.2.3.4/24 on interface bge1 (linkname net1) and marks the address up, for use.

```
# ipadm create-ip net1
# ipadm create-addr  -T static  -a local=10.2.3.4/24 net1/v4static1
```

Alternatively automatic address object name generation can be used. The automatically generated name will be displayed to the console and can be used in any future `ipadm` commands requiring an address object name.

```
# ipadm create-ip net1
# ipadm create-addr  -T static  -a local=10.2.3.4/24 net1
net1/v4
```

The following command creates another address 10.2.3.5/24 on interface net1 but marks the address down until explicitly marked up.

```
# ipadm create-addr  -T static  -d  -a 10.2.3.5/24 net1
net1/v4
```

Note that 10.2.3.5/24 is assumed to be the local address, because `local` was not used and there was only one address.

The following command marks the address object net1/v4a up that was previously marked down.

```
# ipadm up-addr net1/v4a
```

If the DUPLICATE flag was set on the address object, then `refresh-addr` will verify that the address is still a duplicate on the network. If it is not, the address will be marked up.

```
# ipadm refresh-addr net1/v4a
```

The following command lists the addresses that were configured. This shows that the address net1/v4a is not a duplicate.

```
# ipadm show-addr

ADDROBJ  TYPE  STATE  ADDR
lo0/v4   static ok  127.0.0.1/8
lo0/v6   static ok  ::/128
net1/v4  static ok  10.2.3.4/24
net1/v4a static ok  10.2.3.10/24
```
EXAMPLE 3 Creating DHCPv4-controlled Addresses

The following command obtains a DHCPv4 address on interface bge1 (linkname net1).

```
# ipadm create-ip net1
# ipadm create-addr -T dhcp net1/dhaddr
# ipadm show-addr net1/dhaddr
```

<table>
<thead>
<tr>
<th>ADDROBJ</th>
<th>TYPE</th>
<th>STATE</th>
<th>ADDR</th>
</tr>
</thead>
<tbody>
<tr>
<td>net1/dhaddr</td>
<td>dhcp</td>
<td>ok</td>
<td>10.8.48.173/25</td>
</tr>
</tbody>
</table>

The following command extends the lease duration for the DHCPv4 address object net1/dhaddr.

```
# ipadm refresh-addr net1/dhaddr
```

EXAMPLE 4 Creating IPv6 Addresses

The following sequence of commands auto-configures IPv6 addresses on bge1 (linkname net1) using in.ndpd with the default interface ID. A link-local address is configured first, followed by in.ndpd adding the stateless and stateful auto-configured addresses.

```
# ipadm create-ip net1
# ipadm create-addr -T addrconf net1/v6addr
```

The following command creates a IPv6 static address. To be able to configure an IPv6 address that is not a link-local address, the interface should already have a link-local address configured on it. It was accomplished by the previous step with -T addrconf.

```
# ipadm create-addr -T static -a local=2ff0::f3ad/64 net1/v6static
```

The following command changes the prefix length of an IPv6 address.

```
# ipadm set-addrprop -p prefixlen=80 net1/v6static
```

All the auto-configured addresses and the updated prefix length can be viewed by listing the addresses:

```
# ipadm show-addr
```

<table>
<thead>
<tr>
<th>ADDROBJ</th>
<th>TYPE</th>
<th>STATE</th>
<th>ADDR</th>
</tr>
</thead>
<tbody>
<tr>
<td>lo0/v4</td>
<td>static</td>
<td>ok</td>
<td>127.0.0.1/8</td>
</tr>
<tr>
<td>lo0/v6</td>
<td>static</td>
<td>ok</td>
<td>::/128</td>
</tr>
<tr>
<td>net1/v6addr</td>
<td>addrconf</td>
<td>ok</td>
<td>fe80::203:baff:fe94:2f01/10</td>
</tr>
<tr>
<td>net1/v6addr</td>
<td>addrconf</td>
<td>ok</td>
<td>2002:a08:39f0:1:203:baff:fe94:2f00/64</td>
</tr>
<tr>
<td>net1/v6addr</td>
<td>addrconf</td>
<td>ok</td>
<td>2001:db8:1:2::402f/128</td>
</tr>
<tr>
<td>net1/v6static</td>
<td>static</td>
<td>ok</td>
<td>2ff0::f3ad/80</td>
</tr>
</tbody>
</table>

EXAMPLE 5 Configuring an IPv4 Tunnel

The first command below (ipadm) creates the tunnel source address. Then, a dladm command creates the tunnel link. The final ipadm commands configure the IPv4 and IPv6 addresses on the tunnel IP interface.
EXAMPLE 5  Configuring an IPv4 Tunnel  (Continued)

# ipadm create-ip net1
# ipadm create-addr -T static -a local=10.2.3.4/24 net1/v4static
# dladm create-iptun -T ipv4 -a local=10.2.3.4,remote=10.2.3.5 tun0
# ipadm create-ip tun0
# ipadm create-addr -T static \
   -a local=173.129.134.1,remote=173.129.134.2 tun0/v4tunaddr
# ipadm create-addr -T static \
   -a local=2ff1::3344,remote=2ff1::3345 tun0/v6tunaddr
# ipadm show-addr
ADDR OBJ    TYPE    STATE    ADDR
lo0/v4     static  ok       127.0.0.1/8
lo0/v6     static  ok       ::/128
net1/v4static     static  ok       10.2.3.4/24
tun0/v4tunaddr     static  ok       173.129.134.1-->173.129.134.2
tun0/v6tunaddr     static  ok       2ff1::3344-->2ff1::3345

EXAMPLE 6  Viewing All of the Interfaces

The following command enables you to view all interfaces.

# ipadm show-if -o all
IFNAME CLASS STATE   ACTIVE   CURRENT   PERSISTENT OVER
lo0   loopback   ok yes    m-v-----46 --46  --
net0   ip         ok yes    b-m-----46 --46  --
e1000g0    ip     ok yes    b-m-l-----46 -l46  --
e1000g1    ip     ok yes    b-m-l-----46 -l46  --
ipmp0     ipmp    down yes    b-m------46 --46  e1000g0 e1000g1
tun0     ip      failed no -m-p------46 --46  --
vn10     vni     disabled no bm-v------ --46  --

EXAMPLE 7  Displaying Interface Properties

The following command displays all interface properties for a specified interface.

# ipadm show-ifprop net0
IFNAME PROPERTY PROTO PERM CURRENT PERSISTENT DEFAULT POSSIBLE
net0   arp     ipv4 rw on   --   on   on,off
net0   forwarding ipv4 rw off on off on,off
net0   metric  ipv4 rw 2 2 0   --
net0   mtu     ipv4 rw 1500 -- 1500 68-1500
net0   exchange_routes ipv4 rw off -- off on,off
net0   usesrc  ipv4 rw none -- none --
net0   forwarding ipv6 rw off -- off on,off
net0   metric  ipv6 rw 2 2 0   --
net0   mtu     ipv6 rw 1500 -- 1500 1280-1500
net0   nud     ipv6 rw on   -- on   on,off
net0   exchange_routes ipv6 rw off on on,off
net0   usesrc  ipv6 rw none -- none --

EXAMPLE 7  Displaying Interface Properties  (Continued)

net0  group       ip   rw  grp0   --   --   --
network  standby ip   r-  off   --   off  on,off

EXAMPLE 8  Configuring per-Interface Properties

The following command sets the IPv4 MTU of the interface net0 to 900.

# ipadm set-ifprop -m ipv4 -p mtu=900 net0

The following command sets the IPv6 MTU of the interface net0 to 1400.

# ipadm set-ifprop -m ipv6 -p mtu 1400 net0

View the results:

# ipadm show-ifprop -p mtu net0

EXAMPLE 10  Configuring Global IPv4 Forwarding

The following command sequence configures global IPv4 forwarding and overrides that setting for interface net0.

# ipadm set-prop -p forwarding=on ipv4
# ipadm set-ifprop -p forwarding=off -m ipv4 net0
# ipadm show-prop -p forwarding ipv4
EXAMPLE 10  Configuring Global IPv4 Forwarding  (Continued)

PROTO PROPERTY PERM CURRENT PERSISTENT DEFAULT POSSIBLE
ipv4 forwarding rw on on on,off on,off

# show-ifprop -p forwarding -m ipv4 net0
IFNAME PROPERTY PROTO PERM CURRENT PERSISTENT DEFAULT POSSIBLE
net0 forwarding ipv4 rw off off off on,off

EXAMPLE 11  Using Qualifiers in set-prop Subcommand

The following command sequence uses the plus and minus (+, –) qualifiers to add 1047, 1048, and 1049 as extra privileged ports for TCP.

# ipadm set-prop -p extra_priv_ports=1047 tcp
# ipadm set-prop -p extra_priv_ports+=1048 tcp
# ipadm set-prop -p extra_priv_ports+=1049 tcp
# ipadm set-prop -p extra_priv_ports+=1050 tcp

The following command deletes 1048 as extra privileged port.

# ipadm set-prop -p extra_priv_ports-=1048

The following command displays all the extra privileged ports for TCP.

# ipadm show-prop -p extra_priv_ports tcp

EXAMPLE 12  Enabling and Disabling Objects

The following command sequences enables and disables interface and address objects and display the results of those actions.

# ipadm create-ip net1
# ipadm create-addr -T static -a local=10.2.3.4/24 net1/v4static
# ipadm set-addrprop -p private=yes net1/v4static
# ipadm show-addr net1/v4static

ADDROBJ TYPE STATE ADDR
net1/v4static static ok 10.2.3.4/24

The following command disables the address object net1/v4static.

# ipadm disable-addr -t net1/v4static
# ipadm show-addr net1/v4static

ADDROBJ TYPE STATE ADDR
net1/v4static static ok 10.2.3.4/24

The following command disables the interface object net1.
EXAMPLE 12  Enabling and Disabling Objects  (Continued)

# ipadm disable-if -t net1
# ipadm show-if net1 -o all

IFNAME  CLASS  STATE  ACTIVE  CURRENT  PERSISTENT  OVER
net1   ip disabled no  bm--------- --46   --

The following command enables the interface object from the persistent configuration.

# ipadm enable-if -t net1
# ipadm show-if net1 -o all

IFNAME  CLASS  STATE  ACTIVE  CURRENT  PERSISTENT  OVER
net1   ip  ok yes  bm--------46 --46   --

# ipadm show-addr net1/v4static

ADDROBJ  TYPE  STATE  ADDR
net1/v4static  static  ok  10.2.3.4/24

Note that when the interface object is enabled all the address objects configured on that
interface are enabled also.

The following command creates persistent configuration for the net0 interface in a
non-global exclusive-IP zone so that the net0 interface will be configured with the set
of addresses made available through the allowed-address resource from the global zone on the
next reboot.

# ipadm create-ip net0

The net0 interface can also be configured with the available set of allowed-address values in
the non-global exclusive-IP zone without a reboot by executing the following commands:

# ipadm disable-if -t net0
# ipadm enable-if -t net0

EXAMPLE 13  Creating IPMP Interfaces

The following command sequence creates an IPMP interface and adds underlying interfaces
to it.

# ipadm create-ip e1000g0
# ipadm create-ip e1000g1
# ipadm create-ip e1000g2
# ipadm set-ifprop -p standby=on -m ip e1000g2
# ipadm create-ipmp testgroup0
# ipadm add-ipmp -i e1000g0 -i e1000g1 -i e1000g2 testgroup0
# ipadm create-addr -T static -a local=192.168.80.5/24 testgroup0/data1
# ipadm create-addr -T static -a local=192.168.80.6/24 testgroup0/data2
# ipadm show-if

IFNAME  CLASS  STATE  ACTIVE  OVER
lo0  loopback  ok  yes  --
Creating IPMP Interfaces (Continued)

net0 ip ok yes --
e1000g0 ip ok yes --
e1000g1 ip ok yes --
ipmp0 ipmp ok yes e1000g0 e1000g1

The following command sequence disables and subsequently enables the IPMP interface.

```
# ipadm disable-if -t testgroup0
ipadm show-if
```

```
IFNAME   CLASS STATE ACTIVE OVER
lo0      loopback ok yes --
net0     ip ok yes --
e1000g0  ip disabled no --
e1000g1  ip disabled no --
ipmp0    ipmp disabled no e1000g0 e1000g1
```

```
# ipadm enable-if -t testgroup0
```

The following command sequence removes underlying interface from the IPMP interface and then deletes the IPMP interface.

```
ipadm remove-ipmp -i e1000g0 -i e1000g1 testgroup0
ipadm delete-ipmp testgroup0
```

Displaying Help

The following command illustrates the use of the `help` subcommand without any arguments.

```
# ipadm help
```

The following subcommands are supported:

- **Address subcommands**: `create-addr`, `delete-addr`, `disable-addr`, `down-addr`, `enable-addr`, `refresh-addr`, `reset-addrprop`, `set-addrprop`, `show-addr`, `show-addrprop`, `up-addr`
- **Interface subcommands**: `disable-if`, `enable-if`, `reset-ifprop`, `set-ifprop`, `show-if`, `show-ifprop`
- **IP interface subcommands**: `create-ip`, `delete-ip`
- **IPMP interface subcommands**: `add-ipmp`, `create-ipmp`, `delete-ipmp`, `remove-ipmp`
- **Protocol property subcommands**: `reset-prop`, `set-prop`, `show-prop`
- **VNI interface subcommands**: `create-vni`, `delete-vni`

For more info, run: `ipadm help subcommand`

The following command illustrates the use of the `help` subcommand with a subcommand argument.

```
# ipadm help create-ipmp
usage: create-ipmp [-t] [-i under-interface[,...]]
```
EXAMPLE 14 Displaying Help (Continued)

... IPMP-interface

element:

# ipadm create-ipmp -i net0,net1 ipmp0

### ipf(1M)

**Name**
ipf – alter packet filtering lists for IP packet input and output

**Synopsis**
```
ipf [-6AdDEInoPRrsvVyzZ] [-l block | pass | nomatch]
    [-T optionlist] [-F i | o | a | s | S] -f filename
    [-t filename...]
```

**Description**
The `ipf` utility is part of a suite of commands associated with the Solaris IP Filter feature. See `ipfilter(5)`.

The `ipf` utility opens the filenames listed (treating a hyphen (-) as stdin) and parses the file for a set of rules which are to be added or removed from the packet filter rule set.

If there are no parsing problems, each rule processed by `ipf` is added to the kernel's internal lists. Rules are added to the end of the internal lists, matching the order in which they appear when given to `ipf`.

`ipf`'s use is restricted through access to `/dev/ipauth`, `/dev/ip1`, and `/dev/ipstate`. The default permissions of these files require `ipf` to be run as root for all operations.

#### Enabling Solaris IP Filter Feature
Solaris IP Filter is installed with the Solaris operating system. However, packet filtering is not enabled by default. Use the following procedure to activate the Solaris IP Filter feature.

1. Assume a role that includes the IP Filter Management rights profile (see `rbac(5)`) or become superuser.
2. Configure system and services' firewall policies. See `svc.ipfd(1M)` and `ipf(4)`.
3. (Optional) Create a network address translation (NAT) configuration file. See `ipnat.conf(4)`.
4. (Optional) Create an address pool configuration file. See `ippool(4)`.

Create an `ippool.conf` file if you want to refer to a group of addresses as a single address pool. If you want the address pool configuration file to be loaded at boot time, create a file called `/etc/ipf/ippool.conf` in which to put the address pool. If you do not want the address pool configuration file to be loaded at boot time, put the `ippool.conf` file in a location other than `/etc/ipf` and manually activate the rules.

5. Enable Solaris IP Filter, as follows:

   ```
   # svcadm enable network/ipfilter
   ```

To re-enable packet filtering after it has been temporarily disabled either reboot the machine or enter the following command:

   ```
   # svcadm enable network/ipfilter
   ```

...which essentially executes the following `ipf` commands:

1. Enable Solaris IP Filter:
   ```
   # ipf -E
   ```
2. Load `ippools`:
# ippool -f <ippool configuration file>

See ippool(1M).

3. (Optional) Activate packet filtering:

   ipf -f <ipf configuration file>

4. (Optional) Activate NAT:

   ipnat -f <IPNAT configuration file>

   See ipnat(1M).

Note – If you reboot your system, the IP filter configuration is automatically activated.

Options

The following options are supported:

- **-6**
  
  This option is required to parse IPv6 rules and to have them loaded. Loading of IPv6 rules is subject to change in the future.

- **-A**
  
  Set the list to make changes to the active list (default).

- **-d**
  
  Turn debug mode on. Causes a hex dump of filter rules to be generated as it processes each one.

- **-D**
  
  Disable the filter (if enabled). Not effective for loadable kernel versions.

- **-E**
  
  Enable the filter (if disabled). Not effective for loadable kernel versions.

- **-F i | o | a**
  
  Specifies which filter list to flush. The parameter should either be i (input), o (output) or a (remove all filter rules). Either a single letter or an entire word starting with the appropriate letter can be used. This option can be before or after any other, with the order on the command line determining that used to execute options.

- **-F s | S**
  
  To flush entries from the state table, use the -F option in conjunction with either s (removes state information about any non-fully established connections) or S (deletes the entire state table). You can specify only one of these two options. A fully established connection will show up in ipfstat -s output as 4/4, with deviations either way indicating the connection is not fully established.

- **-f filename**
  
  Specifies which files ipf should use to get input from for modifying the packet filter rule lists.
-I
Set the list to make changes to the inactive list.

-l pass | block | nomatch
Toggles default logging of packets. Valid arguments to this option are pass, block and nomatch. When an option is set, any packet which exits filtering and matches the set category is logged. This is most useful for causing all packets that do not match any of the loaded rules to be logged.

-n
Prevents ipf from making any ioctl calls or doing anything which would alter the currently running kernel.

-o
Force rules by default to be added/deleted to/from the output list, rather than the (default) input list.

-P
Add rules as temporary entries in the authentication rule table.

-R
Disable both IP address-to-hostname resolution and port number-to-service name resolution.

-r
Remove matching filter rules rather than add them to the internal lists.

-s
Swap the currently active filter list to be an alternative list.

-T optionlist
Allows run-time changing of IPFilter kernel variables. To allow for changing, some variables require IPFilter to be in a disabled state (-D), others do not. The optionlist parameter is a comma-separated list of tuning commands. A tuning command is one of the following:

list
Retrieve a list of all variables in the kernel, their maximum, minimum, and current value.

single variable name
Retrieve its current value.

variable name with a following assignment
To set a new value.

Examples follow:

# Print out all IPFilter kernel tunable parameters
ipf -T list
# Display the current TCP idle timeout and then set it to 3600
ipf -D -T fr_tcpidletimeout,fr_tcpidletimeout=3600 -E

# Display current values for fr_pass and fr_chksrc, then set
# fr_chksrc to 1.
ipf -T fr_pass,fr_chksrc,fr_chksrc=1

-v
  Turn verbose mode on. Displays information relating to rule processing.

-V
  Show version information. This will display the version information compiled into the ipf binary and retrieve it from the kernel code (if running or present). If it is present in the kernel, information about its current state will be displayed; for example, whether logging is active, default filtering, and so forth).

-y
  Manually resync the in-kernel interface list maintained by IP Filter with the current interface status list.

-z
  For each rule in the input file, reset the statistics for it to zero and display the statistics prior to them being zeroed.

-Z
  Zero global statistics held in the kernel for filtering only. This does not affect fragment or state statistics.

Files
/dev/ipauth
/dev/ipl
/dev/ipstate
  Links to IP Filter pseudo devices.
/etc/ipf/ipf.conf
  Location of ipf startup configuration file. See ipf(4).
/usr/share/ipfilter/examples/
  Contains numerous IP Filter examples.

System Administration Guide: IP Services

Diagnostics  Needs to be run as root for the packet filtering lists to actually be affected inside the kernel.
Name  ipfs – saves and restores information for NAT and state tables

Synopsis  ipfs [-nv] -l
          ipfs [-nv] -u
          ipfs [-nv] [-d dirname] -R
          ipfs [-nv] [-d dirname] -W
          ipfs [-nNSv] [-f filename] -r
          ipfs [-nNSv] [-f filename] -w
          ipfs [-nNSv] -f filename -i <if1>,<if2>

Description  The ipfs utility enables the saving of state information across reboots. Specifically, the utility allows state information created for NAT entries and rules using "keep state" to be locked (modification prevented) and then saved to disk. Then, after a reboot, that information is restored. The result of this state-saving is that connections are not interrupted.

Options  The following options are supported:
- -d  Change the default directory used with -R and -W options for saving state information.
- -n  Do not take any action that would affect information stored in the kernel or on disk.
- -v  Provides a verbose description of ipfs activities.
- -N  Operate on NAT information.
- -S  Operate on filtering state information.
- -u  Unlock state tables in the kernel.
- -l  Lock state tables in the kernel.
- -r  Read information in from the specified file and load it into the kernel. This requires the state tables to have already been locked and does not change the lock once complete.
- -w  Write information out to the specified file and from the kernel. This requires the state tables to have already been locked and does not change the lock once complete.
- -R  Restores all saved state information, if any, from two files, ipstate.ipf and ipnat.ipf, stored in the /var/db/ipf directory. This directory can be changed with the -d option. The state tables are locked at the beginning of this operation and unlocked once complete.
- -W  Saves in-kernel state information, if any, out to two files, ipstate.ipf and ipnat.ipf, stored in the /var/db/ipf directory. This directory can be changed with the -d option. The state tables are locked at the beginning of this operation and unlocked once complete.
### Files
- `/var/db/ipf/ipstate.ipf`
- `/var/db/ipf/ipnat.ipf`
- `/dev/ipl`
- `/dev/ipstate`
- `/dev/ipnat`

### Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>network/ipfilter</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

### See Also
`ipf(1M), ipmon(1M), ipnat(1M), attributes(5)`

### Diagnostics
Arguably, the `-W` and `-R` operations should set the locking and, rather than undo it, restore it to what it was previously.

Fragment table information is currently not saved.
Name  ipfstat – reports on packet filter statistics and filter list

Synopsis  ipfstat [-6aACdfghIlnoRstv]
          [-T refresh_time]

Description  The ipfstat command is part of a suite of commands associated with the Solaris IP Filter feature. See ipfilter(5).

The ipfstat command examines /dev/kmem using the symbols _fr_flags, _frstats, _filterin, and _filterout. To run and work, it needs to be able to read both /dev/kmem and the kernel itself.

The default behavior of ipfstat is to retrieve and display the statistics which have been accumulated over time as the kernel has put packets through the filter.

The role of ipfstat is to display current kernel statistics gathered as a result of applying the filters in place (if any) to packets going in and out of the kernel. This is the default operation when no command line parameters are present. When supplied with either -i or -o, ipfstat will retrieve and display the appropriate list of filter rules currently installed and in use by the kernel.

ipfstat uses kernel device files to obtain information. The default permissions of these files require ipfstat to be run as root for all operations.

The ipfstat command supports the kstat(3KSTAT) kernel facility. Because of this support, as an alternative to ipfstat, you can use kstat(1M). For example:

# kstat -m ipf

Using the ipfstat -t option causes ipfstat to enter the state top mode. In this mode the state table is displayed similarly to the way the Unix top utility displays the process table. The -C, -D, -P, -S and -T command line options can be used to restrict the state entries that will be shown and to specify the frequency of display updates.

In state top mode, use the following keys to influence the displayed information:

d  Select information to display.

l  Redraw the screen.

q  Quit the program.

s  Switch between different sorting criteria.

r  Reverse the sorting criteria.

States can be sorted by protocol number, by number of IP packets, by number of bytes, and by time-to-live of the state entry. The default is to sort by the number of bytes. States are sorted in descending order, but you can use the r key to sort them in ascending order.
It is not possible to interactively change the source, destination, and protocol filters or the refresh frequency. This must be done from the command line.

The screen must have at least 80 columns for correct display. However, `ipfstat` does not check the screen width.

Only the first \(X\cdot5\) entries that match the sort and filter criteria are displayed (where \(X\) is the number of rows on the display). There is no way to see additional entries.

**Options**

The following options are supported:

- `-6` Display filter lists and states for IPv6, if available. This option might change in the future.

- `-a` Display the accounting filter list and show bytes counted against each rule.

- `-A` Display packet authentication statistics.

- `-C` Valid only in combination with `-t`. Display “closed” states as well in the top. Normally, a TCP connection is not displayed when it reaches the `CLOSE_WAIT` protocol state. With this option enabled, all state entries are displayed.

- `-d` Produce debugging output when displaying data.

- `-D addrport` Valid only in combination with `-t`. Limit the state top display to show only state entries whose destination IP address and port match the `addrport` argument. The `addrport` specification is of the form `ipaddress[,port]`. The `ipaddress` and `port` should be either numerical or the string `any` (specifying any IP address and any port, in that order). If the `-D` option is not specified, it defaults to `-D any, any`.

- `-f` Show fragment state information (statistics) and held state information (in the kernel) if any is present.

- `-g` Show groups currently configured (both active and inactive).

- `-h` Show per-rule the number of times each one scores a “hit”. For use in combination with `-i`.

- `-i` Display the filter list used for the input side of the kernel IP processing.

- `-I` Swap between retrieving inactive/active filter list details. For use in combination with `-i`.

- `-l` When used with `-s`, show a list of active state entries (no statistics).

- `-n` Show the rule number for each rule as it is printed.

- `-o` Display the filter list used for the output side of the kernel IP processing.
-P protocol  Valid only in combination with -t. Limit the state top display to show only state entries that match a specific protocol. The argument can be a protocol name (as defined in /etc/protocols) or a protocol number. If this option is not specified, state entries for any protocol are specified.

-R         Disable both IP address-to-hostname resolution and port number-to-service name resolution.

-S addrport Valid only in combination with -t. Limit the state top display to show only state entries whose source IP address and port match the addrport argument. The addrport specification is of the form ipaddress[,port]. The ipaddress and port should be either numerical or the string any (specifying any IP address and any port, in that order). If the -S option is not specified, it defaults to -S any, any.

-s         Show packet/flow state information (statistics only).

-T refreshtime Valid only in combination with -t. Specifies how often the state top display should be updated. The refresh time is the number of seconds between an update. Any positive integer can be used. The default (and minimal update time) is 1.

-t         Show the state table in a way similar to the way the Unix utility, top, shows the process table. States can be sorted in a number of different ways.

-v         Turn verbose mode on. Displays additional debugging information.

System Administration Guide: IP Services
Name  ipmgmtd – IP network interfaces and TCP/IP tunables management daemon

Synopsis
/lib/inet/ipmgmtd

svc:/network/ip-interface-management:default

Description  ipmgmtd is a system daemon that handles administrative events for network IP interfaces and IP/TCP/UDP/SCTP/ICMP tunables. It is controlled through the service management facility (SMF) service instance:

svc:/network/ip-interface-management:default

The ipmgmtd daemon is started automatically by the SMF service and should not be invoked directly. It does not constitute an administrative or a programming interface. The administrative interface for managing IP interfaces and the aforementioned protocol tunables is through ipadm(1M).

Name  ipmon – monitors /dev/ipl for logged packets

Synopsis  

```
ipmon [-abDFhmnpvxX] [-N device] [ [o] [NSI]] [-O [NSI]]
       [-P pidfile] [-S device] [-f device] [filename]
```

Description  The ipmon command is part of a suite of commands associated with the Solaris IP Filter feature. See ipfilter(5).

The ipmon command opens /dev/ipl for reading and awaits data to be saved from the packet filter. The binary data read from the device is reprinted in human readable form. However, IP addresses are not mapped back to hostnames, nor are ports mapped back to service names.

The output goes to standard output, by default, or a filename, if specified on the command line. Should the -s option be used, output is sent instead to syslogd(1M). Messages sent by means of syslog have the day, month, and year removed from the message, but the time (including microseconds), as recorded in the log, is still included.

Messages generated by ipmon consist of whitespace-separated fields. Fields common to all messages are:

- The date of packet receipt. This is suppressed when the message is sent to syslog.
- The time of packet receipt. This is in the form HH:MM:SS.F, for hours, minutes, seconds, and fractions of a second (which can be several digits long).
- The name of the interface on which the packet was processed, for example, ib1.
- The group and rule number of the rule, for example, @0:17. These can be viewed with ipfstat -in for input rules or ipfstat -out for output rules. See ipfstat(1M).
- The action: p for passed, b for blocked, s for a short packet, n did not match any rules, or L for a log rule.
- The addresses. This is actually three fields: the source address and port (separated by a comma), the symbol →, and the destination address and port. For example:

```
209.53.17.22,80 → 198.73.220.17,1722.
```

- PR followed by the protocol name or number, for example, PR tcp.
- len followed by the header length and total length of the packet, for example, \len 20 40.

If the packet is a TCP packet, there will be an additional field starting with a hyphen followed by letters corresponding to any flags that were set. See ipf.conf(4) for a list of letters and their flags.

If the packet is an ICMP packet, there will be two fields at the end, the first always being icmp, the next being the ICMP message and submessage type, separated by a slash. For example, icmp 3/3 for a port unreachable message.

Options  The following options are supported:

- a

  Open all of the device logfiles for reading log entries. All entries are displayed to the same output device (stderr or syslog).
For rules which log the body of a packet, generate hex output representing the packet contents after the headers.

-D
Cause `ipmon` to turn itself into a daemon. Using subshells or backgrounding of `ipmon` is not required to turn it into an orphan so it can run indefinitely.

-† device
Specify an alternative device/file from which to read the log information for normal IP Filter log records.

-F
Flush the current packet log buffer. The number of bytes flushed is displayed, even if the result is zero.

-h
Displays usage information.

-n
IP addresses and port numbers will be mapped, where possible, back into hostnames and service names.

-N device
Set the logfile to be opened for reading NAT log records from or to device.

-o letter
Specify which log files from which to actually read data. N, NAT logfile; S, state logfile; I, normal IP Filter logfile. The -a option is equivalent to using -o NSI.

-O letter
Specify which log files you do not wish to read from. This is most commonly used in conjunction with the -a. Letters available as parameters are the same as for -o.

-p
Cause the port number in log messages always to be printed as a number and never attempt to look it up.

-P pidfile
Write the PD of the `ipmon` process to a file. By default this is `/var/run/ipmon.pid`.

-s
Packet information read in will be sent through `syslogd` rather than saved to a file. The default facility when compiled and installed is `local0`. The following levels are used:

LOG_INFO
Packets logged using the `log` keyword as the action rather than `pass` or `block`.

LOG_NOTICE
Packets logged that are also passed.
LOG WARNING
   Packets logged that are also blocked.

LOG ERR
   Packets that have been logged and that can be considered "short".

-S device
   Set the logfile to be opened for reading state log records from or to device.

-t
   Read the input file/device in the way performed by tail(1).

-v
   Show TCP window, ack, and sequence fields

-x
   Show the packet data in hex.

-X
   Show the log header record data in hex.

System Administration Guide: IP Services

Diagnostics
   ipmon expects data that it reads to be consistent with how it should be saved and aborts if it fails an assertion which detects an anomaly in the recorded data.
**Name**

ipmpstat – display IPMP subsystem status

**Synopsis**

```
ipmpstat [-n] [-o field[,...] [-P]] -a|-g|-i|-p|-t
```

**Description**

The `ipmpstat` command concisely displays information about the IPMP subsystem. It supports five different output modes, each of which provides a different view of the IPMP subsystem (address, group, interface, probe, and target), described below. At most one output mode may be specified per invocation, and the displayed information is guaranteed to be self-consistent. It also provides a parseable output format which may be used by scripts to examine the state of the IPMP subsystem. Only basic privileges are needed to invoke `ipmpstat`, with the exception of probe mode which requires all privileges.

**Options**

The following options are supported:

- `-a`
  Display IPMP data address information (“address” output mode).

- `-g`
  Display IPMP group information (“group” output mode).

- `-i`
  Display IP interface information (“interface” output mode).

- `-n`
  Display IP addresses numerically, rather than attempting to resolve them to hostnames. This option may be used in any output mode.

- `-o field[,...]`
  Display only the specified output fields, in order. The list of field names is case-insensitive and comma-separated. The field names that are supported depend on the selected output mode, described below. The special field name `all` may be used to display all fields for a given output mode.

- `-p`
  Display IPMP probe information (“probe” output mode).

- `-t`
  Display IPMP target information (“target” output mode).

- `-P`
  Display using a machine-parseable format, described below. If this option is specified, an explicit list of fields must be specified using the `-o` option.

**Output Modes**

The `ipmpstat` utility supports the output modes listed below. Note that these modes map to some of the options described above.

**Address Mode**

Address mode displays the state of all IPMP data addresses on the system. The following output fields are supported:
ADDRESS
  The hostname (or IP address) associated with the information. Note that because
duplicate down addresses may exist, the address must be taken together with the GROUP
to form a unique identity. For a given IPMP group, if duplicate addresses exist, at most
one will be displayed, and an up address will always take precedence.

STATE
  The state of the address. Either up if the address is IFF_UP (see ifconfig(1M)), or down
if the address is not IFF_UP.

GROUP
  The IPMP IP interface hosting the address.

INBOUND
  The underlying IP interface that will receive packets for this address. This may change in
response to external events such as IP interface failure. If this field is empty, then the
system will not accept IP packets sent to this address (for example, because the address
is down or because there are no active IP interfaces left in the IPMP group).

OUTBOUND
  The underlying IP interfaces that will send packets using this source address. This may
change in response to external events such as IP interface failure. If this field is empty,
then the system will not send packets with this address as a source (for example, because
the address is down or because there are no active IP interfaces left in the IPMP group).

If -o is not specified, all output fields are displayed.

Group Mode
  Group mode displays the state of all IPMP groups on the system. The following output
fields are supported:

GROUP
  The IPMP IP interface name associated with the information. For the anonymous group
(see in.mpathd(1M)), this field will be empty.

GROUPNAME
  The IPMP group name. For the anonymous group, this field will be empty.

STATE
  The state of the group:

ok   All interfaces in the group are usable.
degraded   Some (but not all) interfaces in the group are usable.
failed   No interfaces in the group are usable.

FDT
  The probe-based failure detection time. If probe-based failure detection is disabled, this
field will be empty.
INTERFACES
The list of underlying IP interfaces in the group. The list is divided into three parts:

1. Active interfaces are listed first and not enclosed in any brackets or parenthesis. Active interfaces are those being used by the system to send or receive data traffic.

2. INACTIVE interfaces are listed next and enclosed in parenthesis. INACTIVE interfaces are those that are functioning, but not being used according to administrative policy.

3. Unusable interfaces are listed last and enclosed in brackets. Unusable interfaces are those that cannot be used at all in their present configuration (for example, FAILED or OFFLINE).

If -o is not specified, all output fields are displayed.

Interface Mode
Interface mode displays the state of all IP interfaces that are tracked by in.mpathd on the system. The following output fields are supported:

INTERFACE
The IP interface name associated with the information.

ACTIVE
Either yes or no, depending on whether the IP interface is being used by the system for IP data traffic.

GROUP
The IPMP IP interface associated with the IP interface. For IP interfaces in the anonymous group (see in.mpathd(1M)), this field will be empty.

FLAGS
Assorted information about the IP interface:

i Unusable due to being INACTIVE.
s Marked STANDBY.
m Nominated to send/receive IPv4 multicast for its IPMP group.
b Nominated to send/receive IPv4 broadcast for its IPMP group.
M Nominated to send/receive IPv6 multicast for its IPMP group.
d Unusable due to being down.
h Unusable due to being brought OFFLINE by in.mpathd because of a duplicate hardware address.

LINK
The state of link-based failure detection:

up The link is up.
down
The link is down.

unknown
The network driver does not report link state changes.

PROBE
The state of probe-based failure detection:
ok
Probes detect no problems.
failed
Probes detect failure.
unknown
Probes cannot be sent since no suitable probe targets are known.
disabled
Probes have been disabled because a unique IP test address has not been configured.

STATE
The overall state of the interface:
ok
The interface is online and functioning properly based on the configured failure
detection methods.
failed
The interface is online but has a link state of down or a probe state of failed.
offline
The interface is offline.
unknown
The interface is online but may or may not be functioning because the configured
failure detection methods are in unknown states.

If -o is not specified, all output fields are displayed.

Probe Mode
Probe mode displays information about the probes being sent by in.mpathd. Unlike other
output modes, this mode runs until explicitly terminated using Ctrl-C. The following
output fields are supported:

TIME
The time the probe was sent, relative to when ipmpstat was started. If the probe was
sent prior to starting ipmpstat, the time will be negative.
PROBE
An identifier representing the probe. The identifier embeds a prefix denoting the probe type, followed by a numerical identifier for the probe. The permissible values for the probe type are:

i  ICMP probes

 t  transitive probes

ICMP probes are sent from active interfaces; the numeric identifier of the probe is incremented for each IP probe sent by `in.mpathd` over a given active interface. The numeric identifier matches the `icmp_seq` field of the ICMP probe packet and can be used for a more detailed analysis by packet monitoring tools.

When the IPMP group does not have any NOFAILOVER test addresses configured on any of the interfaces in the group, transitive probes are sent from all interfaces that are not actively being used for receiving data packets. The numeric identifier of transitive probes is incremented for each transitive probe sent from a given interface. The format of a probe packet is internal to the implementation.

INTERFACE
The IP interface the probe was sent on.

TARGET
The hostname (or IP address) of the target to which an ICMP probe is sent from an active interface or the name of the IP interface to which the transitive probe is sent.

NETRTT
The network round-trip-time for the probe. This is the time between when the IP module sends the probe and when the IP module receives the acknowledgment. If `in.mpathd` has concluded that the probe has been lost, this field will be empty.

RTT
The total round-trip-time for the probe. This is the time between when `in.mpathd` starts executing the code to send the probe, and when it completes processing the `ack`. If `in.mpathd` has concluded that the probe has been lost, this field will be empty. Spikes in the total round-trip time that are not present in the network round-trip time indicate that the local system itself is overloaded.

RTTAVG
The average round-trip-time to TARGET over INTERFACE. This aids identification of slow targets. If there is insufficient data to calculate the average, this field will be empty.

RTTDEV
The standard deviation for the round-trip-time to TARGET over INTERFACE. This aids identification of jittery targets. If there is insufficient data to calculate the standard deviation, this field will be empty.

If `-o` is not specified, all fields except for RTTAVG and RTTDEV are displayed.
Target Mode
Target mode displays IPMP probe target information. The following output fields are supported:

**INTERFACE**
The IP interface name associated with the information.

**MODE**
The probe target discovery mode:
- routes: Probe targets found by means of the routing table.
- multicast: Probe targets found by means of multicast ICMP probes.
- disabled: All probe-based failure detection is disabled.
- transitive: Failure detection is by means of transitive probing, where the health of the IP interface is determined by probing other active interfaces in the group.

**TESTADDR**
The source address used in outgoing probes. Active interfaces that are being used for data traffic, as well as interfaces that have been explicitly configured with NOFAILOVER test addresses, will have the hostname (or IP address) that is used for sending and receiving the ICMP probes. All other interfaces in the group will display the name of the interface from which the probes are sent. Note that if an active IP interface is configured with both IPv4 and IPv6 test addresses, probe target information will be displayed separately for each test address.

**TARGETS**
A space-separated list of probe target hostnames (or IP addresses) for ICMP probes, or target interfaces for transitive probes. The IP targets will be listed in firing order, and, if no probe targets could be found, this field will be empty.

If `-o` is not specified, all output fields are displayed.

### Output Format
By default, `ipmpstat` uses a human-friendly tabular format for its output modes, where each row contains one or more fields of information about a given object, which is in turn uniquely identified by one or more of those fields. In this format, a header identifying the fields is displayed above the table (and after each screenful of information), fields are separated by whitespace, empty fields are represented by `--` (double hyphens), and other visual aids are used. If the value for a field cannot be determined, its value will be displayed as “?” and a diagnostic message will be output to standard error.

Machine-parseable format also uses a tabular format, but is designed to be efficient to programmatically parse. Specifically, machine-parseable format differs from human-friendly format in the following ways:

- No headers are displayed.
Fields with empty values yield no output, rather than showing ... Fields are separated by a single colon (:) rather than variable amounts of whitespace.
If multiple fields are requested, and a literal : or a backslash (\) occur in a field's value, they are escaped by prefixing them with \.

**Examples**

**EXAMPLE 1** Obtaining Failure Detection Time of a Specific Interface

The following code uses the machine-parseable output format to create a ksh function that outputs the failure detection time of a given IPMP IP interface:

```bash
defdt() {
  ipmpstat -gP -o group,fdt | while IFS= read group fdt; do
    [[ "$group" = "$1" ]] && { echo "$fdt"; return; }
  done
}
```

**Attributes**

/usr/sbin/ipmpstat is not a Committed interface.

**See Also** if_mpadm(1M), ifconfig(1M), in_mpathd(1M), attributes(5)
**Name**  
`ipnat` – user interface to the NAT subsystem

**Synopsis**  
`ipnat [-CdFlnRrsv] -f filename`

**Description**  
The `ipnat` utility opens a specified file (treating `stdin` as stdin) and parses it for a set of rules that are to be added or removed from the IP NAT.

If there are no parsing problems, each rule processed by `ipnat` is added to the kernel's internal lists. Rules are appended to the internal lists, matching the order in which they appear when given to `ipnat`.

`ipnat`'s use is restricted through access to `/dev/ipauth`, `/dev/ip1`, and `/dev/ipstate`. The default permissions of these files require `ipnat` to be run as root for all operations.

`ipnat`'s use is restricted through access to `/dev/ipnat`. The default permissions of `/dev/ipnat` require `ipnat` to be run as root for all operations.

**Options**  
The following options are supported:

- `-C`  
  Delete all entries in the current NAT rule listing (NAT rules).

- `-d`  
  Turn debug mode on. Causes a hex dump of filter rules to be generated as it processes each one.

- `-F`  
  Delete all active entries in the current NAT translation table (currently active NAT mappings).

- `-f filename`  
  Parse specified file for rules to be added or removed from the IP NAT. `filename` can be `stdin`.

- `-h`  
  Print number of hits for each MAP/Redirect filter.

- `-l`  
  Show the list of current NAT table entry mappings.

- `-n`  
  Prevents `ipf` from doing anything, such as making `ioctl` calls, which might alter the currently running kernel.

- `-R`  
  Disable both IP address-to-hostname resolution and port number-to-service name resolution.

- `-r`  
  Remove matching NAT rules rather than add them to the internal lists.

- `-s`  
  Retrieve and display NAT statistics.

- `-v`  
  Turn verbose mode on. Displays information relating to rule processing and active rules/table entries.

**Files**  
`/dev/ipnat`  
Link to IP Filter pseudo device.

`/dev/kmem`  
Special file that provides access to virtual address space.

`/etc/ipf/ipnat.conf`  
Location of `ipnat` startup configuration file.
Contains numerous IP Filter examples.

### Name
ippool – user interface to the IP Filter pools

### Synopsis

```
ippool -a [-dnv] [-m poolname] [-o role] [-i ipaddr
  [/netmask]

ippool -A [-dnv] [-m poolname] [-o role] [-S seed]
  [-t type]

ippool -f file [-dnuv]

ippool -F [-dv] [-o role] [-t type]

ippool -h [-dv] [-m poolname] [-t type]

ippool -l [-dv] [-m poolname] [-t type]

ippool -r [-dnv] [-m poolname] [-o role] [-i ipaddr
  [/netmask]

ippool -R [-dnv] [-m poolname] [-o role] [-t type]

ippool -s [-dtv] [-M core] [-N namelist]
```

### Description

The `ippool` utility is used to manage information stored in the IP pools subsystem of IP Filter software. Configuration file information can be parsed and loaded into the kernel and currently configured pools can be removed, changed, or inspected.

`ippool`’s use is restricted through access to `/dev/ippool`. The default permissions of `/dev/ippool` require `ippool` to be run as root for all operations.

The command line options used are divided into two sections: the global options and the instance-specific options.

`ippool`’s use is restricted through access to `/dev/ipauth`, `/dev/ip1`, and `/dev/ipstate`. The default permissions of these files require `ippool` to be run as root for all operations.

### Options

`ippool` supports the option categories described below.

#### Global Options

The following global options are supported:

- `-d` Toggle debugging of processing the configuration file.
- `-n` Prevents `ippool` from doing anything, such as making ioctl calls, that would alter the currently running kernel.
- `-v` Turn verbose mode on.

#### Instance-Specific Options

The following instance-specific options are supported:

- `-a` Add a new data node to an existing pool in the kernel.
- `-A` Add a new (empty) pool to the kernel.
- `-f file` Read in IP pool configuration information from `file` and load it into the kernel.
- `-F` Flush loaded pools from the kernel.
-h Display a list of pools of the type: hash loaded in the kernel.
- l Display a list of pools of the type: tree loaded in the kernel.
- r Remove an existing data node from a pool in the kernel.
- R Remove an existing pool from within the kernel.
- s Display IP pool statistical information.

Other Options

The following, additional options are supported:

- i ipaddr[/netmask] Sets the IP address for the operation being undertaken with an all-one’s mask or, optionally, a specific netmask, given in either dotted-quad notation or as a single integer.
- m poolname Sets the pool name for the current operation.
- M core Specify an alternative path to /dev/kmem from which to retrieve statistical information.
- n namelist Specify an alternative path to lookup symbol name information when retrieving statistical information.
- o role Sets the role with which this pool is to be used. Currently only ipf, auth, and count are accepted as arguments to this option.
- S seed Sets the hashing seed to the number specified. For use with hash-type pools only.
- t type Sets the type of pool being defined. Must be one of pool, hash, or group-map.
- u When parsing a configuration file, rather than load new pool data into the kernel, unload it.

Files

/dev/ippool Link to IP Filter pseudo device.
/dev/kmem Special file that provides access to virtual address space.
/etc/ipf/ippool.conf Location of ippool startup configuration file.

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>network/ipfilter</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>
See Also ipf(1M), ipfstat(1M), ippool(4), attributes(5)
**Name**  
ipqosconf – configure the IPQoS facility

**Synopsis**  
/usr/sbin/ipqosconf

/usr/sbin/ipqosconf -a conf_file [-vs]

/usr/sbin/ipqosconf -c

/usr/sbin/ipqosconf -f

/usr/sbin/ipqosconf -l

/usr/sbin/ipqosconf -L

**Description**  
The `ipqosconf` utility configures the Quality of Service facility of the Internet Protocol (IP). Only superusers can use this command.

Without arguments, `ipqosconf` displays the actual IPQoS configuration.

Configuration is not preserved across reboot. To apply the configuration early in the boot phase, you can populate the `/etc/inet/ipqosinit.conf` file and use the `svcadm(1M)` command to enable the following service:

```
svc:/network/ipqos:default
```

This service is disabled by default.

**Options**  
The following options are supported:

`-a conf_file`

Apply the configuration in `conf_file`. If the `conf_file` is `−`, `ipqosconf` reads from standard input.

`-c`

Populate the boot file with the current configuration.

`-f`

Flush the configuration.

`-l`

List the current applied configuration.

`-L`

List the current configuration in verbose mode.

In addition to the information that the `-l` option provides, the `-L` option provides filters and classes configured through other means than the `ipqosconf` command. This option also provides the full set of filters that were created by `ipqosconf` by representing a multi-homed host in a configuration file.

`-s`

Log messages to syslog during an -a operation.
Toggle verbose mode during an -a operation.

The -v option causes all messages to go to the console in addition to their normal destination. Messages intended to go to syslog, because the -s flag is set or because it is a log message, still go to syslog as well as the console.

**Configuration File**

The configuration file is composed of a format version and a succession of configuration (action) blocks. There are different configuration blocks for each type of action that is being configured.

**Format Version**

The first line of the configuration file specifies the format version contained in the configuration file.

The following entry specifies the format version:

```plaintext
fmt_version x.x
```

where `x.x` is the format version. 1.0 is the only supported version.

**Configuration Blocks**

Following the format version, are a succession of configuration (action) blocks that are different for each type of action being configured. A configuration block always has the following structure:

```plaintext
action {
    name action_name
    module module_name
    params_clause | 
    ""
    cf_clauses
}
```

- `action_name` ::= string
- `module_name` ::= ipqos | dlcosmk | dsdmpk | flowacct | tswtclmt | tokenmt
- `params_clause` ::= params {
    parameters
    params_stats | ""
}
- `parameters` ::= prm_name_value parameters | ""
- `prm_name_value` ::= param_name param_value

**Modules**

The `param_name` and the types of `param_value` are specific to a given module.

- `params_stats` ::= global_stats boolean
- `cf_clauses` ::= class_clause cf_clauses | ""
class_clause ::= class {
  name class_name
  next_action next_action_name
  class_stats | ""
}

class_name ::= string
next_action_name ::= string
class_stats ::= enable_stats boolean
boolean ::= TRUE | FALSE

filter_clause ::= filter {
  name filter_name
  class class_name
  parameters
}

filter_name ::= string

There must be exactly one configuration block belonging to module ipgpc. The action must
be named ipgpc.classify. All other actions should be reachable from ipgpc by way of
parameters of type action or the next_action of a class.

The set of types that are used for parameters of the different modules are:

action ::= string
protocol ::= 1..255
port ::= 1..65535
uint8 ::= 0..255
uint32 ::= 0..4294967296
int32 ::= -2147483648..2147483648
address ::= <see the description section>
ifname ::= <interface name recognized by SIOGLIFINDEX ioctl>
enum ::= string | { string_list }
boolean ::= TRUE | FALSE
integer_array ::= { range_value_list }
map_index ::= uint32
address ::= ip.address | ip.node_name
user ::= uid | username
uid ::= 0..65535
username ::= string
string_list ::= string sl_entries
sl_entries ::= ',' string sl_entries | ""
range_value_list ::= range_value_entry range_value_entrys
range_value_entry ::= range ':' integer_array_value
range ::= uint32 '-' uint32
integer_array_value ::= string | integer_array_number
integer_array_number ::= uint8 | uint32
range_value_entrys ::= ';' range_value_entry range_value_entrys | ""

ip_node_name ::= string

ip_address ::= v4_address | v6_address
v4_address ::= v4_ip_address / v4_cidr_mask |

v4_ip_address ::= 1-32
v6_address ::= v6_ip_address / v6_cidr_mask |

v6_ip_address ::= 1-128

METER module tokenmt configuration syntax:

red_action_name action
yellow_action_name action
green_action_name action
committed_rate uint32
committed_burst uint32
peak_rate uint32
<if present this signifies that this will be a two rate meter, not
a single rate meter>
peak_burst uint32
<this is the 'peak' burst size for a two rate meter, but
the 'excess' burst size for a single rate meter>
color_aware boolean
color_map integer_array
global_stats boolean

METER module tswtclmt configuration syntax:

red_action_name action
yellow_action_name action
green_action_name action
committed_rate uint32
peak_rate uint32
window uint32
global_stats boolean

MARKER module dscpmk configuration syntax:

next_action action
dscp_map int_array
dscp_detailed_stats boolean
global_stats boolean

MARKER module dlcosmk configuration syntax:

next_action action
cos map_index
global_stats boolean

CLASSIFIER module ipgpc configuration syntax:
ACCOUNTING module flowacct configuration syntax:

- next_action: action
- timer: uint32
- timeout: uint32
- max_limit: uint32

**Types**

- **action**: A string of characters with a matching action definition. The character string can be up to twenty three characters in length. To allow for spaces the string needs to be enclosed in quotes and cannot span lines. Two special actions are pre-defined and can not have an explicit action definition. The two pre-defined actions are continue and drop. continue causes the packet that is passed to it to continue normal processing, drop causes the packet that is passed to it to be dropped.

- **address**: A machine name or address recognized by **getipnodebyname(3SOCKET)**. If a machine name is specified, and **ip_version** has been defined, the query is done using that address family. If a machine name is not specified and **ip_version** has not been defined, the query is done using the AI_DEFAULT flag to **getipnodebyname()**(..AF_INET6..). CIDR address masks following an IP address are allowed. Specify the CIDR address masks as 1-32 (for v4) or 1-128 (for v6). CIDR addresses are disallowed for node names.

- **enum**: Either one of the supported values or comma delimited list of support values, enclosed in curly braces.
ifdef

A non-NULL, existing interface name recognized by the SIOGLIFINDEX socket ioctl.

integer_array

A comma delimited set of range/value pairs, enclosed in curly braces.

Specify range in the format x-y, where x and y are integers that denote the range of array indexes to which the value applies. The minimum value for both x and y is 0. The maximum value for x is particular to the parameter. Any array indexes not referred to in the set of ranges are left at their previous value.

map_index

A non-negative integer used as an index into any maps associated with a parameter of this type.

The maximum value of this type is dictated by the number of entries in the associated maps. The index starts at 0.

port

Either a service name recognized by getservbyname(3SOCKET) or an integer 1-65535.

protocol

Either a protocol name recognized by getprotobynumber(3SOCKET) or an integer 1-255.

string

A character string. Enclose string in quotes. string cannot span multiple lines.

user

Either a valid user ID or username for the system that is being configured.

Parameters

The configuration file can contain the following parameters

color_aware

A value of TRUE or FALSE, indicating whether or not the configured action takes account of the previous packet coloring when classifying.

color_map

An integer array that defines which values of the dscp field correspond with which colors for when the color_aware parameter is set to TRUE.

committed_burst

The committed burst size in bits.

committed_rate

The committed rate in bits per second.

cos

The value used to determine the underlying driver level priority applied to the packet which is defined in 802.1D.
daddr
The destination address of the datagram.

direction
The value used to build a filter matching only part of the traffic.

This parameter is of type enum with valid values of LOCAL_IN (local bound traffic), LOCAL_OUT (local sourced traffic), FWD_IN (forwarded traffic entering the system), and FWD_OUT (forwarded traffic exiting the system).

dport
The destination port of the datagram.

dscp_detailed_stats
A value of TRUE or FALSE that determines whether detailed statistics are switched on for this dscp action.

Specify TRUE to switch on or FALSE to switch off.

dscp_map
The integer_array that supplies the values that IP packets with a given dscp value have their dscp re-marked with.

The existing value is used to index into the array where the new value is taken from. The array is of size 64, meaning valid indexes are 0-63 and valid values are also 0-63.

dsfield
The DS field of the IP datagram header. This is an 8-bit value, with each bit position corresponding with the same one in the header; this enables matches to be done on the CU bits. If you specify this parameter, you must also specify the dsfield_mask parameter.

dsfield_mask
The mask applied to the dsfield parameter to determine the bits against which to match. This is an 8-bit value, with each bit position corresponding with the same one in the dsfield parameter.

global_stats
A value of TRUE or FALSE to enable or disable the statistic collection for this action.

green_action_name
The action to be executed for packets that are deemed to be green.

if_name
The name of an interface recognized by the SIOGLIFINDEX ioctl. This parameter is of type ifname.

ip_version
This parameter is of type enum and has valid values of V4 and V6.

If it is set to V4 only then only IPv4 addresses are requested for a specified hostname. If it is set to V6, only IPv6 addresses are returned if there are any, otherwise v4 mapped v6
addresses are returned. If both V4 and V6 are specified, or if ip_version is not specified, then both ipv4 and ipv6 addresses are requested for a specified hostname.

max_limit
The maximum number of flow entries present at one time in the flowacct actions in the memory resident table.

next_action
The action to be executed when the current action is complete.

This value can be either the name of an action defined in the configuration file, or one of the two special action types: drop and continue.

peak_burst
The peak burst size, for a two rate meter, or excess burst size, for a single rate meter, in bits.

peak_rate
The peak rate in bits per second.

precedence
An integer that is used to order filters. If there are two matching filters that have the same priority value, the one with the lower precedence value is the one matched. This parameter should be used because the order of the filters in a configuration file has no influence on their relative precedence.

priority
An integer that represents the relative priority of a filter. If there are two matching filters, the one with the higher priority value is the one matched. Multiple filters can have the same priority.

projid
The project ID of the process sending the data. This value is always -1 for received traffic.

protocol
The Upper Layer Protocol against which this entry is matched.

red_action_name
The action to be executed for packets that are determined to be red.

saddr
The source address of the datagram.

sport
The source port of the datagram.

timeout
The timeout in milliseconds after which flows are written to the accounting file.

timer
The period in milliseconds at which timed-out flows are checked for.
The user ID or username of the process sending the data. This value is always -1 for received traffic.

The window size in ms.

The action to be executed for packets that are determined to be yellow.

Security None.

Examples

**EXAMPLE 1  Sending All Traffic From eng to the AF 1 Class of Service**

This example sends all traffic from eng to the AF 1 class of service. It is documented in four separate steps:

The following step creates a `tokenmt` action with three outcomes:

```plaintext
#meter for class 1.
action {
    name AF_CL1
    module tokenmt
    params{
        committed_rate 64
        committed_burst 75
        peak_burst 150
        global_stats TRUE
        red_action_name drop
        yellow_action_name markAF12
        green_action_name markAF11
    }
}
```

The following step creates two `dscpmk` actions:

```plaintext
#class 1, low drop precedence.
action {
    name markAF11
    module dscpmk
    params{
        dscp_map {0-63:28}
        dscp_detailed_stats TRUE
        global_stats TRUE
        next_action acct1
    }
}
```

```plaintext
#class 1, medium drop precedence.
action {
    name markAF12
}```
EXAMPLE 1  Sending All Traffic From eng to the AF 1 Class of Service  (Continued)

```
module dscpmk
params {
    dscp_map {0-63:30}
    dscp_detailed_stats TRUE
    global_stats TRUE
    next_action acct1
}
}

The following step creates an accounting action:

#billing for transmitted class 1 traffic.
action {
    name acct1
    module flowacct
    params {
        timer 10
        timeout 30
        global_stats TRUE
        max_limit 1024
        next_action continue
    }
}

The following step creates an ipgpc action:

#traffic from eng sent, traffic from ebay dropped.
action {
    name ipgpc.classify
    module ipgpc
    class {
        name from_eng
        enable_stats TRUE
        next_action AF_CL1
    }
    class {
        name from_ebay
        enable_stats TRUE
        next_action drop
    }
}

filter {
    name from_eng
    saddr eng-subnet
    class from_eng
}
filter {
```
EXAMPLE 1 Sending All Traffic From eng to the AF 1 Class of Service (Continued)

```
name from_ebay
saddr ebay-subnet
class from_ebay
```

Files

/etc/inet/ipqosinit.conf
Contains the IPQoS configuration loaded at boot time. If this file exists, it is read by the
svc:/network/ipqos:default service.

/etc/inet/ipqosconf.1.sample
Sample configuration file for an application server.

/etc/inet/ipqosconf.2.sample
Sample configuration file that meters the traffic for a specified application

/etc/inet/ipqosconf.3.sample
Sample configuration file that marks the ethernet headers of web traffic with a given user
priority

Diagnostics

ipqosconf sends messages to syslog of facility user, severity notice when any changes are
made to the IPQoS configuration.

Errors that occur during an ipqosconf operation send an error message to the console by
default. For the application of a new configuration if the -s option is set then these messages
are sent to syslog as facility user, severity error instead. If the -v option is present during an
application then all error and change notification messages are sent to the console as well as
their default destination.

Notes

The ipqos service is controlled through the service management facility (SMF) under the
service identifier:
svc:/network/ipqos:default
Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

The IPQoS facility may be removed in a future release. Users are encouraged to migrate to `dladm(1M), dlstat(1M), flowadm(1M), and flowstat(1M), which support similar bandwidth resource control features.`
ipsecalgs - configure the IPsec protocols and algorithms table

**Synopsis**

```bash
ipsecalgs

ipsecalgs -l

ipsecalgs -s

ipsecalgs -a [-P protocol-number | -p protocol-name] [-k keylen-list
[-i inc] [-K default-keylen] -b blocklen-list -n alg-names
-N alg-number -m mech-name [-I initialization-vector_length]

ipsecalgs -P protocol-number -p protocol-name

[-e exec-mode] [-f] [-s]

ipsecalgs -r -p protocol-name [-n alg-name] [-s]

ipsecalgs -r -p protocol-name [-N alg-number] [-s]

ipsecalgs -R -P protocol-number [-s]

ipsecalgs -R -p protocol-name [-s]

ipsecalgs -e exec-mode - P protocol-number [-s]

ipsecalgs - e exec-mode - p protocol-name [-s]
```

**Description**

Use the `ipsecalgs` command to query and modify the IPsec protocol and algorithms stored in `/etc/inet/ipsecalgs`. You can use the `ipsecalgs` command to do the following:

- list the currently defined IPsec protocols and algorithms
- modify IPsec protocols definitions
- modify IPsec algorithms definitions

Never edit the `/etc/inet/ipsecalgs` file manually. The valid IPsec protocols and algorithms are described by the ISAKMP DOI. See RFC 2407. In the general sense, a Domain of Interpretation (DOI) defines data formats, network traffic exchange types, and conventions for naming security-relevant information such as security policies or cryptographic algorithms and modes. For `ipsecalgs`, the DOI defines naming and numbering conventions for algorithms and the protocols they belong to. These numbers are defined by the Internet Assigned Numbers Authority (IANA). Each algorithm belongs to a protocol. Algorithm information includes supported key lengths, block or MAC length, and the name of the cryptographic mechanism corresponding to that algorithm. This information is used by the IPsec modules, `ipsecesp(7P)` and `ipsecah(7P)`, to determine the authentication and encryption algorithms that can be applied to IPsec traffic.

The following protocols are predefined:

**IPSEC_PROTO_ESP**  Defines the encryption algorithms (transforms) that can be used by IPsec to provide data confidentiality.

**IPSEC_PROTO_AH**  Defines the authentication algorithms (transforms) that can be used by IPsec to provide authentication.
The mechanism name specified by an algorithm entry must correspond to a valid Solaris Cryptographic Framework mechanism. You can obtain the list of available mechanisms by using the `cryptoadm(1M)` command.

Applications can retrieve the supported algorithms and their associated protocols by using the functions `getipsecalgbyname(3NSL)`, `getipsecalgbynum(3NSL)`, `getipsecprotobyname(3NSL)` and `getipsecprotobynum(3NSL)`.

Modifications to the protocols and algorithm by default update only the contents of the `/etc/inet/ipsecalgs` configuration file. In order for the new definitions to be used for IPsec processing, the changes must be communicated to the kernel using the `-s` option. See NOTES for a description of how the `ipsecalgs` configuration is synchronized with the kernel at system restart.

When invoked without arguments, `ipsecalgs` displays the list of mappings that are currently defined in `/etc/inet/ipsecalgs`. You can obtain the corresponding kernel table of protocols and algorithms by using the `-l` option.

**Options**

`ipsecalgs` supports the following options:

- **-a**
  Adds an algorithm of the protocol specified by the `-P` option. The algorithm name(s) are specified with the `-n` option. The supported key lengths and block sizes are specified with the `-k`, `-i`, and `-b` options.

- **-b**
  Specifies the block or MAC lengths of an algorithm, in bytes. Set more than one block length by separating the values with commas.

- **-e**
  Designates the execution mode of cryptographic requests for the specified protocol in the absence of cryptographic hardware provider. See `cryptoadm(1M)`. `exec-mode` can be one of the following values:

  ```
  sync  Cryptographic requests are processed synchronously in the absence of a cryptographic hardware provider. This execution mode leads to better latency when no cryptographic hardware providers are available
  async Cryptographic requests are always processed asynchronously in the absence of cryptographic hardware provider. This execution can improve the resource utilization on a multi-CPU system, but can lead to higher latency when no cryptographic hardware providers are available.
  ```

  This option can be specified when defining a new protocol or to modify the execution mode of an existing protocol. By default, the `sync` execution mode is used in the absence of a cryptographic hardware provider.
-f
Used with the -a option to force the addition of an algorithm or protocol if an entry with the same name or number already exists.

-i
Specifies the valid key length increments in bits. This option must be used when the valid key lengths for an algorithm are specified by a range with the -k option.

-K
Specifies the default key lengths for an algorithm, in bits. If the -K option is not specified, the minimum key length will be determined as follows:
- If the supported key lengths are specified by range, the default key length will be the minimum key length.
- If the supported key lengths are specified by enumeration, the default key length will be the first listed key length.

-k
Specifies the supported key lengths for an algorithm, in bits. You can designate the supported key lengths by enumeration or by range.

Without the -i option, -k specifies the supported key lengths by enumeration. In this case, keylen-list consists of a list of one or more key lengths separated by commas, for example: 128, 192, 256

The listed key lengths need not be increasing, and the first listed key length will be used as the default key length for that algorithm unless the -K option is used.

With the -i option, -k specifies the range of supported key lengths for the algorithm. The minimum and maximum key lengths must be separated by a dash (‘-‘) character, for example: 32-448

-l
Displays the kernel algorithm tables.

-m
Specifies the name of the cryptographic framework mechanism corresponding to the algorithm. Cryptographic framework mechanisms are described in the cryptoadm(1M) man page.

-N
Specifies an algorithm number. The algorithm number for a protocol must be unique. IANA manages the algorithm numbers. See RFC 2407.

-n
Specifies one or more names for an algorithm. When adding an algorithm with the -a option, alg-names contains a string or a comma-separated list of strings, for example:
When used with the `-r` option to remove an algorithm, `alg-names` contains one of the valid algorithm names.

**-P**
Adds a protocol of the number specified by `protocol-number` with the name specified by the `-p` option. This option is also used to specify an IPsec protocol when used with the `-a` and the `-R` options. Protocol numbers are managed by the IANA. See RFC 2407.

**-p**
Specifies the name of the IPSec protocol.

**-R**
Removes an IPsec protocol from the algorithm table. The protocol can be specified by number by using the `-P` option or by name by using the `-p` option. The algorithms associated with the protocol are removed as well.

**-r**
Removes the mapping for an algorithm. The algorithm can be specified by algorithm number using the `-N` option or by algorithm name using the `-A` option.

**-S**
Synchronizes the kernel with the contents of `/etc/inet/ipsecalgs`. The contents of `/etc/inet/ipsecalgs` are always updated, but new information is not passed on to the kernel unless the `-s` is used. See NOTES for a description of how the `ipsecalgs` configuration is synchronized with the kernel at system restart.

The following options allow optional parameters to be configured. These are currently only used for combined mode algorithms, that is, algorithms that provide encryption and authentication in a single operation.

**-I**
The length of the Initialization Vector (IV) in bytes. The default IV length is the same as the block length.

**-M**
The length of the MAC or ICV in bytes for combined mode algorithms.

**-S**
The number of bytes of salt needed by the algorithm. The salt needs to be provided by the key management mechanism.

**-F**
Algorithm flags. These influence the way in which the kernel handles security tasks, especially authentication, in the kernel. They are also used by `ipseckey(1M)` and `ipseconf(1M)`. Flags can be specified as a comma-separated list of tokens; see the example below. The following tokens are supported:
COUNTERMODE
   The algorithm uses counter mode.

COMBINED
   The algorithm provides encryption and authentication in the same operation.

CCM
   The cryptographic framework mechanism needs a CK_AES_CCM_PARAMS structure.

GMAC
   The cryptographic framework mechanism needs a CK_AES_GMAC_PARAMS structure.

GCM
   The cryptographic framework mechanism needs a CK_AES_GCM_PARAMS structure.

CBC
   This flag indicates the algorithm uses Cipher-block chaining. The cryptographic framework mechanism does not need a params structure. This is also the default, this flag can be omitted.

The algorithm flags can be displayed with the -l option.

Examples

**EXAMPLE 1**  Adding a Protocol for IPsec Encryption
The following example shows how to add a protocol for IPsec encryption:

```
example# ipsecalgs -P 3 -p "IPSEC_PROTO_ESP"
```

**EXAMPLE 2**  Adding the Blowfish Algorithm
The following example shows how to add the Blowfish algorithm:

```
example# ipsecalgs -a -P 3 -k 32-488 -K 128 -i 8 -n "blowfish" \
   -b 8 -N 7 -m CKM_BF_CBC
```

**EXAMPLE 3**  Updating the Kernel Algorithm Table
The following example updates the kernel algorithm table with the currently defined protocol and algorithm definitions:

```
example# svcadm refresh ipsecalgs
```

**EXAMPLE 4**  Adding the AES Galois/Counter Mode (GCM) Algorithm
The following command adds this algorithm.

```
example# ipsecalgs -a -P3 -k 128-256 -K 128 -i 64 -N 20 -b 16 \
   -n "aes-gcm16,aes-gcm" -m CKM_AES_GCM -M 16 -I 8 -S 4 \
   -F GCM,COMBINED,COUNTER
```
Files

/etc/inet/ipsecalgs

File that contains the configured IPsec protocols and algorithm definitions. Never edit this file manually.

ipsecah(7P)

Piper, Derrell, RFC 2407, The Internet IP Security Domain of Interpretation for ISAKMP.

Notes

When protocols or algorithm definitions that are removed or altered, services that rely upon
these definitions can become unavailable. For example, if the IPSEC PROT0 ESP protocol is
removed, then IPsec cannot encrypt and decrypt packets.

Synchronization of the ipsecalgs configuration with the kernel at system startup is provided
by the following smf(5) service:

svc:/network/ipsec/ipsecalgs:default

The IPsec services are delivered as follows:

svc:/network/ipsec/policy:default (enabled)
svc:/network/ipsec/ipsecalgs:default (enabled)
svc:/network/ipsec/manual-key:default (disabled)
svc:/network/ipsec/ike:default (disabled)

Services that are delivered disabled are delivered that way because the system administrator
must create configuration files for those services before enabling them. See ipseckey(1M) and
ike.config(4). The default policy for the policy service is to allow all traffic to pass without
IPsec protection. See ipsecconf(1M).

The correct administrative procedure is to create the configuration file for each service, then
enable each service using svcadm(1M), as shown in the following example:

example# svcadm enable ipsecalgs

The service’s status can be queried using the svcs(1) command.

If the ipsecalgs configuration is modified, the new configuration should be resynchronized
as follows:
Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using `svcadm(1M)`. A user who has been assigned the authorization shown below can perform these actions:

```
solaris.smf.manage.ipsec
```

See `auths(1), user_attr(4), rbac(5)`.

The `ipsecalgs smf(5)` service does not have any user-configurable properties.

The `smf(5)` framework records any errors in the service-specific log file. Use any of the following commands to examine the `logfile` property:

```
example# svcs -l ipsecalgs
example# svcprop ipsecalgs
example# svccfg -s ipsecalgs listprop
```

This command requires `sys_ip_config` privilege to operate and thus can run in the global zone and in exclusive-IP zones. All shared-IP zones share the same available set of algorithms; however, you can use `ipsecconf(1M)` to set up system policy that uses differing algorithms for various shared-IP zones. All exclusive-IP zones have their own set of algorithms.
**Name**

ipseconf – configure system wide IPsec policy

**Synopsis**

```
/usr/sbin/ipsecconf
/usr/sbin/ipsecconf -a file [-q]
/usr/sbin/ipsecconf -c file
/usr/sbin/ipsecconf -d [-i tunnel-name] {index, tunnel-name, index}
/usr/sbin/ipsecconf -f [-i tunnel-name]
/usr/sbin/ipsecconf -F
/usr/sbin/ipsecconf -Fa file [-q]
/usr/sbin/ipsecconf -l [-i tunnel-name] [-n]
/usr/sbin/ipsecconf -L [-n]
/usr/sbin/ipsecconf -r file [-q]
```

**Description**

The `ipseconf` utility configures the IPsec policy for a host or for one of its tunnels. Once the policy is configured, all outbound and inbound datagrams are subject to policy checks as they exit and enter the host or tunnel. For the host policy, if no entry is found, no policy checks will be completed, and all the traffic will pass through. For a tunnel, if no entry is found and there is at least one entry for the tunnel, the traffic will automatically drop. The difference in behavior is because of the assumptions about IPsec tunnels made in many implementations. Datagrams that are being forwarded will not be subjected to policy checks that are added using this command. See `ifconfig(1M)` and `dladm(1M)` for information on how to protect forwarded packets. Depending upon the match of the policy entry, a specific action will be taken.

This command can be run only by superuser.

Each entry can protect traffic in either one direction (requiring a pair of entries) or by a single policy entry which installs the needed symmetric sadb rules.

When the command is issued without any arguments, the list of file policy entries loaded are shown. To display the SPD policy entries use the `-l` option. Both will display the index number for the entry. To specify a single tunnel's SPD, use the `-i` option in combination with `-l`. To specify all SPDs, both host and for all tunnels, use `-L`.

Note, since one file policy entry (FPE) can generate multiple SPD pol entries (SPEs), the list of FPEs may not show all the actual entries. However, it is still useful in determining what what rules have been added to get the spd into its current state.

You can use the `-d` option with the index to delete a given policy in the system. If the `-d` option removes an FPE entry that produces multiple SPEs, only then SPD with the same policy index as the FPE will be removed. This can produce a situation where there may be SPEs when there are no FPEs.

As with `-l`, `-d` can use the `-i` flag to indicate a tunnel. An alternate syntax is to specify a tunnel name, followed by a comma (,), followed by an index. For example, `ip.tun0,1`.
With no options, the entries are displayed in the order that they were added, which is not necessarily the order in which the traffic match takes place.

To view the order in which the traffic match will take place, use the `-l` option. The rules are ordered such that all bypass rules are checked first, then ESP rules, then AH rules. After that, they are checked in the order entered.

Policy entries are not preserved across system restarts. Permanent policy entries should be added to `/etc/inet/ipsecinit.conf`. This file is read by the following `smf(5)` service:

```
svc:/network/ipsec/policy
```

See NOTES for more information on managing IPsec security policy and SECURITY for issues in securing `/etc/inet/ipsecinit.conf`.

Options `ipsecconf` supports the following options:

- `-a file`
  Add the IPsec policy to the system as specified by each entry in the file. An IPsec configuration file contains one or more entries that specify the configuration. Once the policy is added, all outbound and inbound datagrams are subject to policy checks.

  Entries in the files are described in the Operands section below. Examples can be found in the Examples section below.

  Policy is latched for TCP/UDP sockets on which a `connect(3SOCKET)` or `accept(3SOCKET)` is issued. So, the addition of new policy entries may not affect such endpoints or sockets. However, the policy will be latched for a socket with an existing non-null policy. Thus, make sure that there are no preexisting connections that will be subject to checks by the new policy entries.

  The feature of policy latching explained above may change in the future. It is not advisable to depend upon this feature.

  The default behavior is to append new rules to the existing policy. If a new rule conflicts with an existing rule, an error is reported, the new rule will not be added.

  To add a new rule that conflicts with an existing rule, the existing rule must be removed (see below) or the existing policy flushed. If the policy is flushed, IPsec will not protect any network traffic until a new policy is added.

  The `-F` (flush) flag can be combined with `-a` to perform an atomic policy replacement; the existing policy will be replaced by the new policy described in the config file. By combining these two flags, there is not even a small window when the system is without a policy, which is the case when the flush and add commands are run sequentially.

- `-c file`
  Check the syntax of the configuration file and report any errors without making any changes to the policy. This option is useful when debugging configurations and when `smf(5)` reports a configuration error. See SECURITY.
-d index
Delete the host policy denoted by the index. The index is obtained by invoking \texttt{ipsecconf} without any arguments, or with the -l option. See DESCRIPTION for more information. Once the entry is deleted, all outbound and inbound datagrams affected by this policy entry will not be subjected to policy checks. Be advised that with connections for which the policy has been latched, packets will continue to go out with the same policy, even if it has been deleted. It is advisable to use the -l option to find the correct policy index.

-d name,index
Delete the policy entry denoted by index on a tunnel denoted by name. Since tunnels affect traffic that might originate off-node, latching does not apply as it does in the host policy case. Equivalent to: -d index -i name.

-f
Flush all the policies in the system. Constraints are similar to the -d option with respect to latching and host versus per-tunnel behavior.

-F
Flush all policies on all tunnels and also flush all host policies. See discussion of combining the -F and -a options, under -a, above.

-i name
Specify a tunnel interface name for use with the -d, -f, or -l flags.

-l
Listing of a single policy table, defaulting to the host policy. When \texttt{ipsecconf} is invoked without any arguments, a complete list of policy entries with indexes added by the user since boot is displayed. The current table can differ from the previous one if, for example, a multi-homed entry was added or policy reordering occurred, or if a single rule entry generates two \texttt{spd} rules. In the case of a multi-homed entry, all the addresses are listed explicitly. If a mask was not specified earlier but was instead inferred from the address, it will be explicitly listed here. This option is used to view policy entries in the correct order. The outbound and inbound policy entries are listed separately.

-L
Lists all policy tables, including host policy and all tunnel instances (including configured but unplumbed).

If -i is specified, -L lists the policy table for a specific tunnel interface.

-n
Show network addresses, ports, protocols in numbers. The -n option may only be used with the -l option.

-q
Quiet mode. Suppresses the warning message generated when adding policies.
- r file
   Remove IPsec policy rules from the system as specified by each entry in file. The format of
   the file contents is the same as is specified with the -a option. The file could be created with
   ipsecconf -l and then modified with an editor.

Operands
   Each policy entry contains three parts specified as follows:
   {pattern} action {properties}
   or
   {pattern} action {properties} "or" action {properties}*

   Every policy entry begins on a new line and can span multiple lines. If an entry exceeds the
   length of a line, you should split it only within a "braced" section or immediately before the
   first (left-hand) brace of a braced section. Avoid using the backslash character (\). See
   EXAMPLES.

   The pattern section, as shown in the syntax above, specifies the traffic pattern that should be
   matched against the outbound and inbound datagrams. If there is a match, a specific action
   determined by the second argument will be taken, depending upon the properties of the policy
   entry.

   If there is an or in the rule (multiple action-properties for a given pattern), a transmitter will
   use the first action-property pair that works, while a receiver will use any that are acceptable.

   pattern and properties are name-value pairs where name and value are separated by a <space>,
   <tab> or <newline>. Multiple name-value pairs should be separated by <space>, <tab> or
   <newline>. The beginning and end of the pattern and properties are marked by { and }
   respectively.

   Files can contain multiple policy entries. An unspecified name-value pair in the pattern will be
   considered as a wildcard. Wildcard entries match any corresponding entry in the datagram.

   One thing to remember is that UDP port 500 is always bypassed regardless of any policy
   entries. This is a requirement for in.iked(1M) to work.

   File can be commented by using a # as the first character. Comments may be inserted either at
   the beginning or the end of a line.

   The complete syntax of a policy entry is:

   policy ::= { <pattern1> } <action1> { <properties1> } |
   { <pattern2> } <action2> { <properties2> }
   [ 'or' <action2> { <properties2> } ]*
   pattern1 ::= <pattern_name_value_pair1>*
   pattern2 ::= <pattern_name_value_pair2>*
action1 ::= apply | permit | bypass | pass
action2 ::= bypass | pass | drop | ipsec

properties1 ::= {<prop_name_value_pair1>}
properties2 ::= {<prop_name_value_pair2>}

pattern_name_value_pair1 ::=  
saddr <address>/<prefix> |

redir6

icmp-code ::= <number> | net-unr | host-unr | proto-unr | port-unr |
needfrag | srcfail | net-unk | host-unk | isolate |
net-prohib | host-prohib | net-tos | host-tos |
filter-prohib | host-preced | cutoff-preced |
no-route6 | adm-prohib6 | addr-unr6 | port-unr6 |
hop-limex6 | frag-re-timex6 | err-head6 | unrec-head6 |
unreq-opt6

Policy entries may contain the following (name value) pairs in the pattern field. Each (name value) pair may appear only once in given policy entry.

laddr/plen
local/plen
The value that follows is the local address of the datagram with the prefix length. Only plen leading bits of the source address of the packet will be matched. plen is optional. Local means destination on incoming and source on outgoing packets. The source address value can be a hostname as described in getaddrinfo(3SOCKET) or a network name as described in getnetbyname(3XNET) or a host address or network address in the Internet standard dot notation. See inet_addr(3XNET). If a hostname is given and getaddrinfo(3SOCKET) returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

raddr/plen
remote/plen
The value that follows is the remote address of the datagram with the prefix length. Only plen leading bits of the remote address of the packet will be matched. plen is optional. Remote means source on incoming packets and destination on outgoing packets. The remote address value can be a hostname as described in getaddrinfo(3SOCKET) or a network name as described in getnetbyname(3XNET) or a host address or network address in the Internet standard dot notation. See inet_addr(3XNET). If a hostname is given and getaddrinfo(3SOCKET) returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

src/plen
srcaddr/plen
saddr/plen
The value that follows is the source address of the datagram with the prefix length. Only plen leading bits of the source address of the packet will be matched. plen is optional.

The source address value can be a hostname as described in getaddrinfo(3SOCKET) or a network name as described in getnetbyname(3XNET) or a host address or network address in the Internet standard dot notation. See inet_addr(3XNET).

If a hostname is given and getaddrinfo(3SOCKET) returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.
daddr/len
dest/plen
dstaddr/plen

The value that follows is the destination address of the datagram with the prefix length. Only plen leading bits of the destination address of the packet will be matched. plen is optional.

See saddr for valid values that can be given. If multiple source and destination addresses are found, then a policy entry that covers each source address-destination address pair will be added to the system.

smask

For IPv4 only. The value that follows is the source mask. If prefix length is given with saddr, this should not be given. This can be represented either in hexadecimal number with a leading 0x or 0X, for example, 0xffffffff, 0Xffffffff or in the Internet decimal dot notation, for example, 255.255.0.0 and 255.255.255.0. The mask should be contiguous and the behavior is not defined for non-contiguous masks.

smask is considered only when saddr is given.

For both IPv4 and IPv6 addresses, the same information can be specified as a slen value attached to the saddr parameter.

dmask

Analogous to smask.

lport

The value that follows is the local port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in getservbyname(3XNET).

rport

The value that follows is the remote port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in getservbyname(3XNET).

sport

The value that follows is the source port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in getservbyname(3XNET).

dport

The value that follows is the destination port of the datagram. This can be either a port number or a string as described in getservbyname(3XNET) searched with NULL proto argument.

proto ulp

The value that follows is the Upper Layer Protocol that this entry should be matched against. It could be a number or a string as described in getprotobynumber(3XNET). If no smash or plen is specified, a plen of 32 for IPv4 or 128 for IPv6 will be used, meaning a host. If the ulp is icmp or ipv6-icmp, any action applying IPSec must be the same for all icmp rules.
**type num or num-num**

The value that follows is the ICMP type that this entry should be matched against. `type` must be a number from 0 to 255, or one of the appropriate `icmp-type` keywords. Also, `ulp` must be present and must specify either `icmp` or `ipv6-icmp`. A range of types can be specified with a hyphen separating numbers.

**code num or num-num**

The value that follows is the ICMP code that this entry should be matched against. The value following the keyword `code` must be a number from 0 to 254 or one of the appropriate `icmp-code` keywords. Also, `type` must be present. A range of codes can be specified with a hyphen separating numbers.

**tunnel name**

Specifies a tunnel network interface, as configured with `ifconfig(1M)`. If a tunnel of `name` does not yet exist, the policy entries are added anyway, and joined with the tunnel state when it is created. If a tunnel is unplumbed, its policy entries disappear.

**negotiate tunnel**

**negotiate transport**

For per-tunnel security, specify whether the IPsec SAs protecting the traffic should be tunnel-mode SAs or transport-mode SAs. If transport-mode SAs are specified, no addresses can appear in the policy entry. Transport-mode is backward compatible with Solaris 9, and tunnel IPsec policies configured with `ifconfig(1M)` will show up as transport mode entries here.

Policy entries may contain the following (name-value) pairs in the properties field. Each (name-value) pair may appear only once in a given policy entry.

**auth_algs**

An acceptable value following this implies that IPsec AH header will be present in the outbound datagram. Values following this describe the authentication algorithms that will be used while applying the IPsec AH on outbound datagrams and verified to be present on inbound datagrams. See `RFC 2402`.

This entry can contain either a string or a decimal number.

**string**

This should be either MD5 or HMAC-MD5 denoting the HMAC-MD5 algorithm as described in `RFC 2403`, and SHA1, or HMAC-SHA1 or SHA or HMAC-SHA denoting the HMAC-SHA algorithm described in `RFC 2404`. You can use the `ipsecalgs(1M)` command to obtain the complete list of authentication algorithms.

The string can also be `ANY`, which denotes no-preference for the algorithm. Default algorithms will be chosen based upon the SAs available at this time for manual SAs and the key negotiating daemon for automatic SAs. Strings are not case-sensitive.
number
A number in the range 1-255. This is useful when new algorithms can be dynamically loaded.

If auth_algs is not present, the AH header will not be present in the outbound datagram, and the same will be verified for the inbound datagram.

encr_algs
An acceptable value following this implies that IPsec ESP header will be present in the outbound datagram. The value following this describes the encryption algorithms that will be used to apply the IPsec ESP protocol to outbound datagrams and verify it to be present on inbound datagrams. See RFC 2406.

This entry can contain either a string or a decimal number. Strings are not case-sensitive.

string
Can be one of the following:

<table>
<thead>
<tr>
<th>string value:</th>
<th>Algorithm Used:</th>
<th>See RFC:</th>
</tr>
</thead>
<tbody>
<tr>
<td>DES or DES-CBC</td>
<td>DES-CBC</td>
<td>2405</td>
</tr>
<tr>
<td>3DES or 3DES-CBC</td>
<td>3DES-CBC</td>
<td>2451</td>
</tr>
<tr>
<td>BLOWFISH or BLOWFISH-CBC</td>
<td>BLOWFISH-CBC</td>
<td>2451</td>
</tr>
<tr>
<td>AES or AES-CBC</td>
<td>AES-CBC</td>
<td>2451</td>
</tr>
<tr>
<td>AES-CCM</td>
<td>AES-CCM</td>
<td>4309</td>
</tr>
<tr>
<td>AES-GCM</td>
<td>AES_GCM</td>
<td>4106</td>
</tr>
</tbody>
</table>

You can use the ipsecalgs(1M) command to obtain the complete list of authentication algorithms.

The value can be NULL, which implies a NULL encryption, pursuant to RFC 2410. This means that the payload will not be encrypted. The string can also be ANY, which indicates no-preference for the algorithm. Default algorithms will be chosen depending upon the SAs available at the time for manual SAs and upon the key negotiating daemon for automatic SAs. Strings are not case-sensitive.

number
A decimal number in the range 1-255. This is useful when new algorithms can be dynamically loaded.

encr_auth_algs
An acceptable value following encr_auth_algs implies that the IPsec ESP header will be present in the outbound datagram. The values following encr_auth_algs describe the
authentication algorithms that will be used while applying the IPsec ESP protocol on outbound datagrams and verified to be present on inbound datagrams. See RFC 2406. This entry can contain either a string or a number. Strings are case-insensitive.

string
Valid values are the same as the ones described for auth_algo above.

number
This should be a decimal number in the range 1-255. This is useful when new algorithms can be dynamically loaded.

If encr_algs is present and encr_auth_algs is not present in a policy entry, the system will use an ESP SA regardless of whether the SA has an authentication algorithm or not.

If encr_algs is not present and encr_auth_algs is present in a policy entry, null encryption will be provided, which is equivalent to encr_algs with NULL, for outbound and inbound datagrams.

If both encr_algs and encr_auth_algs are not present in a policy entry, ESP header will not be present for outbound datagrams and the same will be verified for inbound datagrams.

If both encr_algs and encr_auth_algs are present in a policy entry, ESP header with integrity checksum will be present on outbound datagrams and the same will be verified for inbound datagrams.

For encr_algs, encr_auth_algs, and auth_algs a key length specification may be present. This is either a single value specifying the only valid key length for the algorithm or a range specifying the valid minimum and/or maximum key lengths. Minimum or maximum lengths may be omitted.

dir
Values following this decides whether this entry is for outbound or inbound datagram. Valid values are strings that should be one of the following:

out
This means that this policy entry should be considered only for outbound datagrams.

in
This means that this policy entry should be considered only for inbound datagrams.

both
This means that this policy entry should be considered for both inbound and outbound datagrams

This entry is not needed when the action is “apply”, “permit” or “ipsec”. But if it is given while the action is “apply” or “permit”, it should be “out” or “in” respectively. This is mandatory when the action is “bypass”.
Values following this decide the attribute of the security association. Value indicates whether a unique security association should be used or any existing SA can be used. If there is a policy requirement, SAs are created dynamically on the first outbound datagram using the key management daemon. Static SAs can be created using `ipseckey(1M)`. The values used here determine whether a new SA will be used/obtained. Valid values are strings that could be one of the following:

**unique**
Unique Association. A new/unused association will be obtained/used for packets matching this policy entry. If an SA that was previously used by the same 5 tuples, that is, {Source address, Destination address, Source port, Destination Port, Protocol (for example, TCP/UDP)} exists, it will be reused. Thus uniqueness is expressed by the 5 tuples given above. The security association used by the above 5 tuples will not be used by any other socket. For inbound datagrams, uniqueness will not be verified.

For tunnel-mode tunnels, `unique` is ignored. SAs are assigned per-rule in tunnel-mode tunnels. For transport-mode tunnels, `unique` is implicit, because the enforcement happens only on the outer-packet addresses and protocol value of either IPv4-in-IP or IPv6-in-IP.

**shared**
Shared association. If an SA exists already for this source-destination pair, it will be used. Otherwise a new SA will be obtained. This is the default.

This is mandatory only for outbound policy entries and should not be given for entries whose action is “bypass”. If this entry is not given for inbound entries, for example, when “dir” is in or “action” is permit, it will be assumed to be shared.

Action follows the pattern and should be given before properties. It should be one of the following and this field is mandatory.

**ipsec**
Use IPsec for the datagram as described by the properties, if the pattern matches the datagram. If `ipsec` is given without a `dir` spec, the pattern is matched to incoming and outgoing datagrams.

**apply**
Apply IPsec to the datagram as described by the properties, if the pattern matches the datagram. If `apply` is given, the pattern is matched only on the outbound datagram.

**permit**
Permit the datagram if the pattern matches the incoming datagram and satisfies the constraints described by the properties. If it does not satisfy the properties, discard the datagram. If `permit` is given, the pattern is matched only for inbound datagrams.

**bypass**
**pass**
Bypass any policy checks if the pattern matches the datagram. `dir` in the properties decides whether the check is done on outbound or inbound datagrams. All the bypass entries are checked before checking with any other policy entry in the system. This has the highest precedence over any other entries. `dir` is the only field that should be present when action is `bypass`.

```
drop
    Drop any packets that match the pattern.
```

If the file contains multiple policy entries, for example, they are assumed to be listed in the order in which they are to be applied. In cases of multiple entries matching the outbound and inbound datagram, the first match will be taken. The system will reorder the policy entry, that is, add the new entry before the old entry, only when:

- The level of protection is “stronger” than the old level of protection.

Currently, strength is defined as:

```
AH and ESP > ESP > AH
```

The standard uses of AH and ESP were what drove this ranking of “stronger”. There are flaws with this. ESP can be used either without authentication, which will allow cut-and-paste or replay attacks, or without encryption, which makes it equivalent or slightly weaker than AH. An administrator should take care to use ESP properly. See `ipsecesp(7P)` for more details.

If the new entry has `bypass` as action, `bypass` has the highest precedence. It can be added in any order, and the system will still match all the bypass entries before matching any other entries. This is useful for key management daemons which can use this feature to bypass IPsec as it protects its own traffic.

Entries with both AH (auth_algs present in the policy entry) and ESP (encr_auth_algs or encr_auth_auth_algs present in the policy entry) protection are ordered after all the entries with AH and ESP and before any AH-only and ESP-only entries. In all other cases the order specified by the user is not modified, that is, newer entries are added at the end of all the old entries. See Examples.

A new entry is considered duplicate of the old entry if an old entry matches the same traffic pattern as the new entry. See Examples for information on duplicates.

**Security** If, for example, the policy file comes over the wire from an NFS mounted file system, an adversary can modify the data contained in the file, thus changing the policy configured on the machine to suit his needs. Administrators should be cautious about transmitting a copy of the policy file over a network.

To prevent non-privileged users from modifying the security policy, ensure that the configuration file is writable only by trusted users.
The configuration file is defined by a property of the policy smf(5) service. The default configuration file, is /etc/inet/ipsecinit.conf. This can be changed using the svcprop(1) command. See NOTES for more details.

The policy description language supports the use of tokens that can be resolved by means of a name service, using functions such as gethostbyname(3NSL). While convenient, these functions are only secure as the name service the system is configured to use. Great care should be taken to secure the name service if it is used to resolve elements of the security policy.

If your source address is a host that can be looked up over the network and your naming system itself is compromised, then any names used will no longer be trustworthy.

If the name switch is configured to use a name service that is not local to the system, bypass policy entries might be required to prevent the policy from preventing communication to the name service. See nsswitch.conf(4).

Policy is latched for TCP/UDP sockets on which a connect(3SOCKET) or accept(3SOCKET) has been issued. Adding new policy entries will not have any effect on them. This feature of latching may change in the future. It is not advisable to depend upon this feature.

The ipsecconf command can only be run by a user who has sufficient privilege to open the pf_key(7P) socket. The appropriate privilege can be assigned to a user with the Network IPsec Management profile. See profiles(1), rbac(5), prof_attr(4).

Make sure to set up the policies before starting any communications, as existing connections may be affected by the addition of new policy entries. Similarly, do not change policies in the middle of a communication.

Note that certain ndd tunables affect how policies configured with this tool are enforced; see ipsecesp(7P) for more details.

**Examples**

**EXAMPLE 1**   Protecting Outbound TCP Traffic With ESP and the AES Algorithm

The following example specifies that any TCP packet from spiderweb to arachnid should be encrypted with AES, and the SA could be a shared one. It does not verify whether or not the inbound traffic is encrypted.

```
# Protect the outbound TCP traffic between hosts spiderweb
# and arachnid with ESP and use AES algorithm.
#
{
  laddr spiderweb
  raddr arachnid
  ulp tcp
  dir out
} ipsec {
```
EXAMPLE 1  Protecting Outbound TCP Traffic With ESP and the AES Algorithm  (Continued)

encr_algs AES
}

EXAMPLE 2  Verifying Whether or Not Inbound Traffic is Encrypted

Example 1 does not verify whether or not the inbound traffic is encrypted. The entry in this example protects inbound traffic:

# Protect the TCP traffic on inbound with ESP/DES from arachnid
to spiderweb
#
{      
  laddr spiderweb
  raddr arachnid
  ulp tcp
  dir in
} ipsec {
  encr_algs AES

sa can be absent for inbound policy entries as it implies that it can be a shared one. Uniqueness is not verified on inbound. Note that in both the above entries, authentication was never specified. This can lead to cut and paste attacks. As mentioned previously, though the authentication is not specified, the system will still use an ESP SA with encr_auth_alg specified, if it was found in the SA tables.

EXAMPLE 3  Protecting All Traffic Between Two Hosts

The following example protects both directions at once:

{      
  laddr spiderweb
  raddr arachnid
  ulp tcp
} ipsec {
  encr_algs AES

EXAMPLE 4  Authenticating All Inbound Traffic to the Telnet Port

This entry specifies that any inbound datagram to telnet port should come in authenticated with the SHA1 algorithm. Otherwise the datagram should not be permitted. Without this entry, traffic destined to port number 23 can come in clear. sa is not specified, which implies that it is shared. This can be done only for inbound entries. You need to have an equivalent entry to protect outbound traffic so that the outbound traffic is authenticated as well, remove the dir.
EXAMPLE 4  Authenticating All Inbound Traffic to the Telnet Port  

(Continued)

# All the inbound traffic to the telnet port should be
# authenticated.
#
{  
  lport telnet
  dir in
} ipsec {  
  auth_algs sha1
}

EXAMPLE 5  Verifying Inbound Traffic is Null-Encrypted

The first entry specifies that any packet with address host-B should not be checked against any policies. The second entry specifies that all inbound traffic from network-B should be encrypted with a NULL encryption algorithm and the MD5 authentication algorithm. NULL encryption implies that ESP header will be used without encrypting the datagram. As the first entry is bypass it need not be given first in order, as bypass entries have the highest precedence. Thus any inbound traffic will be matched against all bypass entries before any other policy entries.

# Make sure that all inbound traffic from network-B is NULL
# encrypted, but bypass for host-B alone from that network.
# Add the bypass first.
{  
  raddr host-B
  dir in
} bypass {}

# Now add for network-B.
{  
  raddr network-B/16
  dir in
} ipsec {  
  encr_algs NULL
  encr_auth_algs md5
}

EXAMPLE 6  Entries to Bypass Traffic from IPsec

The first two entries provide that any datagram leaving the machine with source port 53 or coming into port number 53 should not be subjected to IPsec policy checks, irrespective of any other policy entry in the system. Thus the latter two entries will be considered only for ports other than port number 53.
EXEMPLARY 6 Entries to Bypass Traffic from IPsec (Continued)

# # Bypass traffic for port no 53 #
{lport 53} bypass {}
{rport 53} bypass {}
{raddr spiderweb} ipsec {encr_algs any sa unique}

EXEMPLARY 7 Protecting Outbound Traffic

# # Protect the outbound traffic from all interfaces. #
{raddr spiderweb dir out} ipsec {auth_algs any sa unique}

If the `gethostbyname(3XNET)` call for spiderweb yields multiple addresses, multiple policy entries will be added for all the source address with the same properties.

{  laddr arachnid
    raddr spiderweb
    dir in
} ipsec {auth_algs any sa unique}

If the `gethostbyname(3XNET)` call for spiderweb and the `gethostbyname(3XNET)` call for arachnid yield multiple addresses, multiple policy entries will be added for each `(saddr daddr)` pair with the same properties. Use `ipsecconf -l` to view all the policy entries added.

EXEMPLARY 8 Bypassing Unauthenticated Traffic

# # Protect all the outbound traffic with ESP except any traffic # to network-b which should be authenticated and bypass anything # to network-c #
{raddr network-b/16 dir out} ipsec {auth_algs any}
{dir out} ipsec {encr_algs any}
{raddr network-c/16 dir out} bypass {} # NULL properties

Note that bypass can be given anywhere and it will take precedence over all other entries. NULL pattern matches all the traffic.

EXEMPLARY 9 Encrypting IPv6 Traffic with 3DES and MD5

The following entry on the host with the link local address fe80::a00:20ff:fe21:4483 specifies that any outbound traffic between the hosts with IPv6 link-local addresses fe80::a00:20ff:fe21:4483 and fe80::a00:20ff:fe1f:e346 must be encrypted with 3DES and MD5.
EXAMPLE 9  Encrypting IPv6 Traffic with 3DES and MD5  (Continued)

{  
    laddr fe80::a00:20ff:fe21:4483
    raddr fe80::a00:20ff:fe1f:e346
    dir out
} ipsec {
    encr_algs 3DES
    encr_auth_algs MD5
}

EXAMPLE 10  Verifying IPv6 Traffic is Authenticated with SHA1

The following two entries require that all IPv6 traffic to and from the IPv6 site-local network
 fec0:abcd::0/32 be authenticated with SHA1.
{raddr fec0:abcd::0/32} ipsec { auth_algs SHA1 }

EXAMPLE 11  Key Lengths

# use aes at any key length
{raddr spiderweb} ipsec {encr_algs aes}

# use aes with a 192 bit key
{raddr spiderweb} ipsec {encr_algs aes(192)}

# use aes with any key length up to 192 bits
# i.e. 192 bits or less
{raddr spiderweb} ipsec {encr_algs aes(..192)}

# use aes with any key length of 192 or more
# i.e. 192 bits or more
{raddr spiderweb} ipsec {encr_algs aes(192..)}

# use aes with any key from 192 to 256 bits
{raddr spiderweb} ipsec {encr_algs aes(192..256)}

# use any algorithm with a key of 192 bits or longer
{raddr spiderweb} ipsec {encr_algs any(192..)}

EXAMPLE 12  Correct and Incorrect Policy Entries

The following are examples of correctly formed policy entries:

{ raddr that_system rport telnet } ipsec { encr_algs 3des encr_auth_algs shal sa shared}

{  
    raddr that_system
    rport telnet
}
EXAMPLE 12  Correct and Incorrect Policy Entries  (Continued)

```plaintext
} ipsec {
    encri algs 3des
    encri_auth_algs sha1
    sa shared
}

{ raddr that_system rport telnet } ipsec
    { encri algs 3des encri_auth_algs sha1 sa shared}

{ raddr that_system rport telnet } ipsec
    { encri algs 3des encri_auth_algs sha1 sa shared} or ipsec
    { encri algs aes encri_auth_algs sha1 sa shared}

...and the following is an incorrectly formed entry:

{ raddr that_system rport telnet } ipsec
    { encri_algs 3des encri_auth_algs sha1 sa shared}
    or ipsec { encri_algs aes encri_auth_algs sha1 sa shared}

In the preceding, incorrect entry, note that the third line begins with “or ipsec”. Such an entry causes ipseconf to return an error.

EXAMPLE 13  Allowing Neighbor Discovery to Occur in the Clear

The following two entries require that all IPv6 traffic to and from the IPv6 site-local network fec0:abcd::0/32 be authenticated with SHA1. The second entry allows neighbor discovery to operate correctly.

{raddr fec0:abcd::0/32} ipsec { auth_algs SHA1 }
{raddr fec0:abcd::0/32 ulp ipv6-icmp type 133-137 dir both }
    pass { }

EXAMPLE 14  Using “or”

The following entry allows traffic using the AES or Blowfish algorithms from the remote machine spiderweb:

{raddr spiderweb} ipsec {encr_algs aes} or ipsec {encr_algs blowfish}

EXAMPLE 15  Configuring a Tunnel to be Backward-Compatible with Solaris 9

The following example is equivalent to “encr_algs aes encr_auth_algs md5” in ifconfig(1M):

{tunnel ip.tun0 negotiate transport} ipsec {encr_algs aes
    encri_auth_algs md5}
EXAMPLE 16  Configuring a Tunnel to a VPN client with an Assigned Address

The following example assumes a distinct “inside” network with its own topology, such that a client’s default route goes “inside”.

# Unlike route(1m), the default route has to be spelled-out.
{tunnel ip.tun0 negotiate tunnel raddr client-inside/32 laddr 0.0.0.0/0} ipsec {encr_algs aes encr_auth_algs shal}

EXAMPLE 17  Transit VPN router between Two Tunnelled Subnets and a Third

The following example specifies a configuration for a VPN router that routes between two tunnelled subnets and a third subnet that is on-link. Consider remote-site A, remote-site B, and local site C, each with a /24 address allocation.

# ip.tun0 between me (C) and remote-site A.
# Cover remote-site A to remote-site B.
{tunnel ip.tun0 negotiate tunnel raddr A-prefix/24 laddr B-prefix/24} ipsec {encr_algs 3des encr_auth_algs md5}

# Cover remote-site A traffic to my subnet.
{tunnel ip.tun0 negotiate tunnel raddr A-prefix/24 laddr C-prefix/24} ipsec {encr_algs 3des encr_auth_algs md5}

# ip.tun1 between me (C) and remote-site B.
# Cover remote-site B to remote-site A.
{tunnel ip.tun1 negotiate tunnel raddr B-prefix/24 laddr A-prefix/24} ipsec {encr_algs aes encr_auth_algs shal}

# Cover remote-site B traffic to my subnet.
{tunnel ip.tun1 negotiate tunnel raddr B-prefix/24 laddr C-prefix/24} ipsec {encr_algs aes encr_auth_algs md5}

EXAMPLE 18  Using Combined Mode Ciphers

Combined mode ciphers provide data privacy and message authentication in a single operation. They are treated as special versions of encr_algs. They provide message authentication without the need to specify encr_auth_algs. The two combined mode ciphers supported are:

aes-ccm
AES CCM Mode (Counter with CBC-MAC)

aes-gcm
AES GCM Mode (Galois/Counter)

The parameters used are the same as any other encr_algs value. In both examples, the number in the algorithm token indicates the length of the Integrity Check Vector (ICV). See ipsecalgs(1M).
EXAMPLE 18  Using Combined Mode Ciphers  (Continued)

# simple example using transport mode
{laddr 192.168.99.2 raddr 192.168.99.3} ipsec
  {encr_algs aes-gcm sa shared}
# simple example using CCM mode and 128 bit keys
{laddr 192.168.99.100 raddr 192.168.99.200} ipsec
  {encr_algs aes-ccm(128) sa shared}

EXAMPLE 19  Using AES GMAC
The AES GMAC algorithm is a hash algorithm that provides message authentication. An Integrity Check Vector (ICV) is calculated and transmitted as part of the authenticated packet.

The AES GMAC algorithm can be used in ESP mode, in which case the packet data and the ESP header are authenticated. When used with IPsec ESP, AES GMAC can only be specified as an encryption algorithm, even though it does not provide any encryption.

# simple example using AES GMAC and 128 bit keys for ESP
{laddr 192.168.99.100 raddr 192.168.99.200} ipsec
  {encr_algs aes-none-gmac(128) sa shared}

The above example is analogous to the following invalid example:

{laddr 192.168.99.100 raddr 192.168.99.200} ipsec
  {encr_algs null encr_auth_algs aes-gmac(128) sa shared}

When used with ESP, the aes-none-gmac algorithm takes the key length as an optional argument, the supported key lengths can be displayed using the ipsecalgs(1M) command.

The AES GMAC algorithm can be used in AH mode, in which case the whole packet, including the IP header, is authenticated. When used with IPsec AH, AES GMAC can only be specified as an authentication algorithm.

# simple example using AES GMAC and 128 bit keys for AH
{laddr 192.168.99.100 raddr 192.168.99.200} ipsec
  {auth_algs aes-gmac128 sa shared}

When used with AH, each key length has its own DOI number, the key length does not need to be specified as an argument.

Files
/var/run/ipsecpolicy.conf
  Cache of IPsec policies currently configured for the system, maintained by ipsecconf command. Do not edit this file.

/etc/inet/ipsecinit.conf
  File containing IPsec policies to be installed at system restart by the policy smf(5) service. See NOTES for more information.

/etc/inet/ipsecinit.sample
  Sample input file for ipsecconf.

Diagnostics

Bad "string" on line N.
Duplicate "string" on line N.
string refers to one of the names in pattern or properties. A Bad string indicates that an argument is malformed; a Duplicate string indicates that there are multiple arguments of a similar type, for example, multiple Source Address arguments.

Interface name already selected
Dual use of -i name and name,index for an interface.

Error before or at line N.
Indicates parsing error before or at line N.
Non-existent index
Reported when the index for delete is not a valid one.

spd_msg return: File exists
Reported when there is already a policy entry that matches the traffic of this new entry.

Notes
IPsec manual keys are managed by the service management facility, smf(5). The services listed below manage the components of IPsec. These services are delivered as follows:

- svc:/network/ipsec/policy:default (enabled)
- svc:/network/ipsec/ipsecalgs:default (enabled)
- svc:/network/ipsec/manual-key:default (disabled)
- svc:/network/ipsec/ike:default (disabled)

The manual-key service is delivered disabled. The system administrator must create manual IPsec Security Associations (SAs), as described in ipseckey(1M), before enabling that service.

The policy service is delivered enabled, but without a configuration file, so that, as a starting condition, packets are not protected by IPsec. After you create the configuration file /etc/inet/ipsecinit.conf, as described in this man page, and refresh the service (svcadm refresh, see below), the policy contained in the configuration file is applied. If there is an error in this file, the service enters maintenance mode.

Services that are delivered disabled are delivered that way because the system administrator must create configuration files for those services before enabling them. See ike.config(4) for the ike service.

See ipsecalgs(1M) for the ipsecalgs service.

The correct administrative procedure is to create the configuration file for each service, then enable each service using svcadm(1M).

If the configuration needs to be changed, edit the configuration file then refresh the service, as follows:

example# svcadm refresh policy

The smf(5) framework will record any errors in the service-specific log file. Use any of the following commands to examine the logfile property:

example# svc -l policy
example# svcprop policy
example# svcadm -s policy listprop

The following property is defined for the policy service:
config/config_file

This property can be modified using svccfg(1M) by users who have been assigned the following authorization:
solaris.smf.value.ipsec

See auths(1), user_attr(4), rbac(5).

The service needs to be refreshed using svcadm(1M) before the new property is effective. General non-modifiable properties can be viewed with the svcprop(1) command.

```
# svccfg -s ipsec/policy setprop config/config_file = /new/config_file
# svcadm refresh policy
```

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using svcadm(1M). A user who has been assigned the authorization shown below can perform these actions:

```
solaris.smf.manage.ipsec
```

The service’s status can be queried using the svcs(1) command.

The ipsecconf command is designed to be managed by the policy smf(5) service. While the ipsecconf command can be run from the command line, this is discouraged. If the ipsecconf command is to be run from the command line, the policy smf(5) service should be disabled first. See svcadm(1M).
The `ipseckey` command is used to manually manipulate the security association databases of the network security services, `ipsecrah(7P)` and `ipsecesp(7P)`. You can use the `ipseckey` command to set up security associations between communicating parties when automated key management is not available.

While the `ipseckey` utility has only a limited number of general options, it supports a rich command language. The user may specify requests to be delivered by means of a programmatic interface specific for manual keying. See `pf_key(7P)`. When `ipseckey` is invoked with no arguments, it will enter an interactive mode which prints a prompt to the standard output and accepts commands from the standard input until the end-of-file is reached. Some commands require an explicit security association (“SA”) type, while others permit the SA type to be unspecified and act on all SA types.

`ipseckey` uses a `PF_KEY` socket and the message types `SADB_ADD`, `SADB_DELETE`, `SADB_GET`, `SADB_UPDATE`, `SADB_FLUSH`, and `SADB_X_PROMISC`. Thus, you must be a superuser to use this command.

`ipseckey` handles sensitive cryptographic keying information. Please read the Security section for details on how to use this command securely.

### Options

- `-c [filename]`
  Analogous to the `-f` option (see following), except that the input is not executed but only checked for syntactical correctness. Errors are reported to `stderr`. This option is provided to debug configurations without making changes. See SECURITY and “Service Management Facility” for more information.

- `-f [filename]`
  Read commands from an input file, `filename`. The lines of the input file are identical to the command line language. The `load` command provides similar functionality. The `-s` option or the save command can generate files readable by the `-f` argument.
-n
Prevent attempts to print host and network names symbolically when reporting actions.
This is useful, for example, when all name servers are down or are otherwise unreachable.

-p
Paranoid. Do not print any keying material, even if saving SAs. Instead of an actual hexadecimal digit, print an X when this flag is turned on.

-s [filename]
The opposite of the -f option. If the -f option is given for a filename, then the output goes to the standard output. A snapshot of all current SA tables will be output in a form readable by the -f option. The output will be a series of add commands, but with some names not used. This occurs because a single name may often indicate multiple addresses.

-v
Verbose. Print the messages being sent into the PF_KEY socket, and print raw seconds values for lifetimes.

Commands

add
Add an SA. Because it involves the transfer of keying material, it cannot be invoked from the shell, lest the keys be visible in ps(1) output. It can be used either from the interactive ipseckey> prompt or in a command file specified by the -f command. The add command accepts all extension-value pairs described below.

update
Update SA lifetime, and in the cases of larval SAs (leftover from aborted automated key management), keying material and other extensions. Like add, this command cannot be invoked from the shell because keying material would be seen by the ps(1) command. It can be used either from the interactive ipseckey> prompt or in a command file specified by the -f command. The update command accepts all extension-value pairs, but normally is only used for SA lifetime updates.

update-pair
As update, but apply the update to the SA and its paired SA, if there is one.

delete
Delete a specific SA from a specific SADB. This command requires the spi extension, and the dest extension for IPsec SAs. Other extension-value pairs are superfluous for a delete message. If the SA to be deleted is paired with another SA, the SA is deleted and the paired SA is updated to indicate that it is now unpaired.

delete-pair
Delete a specific SA from a specific SADB. If the SA is paired with another SA, delete that SA too. This command requires the spi extension and the dest extension for the IPsec SA, or its pair.

get
Lookup and display a security association from a specific SADB. Like delete, this command only requires spi and dest for IPsec.
flush
   Remove all SA for a given SA_TYPE, or all SA for all types.

monitor
   Continuously report on any PF_KEY messages. This uses the SADB_X_PROMISC message to
equal messages that a normal PF_KEY socket would not receive to be received. See
   pf_key(7P).

passive_monitor
   Like monitor, except that it does not use the SADB_X_PROMISC message.

pmonitor
   Synonym for passive_monitor.

dump
   Will display all SAs for a given SA type, or will display all SAs. Because of the large amount
of data generated by this command, there is no guarantee that all SA information will be
successfully delivered, or that this command will even complete.

save
   Is the command analog of the -s option. It is included as a command to provide a way to
snapshot a particular SA type, for example, esp or ah.

help
   Prints a brief summary of commands.

SA_TYPE

   all
      Specifies all known SA types. This type is only used for the flush and dump commands.
      This is equivalent to having no SA type for these commands.

   ah
      Specifies the IPsec Authentication Header ("AH") SA.

   esp
      Specifies the IPsec Encapsulating Security Payload ("ESP") SA.

Extension Value Types

Commands like add, delete, get, and update require that certain extensions and associated
values be specified. The extensions will be listed here, followed by the commands that use
them, and the commands that require them. Requirements are currently documented based
upon the IPsec definitions of an SA. Required extensions may change in the future. <number>
can be in either hex (0xnnn), decimal (nnn) or octal (0nnn). <string> is a text string. <hexstr>
is a long hexadecimal number with a bit-length. Extensions are usually paired with values;
however, some extensions require two values after them.

spi <number>
   Specifies the security parameters index of the SA. This extension is required for the add,
delete, get and update commands.
When `pair-spi` is used with the `add` or `update` commands, the SA being added or updated will be paired with the SA defined by `pair-spi`. A pair of SAs can be updated or deleted with a single command.

The two SAs that make up the pair need to be in opposite directions from the same pair of IP addresses. The command will fail if either of the SAs specified are already paired with another SA.

If the `pair-spi` token is used in a command and the SA defined by `pair-spi` does not exist, the command will fail. If the command was `add` and the pairing failed, the SA to be added will instead be removed.

### inbound | outbound

These optional flags specify the direction of the SA. When the `inbound` or `outbound` flag is specified with the `add` command, the kernel will insert the new SA into the specified hash table for faster lookups. If the flag is omitted, the kernel will decide into which hash table to insert the new SA based on its knowledge the IP addresses specified with the `src` and `dst` extensions.

When these flags are used with the `update`, `delete`, `update-pair` or `get` commands, the flags provide a hint as to the hash table in which the kernel should find the SA.

### replay `<number>`

Specifies the replay window size. If not specified, the replay window size is assumed to be zero. It is not recommended that manually added SAs have a replay window. This extension is used by the `add` and `update` commands.

### replay_value `<number>`

Specifies the replay value of the SA. This extension is used by the `add` and `update` commands.

### state `<string>`| `<number>`

Specifies the SA state, either by numeric value or by the strings "larval", "mature", "dying" or "dead". If not specified, the value defaults to `mature`. This extension is used by the `add` and `update` commands.

### auth_alg `<string>`| `<number>`

Specifies the authentication algorithm for an SA, either by numeric value, or by strings indicating an algorithm name. Current authentication algorithms include:

- **HMAC-MD5**
  - `md5`, `hmac-md5`
- **HMAC-SH-1**
  - `sha`, `sha-1`, `hmac-sha1`, `hmac-sha`
Often, algorithm names will have several synonyms. This extension is required by the add command for certain SA types. It is also used by the update command.

Use the `ipsecalgs(1M)` command to obtain the complete list of authentication algorithms.

```
encr_alg <string>|<number>
encralg <string>|<number>
```

Specifies the encryption algorithm for an SA, either by numeric value, or by strings indicating an algorithm name. Current encryption algorithms include DES ("des"), Triple-DES ("3des"), Blowfish ("blowfish"), and AES ("aes"). This extension is required by the add command for certain SA types. It is also used by the update command.

Use the `ipsecalgs(1M)` command to obtain the complete list of encryption algorithms.

The next six extensions are lifetime extensions. There are two varieties, "hard" and "soft". If a hard lifetime expires, the SA will be deleted automatically by the system. If a soft lifetime expires, an SADB_EXPIRE message will be transmitted by the system, and its state will be downgraded to dying from mature. See `pf_key(7P)`. The monitor command to key allows you to view SADB_EXPIRE messages.

```
idle_addtime <number>
idle_usetime <number>
```

Specifies the number of seconds that this SA can exist if the SA is not used before the SA is revalidated. If this extension is not present, the default value is half of the hard_addtime (see below). This extension is used by the add and update commands.

```
soft_bytes <number>
hard_bytes <number>
```

Specifies the number of bytes that this SA can protect. If this extension is not present, the default value is zero, which means that the SA will not expire based on the number of bytes protected. This extension is used by the add and update commands.

```
soft_addtime <number>
hard_addtime <number>
```

Specifies the number of seconds that this SA can exist after being added or updated from a larval SA. An update of a mature SA does not reset the initial time that it was added. If this extension is not present, the default value is zero, which means the SA will not expire based on how long it has been since it was added. This extension is used by the add and update commands.
soft_usetime <number>
hard_usetime <number>

Specifies the number of seconds this SA can exist after first being used. If this extension is not present, the default value is zero, which means the SA will not expire based on how long it has been since it was added. This extension is used by the add and update commands.

saddr address | name
srcaddr address | name
saddr6 IPv6 address
srcaddr6 IPv6 address
src address | name
src6 IPv6 address

saddr address and src address are synonyms that indicate the source address of the SA. If unspecified, the source address will either remain unset, or it will be set to a wildcard address if a destination address was supplied. To not specify the source address is valid for IPsec SAs. Future SA types may alter this assumption. This extension is used by the add, update, get and delete commands.

daddr <address>|<name>
dstaddr <address>|<name>
daddr6 <IPv6 address>|<name>
dstaddr6 <IPv6 address>|<name>
dst <addr>|<name>
dst6 <IPv6 address>|<name>

daddr <addr> and dst <addr> are synonyms that indicate the destination address of the SA. If unspecified, the destination address will remain unset. Because IPsec SAs require a specified destination address and spi for identification, this extension, with a specific value, is required for the add, update, get and delete commands.

If a name is given, ipseckey will attempt to invoke the command on multiple SAs with all of the destination addresses that the name can identify. This is similar to how ipsecconf handles addresses.

If dst6 or dstaddr6 is specified, only the IPv6 addresses identified by a name are used.

sport <portnum>
sport specifies the source port number for an SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

dport <portnum>
sport specifies the destination port number for an SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

encap <protocol>
Identifies the protocol used to encapsulate NAT-traversal IPsec packets. Other NAT-traversal parameters (nat_*) are below. The only acceptable value for <protocol> currently is udp.
proto <protocol number>
ulp <protocol number>
    proto, and its synonym ulp, specify the IP protocol number of the SA.

nat_loc <address>|<name>
    If the local address in the SA (source or destination) is behind a NAT, this extension indicates the NAT node's globally-routable address. This address can match the SA's local address if there is a nat_lport (see below) specified.

nat_rem <address>|<name>
    If the remote address in the SA (source or destination) is behind a NAT, this extension indicates that node's internal (that is, behind-the-NAT) address. This address can match the SA's local address if there is a nat_rport (see below) specified.

nat_lport <portnum>
    Identifies the local UDP port on which encapsulation of ESP occurs.

nat_rport <portnum>
    Identifies the remote UDP port on which encapsulation of ESP occurs.

isrc <address> | <name>|[/<prefix>]

innersrc <address> | <name>|[/<prefix>]

isrc6 <address> | <name>|[/<prefix>]

innersrc6 <address> | <name>|[/<prefix>]

proxyaddr <address> | <name>|[/<prefix>]

proxy <address> | <name>|[/<prefix>]
    isrc <address>|[/<prefix>] and innersrc <address>|[/<prefix>] are synonyms. They indicate the inner source address for a tunnel-mode SA.

    An inner-source can be a prefix instead of an address. As with other address extensions, there are IPv6-specific forms. In such cases, use only IPv6-specific addresses or prefixes.

    Previous versions referred to this value as the proxy address. The usage, while deprecated, remains.

idst <address> | <name>|[/<prefix>]

innerdst <address> | <name>|[/<prefix>]

idst6 <address> | <name>|[/<prefix>]

innerdst6 <address> | <name>|[/<prefix>]
    idst <address>|[/<prefix>] and innerdst <address>|[/<prefix>] are synonyms. They indicate the inner destination address for a tunnel-mode SA.

    An inner-destination can be a prefix instead of an address. As with other address extensions, there are IPv6-specific forms. In such cases, use only IPv6-specific addresses or prefixes.
innersport <portnum>
isport <portnum>
innersport specifies the source port number of the inner header for a tunnel-mode SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

innerport |portnum|
idport |portnum|
innerport specifies the destination port number of the inner header for a tunnel-mode SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

iproto |protocol number|iulp |protocol number|
iproto, and its synonym iulp, specify the IP protocol number of the inner header of a tunnel-mode SA.

authkey |hexstring|
Specifies the authentication key for this SA. The key is expressed as a string of hexadecimal digits, with an optional / at the end, for example, 123/12. Bits are counted from the most-significant bits down. For example, to express three ‘1’ bits, the proper syntax is the string "e/3". For multi-key algorithms, the string is the concatenation of the multiple keys. This extension is used by the add and update commands.

encrkey |hexstring|
Specifies the encryption key for this SA. The syntax of the key is the same as authkey. A concrete example of a multi-key encryption algorithm is 3des, which would express itself as a 192-bit key, which is three 64-bit parity-included DES keys. This extension is used by the add and update commands.

reserved_bits |number|
The last |number| bits of the encrkey string are marked as reserved in the PF_KEY message. This option is only for testing certain encryption algorithms.

Certificate identities are very useful in the context of automated key management, as they tie the SA to the public key certificates used in most automated key management protocols. They are less useful for manually added SAs. Unlike other extensions, srcidtype takes two values, a type, and an actual value. The type can be one of the following:

prefix
An address prefix.

fqdn
A fully-qualified domain name.

domain
Domain name, synonym for fqdn.

user_fqdn
User identity of the form user@fqdn.

mailbox
Synonym for user_fqdn.
The value is an arbitrary text string that should identify the certificate.

srcidtype <type, value>
Specifies a source certificate identity for this SA. This extension is used by the add and update commands.

dstidtype <type, value>
Specifies a destination certificate identity for this SA. This extension is used by the add and update commands.

Label extensions are used on Trusted Extensions to associate sensitivity labels with the traffic carried inside a security association. These extensions are not allowed unless Trusted Extensions is enabled.

label label
Defines the sensitivity label of traffic carried by this SA. Disallowed on systems not using Trusted Extensions.

outer-label label
Defines the sensitivity of the ciphertext traffic belonging to this SA; this label will appear in the outer packet header. Disallowed on systems not using Trusted Extensions. Incorrect use of this extension might allow label policy to be circumvented.

implicit-label label
Defines the sensitivity of the ciphertext traffic belonging to this SA and request that this SA not contain an explicit on-the-wire label. Disallowed on systems not using Trusted Extensions. Incorrect use of this extension might allow label policy to be circumvented.

An IPsec SA is a Tunnel Mode SA if the "proto" value is either 4 (ipip) or 41 (ipv6) and there is an inner-address or inner-port value specified. Otherwise, the SA is a Transport Mode SA.

Security
Keying material is very sensitive and should be generated as randomly as possible. Some algorithms have known weak keys. IPsec algorithms have built-in weak key checks, so that if a weak key is in a newly added SA, the add command will fail with an invalid value.

The ipseckey command allows a privileged user to enter cryptographic keying information. If an adversary gains access to such information, the security of IPsec traffic is compromised. The following issues should be taken into account when using the ipseckey command.

1. Is the TTY going over a network (interactive mode)?
   - If it is, then the security of the keying material is the security of the network path for this TTY’s traffic. Using ipseckey over a clear-text telnet or rlogin session is risky.
   - Even local windows might be vulnerable to attacks where a concealed program that reads window events is present.

2. Is the file accessed over the network or readable to the world (-f option)?
   - A network-mounted file can be sniffs by an adversary as it is being read.
   - A world-readable file with keying material in it is also risky.
3. The `ipseckey` command is designed to be managed by the `manualsemkey` `smf(5)` service. Because the `smf(5)` log files are world-readable, the `ipseckey` does not record any syntax errors in the log files, as these errors might include secret information.

   If a syntax error is found when the `manualsemkey` `smf(5)` service is enabled, the service enters maintenance mode. The log file will indicate that there was a syntax error, but will not specify what the error was.

   The administrator should use `ipseckey -c filename` from the command line to discover the cause of the errors. See OPTIONS.

If your source address is a host that can be looked up over the network and your naming system itself is compromised, then any names used will not be trustworthy.

Security weaknesses often lie in misapplication of tools, not in the tools themselves. Administrators are urged to be cautious when using `ipseckey`. The safest mode of operation is probably on a console or other hard-connected TTY.

For further thoughts on this subject, see the afterward by Matt Blaze in Bruce Schneier’s *Applied Cryptography: Protocols, Algorithms, and Source Code in C*.

IPsec manual keys are managed by the service management facility, `smf(5)`. The services listed below manage the components of IPsec. These services are delivered as follows:

- `svc:/network/ipsec/policy:default (enabled)`
- `svc:/network/ipsec/ipsecalgs:default (enabled)`
- `svc:/network/ipsec/manual-key:default (disabled)`
- `svc:/network/ipsec/ike:default (disabled)`

The `manual-key` service is delivered disabled. The system administrator must create manual IPsec Security Associations (SAs), as described in this man page, before enabling that service.

The policy service is delivered enabled, but without a configuration file, so that, as a starting condition, packets are not protected by IPsec. After you create the configuration file `/etc/inet/ipsecinit.conf` and refresh the service (`svcadm refresh`, see below), the policy contained in the configuration file is applied. If there is an error in this file, the service enters maintenance mode. See `ipsecconf(1M)`.

Services that are delivered disabled are delivered that way because the system administrator must create configuration files for those services before enabling them. See `ike.config(4)` for the `ike` service.

See `ipsecalgs(1M)` for the `ipsecalgs` service.

The correct administrative procedure is to create the configuration file for each service, then enable each service using `svcadm(1M)`.

If the configuration needs to be changed, edit the configuration file then refresh the service, as follows:
Warning: To prevent ipseckey complaining about duplicate Associations, the ipseckey command flushes the Security Association Data Base (SADB) when the ipseckey command is run from smf(5), before adding any new Security Associations defined in the configuration file. This differs from the command line behavior where the SADB is not flushed before adding new Security Associations.

The smf(5) framework will record any errors in the service-specific log file. Use any of the following commands to examine the log file property:

```
example# svc -l manual-key
example# svcprop manual-key
example# svccfg -s manual-key listprop
```

The following property is defined for the manual-key service:

```
config/config_file
```

This property can be modified using svccfg(1M) by users who have been assigned the following authorization:

```
solaris.smf.value.ipsec
```

See auths(1), user_attr(4), rbac(5).

The service needs to be refreshed using svcadm(1M) before the new property is effective. General non-modifiable properties can be viewed with the svcprop(1) command.

```
# svccfg -s ipsec/manual-key setprop config/config_file = /new/config_file
# svcadm refresh manual-key
```

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using svcadm(1M). A user who has been assigned the authorization shown below can perform these actions:

```
solaris.smf.manage.ipsec
```

The service's status can be queried using the svcs(1) command.

The ipseckey command is designed to be run under smf(5) management. While the ipseckeyconf command can be run from the command line, this is discouraged. If the ipseckey command is to be run from the command line, the manual-key smf(5) service should be disabled first. See svcadm(1M).

Note that, unlike IPsec and IKE policy and configuration, IPsec keying material is NOT managed by location profiles. This data is assumed to be for the system in general, and will not change when the location changes.
Examples

EXAMPLE 1  Emptying Out All SAs
To empty out all SA:

example# ipseckey flush

EXAMPLE 2  Flushing Out IPsec AH SAs Only
To flush out only IPsec AH SAs:

example# ipseckey flush ah

EXAMPLE 3  Saving All SAs To Standard Output
To save all SAs to the standard output:

example# ipseckey save all

EXAMPLE 4  Saving ESP SAs To The File /tmp/snapshot
To save ESP SAs to the file /tmp/snapshot:

example# ipseckey save esp /tmp/snapshot

EXAMPLE 5  Deleting an IPsec SA
To delete an IPsec SA, only the SPI and the destination address are needed:

example# ipseckey delete esp spi 0x2112 dst 224.0.0.1

An alternative would be to delete the SA and the SAs pair if it has one:

example# ipseckey delete-pair esp spi 0x2112 dst 224.0.0.1

EXAMPLE 6  Getting Information on an IPsec SA
Likewise, getting information on a SA only requires the destination address and SPI:

example# ipseckey get ah spi 0x5150 dst mypeer

EXAMPLE 7  Adding or Updating IPsec SAs
Adding or updating SAs requires entering interactive mode:

example# ipseckey
ipseckey> add ah spi 0x90125 src me.domain.com dst you.domain.com authalg md5 authkey bde359723576fde908e56cbe876e24ad
ipseckey> update ah spi 0x90125 dst you.domain.com hard_bytes 10000000
ipseckey> exit

Adding two SAs that are linked together as a pair:

example# ipseckey
ipseckey> add esp spi 0x2345 src me.domain.com dst you.domain.com authalg md5 authkey bde359723576fde908e56cbe876e24ad
ipseckey>
Adding or Updating IPsec SAs (Continued)

```plaintext
encrkey be02938e7def2839
ipseckey> add esp spi 0x5432 src me.domain.com dst you.domain.com 
    authalg md5 authkey bde359723576fdea08e56cbe876e24ad 
    encrkey be02938e7def2839 pair-spi 0x2345
ipseckey> exit
```

Adding an SA in the Opposite Direction

In the case of IPsec, SAs are unidirectional. To communicate securely, a second SA needs to be added in the opposite direction. The peer machine also needs to add both SAs.

```plaintext
example# ipseckey
ipseckey> add ah spi 0x2112 src you.domain.com dst me.domain.com 
    authalg md5 authkey bde359723576fdea08e56cbe876e24ad 
    hard_bytes 16000000
ipseckey> exit
```

Monitoring PF_KEY Messages

Monitoring for PF_KEY messages is straightforward:

```plaintext
example# ipseckey monitor
```

Using Commands in a File

Commands can be placed in a file that can be parsed with the `-f` option. This file may contain comment lines that begin with the `#` symbol. For example:

```plaintext
# This is a sample file for flushing out the ESP table and
# adding a pair of SAs.
flush esp

### Watch out! I have keying material in this file. See the
### SECURITY section in this manual page for why this can be
### dangerous.
add esp spi 0x2112 src me.domain.com dst you.domain.com 
    authalg md5 authkey bde359723576fdea08e56cbe876e24ad 
    encrkey be02938e7def2839 hard_usetime 28800
add esp spi 0x5150 src you.domain.com dst me.domain.com 
    authalg md5 authkey 930987dbe09743ade09d92b4097d9e93 
    encrkey 8bd4a52e10127deb hard_usetime 28800

## End of file - This is a gratuitous comment
```
EXAMPLE 11 Adding SAs for IPv6 Addresses

The following commands from the interactive-mode create an SA to protect IPv6 traffic between the site-local addresses.

example # ipseckey
ipseckey> add esp spi 0x6789 src6 fec0:bbbb::4483 dst6 fec0:bbbb::7843\  
    authalg md5 authkey bde359723576fdea08e56cbe876e24ad \  
    encralg des encrkey be02938e7def2839 hard_usetime 28800
ipseckey> exit

EXAMPLE 12 Linking Two SAs as a Pair

The following command links two SAs together, as a pair:

example# ipseckey update esp spi 0x123456 dst 192.168.99.2 \  
pair-spi 0x654321

Files /etc/inet/secret/ipseckey

Default configuration file used at boot time. See “Service Management Facility” and SECURITY for more information.

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>

<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

See Also ps(1), svcprop(1), svc(1), ipseccfg(1M), ipsecalgs(1M), route(1M), svcadm(1M),

Diagnostics The ipseckey command parses the configuration file and reports any errors. In the case of multiple errors, ipseckey reports as many of these as possible.

The ipseckey command does not attempt to use a COMMAND that has a syntax error. A COMMAND might be syntactically correct but can nevertheless generate an error because the kernel rejected the request made to pf_key(7P). This might occur because a key had an invalid length or because an unsupported algorithm was specified.

If there are any errors in the configuration file, ipseckey reports the number of valid COMMANDS and the total number of COMMANDS parsed.
Parse error on line $N$.
   If an interactive use of ipseckey would print usage information, this would print instead.
   Usually proceeded by another diagnostic. Because COMMANDS can cover more than a single
   line in the configuration file by using the backslash character to delimit lines, it's not always
   possible to pinpoint in the configuration file the exact line that caused the error.

Unexpected end of command line.
   An additional argument was expected on the command line.

Unknown
   A value for a specific extension was unknown.

Address type $N$ not supported.
   A name-to-address lookup returned an unsupported address family.

$N$ is not a bit specifier
$N$ is too big for
string is not a hex string
   Keying material was not entered appropriately.

Can only specify single
   A duplicate extension was entered.

Don't use extension for <string> for <command>.
   An extension not used by a command was used.

One of the entered values is incorrect: Diagnostic code NN: <msg>
   This is a general invalid parameter error. The diagnostic code and message provides more
detail about what precise value was incorrect and why.

Notes
   In spite of its IPsec-specific name, ipseckey is analogous to route(1M), in that it is a
   command-line interface to a socket-based administration engine, in this case, PF_KEY. PF_KEY
   was originally developed at the United States Naval Research Laboratory.

   To have machines communicate securely with manual keying, SAs need to be added by all
   communicating parties. If two nodes wish to communicate securely, both nodes need the
   appropriate SAs added.

   In the future ipseckey may be invoked under additional names as other security protocols
   become available to PF_KEY.

   This command requires sys_ip_config privilege to operate and thus can run in the global
   zone and in exclusive-IP zones. The global zone can set up security associations with
   ipseckey to protect traffic for shared-IP zones on the system.
iscsiadm – enable management of iSCSI initiators

**Synopsis**  
iscsiadm subcommand direct-object [options] [operand]

**Description**  
The `iscsiadm` command enables management of the iSCSI (Internet SCSI) initiator on a host. `iscsiadm` is implemented as a set of subcommands, many with their own options, which are described in the section for that subcommand. Options not associated with a particular subcommand are described under OPTIONS.

`iscsiadm` works only when the following service is online:

```
svc:/network/iscsi/initiator:default
```

The `iscsiadm` command supports the following subcommands, which are described in detail in subsections that follow:

- **add**: Adds element(s) to an object.
- **list**: Lists element(s) of an object.
- **modify**: Modifies attributes of an object.
- **remove**: Removes an element from an object.

The `iscsiadm` subcommands operate on a *direct-object*. These are described in the section for each subcommand.

The `iscsiadm` command supports the Internet Storage Name Service (iSNS) for the discovery of iSCSI targets. The command supports the Challenge Handshake Authentication Protocol (CHAP) for authentication.

**add Subcommand**  
The syntax for the `add` subcommand is:

```
# iscsiadm add direct_object [operands...]
```

The `add` subcommand adds the following *direct_objects*:

```
discovery-address discovery-address [...]  
```

Adds a target to a list of discovery addresses. A discovery address (as in the syntax shown below) is an IP address:port combination used in a SendTargets discovery session. Using this discovery approach, a target device can inform an initiator of the target address and target name of each target exposed by that device. Connection to a target is not attempted unless the SendTargets method of discovery has been enabled on the host. You enable this method with the `modify` subcommand.

The `discovery-address` parameter is formatted as:

```
<IP address>[:port]
```

If `port` is not specified, the default of 3260 will be used.
isns-server isns-server [...]  
Add an iSNS server to the list of iSNS server addresses. An iSNS server address (specified in the syntax shown below) is an IP address-port combination used in an iSNS discovery session. By using iSNS discovery, an iSNS server can provide an initiator with information about a portal and the name of each target that belongs to the same discovery domain as that of the initiator. Connection to the iSNS server is not attempted unless the iSNS method of discovery has been enabled on the host. You enable this method with the modify subcommand, described below.

The isns-server parameter is formatted as:

IP_address[ :port ]  
If a port is not specified, the default of 3205 is used.

static-config static_target [...]  
Adds a target to the list of statically configured targets. A connection to the target will not be attempted unless the static configuration method of discovery has been enabled.

The static_target parameter is formatted as:

<target-name>, <target address>[ :port-number], tgt
<target-name> can be up to 223 characters.

list Subcommand  
The syntax for the list subcommand is:

# iscsiadm list direct-object [options]

The list subcommand displays data for the following direct-objects:

discovery  
Lists the discovery methods and their current activation state, enabled or disabled. Discovery methods are:

- iSNS (Internet Storage Name Service)
- Static
- SendTargets

initiator-node  
Lists information for the initiator node on the host. The iSCSI initiator node represents a logical HBA and is a logical host connection point for iSCSI targets. The parameter values listed in the response are default parameter settings for the initiator. Each connected target for an initiator can have parameter values that differ from the parameter values on the initiator node.

static-config [static_target[, ...]]  
Lists the target name and address for specified targets or, if no static targets are specified, all statically discovered targets.
target [-S] [-v] [target[...]]
Lists a target's current parameters, connection state, and which method was used for the
target's discovery. Reports information for specified targets or, if no targets are specified, all
targets that have been discovered or have had parameters modified by the modify target
subcommand.

When used with the -S option for a specified target, this subcommand returns:
- target name
- logical unit number
- vendor ID
- product ID
- OS device name (for example, /dev/rdsk/c0t2d0s0)
The -v option gives more details, such as the current login parameters, the detailed
connection information, and the discovery method used to discover the target.

A return of NA as the discovery method parameter indicates that the target was created with
a iscsiadm modify target-param command and does not exist as a discovered object. To
remove such targets, use iscsiadm remove target-param.

target-param [-v] target [...]
Lists a target's default and user-defined parameters.
discovery-address [-v] [discovery-address[...]]
Lists the discovery-address objects that have been added using the iscsiadm add
discovery-address subcommand.

When used with the -v option, lists all known targets at a specified discovery-address. The
-v option returns one or more target names along with zero or more target addresses and
associated target portal group tags (TPGT), if applicable.

isns-server [-v] [isns-server[...]]
Lists the isns-server objects that have been added using the iscsiadm add isns-server
subcommand.

When used with the -v option, this subcommand lists all known targets at a specified
isns-server address. The -v option returns one of more target names along with zero or
more target addresses and associated target portal group tags, if applicable.

modify Subcommand
The syntax for the modify subcommand is:

# iscsiadm modify direct_object [options]

The modify subcommand supports the following direct_objects:
discovery [options]
Enabling a discovery method initiates a discovery using that method. Disabling a discovery
method that is currently enabled does not affect connections to any targets that have
already been discovered by that method.
Options for modify discovery are as follows:

- `i`, `--iSNS enable` | `disable`
  Enable or disable iSNS discovery.

- `s`, `--static enable` | `disable`
  Enable or disable static discovery.

- `t`, `--sendtargets enable` | `disable`
  Enable or disable SendTargets discovery.

**initiator-node [options]**

Modifies an initiator’s properties. If a target is currently connected, this operation can succeed. However, the modified set of parameters will not be in effect for that target until an existing connection session no longer exists and a new connection has been established. The options `-C` and `--CHAP-secret` require a CHAP secret entry in response to a prompt.

For iSCSI booting when the Solaris I/O multipathing feature (formerly known as Sun StorEdge Traffic Manager [STMS] or MPxIO) is disabled, you can modify only the following initiator-node options:

- `-r`, `--radius-server`
- `-R`, `--radius-access`
- `-P`, `--radius-shared-secret`

For iSCSI booting when the Solaris I/O multipathing feature is enabled, you can modify only the following initiator-node options:

- `-h`, `--headerdigest`
- `-d`, `--datadigest`
- `-c`, `--configured-sessions`

Options for modify initiator-node are as follows:

- `-A`, `--node-alias <initiator node alias>`
  Modifies the initiator node alias. Maximum length of 223 characters.

- `-a`, `--authentication chap` | `none`
  Sets the authentication mode.

- `-C`, `--CHAP-secret`
  Sets the CHAP secret value. There is no default value. Maximum length is 16 characters; minimum required length is 12 characters.

- `-c`, `--configured-sessions <num_sessions> | <IP address> [,<IP address>...]`
  Sets the number of configured iSCSI sessions that will be created for each iSCSI target. The feature should be used in combination with the Solaris I/O multipathing feature described in `scsi_vhci(7D)`.

- `-d`, `--datadigest none` | CRC32
  Sets whether CRC32 is enabled to check SCSI data transfers.
-H, -CHAP-name  CHAP name
  Specifies a CHAP username. If you do not use this option, upon initialization, the CHAP
  name is set to the initiator node name. When the authentication method is set to CHAP
  (see -a/--authentication option, above), the CHAP username is displayed with the
  command iscsiadm list initiator-node.

-h, --header-digest none | CRC32
  Sets whether CRC32 is enabled to check SCSI packet headers.

-m, --max-connections  number_connections
  Modifies the maximum connection number for iSCSI sessions. The default value is 1.
  The maximum number of connections for each session is 65535.

-N, --node-name  <initiator node name>
  Modifies the initiator node name. Maximum of 223 characters.

Note – During Solaris installation, the initiator node name is set to a globally unique
value. Changing this value can adversely affect operation within the iSCSI network.

-P, --radius-shared-secret (exclusive)
  Sets the RADIUS shared secret.

-R, --radius-access enable | disable
  Sets whether a RADIUS server will be used.

-r, --radius-server <IP address>[::<port>]
  Sets the IP address and port of the radius server to be used.

-T, --tunable-param <<tunable-prop>=<value>,...>
  Specify one or more tunable parameters for all targets that initiator node connected.

Note – These values should only be modified by an administrator with a good working
knowledge of the parameter’s impact within the iSCSI network.

Supported tunable-prop options are:

recv-login-rsp-timeout
  Session Login Response Time

  The recv-login-rsp-timeout option specifies how long iSCSI initiator will wait for
  the response of iSCSI session login request from the iSCSI target. Valid value is from
  0 to 60*60, default to 60 seconds.

conn-login-max
  Maximized Connection Retry Time

  The conn-login-max option lets the iSCSI initiator reestablish the connection to the
target in case of IO timeout or connection failure during the given time window.
  Valid value is from 0 to 60*60, default to 180 seconds.
polling-login-delay
Login Retry Time Interval

The polling-login-delay option specifies the time interval between each login retry when iSCSI initiator to target IO timeout or connection failure. Valid value is from 0 to 60*60, default to 60 seconds.

target-param [options] target
Modifies a target's parameters. If a target is currently connected, the modify operation will succeed, although the modified settings might not take effect for a few seconds. To confirm that these settings are active, use iscsiadm list target -v. If a specified target is not associated with any discovery method, a target object is created with the specified parameters. After using this command to modify a target's parameters, the new parameters will persist until they are modified or removed with a iscsiadm remove target-param command on that target. The options -C and --CHAP-secret require a CHAP secret entry in response to a prompt.

Options for modify target-param are as follows:
- B, --bi-directional-authentication enable | disable
  Sets the bidirectional option. If set to enable, the initiator performs bidirectional authentication for the specified target.
- C, --CHAP-secret
  Sets the target's CHAP secret value. There is no default value. Maximum acceptable length is 16 characters.
- c, --configured-sessions <num_sessions> | <IP address>[,<IP address>...]
  Sets the number of configured iSCSI sessions that will be created for each iSCSI target. The feature should be used in combination with the Solaris I/O multipathing feature described in scsi_vhci(7D).
- d, --datadigest none | CRC32
  Sets whether CRC32 is enabled or disabled for the data.
- H, --CHAP-name CHAP name
  Sets a CHAP username. If you do not use this option, upon initialization, the CHAP name is set to the target name. When the authentication method is set to CHAP (see -a/--authentication option, under the initiator-node direct object, above), the CHAP username is displayed with the command iscsiadm list initiator-node.
- h, --headerdigest none | CRC32
  Sets whether CRC32 is enabled or disabled for the header.
- p, --login-param
  Specify one or more login parameter settings.

Note – These values should only be modified by an administrator with a good working knowledge of the parameter's impact within the iSCSI network.
The login parameters are derived from iSCSI proposed standard RFC 3720. Valid values are:

- `dataseqinorder` yes or no
- `defaulttime2retain` 0–3600
- `defaulttime2wait` 0–3600
- `firstburstlength` 512 to $2^{24} - 1$
- `immediatedata` yes or no
- `initialr2t` yes or no
- `maxburstlength` 512 to $2^{24} - 1$
- `datapduinorder` yes or no
- `maxoutstandingr2t` 1 to 65535
- `maxrecvdataseglen` 512 to $2^{24} - 1$

```
-T, --tunable-param <<tunable-prop>>=<value>, ...
```

Specify one or more tunable parameters for all targets that initiator node connected.

**Note** – Tunable values should only be modified by an administrator with a good working knowledge of the parameter’s impact within the iSCSI network.

Supported `tunable-prop` options are:

- `recv-login-rsp-timeout` Session Login Response Time
  
  The `recv-login-rsp-timeout` option specifies how long iSCSI initiator will wait for the response of iSCSI session login request from the iSCSI target. Valid value is from 0 to 60*60, default to 60 seconds.

- `conn-login-max` Maximized Connection Retry Time
  
  The `conn-login-max` option lets the iSCSI initiator reestablish the connection to the target in case of IO timeout or connection failure during the given time window. Valid value is from 0 to 60*60, default to 180 seconds.

- `polling-login-delay` Login Retry Time Interval
  
  The `polling-login-delay` option specifies the time interval between each login retry when iSCSI initiator to target IO timeout or connection failure. Valid value is from 0 to 60*60, default to 60 seconds.
The syntax for the remove subcommand is:

```
# iscsiadm remove direct_object
```

The remove subcommand supports the following `direct_object`

```
discovery-address discovery-address, ...
```

Removes a target device from the list of discovery addresses. A discovery address (as in the syntax shown below) is an IP address-port combination used in a SendTargets discovery session. Using this discovery approach, a target device can inform an initiator of the target address and target name of each target exposed by that device. If any target exposed by the discovery address is currently mounted or there is active I/O on the device, an error of "logical unit in use" is returned and the operation fails. If the associated devices are not in use, they are removed.

`discovery-address` must be formatted as:

```
<IP address>[:<port>]
```

There are no options associated with this direct object.

```
isns-server isns-server, ...
```

Removes an iSNS server from the list of iSNS server addresses. An iSNS server address (specified in the syntax shown below) is an IP address-port combination used in an iSNS discovery session. By using iSNS discovery, an iSNS server can provide an initiator with information about a portal and the name of each target that belongs to the same discovery domain as that of the initiator. If any target discovered by means of iSNS is currently mounted or there is active I/O on the device, an error of "logical unit in use" is returned and the operation fails. If the associated devices are not in use, they are removed.

`isns-server` must be formatted as:

```
IP_address[:<port>]
```

There are no options associated with this direct object.

```
static-config static_target, ...
```

Removes a target from the list of statically discovered targets. If the target being removed is currently mounted or there is active I/O on the device, an error of "logical unit in use" is returned and the operation fails. If a device is not in use, it will be removed.

`static_target` must be formatted as:

```
<target-name>,<target-address>[:<port-number]>[,,tpgt]
```

There are no options associated with this direct object.

```
target-param target-name
```

Removes target specified by `target-name`. The target name is formatted as:

```
<target-name>
```
There are no options associated with this direct object. For iSCSI booting when the Solaris I/O multipathing feature (formerly known as Sun StorEdge Traffic Manager [STMS] or MPxIO) is enabled, you cannot remove the target.

Do not configure a target to be discovered by both static and dynamic discovery methods. The consequence of using redundant discovery methods might be slow performance when communicating with the iSCSI target device.

The following generic options are supported:

- **-V, --version** Displays version information. Stops interpretation of subsequent arguments.

- **-?, --help** Displays help information. Can be used following an `iscsiadm` command with no arguments, following a subcommand, or following a subcommand-direct object combination. Responds with help information appropriate for your entry. For example, if you enter:

  ```
  # iscsiadm modify initiator-node --help
  ...
  ```

  `iscsiadm` responds with a display of the options available for that combination of subcommand and direct object.

**Examples**

**EXAMPLE 1** Adding a Discovery Address
The following command uses the add subcommand to add a discovery address.

```
# iscsiadm add discovery-address 10.0.0.1:3260 10.0.0.2:3260
```

**EXAMPLE 2** Adding a Static Target
The following command uses the add subcommand to add a static target.

```
# iscsiadm add static-config \
  iqn.1999-08.com.array:sn.01234567,10.0.0.1:3260
```

**EXAMPLE 3** Listing Current Discovery Settings
The following command uses the list subcommand to list current discovery settings.

```
# iscsiadm list discovery

  Discovery:
    Static: enabled
    Send Targets: disabled
    iSNS: enabled
```

**EXAMPLE 4** Obtaining Verbose Discovery Output
The following commands use the -v option (one with, one without) with the list subcommand to obtain verbose output.
EXAMPLE 4  Obtaining Verbose Discovery Output  (Continued)

# iscsiadm list discovery-address
Discovery Address: 10.0.0.1:3260
Discovery Address: 10.0.0.2:3260

# iscsiadm list discovery-address -v 10.0.0.1:3260
Discovery Address: 10.0.0.1:3260
  Target name: eui.210000203787d1f7
  Target address: 10.0.0.1:3260
  Target name: eui.210000203787a693
  Target address: 10.0.0.1:3260

EXAMPLE 5  Displaying Information on the Initiator
The following command uses the list subcommand to display information on the initiator.

# iscsiadm list initiator-node
Initiator node name: iqn.1986-03.com.company.central.interopv20-1
Initiator node alias: interopv20-1
  Login Parameters (Default/Configured):
    Header Digest: NONE/NONE
    Data Digest: NONE/NONE
  Authentication Type: CHAP
    CHAP Name: iqn.1986-03.com.company.central.interopv20-1
  RADIUS Server: NONE
  RADIUS access: disabled
  Tunable Parameters (Default/Configured):
    Session Login Response Time: 60/-
    Maximum Connection Retry Time: 180/-
    Login Retry Time Interval: 60/-
  Configured Sessions: 1

EXAMPLE 6  Displaying Static Configuration Information
The following command uses the list subcommand to display information about static configurations.

# iscsiadm list static-config
Static target: eui.210000203787a693,10.0.0.1:3260

EXAMPLE 7  Displaying Target Information
The following commands show the use of the list subcommand with various options to display information about targets.

# iscsiadm list target
  Alias: -
**EXAMPLE 7  Displaying Target Information (Continued)**

TPGT: 12288  
ISID: 4000002a0000  
Connections: 1

```
# iscsiadm list target -v iqn.2004-05.com.abcStorage:Tgt-1
```

Alias: -  
TPGT: 12288  
ISID: 4000002a0000  
Connections: 1  
CID: 0  
  IP address (Local): 10.4.52.158:32803  
  IP address (Peer): 10.4.49.70:3260  
  Discovery Method: SendTargets  
  Login Parameters (Negotiated):  
    Data Sequence In Order: yes  
    Data PDU In Order: yes  
    Default Time To Retain: 20  
    Default Time To Wait: 2  
    Error Recovery Level: 0  
    First Burst Length: 65536  
    Immediate Data: yes  
    Initial Ready To Transfer (R2T): yes  
    Max Burst Length: 262144  
    Max Outstanding R2T: 1  
    Max Receive Data Segment Length: 65536  
    Max Connections: 1  
    Header Digest: NONE  
    Data Digest: NONE

```
# iscsiadm list target -S iqn.2004-05.com.abcStorage:Tgt-1
```

Alias: -  
TPGT: 12288  
ISID: 4000002a0000  
Connections: 1  
LUN: 6  
  Vendor: ABCStorage  
  Product: iSCSI Target  
  OS Device Name: /dev/rdsk/c3t1d0s2

LUN: 5  
  Vendor: ABCStorage  
  Product: iSCSI Target  
  OS Device Name: /dev/rdsk/c3t0d0s2

**EXAMPLE 8  Displaying Target Parameter Information**

The following command uses the list subcommand to display target information for a specific target.
EXAMPLE 8  Displaying Target Parameter Information  (Continued)

```
# iscsiadm list target-param -v iqn.2004-05.com.abcStorage:Tgt-1
   Alias: -
   Bi-directional Authentication: disabled
   Authentication Type: NONE
   Login Parameters (Default/Configured):
      Data Sequence In Order: yes/-
      Data PDU In Order: yes/-
      Default Time To Retain: 20/-
      Default Time To Wait: 2/-
      Error Recovery Level: 0/-
      First Burst Length: 65536/-
      Immediate Data: yes/-
      Initial Ready To Transfer (R2T): yes/-
      Max Burst Length: 262144/-
      Max Outstanding R2T: 1/-
      Max Receive Data Segment Length: 65536/-
      Max Connections: 1/-
      Header Digest: NONE/-
      Data Digest: NONE/-
   Tunable Parameters (Default/Configured):
      Session Login Response Time: 60/-
      Maximum Connection Retry Time: 180/-
      Login Retry Time Interval: 60/-
   Configured Sessions: 1
```

EXAMPLE 9  Enabling Static Discovery Method

The following command uses the `modify` subcommand to enable the static discovery method.

```
# iscsiadm modify discovery --static enable
```

EXAMPLE 10  Setting the IP Address for the Radius Server

The following command uses the `modify` subcommand to set the IP address for the radius server, which will be used for CHAP authentication.

```
# iscsiadm modify initiator --radius-server 10.0.0.1
```

EXAMPLE 11  Setting the Node Name for Initiator

The following command uses the `modify` subcommand to set the node name for the initiator node.

```
# iscsiadm modify initiator-node -N iqn.2004-10.com.SUN.host-1
```
EXAMPLE 12  Setting Max Connections for the Initiator Node

The following command uses the modify subcommand to set the max connection number for the initiator node. This enables multiple connections to exist in one session.

# iscsiadm modify initiator-node -m 3

EXAMPLE 13  Changing Target Parameters

The following command uses the modify subcommand to change the max connection number of the target parameters for a specified target.

# iscsiadm modify target-param -m 3 eui.210000203787a693

EXAMPLE 14  Removing a Discovery Address

The following command uses the remove subcommand to remove a discovery address.

# iscsiadm remove discovery-address 10.0.0.1:3260

EXAMPLE 15  Removing Target Parameters

The following command uses the remove subcommand to remove a set of target parameters.

# iscsiadm remove target-param eui.210000203787a693

EXAMPLE 16  Modifying Maximum Connection Number

The following command modifies the maximum number of connections for each session in the initiator's property. The modified value will be used in all sessions, to all targets.

# iscsiadm modify initiator-node --max-connections 4

Oracle Solaris 11.1 Administration: Devices and File Systems
The Internet Storage Name Service (iSNS) provides consolidated discovery services for Internet SCSI (iSCSI) and Internet Fibre Channel Protocol (iFCP) devices in an IP network. iSNS uses a client/server mechanism: servers store configuration information for clients, and provide that information upon a client's request. IETF RFC 4171 describes the protocols between the server and client.

This man page provides a summary of the Solaris iSNS server implementation. The current implementation does not support iFCP devices.

Solaris iSNS server is implemented as the daemon `isns`, which binds to the well-known port 3205 to service client requests. The daemon is started by the service management facility (`smf(5)`), using the fault management resource identifier (FMRI):

```
svc:/network/isns_server
```

Use `svcadm(1M)` to enable `isns`. Enabling the service means that it starts and runs automatically whenever the operating system is booted. The state of service can be displayed with the `svcs(1)` command.

The service properties listed below can be managed using `svccfg(1M)`. The default value is assigned per RFC 4171 and implementation choice.

- **data_store_location**
  Configuration data store location. The default location is `/etc/isns/isnsdata.xml`.

- **ESI_retry_threshold_count**
  Entity Status Inquiry retry threshold counter. The default count is 3.

- **Management_SCNs_Enabled**
  Boolean that determines whether Management State Change Notification is enabled. The default is `yes`.

- **Authorized_Control_Nodes**
  Control node names.

After changing a property value, you must use `svcadm(1M)` `refresh` to enable `isns` to recognize the new value. If you change the `data_store_location` property, you must enter a `svcadm restart` command for the change to take effect.

RFC 4171 defines the default discovery domain, the default domain set, and the “Default DD/DDS” setting with the intent of managing clients that have not been assigned to any user-defined discovery domain. The server adopts the following behaviors with respect to the default discovery domain and domain set:

- An unassigned client is added to the default discovery domain. A newly registered client or a client that was removed from its last discovery domain membership is considered to be an unassigned client.
- When a client gets assigned to a user-defined discovery domain, the server will remove the client from the default discovery domain.
- The default discovery domain set is allowed to be administratively activated or deactivated in order to let the administrator control discovery among clients in the default discovery domain.
- It is not allowed to administratively add a client to the default discovery domain, nor to administratively add a user-defined discovery domain to the default discovery domain set.
- The default state of the Default discovery domain set is inactive.

The isns server supports certain `rbac(5)` authorizations that allow you to administer isns activity. These authorizations include the following `auth_attr(4)` privileges:

`solaris.isnsmgr.write`
- Required to create a discovery domain or domain set, to enable/disable a discovery domain set and to change grouping of iSNS clients in a discovery domain or grouping of discovery domains in a discovery domain set.

`solaris.smf.manage.isns`
- Required to manage the isns server through the `smf(5)`.

`solaris.smf.value.isns`
- Required to change the SMF service properties associated with isns.

The iSNS Server Management profile (see `prof_attr(4)`) includes all of the preceding authorizations. See `rbac(5)` for an overview of roles and authorizations.

**Options** There are no options supported by the isns daemon.

**Examples**

**EXAMPLE 1** Starting an isns Server
The following command starts the isns server.

```# svcadm enable svc:/network/isns_server```

**EXAMPLE 2** Stopping an isns Server
The following command stops the isns server.

```# svcadm disable svc:/network/isns_server```

**EXAMPLE 3** Changing an isns Property
The following sequence of commands changes the value of the `ESI_retry_threshold_count` property.

```# svccfg -s svc:/network/isns_server setprop \
config/ESI_retry_threshold_count = 6
# svcadm refresh svc:/network/isns_server```
Files
/usr/sbin/isns
iSNS daemon binary.

Notes
It is strongly recommended that you restart the server (svcadm restart) after a service property is changed. This allows the server to apply a uniform setting for existing and new clients.

A control node, as described in RFC 4171, is not required to administer the server. Control node operations can be achieved through the isnsadm(1M) command interface on the local host. For example, isnsadm enables you to create a discovery domain and a discovery domain set and to add a member to it, in order to create discovery domain and discovery domain set associations.
**Synopsis**

```
isnsadm options

isnsadm subcommand [subcommand_options] [operand]
```

**Description**

The `isnsadm` command is the command-line interface to the Internet Storage Name Service (iSNS) server. `isnsadm` comprises a set of subcommands, described in their own section, each of which accomplishes one of the iSNS server management functions.

For any operations that will change the iSNS configurations the `solaris.isnsmgr.write` authorization is required. Refer to `isns(1M)`. For read operations, the command does not require special authorizations.

`isnsadm` has a set of general options and a set of subcommand-specific options. The first category is described under OPTIONS; the second category is described in the context of each subcommand description.

**Options**

The following options are supported:

- `-?`, `--help`
  - Displays context help. Stops interpretation of any subsequent arguments.

- `-V`, `--version`
  - Displays version information. Stops interpretation of any subsequent arguments.

**Operands**

The following operands are used by one or more `isnsadm` subcommands.

- `iscsi-node-name`
  - iSCSI target or iSCSI initiator symbolic name. A string with a maximum length of 223 characters.

- `discovery-domain-name`
  - Discovery domain symbolic name. A string with a maximum length of 256 characters.

- `discovery-domain-set-name`
  - Discovery domain set symbolic name. A string with a maximum length of 256 characters.

**Subcommands**

The `isnsadm` command supports the subcommands described below.

**add-dd**

The `add-dd` subcommand adds a discovery domain to a discovery domain set.

The `add-dd` subcommand has the following syntax:

```
# isnsadm add-dd option discovery-domain-name, ...
```

`add-dd` has the following option:

- `-s discovery-domain-set-name`
  - Specifies a discovery domain set.
add-node  The add-node subcommand adds a node to a specified discovery-domain.

The add-node subcommand has the following syntax:

```
# isnsadm add-node option iscsi-node-name, ...
```

add-node has the following options:

- `-d`, `--dd discovery-domain-name`
  Specifies a discovery domain.

create-dd  The create-dd subcommand creates a discovery domain with the name you specify.

The create-dd subcommand has the following syntax:

```
# isnsadm create-dd discovery-domain-name, ...
```

create-dd has no options.

create-dd-set  The create-dd-set subcommand creates a discovery domain set with the name you specify.

The create-dd-set subcommand has the following syntax:

```
# isnsadm create-dd-set discovery-domain-set-name, ...
```

create-dd-set has no options.

delete-dd  The delete-dd subcommand deletes a discovery domain of the name you specify.

The delete-dd subcommand has the following syntax:

```
# isnsadm delete-dd discovery-domain-name, ...
```

delete-dd has no options.

delete-dd-set  The delete-dd-set subcommand deletes a discovery domain set of the name you specify.

The delete-dd-set subcommand has the following syntax:

```
# isnsadm delete-dd-set discovery-domain-set-name, ...
```

delete-dd-set has no options.

disable-dd-set  The disable-dd-set subcommand disables a discovery domain set.

The disable-dd-set subcommand has the following syntax:

```
# isnsadm disable-dd-set discovery-domain-set-name, ...
```

disable-dd-set has no options.
The `enable-dd-set` subcommand enables a discovery domain set.

The `enable-dd-set` subcommand has the following syntax:

```
# isnsadm enable-dd-set discovery-domain-set-name, ...
```

`enable-dd-set` has no options.

The `list-dd` subcommand displays information about discovery domains. If no operand is specified, it lists all discovery domains that currently exist on the iSNS server.

The `list-dd` subcommand has the following syntax:

```
# isnsadm list-dd [option] [discovery-domain-name, ...]
```

`list-dd` supports the following option:

```
-v, --verbose
   Displays the member contents of the discovery domain(s).
```

The `list-dd-set` subcommand lists the discovery domain sets, both enabled and disabled, that exist on the iSNS server. Note that there is no `dd-set` registration. If no operand is specified, it lists all of the discovery domain sets.

The `list-dd-set` subcommand has the following syntax:

```
# isnsadm list-dd-set [option] [discovery-domain-set-name, ...]
```

`list-dd-set` supports the following option:

```
-v, --verbose
   Shows all discovery domains within the discovery domain set.
```

The `list-node` subcommand displays information about nodes that are currently registered with the iSNS server or that are not registered and belong to non-default discovery-domain(s). For the latter case, the node has its type field shown as `unknown`. If no operand is specified, `list-node` lists all nodes known by the iSNS server.

The `list-node` subcommand has the following syntax:

```
# isnsadm list-node [options] [iscsi-node-name, ...]
```

`list-node` supports the following options:

```
-t, --target
   Filters the list to display only iSCSI target nodes.

-i, --initiator
   Filters the list to display only iSCSI initiator nodes.

-v, --verbose
   Displays details about a node. Without this option, only the name, alias, and type information are displayed.
```
modify-dd

The `modify-dd` subcommand modifies an attribute of a specified discovery domain.

The `modify-dd` subcommand has the following syntax:

```
# isnsadm modify-dd option discovery-domain-name
```

`modify-dd` has the following option:

- `-n discovery-domain-name`
  Specifies the new name of a discovery domain to be applied to an existing discovery-domain.

modify-dd-set

The `modify-dd-set` subcommand modifies a discovery domain set.

The `modify-dd-set` subcommand has the following syntax:

```
# isnsadm modify-dd-set option discovery-domain-set-name
```

`modify-dd-set` has the following option:

- `-n discovery-domain-set-name`
  Specifies the new name of a discovery domain set to be applied to an existing discovery-domain-set.

remove-dd

The `remove-dd` subcommand removes the association with a specified discovery domain set.

The `remove-dd` subcommand has the following syntax:

```
# isnsadm remove-dd option discovery-domain-name, ...
```

`remove-dd` has the following option:

- `-s discovery-domain-set-name`
  Specifies the discovery domain set from which the discovery domain will be removed.

remove-node

The `remove-node` subcommand removes a node.

The `remove-node` subcommand has the following syntax:

```
# isnsadm remove-node option iscsi-node-name, ...
```

`remove-node` has the following option:

- `-d discovery-domain-name`
  Specifies the discovery domain from which a node will be removed.

show-config

The `show-config` subcommand displays the iSNS server administrative settings. Note that the setting can be modified by means of the service management facility (see `smf(5)`). Refer to `isns(1M)`.

The `show-config` subcommand has the following syntax:

```
# isnsadm show-config
```
show-config has no options.

Examples

**EXAMPLE 1**  Displaying Clients

The following use of the `list-node` subcommand displays clients.

```
# isnsadm list-node -v
```

```

</tr>
</tbody>
</table>
```

**EXAMPLE 3**  Adding a Node

The following use of the `add-node` subcommand adds a node to a discovery domain, creating a discovery domain membership.
EXAMPLE 3  Adding a Node  (Continued)

# isnsadm add-node -d engineering-dd \
  iqn.1986-03.com.sun:01:000e0c9f10da.454F00A2.engr

EXAMPLE 4  Removing a Node

The following use of the remove-node subcommand removes a node from a discovery domain, thereby removing a discovery domain membership.

# isnsadm remove-node -d acct-dd \
  iqn.1986-03.com.sun:01:000e0c9f10da.454F00A2.acct

EXAMPLE 5  Creating a Discovery Domain Set

The following use of the create-dd-set subcommand creates a discovery domain set.

# isnsadm create-dd-set operation-dd-set

EXAMPLE 6  Displaying a Discovery Domain Set

The following use of the list-dd-set subcommand displays discovery domain sets.

# isnsadm list-dd-set -v

DD Set name: Default
  State: Disabled
  DD Name: Default
DD Set name: operation-dd-set
  State: Disabled

EXAMPLE 7  Adding a Discovery Domain

The following use of the add-dd subcommand adds a discovery domain to a discovery domain set.

# isnsadm add-dd -s operation-dd-set engineering-dd

EXAMPLE 8  Displaying a Discovery Domain Set

The following use of the list-dd-set displays the attributes of a discovery domain set.

# isnsadm list-dd-set

DD Set name: Default
  State: Disabled
  DD Name: Default
DD Set name: operation-dd-set
  State: Disabled
  DD Name: engineering-dd
EXAMPLE 9  Enabling a Discovery Domain Set
The following use of the `enable-dd-set` subcommand enables a discovery domain set.

```
# isnsadm enable-dd-set Default
```

EXAMPLE 10  Disabling a Discovery Domain Set
The following use of the `disable-dd-set` subcommand disables a discovery domain set.

```
# isnsadm disable-dd-set Default
```

EXAMPLE 11  Displaying Administrative Settings
The following use of the `show-config` subcommand displays current administrative settings.

```
# isnsadm show-config
Data Store Location: /etc/isns/isnsdata.xml
Entity Status Inquiry Non-Response Threshold: 3
Management SCN Enabled: yes
Authorized Control Node Names: -
```

Attributes  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/storage/isns</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Volatile</td>

</tbody>
</table>

See Also  `iscsiadm(1M), isns(1M), attributes(5), smf(5)`

Notes  When a subcommand is invoked with multiple operands and there are failures on one or more, but not all, operands, `isnsadm` displays a generic message indicating partial failure, with list of failed operands. An error on a specific operand can be found by issuing the same subcommand on the failing operand.
Name  itadm – administer iSCSI targets

Synopsis  itadm create-target [-a, --auth-method radius | chap | none | default] [-s, --chap-secret [S, --chap-secret-file path]] [-u, --chap-user chap-user-name] [-n, --node-name target_node_name] [-l, --alias alias] [-t, --tpg tpg-name[tpg-name]]

itadm modify-target [-a, --auth-method radius | chap | none | default] [-s, --chap-secret [-S, --chap-secret-file path]] [-u, --chap-user chap-user-name] [-n, --node-name new_target_node_name] [-l, --alias alias] [-t, --tpg tpg-name[tpg-name]]

itadm delete-target [-f, --force] target_node_name

itadm list-target [-v, --verbose] [target_node_name]

itadm create-tpg tpg_name IP-address[:port] [IP-address[:port]]...

itadm list-tpg [-v, --verbose] [tpg_name]

itadm delete-tpg [-f, --force] tpg_name

itadm create-initiator [-s, --chap-secret [S, --chap-secret-file path]] [-u, --chap-user chap-user-name] initiator_node_name

itadm modify-initiator [-s, --chap-secret [S, --chap-secret-file path]] [-u, --chap-user chap-user-name] initiator_node_name

itadm list-initiator [-v, --verbose] initiator_node_name

itadm delete-initiator initiator_node_name

itadm modify-defaults [-a, --auth-method radius | chap | none] [-r, --radius-server IP-address[:port]] [-d, --radius-secret] [-D, --radius-secret-file path][-i, --isns enable | disable] [-I, --isns-server IP-address[:port]][,IP-address[:port]]

itadm list-defaults

Description  The itadm command manages Internet SCSI (iSCSI) target nodes within the SCSI Target Mode Framework described in stmfadm(1M) and libstmf(3LIB). This allows the iSCSI initiators to access STMF logical units using the iSCSI protocol. In addition to iSCSI target nodes, itadm manages two other classes of managed objects: iSCSI Target Portal Groups, and iSCSI Initiator Node Contexts.

itadm is implemented as a set of subcommands with options and operands for each subcommand. These subcommands are described in their own section, below. In addition to its subcommands, itadm has a help command, which displays the utility's usage information. The help command is invoked with the -? option.

iSCSI Target Portal Groups

An iSCSI Target Network Portal is an IP address and TCP port that can be used by an initiator node to connect to an iSCSI target. A collection of these portals is called a Target Portal Group (TPG). You can use a TPG to limit access to an iSCSI target. Use the itadm modify -t
A command to bind a specific iSCSI target to the TPG. An iSCSI listener is created on each IP address that belongs to the TPG, and listens for connections to the iSCSI target.

A TPG is identified by a unique name provided when the TPG is created. A numerical “Target Portal Group Tag” from the range 2-65535 is automatically generated when the TPG is created. The Target Portal Group Tag 1 is reserved for the “default” target portal group that is used when no explicit Target Portal Groups are set on the target. The portal for the default TPG matches requests from all network interfaces on port 3260.

Certain operations such as authentication by means of Challenge Handshake Authentication Protocol (CHAP) require parameters associated with a remote iSCSI Initiator Node. These parameters are associated with an iSCSI Initiator Node Context. An iSCSI Initiator Node Context is identified by its Initiator Node Name, formatted in either IQN or EUI format (see RFC 3720). For example:

```
iqn.1986-03.com.sun:01:e00000000000.47d55444
eui.02004567A425678D
```

A number of itadm subcommands require that you specify one or more IP addresses with optional port numbers. For IPv4, use standard dotted decimal notation. For IPv6, enclose addresses in square brackets. The following are example specifications.

**IPv4**:
- 10.2.4.1
- 10.2.4.1:3260

**IPv6**:
- `[1080:0:0:0:8:800:200C:417A]`
- `[1080:0:0:0:8:800:200C:417A]:3260`

The following are the itadm subcommands with their options.

```
create-target
```

Create an iSCSI target with the specified options. Options are as follows.

**-a,--auth-method radius | chap | none | default**

Specifies the authentication method to use for the target. Valid values are radius, chap, and none. chap indicates that initiators connecting to this target must be authenticated using the Challenge Handshake Authentication Protocol (CHAP). radius indicates initiators should also be authenticated by means of CHAP but the required authentication parameters should be obtained from a central RADIUS server (see the radius-server and radius-secret options). none means that no authentication is required to connect to the target. default means the target will use the global setting of this property. (See the modify-defaults subcommand.)

**-s,--chap-secret**

The CHAP secret to send during mutual CHAP authentication. There is no default for this property. Maximum length is 255 characters; minimum required length is 12 characters.
-S,--chap-secret-file path
Path to a temporary file containing the CHAP secret as described in the -s option.

-u,--chap-user chap-user-name
Specifies the CHAP username for a target for use in mutual CHAP authentication. This value is allowed only for targets, cannot be set globally, and is used only when the initiator node is configured to use mutual CHAP authentication. If no value is specified then the target node name is used as the username. See iscsiadm(1M).

-n,--node-name target_node_name
An iSCSI Target Node is identified by its Target Node Name, formatted in either IQN or EUI format (see RFC 3720). This option establishes that name.

-l,--alias alias
An alternate identifier associated with a target node. The identifier does not need to be unique.

-t,--tpg tpg-name[,tpg-name,...]
A list of Target Portal Group (TPG) identifiers that specifies the TPGs that an initiator can use to access a specific target or the keyword default. If default is specified, the target will use the default portal, INADDR_ANY:3260.

Modify an iSCSI target according to the specified options. Options are as follows.

-a,--auth-method radius | chap | none | default
As described under the create-target subcommand, above.

-s,--chap-secret
As described under the create-target subcommand, above.

-S,--chap-secret-file path
As described under the create-target subcommand, above.

-u,--chap-user chap-user-name
As described under the create-target subcommand, above. To remove an explicitly set CHAP username use -u none.

-n,--node-name target_node_name
Renames the target. See also the description of -n under the create-target subcommand, above.

-l,--alias alias
As described under the create-target subcommand, above. To remove an explicitly set alias use -l none.
As described under the create-target subcommand, above.

**itadm list-target**

```bash
itadm list-target [-v,--verbose] [target_node_name]
```

List information about the configured targets. If `target_node_name` is specified, list only the information for that target. Option is as follows.

- `-v,--verbose`
  
  Verbose mode.

**itadm delete-target**

```bash
itadm delete-target [-f,--force] target_node_name
```

Delete the target specified by `target_node_name`. The target must be offline before it can be deleted. Option is as follows.

- `-f,--force`
  
  If the target persists in an online state, this option attempts to offline the target before deleting it.

**itadm create-tpg**

```bash
itadm create-tpg tpg_name IP-address[:port]...
```

Create an iSCSI target portal group made up of the specified portals and assign it the identifier `tpg_name`. Each portal is an IP address and port pair. IPv4 portals are specified in dotted address notation, for example, 172.31.255.255. IPv6 portal addresses must be enclosed in square brackets.

This subcommand has no options.

**itadm list-tpg**

```bash
itadm list-tpg [-v,--verbose] [tpg_name]
```

List information about the configured target portal group. If `tpg_name` is specified then list only the information about the target portal group associated with that `tpg_name`. Option is as follows.

- `-v,--verbose`
  
  Verbose mode.

**itadm delete-tpg**

```bash
itadm delete-tpg [-f,--force] tpg_name
```

Delete the target portal group associated with `tpg_name`. Option is as follows.

- `-f,--force`
  
  If the TPG is associated with any targets, the request to delete will be denied unless this option is specified.

**itadm create-initiator**

```bash
itadm create-initiator [-s,--chap-secret] [-S,--chap-secret-file path] [-u,--chap-user chap-user-name] initiator_node_name
```

Configure parameters associated with the remote initiator named `initiator_node_name`. Options are as follows.
As described under the create-target subcommand, above.

-S,--chap-secret-file path
As described under the create-target subcommand, above.

-u,--chap-user chap-user-name
Specifies the CHAP username for an initiator, for use in CHAP authentication. If no value is specified then the initiator node name is used as the username.

itadm modify-initiator [-s,--chap-secret] [-S,--chap-secret-file path]
[-u,--chap-user chap-user-name] initiator_node_name

Modify parameters associated with the remote initiator named initiator_node_name. Options are as follows.

-s,--chap-secret
As described under the create-target subcommand, above.

-S,--chap-secret-file path
As described under the create-target subcommand, above.

-u,--chap-user chap-user-name
Specifies the CHAP username for an initiator, for use in CHAP authentication. If no value is specified then the initiator node name is used as the username.

itadm delete-initiator initiator_node_name

Delete parameters associated with the remote initiator named initiator_node_name. This subcommand has no options.

itadm list-initiator [-v,--verbose] initiator_node_name

List parameters associated with the initiator named initiator_node_name. Option is as follows.

-v,--verbose
Verbose mode.

itadm modify-defaults [-a,--auth-method radius | chap | none]
[-r,--radius-server IP-address[:port]] [-d,--radius-secret]
[-D,--radius-secret-file path][-i,--isns enable | disable]
[-I,--isns-server IP-address[:port]][,IP-address[:port]]

Modify default parameters. Options are as follows.

-a,--auth-method radius | chap | none
Specifies the default authentication method to use for all targets. Valid values are radius, chap, and none. chap indicates that initiators connecting to this target must be authenticated using Challenge Handshake Authentication Protocol (CHAP). radius indicates initiators should also be authenticated by means of CHAP, but the required authentication parameters should be obtained from a central RADIUS server. (See
--radius-server and --radius-secret options) none means that no authentication is required to connect to the target. Individual targets can override this global setting using the -a option of the create-target and modify-target subcommands.

-d, --radius-secret
RADIUS Shared Secret for centralized CHAP authentication.

-D, --radius-secret-file path
Path to a temporary file containing the CHAP secret as described in the -d option.

-i, --sns enable | disable
Specifies whether targets should be registered with the set of defined iSCSI Name Service (iSNS) servers.

-I, --isns-server IP-address[::port][,IP-address[::port],...]
Defines a list of iSNS servers with which iSCSI target nodes will be registered when the isns option associated with the respective target is set. Up to eight iSNS servers can be specified. To remove all iSNS servers, use -I none.

-r, --radius-server IP-address[::port]
Specify the IP address of the RADIUS server used for centralized CHAP authentication.

Examples

EXAMPLE 1 Creating a Target
The following command creates a target.

# itadm create-target
Target iqn.1986-03.com.sun:02:72eb181-7bce-c0e6-851e-ec0d8cf14b7a
successfully created

EXAMPLE 2 Creating a Target with a Specific Name
The following command creates a target with a specific IQN.

# itadm create-target -n eui.20387ab8943ef7548
or:
# itadm create-target \
- n iqn.1986-03.com.sun:02:a9a366f8-cc2b-f291-840948c7f29e

EXAMPLE 3 Changing a Name
The following command changes an IQN for an existing target.

# itadm modify-target -n eui.20387ab8943ef7548 \
iqn.1986-03.com.sun:02:a9a366f8-909b-cc2b-f291-840948c7f29e
**EXAMPLE 4** Setting up CHAP Authentication

The following command sets up CHAP authentication for a target using the default CHAP username.

```
# itadm modify-initiator -s iqn.1986-03.com.sun:01:e00000000000.47d55444
Enter CHAP secret: **********
Re-enter secret: **********

# itadm modify-target -a chap eui.20387ab8943ef7548
```

**EXAMPLE 5** Creating Target Portal Groups

The following command creates two target portal groups, A and B, using port 8000 for the addresses in TPG 2.

```
# itadm create-tpg A 192.168.0.1 192.168.0.2
# itadm create-tpg B 192.168.0.2:8000 192.168.0.2:8000
```

**EXAMPLE 6** Configuring a Target to Use TPGs

The following command configures a target to use TPGs A and B.

```
# itadm modify-target -t A,B eui.20387ab8943ef7548
```

**EXAMPLE 7** Setting up RADIUS Authentication for Specific Target

The following command sets up RADIUS authentication for a specific target.

```
# itadm modify-defaults -r 192.168.10.1 -d
Enter RADIUS secret: **********
Re-enter secret: **********

# itadm modify-target -a radius eui.20387ab8943ef7548
```

**EXAMPLE 8** Setting up RADIUS Authentication for All Targets

The following command sets up RADIUS authentication for all targets.

```
# itadm modify-defaults -d -r 192.168.10.1 -a radius
Enter RADIUS secret: **********
Re-enter secret: **********

The preceding command assumes all targets were created with -a default.

**EXAMPLE 9** Listing Default Properties

The following command lists default properties.

```
# itadm list-defaults
iSCSI Target Default Properties:

alias: none
```
### Example 9  Listing Default Properties  (Continued)

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>auth</td>
<td>none</td>
</tr>
<tr>
<td>radiusserver</td>
<td>none</td>
</tr>
<tr>

</tr>
<tr>
<td>iqn.1986-03.com.sun:02:94ec46d4-c8e1-6993-ef03-ffcc1dcd66606</td>
<td>online</td>
<td>0</td>
</tr>
</tbody>
</table>

### Example 11  Listing Targets (Verbose)

The following command lists targets with the verbose option.

```bash
# itadm list-target -v
```

<table>
<thead>
<tr>
<th>TARGET NAME</th>
<th>STATE</th>
<th>SESSIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>iqn.1986-03.com.sun:02:94ec46d4-c8e1-6993-ef03-ffcc1dcd66606</td>
<td>online</td>
<td>1</td>
</tr>
</tbody>
</table>

### Example 12  Listing a Specific Target

The following command lists targets with the verbose option.

```bash
# itadm list-target -v \ ign.1986-03.com.sun:02:2cb0c526-c05a-e279-e396-a367006f4227
```

The \texttt{itu} utility converts driver packages to Driver Update (DU) format and patches a Solaris install media with driver packages and patches for Install Time Update (ITU). ITU has three subcommands: \texttt{makedu}, \texttt{updatemedia} and \texttt{makeiso}.

### Options
The following options are supported:

- \texttt{-d output_dir}
  Directory where the Driver Update directory is to be created.

- \texttt{-f}
  If \texttt{output_dir}/DU or \texttt{iso_file} already exists, remove it without asking first.

- \texttt{-l iso_label}
  Label/volume name of the ISO image (if \texttt{-o} option is specified).

- \texttt{-o iso_file}
  Path of the ISO image file to be created. For subcommands \texttt{updatemedia} and \texttt{makeiso}, it will be a bootable ISO image. This option must be specified for subcommand \texttt{makeiso}.

- \texttt{-R media_root}
  Top-level directory of on-disk image of Solaris installation media. This option must be specified for subcommand \texttt{updatemedia}.

- \texttt{-r solaris_release}
  Solaris release number for which the Driver Update is intended. It takes the form of the output of \texttt{uname -r}, for example, 5.10. This option must be specified for subcommand \texttt{makedu}.

- \texttt{-v}
  Verbose. Multiple \texttt{-v} options increase verbosity.

### Sub-commands
The \texttt{itu} subcommands are described as follows.

- \texttt{makedu} The \texttt{makedu} subcommand takes one or more driver packages as input and converts them to DU format. At the beginning of an interactive Solaris installation session, these driver updates can be applied to the running kernel, which will then also automatically apply them to the newly installed Solaris at the end of the installation process.

  The \texttt{-r} option is required to specify the Solaris release number for which the driver updates apply. The \texttt{solaris_release} option argument takes the form \texttt{uname -r output}, for example, 5.10 or 5.11.
If the `-d` option is specified, the resulting DU directory tree is placed in the directory `output_dir`.

If the `-o` option is specified, a (non-bootable) ISO image of the DU directory tree is written in the file `iso_file`. This ISO image can be burned onto a CD/DVD using `cdrw(1)` or `cdrecord(1)` (not a SunOS man page).

At least one of `-d` and `-o` option must be specified. If both are specified, then both an ISO image and a directory tree are generated.

**Operands**

The following operands are supported:

- `package [package...]`
  - One or more driver packages.

- `pkg_or_patch [pkg_or_patch...]`
  - One or more patches or packages.

- `media_root`
  - The top-level directory of a Solaris install media.
Examples

**EXAMPLE 1**  Creating a DU CD/DVD

The following commands create a Driver Update CD/DVD containing the packages SAMPLEpkg1 and SAMPLEpkg2.

```
# itu makedu -r 5.10 -o my.iso SAMPLEpkg1 SAMPLEpkg2
# cdrw -i my.iso
```

**EXAMPLE 2**  Patching the Solaris Install Media

The following command patches the Solaris install media in `/export/s10u1` with patch `/opt/patches/123456-07` and driver package `/opt/pkgs/MYdriver`. The command also creates a bootable ISO image with ISO label “MyS10U1” in the file `/tmp/dvd.iso`.

```
#/usr/bin/itu updatemedia -R /export/s10u1 -o /tmp/dvd.iso -l MyS10U1 \ 
  /opt/patches/123456-07 /opt/pkgs/MYdriver
```

**EXAMPLE 3**  Creating a Bootable ISO Image

The following commands create the bootable ISO image `mydvd.iso` of the Solaris install image `/export/solaris-10u1` with ISO label “Special-S10”.

```
#/usr/bin/itu makeiso -o mydvd.iso -l "Special-S10" \ 
  /export/solaris-10u1
# cdrw -i mydvd.iso
```

Attributes  See attributes(5) for descriptions of the following attributes:

<table>

`mkisofs(8),(/usr/share/man/man8/mkisofs.8), in the SUNWfsman package (not a SunOS man page)`
Name  js2ai – Translate JumpStart rules and profiles for use with the Automated Installer (AI).

Synopsis  js2ai [-h | --version]
          js2ai -r | -p profile [-d jsdir]
                   [-D destdir] [-Sv]
          js2ai -s [-d jsdir]
                   [-D destdir] [-Sv]
          js2ai -V manifest

Description  js2ai is a utility for converting Oracle Solaris 10 JumpStart rules, profile, and syscfg configuration files to a format compatible with Automated Installer (AI). This utility makes a “best effort” to translate those JumpStart keywords that can be translated to the AI context. While this conversion does not create a complete one-to-one equivalence with JumpStart, it does provide AI manifest and system configuration profile entries that can then be used as a template for creating a complete AI configuration setup based on information gathered from JumpStart configuration files.

Using js2ai, you can do the following:

- Process the rules file and the associated profiles in the current working directory.
- Process the rules file and the associated profiles in a specified directory.
- Process a specific profile or sysidcfg file.
- Direct the resulting output files to a specific directory. For more information on the js2ai output files, see the “Examples” and “Files” sections.

<table>
<thead>
<tr>

<tr>
<td>locale</td>
<td>No translation is performed. Make sure the locale specified is supported in Oracle Solaris 11.</td>
</tr>
<tr>
<td>package</td>
<td>An attempt to convert the specified package to its Oracle Solaris 11 equivalent is performed. Specifying the location of the package is not supported. Package lookups can take a considerable amount of time. If your profiles contain a long list of packages, you might want to use the --local flag during the conversion process.</td>
</tr>
<tr>
<td>partitioning</td>
<td>Supported types are default and explicit. Unlike JumpStart, when partitioning default is specified, only the disks that js2ai knows about are used. If no disks are specified in any keywords, the generated profile tells AI to choose which disk to use.</td>
</tr>
<tr>
<td>pool</td>
<td>If a pool is specified in a profile, the ZFS root pool is created using the specified devices. The pool keyword supersedes all other keywords when determining which devices to use for the ZFS root pool. No validation of the pool size, swap size, or dump size is performed. These sizes might need to be adjusted in the resulting AI manifest to achieve a successful installation with this manifest.</td>
</tr>
<tr>
<td>root_device</td>
<td>The rootdisk is set to the specified device.</td>
</tr>
<tr>
<td>system_type</td>
<td>Only the value standalone is supported.</td>
</tr>
<tr>
<td>usedisk</td>
<td>The specified device might be used to resolve the any or rootdisk device during the conversion. Any devices specified that are not used for this purpose are added to the ZFS root pool, when that pool is not mirrored.</td>
</tr>
</tbody>
</table>

**JumpStart profile keywords not supported by js2ai:**
How the System's Root Disk is Determined During Profile Translation

Since js2ai does not have access to the actual system a profile references during the profile translation process, js2ai attempts to determine what the root disk is during translation using a process that matches JumpStart as much as possible.

The js2ai tool performs the following steps to determine what device to use for the root disk.

<table>
<thead>
<tr>
<th>Stage</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>If the root_device keyword is specified in the profile, js2ai sets rootdisk to the device on which the slice resides.</td>
</tr>
<tr>
<td>2</td>
<td>If rootdisk is not set and the boot_device keyword is specified in the profile, js2ai sets rootdisk to the boot device.</td>
</tr>
<tr>
<td>3</td>
<td>If rootdisk is not set, partitioning default is specified, and a solaris fdisk entry is encountered, js2ai sets rootdisk to the specified disk_name.</td>
</tr>
<tr>
<td>4</td>
<td>If rootdisk is not set and a filesystem cwtxdysz size / entry is specified in the profile, js2ai sets rootdisk to the cwtxdysz disk specified in the entry.</td>
</tr>
<tr>
<td>5</td>
<td>If rootdisk is not set and a usedisk disk entry is specified in the profile, js2ai sets rootdisk to the disk specified in the entry.</td>
</tr>
<tr>
<td>6</td>
<td>If rootdisk is not set and the following specification is encountered in the profile where size is not 0 or delete and disk is not all, then rootdisk is set to this disk name. fdisk disk solaris size</td>
</tr>
<tr>
<td>7</td>
<td>If rootdisk is not set, any occurrence where the device is specified as rootdisk generates a conversion error.</td>
</tr>
</tbody>
</table>

How the any Device Is Translated During Profile Translation

The js2ai tool performs the following steps to determine what device to use when the any keyword is specified.
Stage Action
1 If the any device is specified and the keyword action specified (non-mirrored pool, or filesys with a / mount point), the any device is set to rootdisk if rootdisk is set.
2 If the any device has not been translated and a usedisk statement exists in the profile, the any device is set to the device specified by the usedisk statement.
3 If the any device has not been translated and the action where the any device is specified causes the ZFS root pool to be created, AI chooses the device. This is not applicable when a mirrored pool is specified.

How the ZFS Root Pool is Determined During Profile Translation

The js2ai tool performs the following steps to determine what device to use for the ZFS root pool. Once the ZFS root pool is determined, subsequent definitions encountered are flagged as errors if they conflict with the ZFS root pool that has already been determined.

Stage Action
1 If the profile specifies the pool keyword, js2ai sets the ZFS root pool to the devices specified by the pool keyword.
2 If the ZFS root pool has not been determined and the profile specifies a filesys with a mount point of /, the ZFS root pool is created using the devices specified.
3 If the ZFS root pool has not been determined and all keywords in the profile have been processed, and if rootdisk is set, the ZFS root pool is created using the rootdisk device.
4 If the ZFS root pool has not been determined and the partition type is default, AI chooses the device to use for the ZFS root pool.
5 If the ZFS root pool has not been determined and no errors have occurred during processing, AI chooses the device to use for the ZFS root pool.
6 If the ZFS root pool is not a mirrored pool and one or more usedisk devices that were specified have not been used for a rootdisk or any device translation, those disks are added to the ZFS root pool.

Converting sysidcfg Keywords

<table>
<thead>
<tr>
<th>sysidcfg Keyword</th>

</table>

JumpStart sysidcfg keywords not supported by js2ai:

nfs4_domain

Options

The js2ai command has the following options. The use of these options is illustrated in the “Examples” section.

- **-h, --help**
  Show the usage help message.

- **--version**
  Show the version number of the js2ai utility.

- **-d jsdir, --dir jsdir**
  Specify the location of the rules and profile files or the sysidcfg file.

- **-D destdir, --dest destdir**
  Specify the location for the output files.

- **-l, --local**
  When searching for Image Packaging System (IPS) equivalents for the package keyword value in a JumpStart profile, search the IPS packages installed on the host system rather than the packages in an IPS package repository.
-p profile, --profile profile
   Convert the specified JumpStart profile and generate a manifest for the profile processed.
   In this case, no criteria file is needed or generated.

-r, --rule
   Convert rules and associated profiles and generate a manifest for each profile processed.

-s, --sysidcfg
   Process the sysidcfg file and output the results to sc_profile.xml.

-S, --skip
   Skip validation.

-v, --verbose
   Provide details on the actions that occurred during processing.

-V filename
   Validate the specified AI manifest file or SMF system configuration profile file. AI criteria
   validation is not supported.

The js2ai tool generates an error report when one or more errors occurs during the
conversion.

# js2ai -r

<table>
<thead>
<tr>
<th>Name</th>
<th>Warnings</th>
<th>Process Errors</th>
<th>Unsupported Errors</th>
<th>Conversion Errors</th>
<th>Validation Errors</th>
</tr>
</thead>
<tbody>
<tr>
<td>rules</td>
<td>0</td>
<td>0</td>
<td>2</td>
<td>0</td>
<td>-</td>
</tr>
<tr>
<td>profile1</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

Conversion completed. One or more failures occurred.
For errors see ./js2ai.log

The report contains one entry for each file in which js2ai encountered an error. To generate
an error report even when no errors occur, specify -v or --verbose.

The report tells you what type of errors occurred in what files. Five error types are defined: Warnings, Process Errors, Unsupported Items, Conversion Errors, and Validation Errors.

Warnings
   Items in these messages are not required to be corrected. For example, you might receive a warning message that information such as host name or root password was not provided, and default values will be used.

Process Errors
   These errors refer to problems that prevent js2ai from processing a file or a line within the file. Process errors typically occur when the file has a syntax error.

Unsupported Items
   These items refer to a line that js2ai does not support. Changing the value associated with a keyword might eliminate this error.
Conversion Errors
These errors refer to a condition that prevents js2ai from processing a line. These errors should be manually corrected, or the offending lines should be removed from the file.

Validation Errors
These errors refer to the errors that occurred when the generated manifest was validated against the schema definition used by AI. These errors must to be corrected before the manifest can be used by AI.

The js2ai.log file indicates what error occurred on what line.

```
# cat js2ai.log
rules: line 4: unsupported keyword: disksize
rules: line 4: unsupported keyword: installed
net924_sun4c: line 4: unsupported keyword: cluster
net924_sun4c: line 5: unsupported keyword: num_clients
net924_sun4c: line 6: unsupported keyword: client_swap
net924_sun4c: line 7: unsupported keyword: client_arch
upgrade: line 1: unsupported value for ‘install_type’ specified: upgrade
```

If a validation error of the manifest occurs, the js2ai.log file contains a pointer to the log file that contains the validation errors, as shown in the following example:

```
Validation Errors:
profile1: manifest validation of ./AI_profile1/profile1.xml failed.
For details see ./AI_profile1/profile_validation.log
```

Recommended Strategy for Rule and Profile Conversion
A one-to-one conversion between JumpStart and AI does not exist. The following steps provide a general procedure for performing the conversion.

1. The js2ai utility attempts to flag any errors it encounters, but js2ai assumes the rules, profiles, and sysidcfg files that are being converted are valid.
2. Copy the JumpStart configuration directory of rules, profile, and syscfg configuration files to an Oracle Solaris 11 system that has the install/installadm package installed.
3. In the JumpStart configuration directory that you copied to the Oracle Solaris 11 system in step 2, run the js2ai conversion tool.

```
# js2ai -rS
```

This command performs a conversion operation on the rules file and the profiles referenced by the rules file. Each profile referenced in the rules file is processed against the AI client provisioning manifest, /usr/share/auto_install/manifest/default.xml. This step creates a directory named AI_profile for each profile specified in the JumpStart rules file. The AI_profile directory contains one or more AI manifests for the translated profile in the form profiles${arch}.xml. See the “Files” section for more information.

The -S option skips the validation sequence. Validation is done in step 5.
4. If the message “Successfully completed conversion” is output, skip to step 5. Otherwise, examine the `js2ai.log` file and follow these steps:
   a. Correct any process errors.
   b. Remove any lines from the `rules` and profile files that are listed as Unsupported Items.
   c. Examine the conversion errors and correct the errors if possible. Otherwise, remove the lines that are causing the errors.
   d. Examine any warning messages and make sure no corrections are necessary.
   e. Repeat step 3 until no processing errors, unsupported items, and conversion errors are reported.

5. Rerun `js2ai` without the `-S` option.

   ```
   # js2ai -r
   ```

   If any validation errors occur for any of the processed profiles, the resulting AI manifest must be manually corrected. Examine the `js2ai.log` file for details of the failure. See the AI documentation for information about AI manifests.

6. Convert any `sysidcfg` files that are associated with this JumpStart configuration.
   For each `sysidcfg` file, execute the following command:

   ```
   # js2ai -s -d sysidcfgdir
   ```

   For each `sysidcfg` file processed, this step creates an AI system configuration profile file named `sc_profile.xml` in the directory where the `js2ai` command was invoked. Use the `-D` option to specify a different directory for the `sc_profile.xml` file.

7. If the message “Successfully completed conversion” is output, skip to step 8. Otherwise, examine the `js2ai.log` file and follow these steps:
   a. Correct any process errors.
   b. Remove any lines from the `sysidcfg` file that are listed as unsupported items.
   c. Examine the conversion errors and correct the errors if possible. Otherwise, remove the lines that are causing the errors.
   d. Examine any warning messages and make sure no corrections are necessary.
   e. Repeat step 6 until no processing errors, unsupported items, and conversion errors are reported.

8. Rerun `js2ai` without the `-S` option.

   ```
   # js2ai -s -d sysidcfgdir
   ```

   If any validation errors occur for any of the processed `sysidcfg` files, the resulting AI system configuration profile must be manually corrected. Examine the `js2ai.log` file for details of the failure. See the AI documentation for information about system configuration profiles.
9. The js2ai conversion process is complete. Perform a manual verification of the resulting criteria, AI manifest, and system configuration profile files. The disk space requirements for an Oracle Solaris 11 installation are different from the disk space required for an Oracle Solaris 10 installation. Make sure the disk space allocated in your AI manifests meets the requirements of Oracle Solaris 11.

10. Configure AI to use the newly generated files. Add the newly generated criteria, AI manifest, and system configuration profile files to an existing AI install service.

   Use the `installadm` command with the `create-manifest` subcommand to add each AI manifest with criteria for selecting that manifest. Each client can use only one AI manifest.

   ```
   # installadm create-manifest -n svcname \
   -f filename -m manifest \ 
   -C criteriafile
   ```

   Use the `create-profile` subcommand to add each profile with criteria for selecting that configuration profile. Each client can use one or more system configuration profiles.

   ```
   # installadm create-profile -n svcname \
   -f filename -p profile \ 
   -C criteriafile
   ```

   See the AI documentation and the `installadm(1M)` man page for information about configuring AI install services.

**Examples**

**EXAMPLE 1** Processing a JumpStart Configuration

The following command processes the JumpStart rules and profiles in the current directory. The output is also placed in this directory.

```
# js2ai -r
```

**EXAMPLE 2** Processing a Specific JumpStart Directory

The following command processes the JumpStart rules and profiles from the specified directory and places the output files in the same directory.

```
# js2ai -r -d /export/jumpstart
```

For more information about the output files, see Example 4 and the “Files” section.

**EXAMPLE 3** Processing a Profile in a Specific JumpStart Directory and Separate Destination Directory

The following command processes the JumpStart rules and profile files from the `/export/jumpstart` directory and places the output files in `/export/output`.

```
# js2ai -p profile1 -d /export/jumpstart -D /export/output
```

**EXAMPLE 4** Example Input and the Resulting Output for a Specified Rule and Its Profile

Rule:
EXAMPLE 4  Example Input and the Resulting Output for a Specified Rule and Its Profile  (Continued)

arch sparc && karch sun4u && \
   model 'SUNW,Serverblade1' - profile -

Profile:
install_type initial_install
pool mypool auto auto auto c1t0d0s0

Conversion command:
# js2ai -r -d /jumpstart -D /tmp/output

Output files:
/tmp/output/AI_profile/profile.x86.xml
/tmp/output/AI_profile/profile.sparc.xml
/tmp/output/AI_profile/criteria-1.xml

Two manifest files are created, one for SPARC and one for x86, even though the rules file specifies the CPU type as SPARC. During the conversion process, rules and profiles are processed independently of one another.

EXAMPLE 5  Adding Generated Files to an AI Install Service
This example adds the manifest and criteria to an existing service, using the files generated in Example 4.

Files:
/tmp/output/AI_profile/profile.sparc.xml
/tmp/output/AI_profile/criteria-1.xml

installadm command:
# installadm create-manifest -n svc-name \
-f /tmp/output/AI_profile/profile.sparc.xml \
-m sparc_profile \ 
-C /tmp/output/AI_profile/criteria-1.xml

EXAMPLE 6  Processing a sysidcfg File
The following command processes the sysidcfg file in the current directory and outputs the resulting SMF system configuration profile as sc_profile.xml in the same directory.

# js2ai -s

Exit Status  The following exit values are returned:

0       All the files were processed successfully.
>0      An error occurred.
**Files**

`outputdir/AI_${profile}`
Directory that contains all the corresponding files that have been translated to the new AI syntax associated with the profile.

`outputdir/AI_${profile}.${arch}.xml`
The manifest file created as a result of translating the profile. `${arch}` can be one of these three values: `sparc`, `x86`, or `generic`. A manifest file that is in the form `${profile}.generic.xml` can be used to install both x86 and SPARC systems.

`outputdir/AI_${profile}/criteria-rule.xml`
The `criteria-rule.xml` file produced corresponds to the rule in the `rules` file. The `rule` is the rule number based on its position in the `rules` file. This criteria file can then be used with the `-C` option to the `installadm` command.

Since more than one rule can specify the same profile, more than one criteria file can exist in each directory, but only one instance of the `${profile}.${arch}.xml` file should exist in each output directory.

**Note** – If the `-p` option is used, no criteria file is produced for the profile that is processed. Criteria files are only generated when used with the `-r` option.

`outputdir/js2ai.err`
This file contains a stack trace of an unexpected condition that occurred during processing. This file is not typically created.

`outputdir/js2ai.log`
This file contains a log of the files processed and any errors found during processing.

`outputdir/sc_profile.xml`
This file is the SMF system configuration profile that is generated when the `-s` option is used to convert a `sysidcfg` file.

*Transitioning From Oracle Solaris 10 JumpStart to Oracle Solaris 11.1 Automated Installer*

Part III, “Installing Using an Install Server,” in *Installing Oracle Solaris 11.1 Systems*
The `k5srvutil` command allows a system manager to list or change keys currently in his keytab or to add new keys to the keytab.

The operand `operation` must be one of the following:

- **list**
  Lists the keys in a keytab, showing version number and principal name.

- **change**
  Changes all the keys in the keytab to new randomly-generated keys, updating the keys in the Kerberos server's database to match those by using the `kadmin` protocol. If a key's version number does not match the version number stored in the Kerberos server's database, the operation fails. The old keys are retained so that existing tickets continue to work. If the `-i` flag is specified, `k5srvutil` prompts for yes or no before changing each key. If the `-k` option is used, the old and new keys are displayed.

- **delold**
  Deletes keys that are not the most recent version from the keytab. This operation should be used at some point after a change operation to remove old keys. If the `-i` flag is specified, `k5srvutil` asks the user whether the old keys associated with each principal should be removed.

- **delete**
  Deletes particular keys in the keytab, interactively prompting for each key.

In all cases, the default keytab file is `/etc/krb5.keytab` file unless this is overridden by the `-f` option.

`k5srvutil` uses the `kadmin(1M)` program to edit the keytab in place. However, old keys are retained, so they are available in case of failure.

The following options are supported:

- `-f filename`
  Specify a keytab file other than the default file, `/etc/krb5.keytab`.

- `-i`
  Prompts user before changing keys when using the `change` or `delold` operands.

- `-k`
  Displays old and new keys when using the `change` operand.

**Name**  
kadb – a kernel debugger

**Synopsis**

SPARC  
ok boot device_specifier kadb [-d] [boot-flags]

x86  
select (b)oot or (i)nterpreter: b kadb [-d] [boot-flags]

**Description**  

kadb, an interactive kernel debugger, has been replaced by kmdb(1). For backwards compatibility, the methods used to load kadb will be interpreted as requests to load kmdb(1). Unlike with the compatibility link from adb(1) to mdb(1), kmdb(1) will always load in its native user interface mode, regardless of the name used to load it.

kmdb(1) is based on mdb(1), and thus shares mdb's user interface style and feature set. The mdb(1) man page describes the features and operation of mdb. The kmdb(1) man page describes the differences between mdb and kmdb. This man page describes the major changes and incompatibilities between kadb and kmdb.

Consult the Solaris Modular Debugger Guide for a detailed description of both mdb and kmdb.

**Major changes**  

This section briefly lists the major differences between kadb and kmdb. It is not intended to be exhaustive.

**Debugger Loading and Unloading**  

kmdb(1) may be loaded at boot, as with kadb. It may also be loaded after boot, thus allowing for kernel debugging and execution control without requiring a system reboot. If kmdb(1) is loaded after boot, it may be unloaded.

**mdb Feature Set**  

The features introduced by mdb(1), including access to kernel type data, debugger commands (dcmds), debugger modules (dmods), and enhanced execution control facilities, are available under kmdb(1). Support for changing the representative CPU (:x) is available for both SPARC and x86. Furthermore, full execution-control facilities are available after the representative CPU has been changed.

**Significant Incompatibilities**  

This section lists the significant features that have changed incompatibly between kadb and kmdb(1). It is not intended to be exhaustive. All kmdb(1) commands referenced here are fully described in the kmdb(1) man page. A description as well as examples can be found in the Solaris Modular Debugger Guide.

**Deferred Breakpoints**  

The kadb-style “module#symbol:b” syntax is not supported under kmdb(1). Instead, use “::bp module’symbol”.

**Watchpoints**  

The ::wp dcmd is the preferred way to set watchpoint with kmdb. Various options are available to control the type of watchpoint set, including -p for physical watchpoints.
(SPARC only), and -i for I/O port watchpoints (x86 only).
Sl is not supported, therefore, the watchpoint size must be
specified for each watchpoint created.

Access to I/O Ports (x86 only)  The commands used to access I/O ports under kadb have
been replaced with the ::in and ::out dcmds. These two
dcmds allow both read and write of all I/O port sizes
supported by kadb.

Solaris Modular Debugger Guide
Name  kadmin, kadmin.local – Kerberos database administration program

Synopsis  
```
/usr/sbin/kadmin [-r realm] [-p principal] [-q query]  
[-s admin_server [:port]] [-c credential_cache]  
[-k [-t keytab] [-n]] [-w password] [-x db_args]...  

/usr/sbin/kadmin.local [-r realm] [-p principal]  
[-q query] [-d dbname] [-e "encsalt..."] [-m] [-D]
```

Description  kadmin and kadmin.local are interactive command-line interfaces to the Kerberos V5 administration system. They provide for the maintenance of Kerberos principals, policies, and service key tables (keytabs). kadmin and kadmin.local provide identical functionality; the difference is that kadmin.local can run only on the master KDC and does not use Kerberos authentication.

Except as explicitly noted otherwise, this man page uses kadmin to refer to both versions.

By default, both versions of kadmin attempt to determine your username and perform operations on behalf of your "username/admin" instance. Operations performed are subject to privileges granted or denied to this user instance by the Kerberos ACL file (see `kadm5.acl(4)`). You may perform administration as another user instance by using the `-p` option.

The remote version, kadmin, uses Kerberos authentication and an encrypted RPC to operate securely from anywhere on the network. It normally prompts for a password and authenticates the user to the Kerberos administration server, kadmind, whose service principal is kadmin/fqdn. Some options specific to the remote version permit the password prompt to be bypassed. The `-c` option searches the named credentials cache for a valid ticket for the kadmin/fqdn service and uses it to authenticate the user to the Kerberos admin server without a password. The `-k` option searches a keytab for a credential to authenticate to the kadmin/fqdn service, and again no password is collected. If kadmin has collected a password, it requests a kadmin/fqdn Kerberos service ticket from the KDC, and uses that service ticket to interact with kadmind.

The local version, kadmin.local, must be run with an effective UID of root, and normally uses a key from the `/var/krb5/.k5.realm` stash file (see `kdb5_util(1M)`) to decrypt information from the database rather than prompting for a password. The `-m` option will bypass the .k5.realm stash file and prompt for the master password.

Options  The following options are supported:

- `-c credentials_cache`
  Search credentials_cache for a service ticket for the kadmin/fqdn service; it can be acquired with the `kinit(1)` program. If this option is not specified, kadmin requests a new service ticket from the KDC, and stores it in its own temporary credentials cache.

- `-d dbname`
  Specify a non-standard database name. [Local only]

- `-D`
  Turn on debug mode. [Local only]
-e "enc:salt ..."
  Specify a different encryption type and/or key salt. [Local only]

-k [-t keytab]
  Use the default keytab (-k) or a specific keytab (-t keytab) to decrypt the KDC response instead of prompting for a password. In this case, the default principal will be host/hostname. This is primarily used for keytab maintenance.

-m
  Accept the database master password from the keyboard rather than using the /var/krb5/.k5.realm stash file. [Local only]

-n
  Requests anonymous processing. Two types of anonymous principals are supported. For fully anonymous Kerberos, configure pkinit on the KDC and configure pkinit_anchors in the client's krb5.conf. Then use the -n option with a principal of the form @REALM (an empty principal name followed by the at-sign and a realm name). If permitted by the KDC, an anonymous ticket will be returned. A second form of anonymous tickets is supported; these realm-exposed tickets hide the identity of the client but not the client's realm. For this mode, use kinit -n with a normal principal name. If supported by the KDC, the principal (but not realm) will be replaced by the anonymous principal. As of release 1.8, the MIT Kerberos KDC supports only fully anonymous operation.

-p principal
  Authenticate principal to the kadmin/fqdn service. Otherwise, kadmin will append /admin to the primary principal name of the default credentials cache, the value of the USER environment variable, or the username as obtained with getpwuid, in that order of preference.

-q query
  Pass query directly to kadmin, which will perform query and then exit. This can be useful for writing scripts.

-r realm
  Use realm as the default database realm.

-s admin_server[:port]
  Administer the specified admin server at the specified port number (port). This can be useful in administering a realm not known to your client.

-w password
  Use password instead of prompting for one. Note that placing the password for a Kerberos principal with administration access into a shell script can be dangerous if unauthorized users gain read access to the script or can read arguments of this command through ps(1).

-x db_args
  Pass database-specific arguments to kadmin. Supported arguments are for LDAP and the Berkeley-db2 plug-in. These arguments are:
binddn=binddn
   LDAP simple bind DN for authorization on the directory server. Overrides the
   ldap_kadmind_dn parameter setting in krb5.conf(4).

bindpwd=bindpwd
   Bind password.

dbname=name
   For the Berkeley-db2 plug-in, specifies a name for the Kerberos database.

nconns=num
   Maximum number of server connections.

port=num
   Directory server connection port.

Commands

list_requests
   Lists all the commands available for kadmin. Aliased by lr and ?.

get_prives
   Lists the current Kerberos administration privileges (ACLs) for the principal that is
   currently running kadmin. The privileges are based on the /etc/krb5/kadm5.acl file on
   the master KDC. Aliased by getprivs.

add_principal [options] newprinc
   Creates a new principal, newprinc, prompting twice for a password. If the -policy option is
   not specified and a policy named default exists, then the default policy is assigned to the
   principal; note that the assignment of the default policy occurs automatically only when a
   principal is first created, so the default policy must already exist for the assignment to
   occur. The automatic assignment of the default policy can be suppressed with the
   -clearpolicy option. This command requires the add privilege. Aliased by addprinc and
   ank. The options are:

   -expire expdate
      Expiration date of the principal. See the Time Formats section for the valid absolute time
      formats that you can specify for expdate.

   -pwexpire pwexpdate
      Password expiration date. See the Time Formats section for the valid absolute time
      formats that you can specify for pwexpdate.

   -maxlife maxlife
      Maximum ticket life for the principal. See the Time Formats section for the valid time
      duration formats that you can specify for maxlife.

   -maxrenewlife maxrenewlife
      Maximum renewable life of tickets for the principal. See the Time Formats section for
      the valid time duration formats that you can specify for maxrenewlife.

   -kvno kvno
      Explicitly set the key version number.
-policy policy
    Policy used by the principal. If both the -policy and -clearpolicy options are not
    specified, the default policy is used if it exists; otherwise, the principal will have no
    policy. Also note that the password and principal name must be different when you add
    a new principal with a specific policy or the default policy.

-clearpolicy
    -clearpolicy prevents the default policy from being assigned when -policy is not
    specified. This option has no effect if the default policy does not exist.

[-]+allow_postdated
    -allow_postdated prohibits the principal from obtaining postdated tickets. (Sets the
    KRB5_KDB_DISALLOW_POSTDATED flag.) +allow_postdated clears this flag.

[-]+allow_forwardable
    -allow_forwardable prohibits the principal from obtaining forwardable tickets. (Sets the
    KRB5_KDB_DISALLOW_FORWARDABLE flag.) +allow_forwardable clears this flag.

[-]+allow_renewable
    -allow_renewable prohibits the principal from obtaining renewable tickets. (Sets the
    KRB5_KDB_DISALLOW_RENEWABLE flag.) +allow_renewable clears this flag.

[-]+allow_proxiable
    -allow_proxiable prohibits the principal from obtaining proxiable tickets. (Sets the
    KRB5_KDB_DISALLOW_PROXIABLE flag.) +allow_proxiable clears this flag.

[-]+allow_dup_skey
    -allow_dup_skey disables user-to-user authentication for the principal by prohibiting
    this principal from obtaining a session key for another user. (Sets the
    KRB5_KDB_DISALLOW_DUP_SKEY flag.) +allow_dup_skey clears this flag.

[-]+requires_preauth
    +requires_preauth requires the principal to preauthenticate before being allowed to
    kinit. (Sets the KRB5_KDB_REQUIRES_PRE_AUTH flag.) -requires_preauth clears this
    flag.

[-]+requires_hwauth
    +requires_hwauth requires the principal to preauthenticate using a hardware device
    before being allowed to kinit. (Sets the KRB5_KDB_REQUIRES_HW_AUTH flag.)
    -requires_hwauth clears this flag.

[-]+allow_svr
    -allow_svr prohibits the issuance of service tickets for the principal. (Sets the
    KRB5_KDB_DISALLOW_SVR flag.) +allow_svr clears this flag.

[-]+allow_tgs_req
    -allow_tgs_req specifies that a Ticket-Granting Service (TGS) request for a service
    ticket for the principal is not permitted. This option is useless for most things.
+allow_tgs_req clears this flag. The default is +allow_tgs_req. In effect, 
–allow_tgs_req sets the KRB5_KDB_DISALLOW_TGT_BASED flag on the principal in the 
database.

{-}+allow_tix
–allow_tix forbids the issuance of any tickets for the principal. +allow_tix clears this 
flag. The default is +allow_tix. In effect, –allow_tix sets the 
KRB5_KDB_DISALLOW_ALL_TIX flag on the principal in the database.

{-}+needchange
+needchange sets a flag in attributes field to force a password change; –needchange 
clears it. The default is –needchange. In effect, +needchange sets the 
KRB5_KDB_REQUIRES_PWDCHANGE flag on the principal in the database.

{-}+password_changing_service
+password_changing_service sets a flag in the attributes field marking this as a 
password change service principal (useless for most things). 
–password_changing_service clears the flag. This flag intentionally has a long name. 
The default is –password_changing_service. In effect, +password_changing_service 
sets the KRB5_KDB_PWCHANGE_SERVICE flag on the principal in the database.

{-}+ok_as_delegate
+ok_as_delegate sets the OK-AS-DELEGATE flag on tickets issued for use with this 
principal as the service, which clients may use as a hint that credentials can and should 
be delegated when authenticating to the service. (Sets the KRB5_KDB_OK_AS_DELEGATE 
flag.) –ok_as_delegate clears this flag.

{-}+ok_to_auth_as_delegate
+ok_to_auth_as_delegate sets the service to allow the use of S4U2Self. 
–ok_to_auth_as_delegate clears this flag.

-randkey
Sets the key of the principal to a random value.

-pw password
Sets the key of the principal to the specified string and does not prompt for a password. 
Note that using this option in a shell script can be dangerous if unauthorized users gain 
read access to the script.

-e "enc:salt..."
Override the list of enctype:salttype pairs given in kdc.conf(4) for setting the key of the 
principal. The quotes are necessary if there are multiple enctype:salttype pairs. One key 
for each similar enctype and same salttype will be created and the first one listed will be 
used. For example, in a list of two similar encyctypes with the same salt, 
“des-cbc-crc:normal des-cbc-md5:normal”, one key will be created and it will be of type 
des-cbc-crc:normal.
Example:

```bash
kadmin: addprinc tlyu/admin
WARNING: no policy specified for "tlyu/admin@ACME.COM";
defaulting to no policy.
Enter password for principal tlyu/admin@ACME.COM:
Re-enter password for principal tlyu/admin@ACME.COM:
Principal "tlyu/admin@ACME.COM" created.
kadmin:
```

Errors:

- **KADM5_AUTH_ADD** (requires add privilege)
- **KADM5_BAD_MASK** (should not happen)
- **KADM5_DUP** (principal exists already)
- **KADM5_UNK_POLICY** (policy does not exist)
- **KADM5_PASS_Q_*** (password quality violations)

**delete_principal** [-force] **principal**

Deletes the specified principal from the database. This command prompts for deletion, unless the -force option is given. This command requires the delete privilege. Aliased by delprinc.

Example:

```bash
kadmin: delprinc mwm_user
Are you sure you want to delete the principal "mwm_user@ACME.COM"? (yes/no): yes
Principal "mwm_user@ACME.COM" deleted.
Make sure that you have removed this principal from all kadmind ACLs before reusing.
kadmin:
```

Errors:

- **KADM5_AUTH_DELETE** (requires delete privilege)
- **KADM5_UNK_PRINC** (principal does not exist)

**modify_principal** [options] **principal**

Modifies the specified principal, changing the fields as specified. The options are as above for add_principal, except that password changing is forbidden by this command. In addition, the option -clearpolicy will clear the current policy of a principal. This command requires the modify privilege. Aliased by modprinc.

- **unlock**

  Unlocks the principal so that it can successfully authenticate. If the principal had previously been locked due to reaching maxfailure in failurecountinterval time then the principal will be locked for lockoutduration time.
Errors:
   KADM5_AUTH_MODIFY (requires modify privilege)
   KADM5_UNK_PRINC (principal does not exist)
   KADM5_UNK_POLICY (policy does not exist)
   KADM5_BAD_MASK (should not happen)

change_password [options] principal
Changes the password of principal. Prompts for a new password if neither -randkey or -pw is specified. Requires the changepw privilege, or that the principal that is running the program to be the same as the one changed. Aliased by cpw. The following options are available:

- randkey
   Sets the key of the principal to a random value.

- pw password
   Sets the password to the specified string. Not recommended.

-e "enc:salt..."
   Override the list of enctypes:sa salt pairs given in kdc.conf(4) for setting the key of the principal. The quotes are necessary if there are multiple enctypes:sa salt pairs. For each key, the first matching similar enctype and same salttype in the list will be used to set the new key(s).

-keepold
   Keeps the previous kvno’s keys around. There is no easy way to delete the old keys, and this flag is usually not necessary except perhaps for TGS keys as it will allow existing valid TGTs to continue to work.

Example:

   kadmin: cpw systest
   Enter password for principal systest@ACME.COM:
   Re-enter password for principal systest@ACME.COM:
   Password for systest@ACME.COM changed.
   kadmin:

Errors:
   KADM5_AUTH_MODIFY (requires the modify privilege)
   KADM5_UNK_PRINC (principal does not exist)
   KADM5_PASS_Q_* (password policy violation errors)
   KADM5_PASS_REUSE (password is in principal’s password history)
   KADM5_PASS_TOO_SOON (current password minimum life not expired)
get_principal [-terse] principal

Gets the attributes of principal. Requires the inquire privilege, or that the principal that is running the program to be the same as the one being listed. With the -terse option, outputs fields as quoted tab-separated strings. Aliased by getprinc.

Examples:

kadmin: getprinc tlyu/admin
Principal: tlyu/admin@ACME.COM
Expiration date: [never]
Last password change: Thu Jan 03 12:17:46 CET 2008
Password expiration date: [none]
Maximum ticket life: 24855 days 03:14:07
Maximum renewable life: 24855 days 03:14:07
Last modified: Thu Jan 03 12:17:46 CET 2008 (root/admin@ACME.COM)
Last successful authentication: [never]
Last failed authentication: [never]
Failed password attempts: 0
Number of keys: 5
Key: vno 2, AES-256 CTS mode with 96-bit SHA-1 HMAC, no salt
Key: vno 2, AES-128 CTS mode with 96-bit SHA-1 HMAC, no salt
Key: vno 2, Triple DES cbc mode with HMAC/shal, no salt
Key: vno 2, ArcFour with HMAC/md5, no salt
Key: vno 2, DES cbc mode with RSA-MD5, no salt
Attributes: REQUIRES_PRE_AUTH
Policy: [none]

kadmin: getprinc -terse tlyu/admin
"tlyu/admin@ACME.COM" 0 1199359066 0 2147483647
"root/admin@ACME.COM" 1199359066 128 2 0 "[none]" 21474836
47 0 0 0 5 1 2 18 0 1 2
17 0 1 2 16 0 1 2 23 0 12
3 0

Errors:
KADM5_AUTH_GET (requires the get [inquire] privilege)
KADM5_UNK_PRINC (principal does not exist)

list_principals [expression]

Retrieves all or some principal names. expression is a shell-style glob expression that can contain the wild-card characters ?, *, and []'s. All principal names matching the expression are printed. If no expression is provided, all principal names are printed. If the expression does not contain an "@" character, an "@" character followed by the local realm is appended to the expression. Requires the list privilege. Aliased by listprincs, get_principals, and getprincs.
Examples:

```
  kadmin: listprincs test*
  test3@ACME.COM
test2@ACME.COM
test1@ACME.COM
testuser@ACME.COM
  kadmin:
```

`add_policy [options] policy`

Adds the named policy to the policy database. Requires the `add` privilege. Aliased by `addpol`. The following options are available:

- **-maxfailure maxnumber**
  sets the maximum number of failures before the principal is locked after authentication failures in `failurecountinterval` time.

- **-failurecountinterval failuretime**
  sets the time after which the authentication failure count is reset to 0. See the “Time Formats” section, below, for the valid time duration formats that you can specify for `failuretime`.

- **-lockoutduration lockouttime**
  sets the time in which the principal is locked from authenticating if `maxfailure` authentication failures occur within `failurecountinterval` time. See the “Time Formats” section, below, for the valid time duration formats that you can specify for `lockouttime`.

- **-maxlife maxlife**
  sets the maximum lifetime of a password. See the “Time Formats” section for the valid time duration formats that you can specify for `maxlife`.

- **-minlife minlife**
  sets the minimum lifetime of a password. See the “Time Formats” section for the valid time duration formats that you can specify for `minlife`.

- **-minlength length**
  sets the minimum length of a password.

- **-minclasses number**
  sets the minimum number of character classes allowed in a password. The valid values are:
  1. only letters (himom)
  2. both letters and numbers (hi2mom)
  3. letters, numbers, and punctuation (hi2mom!)
-history number
  sets the number of past keys kept for a principal.

Errors:
  KADM5_AUTH_ADD (requires the add privilege)
  KADM5_DUP (policy already exists)

delete_policy [-force] policy
  Deletes the named policy. Unless the -force option is specified, prompts for confirmation before deletion. The command will fail if the policy is in use by any principals. Requires the delete privilege. Aliased by detpol.

Example:
  kadmin: del_policy guests
  Are you sure you want to delete the policy "guests"? (yes/no): yes
  Policy "guests" deleted.
  kadmin:

Errors:
  KADM5_AUTH_DELETE (requires the delete privilege)
  KADM5_UNK_POLICY (policy does not exist)
  KADM5_POLICY_REF (reference count on policy is not zero)

modify_policy [options] policy
  Modifies the named policy. Options are as above for add_policy. Requires the modify privilege. Aliased by modpol.

Errors:
  KADM5_AUTH_MODIFY (requires the modify privilege)
  KADM5_UNK_POLICY (policy does not exist)

get_policy [-terse] policy
  Displays the values of the named policy. Requires the inquire privilege. With the -terse flag, outputs the fields as quoted strings separated by tabs. Aliased by getpol.

Examples:
  kadmin: get_policy admin
  Policy: admin
  Maximum password life: 180 days 00:00:00
  Minimum password life: 00:00:00
  Minimum password length: 6
  Minimum number of password character classes: 2
  Number of old keys kept: 5
  Reference count: 17

kadmin(1M)
Maximum password failures before lockout: 3
Password failure count reset interval: 180
Password lockout duration: 60
kadmin: get_policy -terse admin
admin admin 1552000 0 6 2 5 17 3 180 60
kadmin:

Errors:
KADM5_AUTH_GET (requires the get privilege)
KADM5_UNK_POLICY (policy does not exist)

list_policies [expression]
Retrieves all or some policy names. expression is a shell-style glob expression that can
contain the wild-card characters ?, *, and []'s. All policy names matching the expression are
printed. If no expression is provided, all existing policy names are printed. Requires the
list privilege. Aliased by listpols, get_policies, and getpols.

Examples:
    kadmin: listpols
test-pol dict-only once-a-min test-pol-nopw
    kadmin: listpols t*
test-pol test-pol-nopw kadmin:

ktadd [-k keytab] [-q] [-e keysaltlist] [-norandkey] [[principal | -glob princ-exp]] [...]
Adds a principal or all principals matching princ-exp to a keytab. It randomizes each
principal’s key in the process, to prevent a compromised admin account from reading out
all of the keys from the database. However, kadmin.local has the -norandkey option,
which leaves the keys and their version numbers unchanged, similar to the Kerberos V4
ext_srtab command. That allows users to continue to use the passwords they know to
login normally, while simultaneously allowing scripts to login to the same account using a
keytab. There is no significant security risk added since kadmin.local must be run by root
on the KDC anyway.

ktadd requires the inquire and changepw privileges. An entry for each of the principal’s
unique encryption types is added, ignoring multiple keys with the same encryption type
but different salt types. If the -k argument is not specified, the default keytab file,
/etc/krb5/krb5.keytab, is used.

The "-e enctype:salt" option overrides the list of encotypes given in krb5.conf(4), in the
permitted_encotypes parameter. If "-e enctype:salt" is not used and
permitted_encotypes is not defined in krb5.conf(4), a key for each enctype supported by
the system on which kadmin is run will be created and added to the keytab. Restricting the
encotypes of keys in the keytab is useful when the system for which keys are being created
does not support the same set of encotypes as the KDC. Note that ktadd modifies the enctype
of the keys in the principal database as well.
If the -q option is specified, less status information is displayed. Aliased by \texttt{xst}. The -glob option requires the list privilege. Also, note that if you use -glob to create a keytab, you need to remove \texttt{/etc/krb5/kadm5.keytab} and create it again if you want to use \texttt{-p */admin} with \texttt{kadmin}.

\texttt{princ-exp}

\texttt{princ-exp} follows the same rules described for the \texttt{list_principals} command.

Example:

\begin{verbatim}
  kadmin: ktadd -k /tmp/new-keytab nfs/chicago
          Entry for principal nfs/chicago with kvno 2,
          encryption type DES-CBC-CRC added to keytab
          WRFILE:/tmp/new-keytab.
  kadmin:

kadmin: ktremove [-k keytab] [-q] principal [kvno | all | old]
          Removes entries for the specified principal from a keytab. Requires no privileges, since this
          does not require database access. If \texttt{all} is specified, all entries for that principal are
          removed; if \texttt{old} is specified, all entries for that principal except those with the highest \texttt{kvno}
          are removed. Otherwise, the value specified is parsed as an integer, and all entries whose
          \texttt{kvno} match that integer are removed. If the \texttt{-k} argument is not specified, the default keytab
          file, \texttt{/etc/krb5/krb5.keytab}, is used. If the \texttt{-q} option is specified, less status information is
          displayed. Aliased by \texttt{ktrem}.

          Example:

          kadmin: ktremove -k /tmp/new-keytab nfs/chicago
                  Entry for principal nfs/chicago with kvno 2
                  removed from keytab
                  WRFILE:/tmp/new-keytab.
          kadmin:

quint

          Quits \texttt{kadmin}. Aliased by \texttt{exit} and \texttt{q}.
\end{verbatim}

Time Formats

Various commands in \texttt{kadmin} can take a variety of time formats, specifying time durations or
absolute times. The \texttt{kadmin} option variables \texttt{maxrenewlife}, \texttt{maxlife}, and \texttt{minlife} are time
durations, whereas \texttt{expdate} and \texttt{pwexpdate} are absolute times.

Examples:

\begin{verbatim}
  kadmin: modprinc -expire "12/31 7pm" jdb
  kadmin: modprinc -maxrenewlife "2 fortnight" jdb
  kadmin: modprinc -pwexpire "this sunday" jdb
  kadmin: modprinc -expire never jdb
  kadmin: modprinc -maxlife "7:00:00pm tomorrow" jdb
\end{verbatim}

Note that times which do not have the "ago" specifier default to being absolute times, unless
they appear in a field where a duration is expected. In that case, the time specifier will be
interpreted as relative. Specifying "ago" in a duration can result in unexpected behavior.
The following time formats and units can be combined to specify a time. The time and date format examples are based on the date and time of July 2, 1999, 1:35:30 p.m.

<table>
<thead>
<tr>
<th>Time Format</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>hh[:mm][:ss][am/pm/a.m./p.m.]</td>
<td>1p.m., 1:35, 1:35:30pm</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hh</td>
<td>hour (12-hour clock, leading zero permitted but not required)</td>
</tr>
<tr>
<td>mm</td>
<td>minutes</td>
</tr>
<tr>
<td>ss</td>
<td>seconds</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Date Format</th>

<td>never</td>
<td></td>
</tr>
</tbody>
</table>

**Environment Variables**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `kadmin`:

**PAGER**

The command to use as a filter for paging output. This can also be used to specify options. The default is `more(1)`.
Files
/var/krb5/principal
    Kerberos principal database.
/var/krb5/principal.ulo
    The update log file for incremental propagation.
/var/krb5/principal.kadm5
    Kerberos administrative database. Contains policy information.
/var/krb5/principal.kadm5.lock
    Lock file for the Kerberos administrative database. This file works backwards from most other lock files (that is, kadmin will exit with an error if this file does not exist).
/var/krb5/kadm5.dict
    Dictionary of strings explicitly disallowed as passwords.
/etc/krb5/kadm5.acl
    List of principals and their kadmin administrative privileges.
/etc/krb5/kadm5.keytab
    Keytab for kadmin principals: kadmin/fqdn, changepw/fqdn, and kadmin/changepw.

Attributes
See attributes(5) for descriptions of the following attributes:

History
The kadmin program was originally written by Tom Yu at MIT, as an interface to the OpenVision Kerberos administration program.

Diagnostics
The kadmin command is currently incompatible with the MIT kadmin daemon interface, so you cannot use this command to administer an MIT-based Kerberos database. However, clients running the Solaris implementation of Kerberos can still use an MIT-based KDC.
kadmind – Kerberos administration daemon

kadmind runs on the master key distribution center (KDC), which stores the principal and policy databases. kadmind accepts remote requests to administer the information in these databases. Remote requests are sent, for example, by kpasswd(1), gkadmin(1M), and kadmin(1M) commands, all of which are clients of kadmind. When you install a KDC, kadmind is set up in the init scripts to start automatically when the KDC is rebooted.

kadmind requires a number of configuration files to be set up for it to work:

/etc/krb5/kdc.conf
The KDC configuration file contains configuration information for the KDC and the Kerberos administration system. kadmind understands a number of configuration variables (called relations) in this file, some of which are mandatory and some of which are optional. In particular, kadmind uses the acl_file, dict_file, admin_keytab, and kadmind_port relations in the [realms] section. Refer to the kdc.conf(4) man page for information regarding the format of the KDC configuration file.

/etc/krb5/kadm5.keytab
kadmind requires a keytab (key table) containing correct entries for the kadmin/fqdn, kadmin/changepw and kadmin/changepw principals for every realm that kadmind answers requests. The keytab can be created with the kadmin(1M) or kdb5_util(1M) command. The location of the keytab is determined by the admin_keytab relation in the kdc.conf(4) file.

/etc/krb5/kadm5.acl
kadmind uses an ACL (access control list) to determine which principals are allowed to perform Kerberos administration actions. The path of the ACL file is determined by the acl_file relation in the kdc.conf file. See kdc.conf(4). For information regarding the format of the ACL file, refer to kadm5.acl(4).

The kadmind daemon will need to be restarted to reread the kadm5.acl file after it has been modified. You can do this, as root, with the following command:

# svcadm restart svc:/network/security/kadmin:default

After kadmind begins running, it puts itself in the background and disassociates itself from its controlling terminal.

kadmind can be configured for incremental database propagation. Incremental propagation allows slave KDC servers to receive principal and policy updates incrementally instead of receiving full dumps of the database. These settings can be changed in the kdc.conf(4) file:

sunw_dbprop_enable = [true | false]
Enable or disable incremental database propagation. Default is false.
sunw_dbprop_master_uloysize = N
  Specifies the maximum amount of log entries available for incremental propagation to the slave KDC servers. The maximum value that this can be is 2500 entries. Default value is 1000 entries.

The kprop/<hostname>@<REALM> principal must exist in the master's kadm5.keytab file to enable the slave to authenticate incremental propagation from the master. In the principal syntax above, <hostname> is the master KDC's host name and <REALM> is the realm in which the master KDC resides.

Kerberos client machines can automatically migrate Unix users to the default Kerberos realm specified in the local krb5.conf, if the user does not have a valid kerberos account already. You achieve this by using the pam_krb5_migrate service module for the service in question. The Kerberos service principal used by the client machine attempting the migration needs to be validated using the u privilege in kadm5.acl. When using the u privilege, kadm validates user passwords using PAM, specifically using a PAM_SERVICE name of k5migrate by calling pam_authenticate(3PAM) and pam_acct_mgmt(3PAM).

A suitable PAM stack configuration example for k5migrate would look like:

```
k5migrate auth required pam_unix_auth.so.1
k5migrate account required pam_unix_account.so.1
```

**Options**

The following options are supported:

- **-nofork**
  Specifies that kadm does not put itself in the background and does not disassociate itself from the terminal. In normal operation, you should use the default behavior, which is to allow the daemon to put itself in the background.

- **-m**
  Specifies that the master database password should be retrieved from the keyboard rather than from the stash file. When using -m, the kadm daemon receives the password prior to putting itself in the background. If used in combination with the -d option, you must explicitly place the daemon in the background.

- **-port port-number**
  Specifies the port on which the kadm daemon listens for connections. The default is controlled by the kadm_port relation in the kdc.conf file.

- **-P pid_file**
  Specifies the file to which the PID of kadm process should be written to after it starts up. This can be used to identify whether kadm is still running and to allow init scripts to stop the correct process.

- **-r realm**
  Specifies the default realm that kadm serves. If realm is not specified, the default realm of the host is used. kadm answers requests for any realm that exists in the local KDC database and for which the appropriate principals are in its keytab.
Pass database-specific arguments to kadmind. Supported arguments are for LDAP and the Berkeley-db2 plug-in. These arguments are:

- `binddn=binddn`
  LDAP simple bind DN for authorization on the directory server. Overrides the `ldap_kadmind_dn` parameter setting in `krb5.conf`.

- `bindpwd=bindpwd`
  Bind password.

- `dbname=name`
  For the Berkeley-db2 plug-in, specifies a name for the Kerberos database.

- `nconns=num`
  Maximum number of server connections.

- `port=num`
  Directory server connection port.

### Files

- `/var/krb5/principal`
  Kerberos principal database.

- `/var/krb5/principal.olog`
  The update log file for incremental propagation.

- `/var/krb5/principal.kadm5`
  Kerberos administrative database containing policy information.

- `/var/krb5/principal.kadm5.lock`
  Kerberos administrative database lock file. This file works backwards from most other lock files (that is, `kadmin` exits with an error if this file does not exist).

- `/var/krb5/kadm5.dict`
  Dictionary of strings explicitly disallowed as passwords.

- `/etc/krb5/kadm5.acl`
  List of principals and their `kadmin` administrative privileges.

- `/etc/krb5/kadm5.keytab`
  Keytab for `kadmin` principals: `kadmin/fqdn`, `changepw/fqdn`, and `kadmin/changepw`.

- `/etc/krb5/kdc.conf`
  KDC configuration information.

### Attributes

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/security/kerberos-5</td>
</tr>
</tbody>
</table>
The Kerberos administration daemon (kadmind) is now compliant with the change-password standard mentioned in RFC 3244, which means it can now handle change-password requests from non-Solaris Kerberos clients.

The kadmind service is managed by the service management facility, smf(5), under the service identifier: svc:/network/security/kadmin

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service’s status can be queried using the svcs(1) command.

The -d and -p arguments are made obsolete with the -nofork and -port arguments, respectively. The -d and -p arguments might be removed in a future release of the Solaris operating system.
**Name**  
kcfd – kernel-level cryptographic framework daemon

**Synopsis**  
kcfd

**Description**  
The kcfd daemon helps in managing CPU usage by cryptographic operations performed in software by kernel threads. The system utilization associated with these threads is charged to the kcfd process. It also does module verification for kernel cryptographic modules.

Only a privileged user can run this daemon. The kcfd daemon is automatically invoked in run level 1, after /usr is mounted. A previously invoked kcfd daemon that is still running must be stopped before invoking another kcfd command.

Manually starting and restarting kcfd is not recommended. If it is necessary to do so, use the cryptoadm(1M) start and stop subcommands.

**Exit Status**  
The following exit values are returned:

- 0  
  Daemon started successfully.
- > 1  
  Daemon failed to start.

**Attributes**

kclient – set up a machine as a Kerberos client

Synopsis

/usr/sbin/kclient [-n] [-R realm] [-a adminuser] [-c filepath]
[-d dnsarg] [-f fqdn_list] [-h logical_host_name] [-k kdc_list]
[-m master_kdc_list] [-p profile] [-s pam_service] [-T kdc_vendor]

Description

By specifying the various command options, you can use the kclient utility to:

- Configure a machine as a Kerberos client for a specified realm and for KDC by setting up krb5.conf.
- Add the Kerberos host principal to the local host’s keytab file (/etc/krb5/krb5.keytab).
- Set up the machine to do kerberized NFS.
- Bring over a master krb5.conf copy from a specified pathname.
- Setup a machine to do server and/or host/domain name-to-realm mapping lookups by means of DNS.
- Configure a Kerberos client to use an MS Active Directory server. This generates a keytab file with the Kerberos client’s service keys populated.
- Setup a Kerberos client that has no service keys. This is useful when the client does not require service keys, because the client does not wish to host a service that uses Kerberos for security.
- Configure a Kerberos client that is part of a cluster. This option requires the logical host name of the cluster so that the proper service keys are created and populated in the client’s keytab file.
- Setup a Kerberos client to join an environment that consists of Kerberos servers that are non-Solaris and non-MS Active Directory servers.
- Configure pam.conf to use Kerberos authentication for specified services.
- Configure the client as a simple NTP broadcast/multicast client.
- Specify custom domain/host name-to-realm name mappings.
- Setup the Kerberos client to use multiple KDC servers.

The kclient utility needs to be run on the client machine with root permission and can be run either interactively or non-interactively. In the non-interactive mode, the user feeds in the required inputs by means of a profile, command-line options, or a combination of profile and command-line options. The user is prompted for “required” parameter values (realm and adminuser), if found missing in the non-interactive run. The interactive mode is invoked when the utility is run without any command-line arguments.

Both the interactive and non-interactive forms of kclient can add the host/fqdn entry to the local host’s keytab file. They also can require the user to enter the password for the administrative user requested, to obtain the Kerberos Ticket Granting Ticket (TGT) for adminuser. The host/fqdn, nfs/fqdn, and root/fqdn principals can be added to the KDC database (if not already present) before their possible addition to the local host’s keytab.
The `kclient` utility assumes that the local host has been set up for DNS and requires the presence of a valid `resolv.conf(4)`. Also, `kclient` can fail if the localhost time is not synchronized with that of the KDC. For Kerberos to function the localhost time must be within five minutes of that of the KDC. It is advised that both systems run some form of time synchronization protocol, such as the Network Time Protocol (NTP). See the `ntpd man page`, delivered in the `SUNWntpu` package (not a SunOS man page).

**Options**

The non-interactive mode supports the following options:

- `-n`
  Set up the machine for kerberized NFS. This involves making changes to `krb5*` security flavors in `nfssec.conf(4)`. This option will also add `nfs/fqdn` and `root/fqdn` entries to the local host's `keytab` file if the `-K` option has not been specified.

- `-R [ realm ]`
  Specifies the Kerberos realm.

- `-k kdc_list`
  The `-k` option specifies the KDC host names for the Kerberos client. `kdc_list` is a comma-separated list of KDCs. If the `-m` option is not used, it is assumed that the first (or only) host in `kdc_list` is the master KDC host name. Note that the list specified is used verbatim. This is helpful when specifying non-fully qualified KDC host names that can be canonicalized by DNS.

- `-a [ adminuser ]`
  Specifies the Kerberos administrative user.

- `-T kdc_vendor`
  Configure the Kerberos client to associate with a third party server. Valid `kdc_vendor` currently supported are:

  - `ms_ad`
    Microsoft Active Directory

  - `mit`
    MIT KDC server

  - `heimdal`
    Heimdal KDC server

  - `shishi`
    Shishi KDC server

  Knowing the administrative password will be required to associate the client with the server if the `ms_ad` option is specified.

- `c [ filepath ]`
  Specifies the pathname to the `krb5.conf(4)` master file, to be copied over to the local host. The path specified normally points to a master copy on a remote host and brought over to the local host by means of NFS.
-d [ dnsarg ]
  Specifies the DNS lookup option to be used and specified in the krb5.conf(4) file. Valid
dnsarg entries are: none, dns_lookup_kdc, dns_lookup_realm and dns_fallback. Any
other entry is considered invalid. The latter three dnsarg values assume the same meaning
as those described in krb5.conf. dns_lookup_kdc implies DNS lookups for the KDC and
the other servers. dns_lookup_realm is for host/domain name-to-realm mapping by
means of DNS. dns_fallback is a superset and does DNS lookups for both the servers and
the host/domain name-to-realm mapping. A lookup option of none specifies that DNS is
not be used for any kind of mapping lookup.

-D domain_list
  Specifies the host and/or domain names to be mapped to the Kerberos client's default realm
name. domain_list is a comma-separated list, for example
"example.com,host1.example.com". If the -D option is not used, then only the client's
domain is used for this mapping. For example, if the client is host1.eng.example.com,
then the domain that is mapped to the EXAMPLE.COM realm is example.com.

-K
  Configure the Kerberos client without service keys, which are usually stored in
/etc/krb5/krb5.keytab. This is useful in the following scenarios:
  - The client IP address is dynamically assigned and therefore does not host Kerberized
    services.
  - Client has a static IP address, but does not want to host any Kerberized services.
  - Client has a static IP address, but the local administrator does not currently have service
    keys available for the machine. It is expected that, at a later time, these keys will be
    installed on the machine.

-f [ fqdn_list ]
  This option creates a service principal entry (host/nfs/root) associated with each of the
listed fqdn's, if required, and subsequently adds the entries to the local host's keytab.
  fqdn_list is a comma-separated list of one or more fully qualified DNS domain names.
  This option is especially useful in Kerberos realms having systems offering kerberized
services, but situated in multiple different DNS domains.

-h logical_host_name
  Specifies that the Kerberos client is a node in a cluster. The logical_host_name is the logical
host name given to the cluster. The resulting /etc/krb5/krb5.conf and
/etc/krb5/krb5.keytab files must be manually copied over to the other members of the
cluster.

-m master_kdc_list
  This option specifies the master KDC host names to be used by the Kerberos client.
master_kdc_list is a comma-separated list of the host names of master KDCs for the client.
If the -m option is not used, then it is assumed that the first KDC host name listed with the
-k option is the master KDC.
Specifiesthe profile to be used to enable the reading in of the values of all the parameters required for setup of the machine as a Kerberos client.

The profile should have entries in the format:

```
PARAM <value>
```

Valid `PARAM` entries are: REALM, KDC, ADMIN, FILEPATH, NFS, DNSLOOKUP, FQDN, NOKEY, NOSOL, LHN, KDCVENDOR, RMAP, MAS, and PAM.

[domain_list]`, `-m [master_kdc]`, and `-s [pam_service]` command-line options, respectively. Any other `PARAM` entry is considered invalid and is ignored.

The NFS profile entry can have a value of 0 (do nothing) or 1 (operation is requested). Any other value is considered invalid and is ignored.

Keep in mind that the command line options override the `PARAM` values listed in the profile.

```
-s pam_service auth_type[,...]
```

Specifies that the PAM service names, listed in `pam_service`, are authenticated through Kerberos. Using this option updates `pam.conf(4)` to include a separate authentication stack with `pam_krb5(5)`. Examples of `pam_service` names are sshd-kbdint, xscreensaver, and so forth.

`auth_type` can be one of the following keywords:

```
first
   Try authenticating through Kerberos first. If this fails try to authenticate through Unix.
only
   Try to authenticate only through Kerberos.
optional
   Try authenticating through Unix first. If this is successful try to authenticate through Kerberos.
```

Examples

**EXAMPLE 1**  Setting Up a Kerberos Client Using Command-Line Options

To setup a Kerberos client using the `clntconfig/admin` administrative principal for realm 'ABC.COM', kdc 'example1.com' and that also does kerberized NFS, enter:

```
# /usr/sbin/kclient -n -R ABC.COM -k example1.com -a clntconfig
```

Alternatively, to set up a Kerberos client using the `clntconfig/admin` administrative principal for the realm 'EAST.ABC.COM', kdc 'example2.east.abc.com' and that also needs service principal(s) created and/or added to the local keytab for multiple DNS domains, enter:
EXAMPLE 1  Setting Up a Kerberos Client Using Command-Line Options

(Continued)

# /usr/sbin/kclient -n -R EAST.ABC.COM -k example2.east.abc.com \ 
  -f west.abc.com,central.abc.com -a clntconfig

Note that the krb5 administrative principal used by the administrator needs to have only add, 
inquire, change-pwd and modify privileges (for the principals in the KDC database) in order 
for the kclient utility to run. A sample `kadm5.acl(4)` entry is:

clntconfig/admin@ABC.COM acmi

EXAMPLE 2  Setting Up a Kerberos Client Using the Profile Option

To set up a Kerberos client using the clntconfig/admin administrative principal for realm 
'ABC.COM', kdc 'example1.com' and that also copies over the master krb5.conf from a 
specified location, enter:

# /usr/sbin/kclient -p /net/example1.com/export/profile.krb5

The contents of `profile.krb5`:

REALM  ABC.COM
KDC example1
ADMIN  clntconfig
FILEPATH /net/example1.com/export/krb5.conf
NFS  0
DNSLOOKUP none

EXAMPLE 3  Setting Up a Kerberos Client That Has a Dynamic IP Address

In this example a Kerberos client is a DHCP client that has a dynamic IP address. This client 
does not wish to host any Kerberized services and therefore does not require a keytab 
(`/etc/krb5/krb5.keytab`) file.

For this type of client the administrator would issue the following command to configure this 
machine to be a Kerberos client of the ABC.COM realm with the KDC server 
kdc1.example.com:

# /usr/sbin/kclient -K -R EXAMPLE.COM -k kdc1.example.com

Files

/etc/krb5/kadm5.acl
    Kerberos access control list (ACL) file.

/etc/krb5/krb5.conf
    Default location for the local host's configuration file.

/etc/krb5/krb5.keytab
    Default location for the local host's keytab file.

/etc/nfssec.conf
    File listing NFS security modes.
/etc/resolv.conf
  DNS resolver configuration file.

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

kadms.acl(4), krb5.conf(4), nfssec.conf(4), pam.conf(4), resolv.conf(4), attributes(5),
pam_krb5(5)

Notes

fqdn stands for the Fully Qualified Domain Name of the local host. The kclient utility saves copies of both the krb5.conf(4) and nfssec.conf(4) files to files with corresponding names and .sav extensions. The optional copy of the krb5.conf(4) master file is neither encrypted nor integrity-protected and it takes place over regular NFS.
kdb5_ldap_util – Kerberos configuration utility

**Synopsis**

```bash
kdb5_ldap_util [-D user_dn [-w passwd]] [-H ldap_uri] command [command_options]
```

**Description**
The kdb5_ldap_util utility allows an administrator to manage realms, Kerberos services, and ticket policies. The utility offers a set of general options, described under OPTIONS, and a set of commands, which, in turn, have their own options. Commands and their options are described in their own subsections, below.

**Options**
The kdb5_ldap_util utility has a small set of general options that apply to the kdb5_ldap_util utility itself and a larger number of options that apply to specific commands. A number of these command-specific options apply to multiple commands and are described in their own section, below.

### General Options
The following general options are supported:

- **-D user_dn**
  Specifies the distinguished name (DN) of a user who has sufficient rights to perform the operation on the LDAP server.

- **-H ldap_uri**
  Specifies the URI of the LDAP server.

- **-w passwd**
  Specifies the password of user_dn. This option is not recommended.

### Command-specific Options
The following options apply to a number of kdb5_ldap_util commands.

- **-subtrees subtree_dn_list**
  Specifies the list of subtrees containing the principals of a realm. The list contains the DNs of the subtree objects separated by a colon.

- **-sscope search_scope**
  Specifies the scope for searching the principals under a subtree. The possible values are 1 or one (one level), 2 or sub (subtrees).

- **-containerref container_reference_dn**
  Specifies the DN of the container object in which the principals of a realm will be created. If the container reference is not configured for a realm, the principals will be created in the realm container.

- **-maxktlife max_ticket_life**
  Specifies maximum ticket life for principals in this realm.

- **-maxrenewlife max_renewable_ticket_life**
  Specifies maximum renewable life of tickets for principals in this realm.

- **-r realm**
  Specifies the Kerberos realm of the database; by default the realm returned by krb5_default_local_realm(3) is used.
The `kdb5_ldap_util` utility comprises a set of commands, each with its own set of options. These commands are described in the following subsections.

### The `create` Command

The `create` command creates a realm in a directory. The command has the following syntax:

```bash
```

The `create` command has the following options:

- `-subtree subtree_dn_list`
  See “Common Command-specific Options,” above.

- `-sscope search_scope`
  See “Common Command-specific Options,” above.

- `-containerref container_reference_dn`
  See “Common Command-specific Options,” above.

- `-k mkeytype`
  Specifies the key type of the master key in the database; the default is that given in `kdc.conf(4)`.

- `-m`
  Specifies that the master database password should be read from the TTY rather than fetched from a file on the disk.

- `-P password`
  Specifies the master database password. This option is not recommended.

- `-sf stashfilename`
  Specifies the stash file of the master database password.

- `-s`
  Specifies that the stash file is to be created.

- `-maxtktlife max_ticket_life`
  See “Common Command-specific Options,” above.

- `-maxrenewlife max_renewable_ticket_life`
  See “Common Command-specific Options,” above.
The modify command modifies the attributes of a realm. The command has the following syntax:

```
modify
[-subtrees subtree_dn_list]
[-sscope search_scope]
[-containerref container_reference_dn]
[-r realm]
[-maxtktlife max_ticket_life]
[-maxrenewlife max_renewable_ticket_life]
[ticket_flags]
```

The modify command has the following options:

- **-subtree subtree_dn_list**
  See “Common Command-specific Options,” above.

- **-sscope search_scope**
  See “Common Command-specific Options,” above.

- **-containerref container_reference_dn**
  See “Common Command-specific Options,” above.

- **-maxtktlife max_ticket_life**
  See “Common Command-specific Options,” above.

- **-maxrenewlife max_renewable_ticket_life**
  See “Common Command-specific Options,” above.

- **-r realm**
  See “Common Command-specific Options,” above.

**ticket_flags**

Specifies the ticket flags. If this option is not specified, by default, none of the flags are set. This means all the ticket options will be allowed and no restriction will be set. See “Ticket Flags” for a list and descriptions of these flags.

The view command displays the attributes of a realm. The command has the following syntax:

```
view [-r realm]
```

The view command has the following option:

- **-r realm**
  See “Common Command-specific Options,” above.
The destroy command destroys a realm, including the master key stash file. The command has the following syntax:

```
destroy [-f] [-r realm]
```

The destroy command has the following options:

- **-f**
  If specified, destroy does not prompt you for confirmation.

- **-r realm**
  See “Common Command-specific Options,” above.

The list command displays the names of realms. The command has the following syntax:

```
list
```

The list command has no options.

The stashsrvpw command enables you to store the password for service object in a file so that a KDC and Administration server can use it to authenticate to the LDAP server. The command has the following syntax:

```
stashsrvpw [-f filename] servicedn
```

The stashsrvpw command has the following option and argument:

- **-f filename**
  Specifies the complete path of the service password file. The default is:
  
  `/var/krb5/service_passwd`

- **servicedn**
  Specifies the distinguished name (DN) of the service object whose password is to be stored in file.

The create_policy command creates a ticket policy in a directory. The command has the following syntax:

```
create_policy \[-r realm\]
[[-maxktl life max_ticket_life]]
[[-maxrenewlife max_renewable_ticket_life]]
[ticket_flags]
policy_name
```

The create_policy command has the following options:

- **-r realm**
  See “Common Command-specific Options,” above.
-maxtktlife max_ticket_life
   See “Common Command-specific Options,” above.

-maxrenewlife max_renewable_ticket_life
   See “Common Command-specific Options,” above.

ticket_flags
   Specifies the ticket flags. If this option is not specified, by default, none of the flags are set. This means all the ticket options will be allowed and no restriction will be set. See “Ticket Flags” for a list and descriptions of these flags.

policy_name
   Specifies the name of the ticket policy.

The modify_policy command modifies the attributes of a ticket policy. The command has the following syntax:

modify_policy \n [-r realm] \n [-maxtktlife max_ticket_life] \n [-maxrenewlife max_renewable_ticket_life] \n [ticket_flags] \n policy_name

The modify_policy command has the same options and argument as those for the create_policy command.

The view_policy command displays the attributes of a ticket policy. The command has the following syntax:

view_policy [-r realm] policy_name

The view_policy command has the following options:

-r realm
   See “Common Command-specific Options,” above.

policy_name
   Specifies the name of the ticket policy.

The destroy_policy command destroys an existing ticket policy. The command has the following syntax:

destroy_policy [-r realm] [force] policy_name

The destroy_policy command has the following options:

-r realm
   See “Common Command-specific Options,” above.
-force
   Forces the deletion of the policy object. If not specified, you will be prompted for
   confirmation before the policy is deleted. Enter yes to confirm the deletion.

policy_name
   Specifies the name of the ticket policy.

The list_policy Command
   The list_policy command lists the ticket policies in the default or a specified realm. The
   command has the following syntax:
   list_policy [-r realm]

   The list_policy command has the following option:
   -r realm
      See "Common Command-specific Options," above.

Ticket Flags
   A number of kdb5_ldap_util commands have ticket_flag options. These flags are
   described as follows:

   {-|+}allow_dup_skey
      -allow_dup_skey disables user-to-user authentication for principals by prohibiting
      principals from obtaining a session key for another user. This setting sets the
      KRB5_KDB_DISALLOW_DUP_SKEY flag. +allow_dup_skey clears this flag.

   {-|+}allow_forwardable
      -allow_forwardable prohibits principals from obtaining forwardable tickets. This setting
      sets the KRB5_KDB_DISALLOW_FORWARDABLE flag. +allow_forwardable clears this flag.

   {-|+}allow_postdated
      -allow_postdated prohibits principals from obtaining postdated tickets. This setting sets
      the KRB5_KDB_DISALLOW_POSTDATED flag. +allow_postdated clears this flag.

   {-|+}allow_proxiable
      -allow_proxiable prohibits principals from obtaining proxiable tickets. This setting sets
      the KRB5_KDB_DISALLOW_PROXIABLE flag. +allow_proxiable clears this flag.

   {-|+}allow_renewable
      -allow_renewable prohibits principals from obtaining renewable tickets. This setting sets
      the KRB5_KDB_DISALLOW_RENEWABLE flag. +allow_renewable clears this flag.

   {-|+}allow_svr
      -allow_svr prohibits the issuance of service tickets for principals. This setting sets the
      KRB5_KDB_DISALLOW_SVR flag. +allow_svr clears this flag.

   {-|+}allow_tgs_req
      -allow_tgs_req specifies that a Ticket-Granting Service (TGS) request for a service ticket
      for principals is not permitted. This option is useless for most purposes. +allow_tgs_req
      clears this flag. The default is +allow_tgs_req. In effect, -allow_tgs_req sets the
      KRB5_KDB_DISALLOW_TGT_BASED flag on principals in the database.
{-|+}allow_tix
-allow_tix forbids the issuance of any tickets for principals. +allow_tix clears this flag.
The default is +allow_tix. In effect, +allow_tix sets the KRBS5_KDB_DISALLOW_ALL_TIX flag on principals in the database.

{-|+}needchange
+needchange sets a flag in the attributes field to force a password change; -needchange clears that flag. The default is -needchange. In effect, +needchange sets the KRBS5_KDB_REQUIRES_PWCHANGE flag on principals in the database.

{-|+}password_changing_service
+password_changing_service sets a flag in the attributes field marking a principal as a password-change-service principal (a designation that is most often not useful).
-password_changing_service clears the flag. That this flag has a long name is intentional. The default is +password_changing_service. In effect, +password_changing_service sets the KRBS5_KDB_PWCHANGE_SERVICE flag on principals in the database.

{-|+}requires_hwauth
+requires_hwauth requires principals to preauthenticate using a hardware device before being allowed to kinit(1). This setting sets the KRBS5_KDB_REQUIRES_HW_AUTH flag.
-requires_hwauth clears this flag.

{-|+}requires_preauth
+requires_preauth requires principals to preauthenticate before being allowed to kinit(1). This setting sets the KRBS5_KDB_REQUIRES_PRE_AUTH flag. -requires_preauth clears this flag.

**Examples**

**EXAMPLE1** Using create

The following is an example of the use of the create command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
create -subtrees o=org -sscope SUB -r ATHENA/MIT.EDU
```

Password for "cn=admin,o=org": password entered
Initializing database for realm 'ATHENA/MIT.EDU'
You will be prompted for the database Master Password.
It is important that you NOT FORGET this password.
Enter KDC database master key: master key entered
Re-enter KDC database master key to verify: master key re-entered jjjjjjj

**EXAMPLE2** Using modify

The following is an example of the use of the modify command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
modify +requires_preauth -r ATHENA/MIT.EDU
```

Password for "cn=admin,o=org": password entered
Password for "cn=admin,o=org": password entered
EXAMPLE3  Using view

The following is an example of the use of the `view` command.

```bash
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
  view -r ATHENA.MIT.EDU
Password for "cn=admin,o=org":
  Realm Name: ATHENA.MIT.EDU
  Subtree: ou=users,o=org
  Subtree: ou=servers,o=org
  SearchScope: ONE
  Maximum ticket life: 0 days 01:00:00
  Maximum renewable life: 0 days 10:00:00
  Ticket flags: DISALLOW_FORWARDABLE REQUIRES_PWCHANGE
```

EXAMPLE4  Using destroy

The following is an example of the use of the `destroy` command.

```bash
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
  destroy -r ATHENA.MIT.EDU
Password for "cn=admin,o=org": password entered
Deleting KDC database of 'ATHENA.MIT.EDU', are you sure?
(type 'yes' to confirm)? yes
OK, deleting database of 'ATHENA.MIT.EDU'...
```

EXAMPLE5  Using list

The following is an example of the use of the `list` command.

```bash
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu list
Password for "cn=admin,o=org": password entered
Re-enter Password for "cn=admin,o=org": password re-entered
ATHENA.MIT.EDU
OPENLDAP.MIT.EDU
MEDIA-LAB.MIT.EDU
```

EXAMPLE6  Using stashsrvpw

The following is an example of the use of the `stashsrvpw` command.

```bash
# kdb5_ldap_util stashsrvpw -f \
/home/andrew/conf_keyfile.cn=service-kdc,o=org
Password for "cn=service-kdc,o=org": password entered
Re-enter password for "cn=service-kdc,o=org": password re-entered
```

EXAMPLE7  Using create_policy

The following is an example of the use of the `create_policy` command.

```bash
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
  create_policy -r ATHENA.MIT.EDU \
  -maxtktlife "1 day" -maxrenewlife "1 week" \
```
EXAMPLE 7 Using create_policy

-allow_postdated +needchange -allow_forwardable tktpolicy
Password for "cn=admin,o=org": password entered

EXAMPLE 8 Using modify_policy
The following is an example of the use of the modify_policy command.

# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \ modify_policy -r ATHENA.MIT.EDU \ -maxtktlife "60 minutes" -maxrenewlife "10 hours" \ +allow_postdated -requires_preauth tktpolicy
Password for "cn=admin,o=org": password entered

EXAMPLE 9 Using view_policy
The following is an example of the use of the view_policy command.

# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \ view_policy -r ATHENA.MIT.EDU tktpolicy
Password for "cn=admin,o=org": password entered
Ticket policy: tktpolicy
  Maximum ticket life: 0 days 01:00:00
  Maximum renewable life: 0 days 10:00:00
  Ticket flags: DISALLOW_FORWARDABLE REQUIRES_PWCHANGE

EXAMPLE 10 Using destroy_policy
The following is an example of the use of the destroy_policy command.

# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \ destroy_policy -r ATHENA.MIT.EDU tktpolicy
Password for "cn=admin,o=org": password entered
This will delete the policy object 'tktpolicy', are you sure?
(type 'yes' to confirm)? yes
** policy object 'tktpolicy' deleted.

EXAMPLE 11 Using list_policy
The following is an example of the use of the list_policy command.

# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \ list_policy -r ATHENA.MIT.EDU tktpolicy
tktpolicy
tmppolicy
userpolicy

EXAMPLE 12 Using setsrvpw
The following is an example of the use of the setsrvpw command.
EXAMPLE 12  Using setsrvpw   (Continued)

    # kdb5_ldap_util setsrvpw -D cn=admin,o=org setsrvpw \
       -fileonly -f /home/andrew/conf_keyfile cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
Password for "cn=service-kdc,o=org": password entered
Re-enter password for "cn=service-kdc,o=org": password re-entered

EXAMPLE 13  Using create_service
The following is an example of the use of the create_service command.

    # kdb5_ldap_util -D cn=admin,o=org create_service \
       -kdc -randpw -f /home/andrew/conf_keyfile cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
File does not exist. Creating the file /home/andrew/conf_keyfile...

EXAMPLE 14  Using modify_service
The following is an example of the use of the modify_service command.

    # kdb5_ldap_util -D cn=admin,o=org modify_service \
       -realm ATHENA.MIT.EDU cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
Changing rights for the service object. Please wait ... done

EXAMPLE 15  Using view_service
The following is an example of the use of the view_service command.

    # kdb5_ldap_util -D cn=admin,o=org view_service \
       cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
    Service dn: cn=service-kdc,o=org
    Service type: kdc
    Service host list: 
    Realm DN list: cn=ATHENA.MIT.EDU,cn=Kerberos,cn=Security

EXAMPLE 16  Using destroy_service
The following is an example of the use of the destroy_service command.

    # kdb5_ldap_util -D cn=admin,o=org destroy_service \
       cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
This will delete the service object 'cn=service-kdc,o=org', are you sure?
(type 'yes' to confirm)? yes
** service object 'cn=service-kdc,o=org' deleted.

EXAMPLE 17  Using list_service
The following is an example of the use of the list_service command.

System Administration Commands - Part 1  1293
EXAMPLE 17 Using list_service (Continued)

# kdb5_ldap_util -D cn=admin,o=org list_service
Password for "cn=admin,o=org": password entered
   cn=service-kdc,o=org
   cn=service-adm,o=org
   cn=service-pwd,o=org

**Name**  
kdb5_util – Kerberos Database maintenance utility

**Synopsis**  
/usr/sbin/kdb5_util [-d dbname] [-k mkeytype] [-kv mkeyVNO] [-m ]  
[-M mkeyname] [-P password] [-r realm] [-sf stashfilename]  
[-x db_args]... cmd

**Description**  
The kdb5_util utility enables you to create, dump, load, and destroy the Kerberos V5 database. You can also use kdb5_util to create a stash file containing the Kerberos database master key.

**Options**  
The following options are supported:

- **-d dbname**  
  Specify the database name. .db is appended to whatever name is specified. You can specify an absolute path. If you do not specify the -d option, the default database name is /var/krb5/principal.

- **-k mkeytype**  

- **-m**  
  Enter the master key manually.

- **-M mkeyname**  
  Specify the master key name.

- **-P password**  
  Use the specified password instead of the stash file.

- **-r realm**  
  Use realm as the default database realm.

- **-sf stashfile_name**  
  Specifies the stash file of the master database password.

- **-x db_args**  
  Pass database-specific arguments to kadmin. Supported arguments are for LDAP and the Berkeley-db2 plug-in. These arguments are:

  binddn=binddn  
  LDAP simple bind DN for authorization on the directory server. Overrides the ldap_kadmind_dn parameter setting in krb5.conf(4).

  bindpwd=bindpwd  
  Bind password.

  dbname=name  
  For the Berkeley-db2 plug-in, specifies a name for the Kerberos database.
nconns = num
Maximum number of server connections.

port = num
Directory server connection port.

Operands
The following operands are supported:

cmd
Specifies whether to create, destroy, dump, or load the database, or to create a stash file.

You can specify the following commands:

create -s
Creates the database specified by the -d option. You will be prompted for the database master password. If you specify -s, a stash file is created as specified by the -f option. If you did not specify -f, the default stash file name is /var/krb5/.k5.realm. If you use the -f, -k, or -M options when you create a database, then you must use the same options when modifying or destroying the database.

destroy
Destroys the database specified by the -d option.

stash
Creates a stash file. If -f was not specified, the default stash file name is /var/krb5/.k5.realm. You will be prompted for the master database password. This command is useful when you want to generate the stash file from the password.

dump [-old][-b6][-b7][-ov][-r13][-verbose][-mkey_convert][-new_mkey_file mkey_file][-rev][-recurse] [filename[principals...]]
Dumpsthe current Kerberos and KADM5 database into an ASCII file. By default, the database is dumped in current format, "kdb5_util load_dump version 6". If filename is not specified or is the string "-", the dump is sent to standard output. Options are as follows:

- old
Causes the dump to be in the Kerberos 5 Beta 5 and earlier dump format ("kdb5_edit load_dump version 2.0").

- b6
Causes the dump to be in the Kerberos 5 Beta 6 format ("kdb5_edit load_dump version 3.0").

- b7
Causes the dump to be in the Kerberos 5 Beta 7 format ("kdb5_util load_dump version 4"). This was the dump format produced on releases prior to 1.2.2.

- ov
Causes the dump to be in ovsecadm_export format.
-r13
Causes the dump to be in the Kerberos 5 1.3 format ("kdb5_util load_dump version 5"). This was the dump format produced on releases prior to 1.8.

-verbose
Causes the name of each principal and policy to be displayed as it is dumped.

-mkey_convert
Prompts for a new master key. This new master key will be used to re-encrypt the key data in the dump file. The key data in the database will not be changed.

-new_mkey_file
The filename of a stash file. The master key in this stash file will be used to re-encrypt the key data in the dump file. The key data in the database will not be changed.

-rev
Dumps in reverse order. This might recover principals that do not dump normally, in cases where database corruption has occurred.

-recurse
Causes the dump to walk the database recursively (btree only). This might recover principals that do not dump normally, in cases where database corruption has occurred. In cases of such corruption, this option will probably retrieve more principals than will the -rev option.

Loads a database dump from filename into dbname. Unless the -old or -b6 option is specified, the format of the dump file is detected automatically and handled appropriately. Unless the -update option is specified, load creates a new database containing only the principals in the dump file, overwriting the contents of any existing database. The -old option requires the database to be in the Kerberos 5 Beta 5 or earlier format ("kdb5_edit load_dump version 2.0").

-b6
Requires the database to be in the Kerberos 5 Beta 6 format ("kdb5_edit load_dump version 3.0").

-b7
Requires the database to be in the Kerberos 5 Beta 7 format ("kdb5_util load_dump version 4").

-ov
Requires the database to be in ovsec_adm_import format. Must be used with the -update option.

-hash
Requires the database to be stored as a hash. If this option is not specified, the database will be stored as a btree. This option is not recommended, as databases stored in hash format are known to corrupt data and lose principals.
-r13
Causes the dump to be in the Kerberos 5.3 format ("kdb5_util load_dump
version 5"). This was the dump format produced on releases prior to 1.8.

-verbose
Causes the name of each principal and policy to be displayed as it is dumped.

-update
Records from the dump file are added to or updated in the existing database.
Otherwise, a new database is created containing only what is in the dump file and the
old one is destroyed upon successful completion.

filename
Required argument that specifies a path to a file containing database dump.

dbname
Required argument that overrides the value specified on the command line or
overrides the default.

admin_dbname
Optional argument that is derived from dbname if not specified.

add_mkey [-e etype] [-s]
Adds a new master key to the K/M (master key) principal. Existing master keys will remain.
The -e etype option allows specification of the enctype of the new master key. The -s
option stashes the new master key in a local stash file which will be created if it does not
already exist.

use_mkey mkeyVNO [time]
Sets the activation time of the master key specified by mkeyVNO. Once a master key is
active (that is, its activation time has been reached) it will then be used to encrypt principal
keys either when the principal keys change, are newly created, or when the
update_princ_encryption command is run. If the time argument is provided, that will be
the activation time; otherwise the current time is used by default. The format of the
optional time argument is that specified in the Time Formats section of the kadmin(1M)
man page.

list_mkeys
List all master keys from most recent to earliest in K/M principal. The output will show the
KVNO, enctype and salt for each mkey, similar to kadmin getprinc output. An asterisk
(*) following an mkey denotes the currently active master key.

purge_mkeys [-f] [-n] [-v]
Delete master keys from the K/M principal that are not used to protect any principals. This
command can be used to remove old master keys from a K/M principal once all principal
keys are protected by a newer master key.

- f
Does not prompt user.
Does a dry run, shows master keys that would be purged, but does not actually purge any keys.

- `v`
  Verbose output.

`update_princ_encryption [-f] [-n] [-v] [princ-pattern]`
Update all principal records (or only those matching the `princ-pattern` glob pattern) to re-encrypt the key data using the active database master key, if they are encrypted using older versions, and give a count at the end of the number of principals updated. If the `-f` option is not given, ask for confirmation before starting to make changes. The `-v` option causes each principal processed (each one matching the pattern) to be listed, and an indication given as to whether it needed updating or not. The `-n` option causes the actions not to be taken, only the normal or verbose status messages displayed; this implies `-f`, since no database changes will be performed and thus there is little reason to seek confirmation.

**Examples**

**EXAMPLE 1**  Creating File that Contains Information about Two Principals

The following example creates a file named `slavedata` that contains the information about two principals, `jdb@ACME.COM` and `pak@ACME.COM`.

```
# /usr/krb5/bin/kdb5_util dump -verbose slavedata
jdb@ACME.COM pak@ACME.COM
```

**Files**

/var/krb5/principal
Kerberos principal database.

/var/krb5/principal.kadm5
Kerberos administrative database. Contains policy information.

/var/krb5/principal.kadm5.lock
Lock file for the Kerberos administrative database. This file works backwards from most other lock files (that is, kadmin exits with an error if this file does not exist).

/var/krb5/principal.uglog
The update log file for incremental propagation.

The global -f is made obsolete with the -sf argument for specifying a non-default stash file location. The global -f argument might be removed in a future release of the Solaris operating system. Use caution in specifying -f as it has different semantics in subcommands as distinguished from its use as a global argument.
Name  kdcmmgr – set up a Kerberos Key Distribution Center (KDC)

Synopsis  
/usr/sbin/kdcmmgr [-a admprincipal] [-e enctype]
        [-h] [-p pwfile] [-r realm] subcommand

Description  Use the kdcmmgr utility to do the following:

- Configure a master Key Distribution Center (KDC) server.
- Configure a slave KDC. This assumes that a master KDC has already been configured. The default propagation method configured is incremental propagation. See kpropd(1M).
- Specify a list of slave KDCs to configure service principals and create access control list for those slaves on the master KDC.

If you specify no options, kdcmmgr prompts you for required information, including a password to generate the master key and a password for the administrative principal. When you specify sufficient options, you are still prompted for these passwords, unless you specified the -p pwfile option.

The kdcmmgr utility must be run by an administrator who is assigned the Kerberos Server Management rights profile or by root. The command must be run on the server from which it is invoked.

Note that kdcmmgr requires the user to enter sensitive information, such as the password used to generate the database's master key and the password for the administrative principal. Great care must be taken to ensure that the connection to the server is secured over the network, by using a protocol such as ssh(1).

You must also exercise great care when selecting the administrative and master key passwords. They should be derived from non-dictionary words and a long string of characters consisting of all of the following character classes:
- special characters (for example, !@#$%^&*]
- numerals (0-9)
- uppercase letters
- lowercase letters

Options  The following options are supported:

- a admprincipal
  When creating a master KDC, specifies the administrative principal, admprincipal, that will be created.

  When creating a slave KDC, admprincipal is used to authenticate as the administrative principal.

  If you omit -a, the suggested default administrative principal name is the output of logname(1) appended by /admin.
- **e enctype**  
  Specifies the encryption type to be used when creating the key for the master key, which is used to encrypt all principal keys in the database. The set of valid encryption types used here are described in `krb5.conf(4)` under the `permitted_enctypes` option. Note that the encryption type specified here must be supported on all KDCs or else they will not be able to decrypt any of the principal keys. Solaris 9 and earlier releases support only the `des-cbc-crc` encryption type for the master key. Therefore, if any of the master or slave KDCs are of these older releases, then `-e des-cbc-crc` would need to be specified on all KDCs configured with `kdcmgr`.

  The default encryption type is `aes256-cts-hmac-sha1-96`.

- **h**  
  Displays usage information for `kdcmgr`.

- **p pwfile**  
  Provides the location of the password file that contains the password used to create the administrative principal and/or master key.

  **Warning:** This option should be used with great care. Make sure that this `pwfile` is accessible only by a privileged user and on a local file system. Once the KDC has been configured, you should remove `pwfile`.

- **r realm**  
  Set the default realm for this server.

  If the `-r` option is not specified, `kdcmgr` attempts to obtain the machine’s local domain name by submitting the canonical form of the machine’s host name to DNS and using the return value to derive the domain name. If successful, the domain name is converted to uppercase and proposed as the default realm name.

**Subcommands**  
The following subcommands are supported:

- `create [ master ]`  
  Creates a KDC. If no option is specified, an attempt to create a master KDC is made.

- `create [ -m masterkdc ] slave`  
  Configures a slave KDC. After configuration, the `krb5kdc(1M)` and `kpropd(1M)` services are enabled on the machine.

  `masterkdc` specifies the master KDC to authenticate and with which to perform administrative tasks. If the `-m` option is not specified, you are prompted for a master KDC host name.
destroy
Remove all Kerberos configuration and database files associated with the KDC server. A confirmation is required before these files are deleted.

status
Determines the role of the KDC, master or slave, and outputs this and the state of such associated processes as:
- krb5kdc(1M)
- kadmin(1M)
- kpropd(1M)

The subcommand also displays information on incremental propagation if the configuration has this feature enabled, as well as any issues with dependent files.

Examples

EXAMPLE 1 Setting up a Master KDC
The following command configures a master KDC with the administrative principal user1/admin and with the realm name EXAMPLE.COM:

$ kdcmgr -a user1/admin -r EXAMPLE.COM create

Note that a password will be required to assign to the newly created user1/admin principal. The password for the master key will also need to be provided.

EXAMPLE 2 Setting up a Slave KDC
The following command configures a slave KDC, authenticates with the administrative principal user1/admin, specifies kdc1 as the master, and uses the EXAMPLE.COM realm name:

$ kdcmgr -a user1/admin -r EXAMPLE.COM create -m kdc1 slave

Note that you must enter the correct password for user1/admin and that the master KDC must already have been created before entering this command. The correct password for the master key is also required.

Files
/etc/krb5/krb5.conf
Main Kerberos configuration file.

/etc/krb5/kdc.conf
KDC configuration, used by both master and slave servers.

/etc/krb5/krb5.keytab
Default location of the local host's service keys.

/etc/krb5/kadm5.acl
Kerberos administrative access control list (ACL).

/etc/krb5/kadm5.keytab
Service keys specific to kadmin(1M).
### Attributes

logname(1), ssh(1), kadmin(1M), kadmind(1M), kdb5_util(1M), kdb5_ldap_util(1M), kpropd(1M), krb5kdc(1M), ping(1M), svcadm(1M), kdc.conf(4), krb5.conf(4), attributes(5)
kernel – UNIX system executable file containing basic operating system services

kernel-name [-asrvx] [-m smf_options] [-i altinit]

The operating system image, or kernel, is the collection of software comprising the image files (unix and genunix) and the modules loaded at any instant in time. The system will not function without a kernel to control it.

The kernel is loaded by the boot(1M) command in a machine-specific way. The kernel may be loaded from disk, CD-ROM, or DVD (disk full boot) or over the network (diskless boot). In either case, the directories under /platform and /kernel must be readable and must contain executable code which is able to perform the required kernel service. If the -a flag is given, the user is able to supply different pathnames for the default locations of the kernel and modules. See boot(1M) for more information on loading a specific kernel.

The moddir variable contains a list of module directories separated by whitespace. moddir can be set in the /etc/system file. The minimal default is:

/platform/platform-name/kernel /kernel /usr/kernel

This default can be supplemented by a specific platform. It is common for many SPARC systems to override the default path with:

/platform/platform-name/kernel:/platform/hardware-class-name/
/kernel:/kernel:/usr/kernel

where platform-name can be found using the -i option of uname(1), and hardware-class-name can be found using the -m option of uname(1).

The kernel configuration can be controlled using the /etc/system file (see system(4)).

genunix is the platform-independent component of the base kernel.

Options

The following options are supported:

-a
Asks the user for configuration information, such as where to find the system file, where to mount root, and even override the name of the kernel itself. Default responses will be contained in square brackets ([ ]), and the user may simply enter RETURN to use the default response (note that RETURN is labeled ENTER on some keyboards). To help repair a damaged /etc/system file, enter /dev/null at the prompt that asks for the pathname of the system configuration file. See system(4).

-i altinit
Select an alternative executable to be the primordial process. altinit must be a valid path to an executable. The default primordial process is init(1M).

-m smf_options
The smf_options include two categories of options to control booting behavior of the service management facility: recovery options and messages options.
Message options determine the type and amount of messages that `smf(5)` displays during boot. Service options determine the services which are used to boot the system.

Recovery options

`debug`
Prints standard per-service output and all `svc.startd` messages to log.

`milestone=[milestone]`
Boot with some SMF services temporarily disabled, as indicated by `milestone`. `milestone` can be "none", "single-user", "multi-user", "multi-user-server", or "all". See the `milestone` subcommand of `svcadm(1M)`.

Messages options

`quiet`
Prints standard per-service output and error messages requiring administrative intervention.

`verbose`
Prints standard per-service output with more informational messages.

- `-r`
Reconfiguration boot. The system will probe all attached hardware devices and configure the logical namespace in `/dev`. See `add_drv(1M)` and `rem_drv(1M)` for additional information about maintaining device drivers.

- `-s`
Boots only to init level 's'. See `init(1M)`.

- `-v`
Boots with verbose messages enabled. If this flag is not given, the messages are still printed, but the output is directed to the system logfile. See `syslogd(1M)`.

- `-x`
Does not boot in clustered mode. This option only has an effect when a version of Sun Cluster software that supports this option has been installed.

Examples
See `boot(1M)` for examples and instructions on how to boot.

Files

 `/kernel`
Contains kernel components common to all platforms within a particular instruction set that are needed for booting the system.

 `/platform/platform-name/kernel`
The platform-specific kernel components.

 `/platform/hardware-class-name/kernel`
The kernel components specific to this hardware class.
```
/usr/kernel
Contains kernel components common to all platforms within a particular instruction set.

The directories in this section can potentially contain the following subdirectories:

drv
   Loadable device drivers
exec
   The modules that execute programs stored in various file formats.
fs
   File system modules
misc
   Miscellaneous system-related modules
sched
   Operating system schedulers
strmod
   System V STREAMS loadable modules
sys
   Loadable system calls

SPARC
   cpu
      Processor specific modules
tod
      Time-Of-Day hardware interface modules

x86
   mach
      x86 hardware support

As only 64-bit SPARC platforms are supported, all SPARC executable modules are contained within `sparcv9` directories in the directories listed above.

x86
   mach
      x86 hardware support

The kernel gives various warnings and error messages. If the kernel detects an unrecoverable fault, it will panic or halt.

**Diagnostics** The kernel gives various warnings and error messages. If the kernel detects an unrecoverable fault, it will panic or halt.

**Notes** Reconfiguration boot will, by design, not remove /dev entries for some classes of devices that have been physically removed from the system.
keyserv – server for storing private encryption keys

keyserv [-c] [-d | -e] [-D] [-n] [-s sizespec]

**Description**

`keyserv` is a daemon that is used for storing the private encryption keys of each user logged into the system. These encryption keys are used for accessing secure network services such as secure NFS.

Normally, root’s key is read from the file `/etc/.rootkey` when the daemon is started. This is useful during power-fail reboots when no one is around to type a password.

`keyserv` does not start up if the system does not have a secure `rpc` domain configured. Set up the domain name by using the `/usr/bin/domainname` command. Usually the `svc:/system/identity:domain` service reads the domain from `/etc/defaultdomain`. Invoking the `domainname` command without arguments tells you if you have a domain set up.

The `/etc/default/keyserv` file contains the following default parameter settings. See Files.

- `ENABLE_NOBODY_KEYS` Specifies whether default keys for `nobody` are used.
  - `ENABLE_NOBODY_KEYS=NO` is equivalent to the `-d` command-line option. The default value for `ENABLE_NOBODY_KEYS` is `YES`.

**Options**

The following options are supported:

- `-c` Do not use disk caches. This option overrides any `-s` option.
- `-D` Run in debugging mode and log all requests to `keyserv`.
- `-d` Disable the use of default keys for `nobody`. See Files.
- `-e` Enable the use of default keys for `nobody`. This is the default behavior. See Files.
- `-n` Root’s secret key is not read from `/etc/.rootkey`. Instead, `keyserv` prompts the user for the password to decrypt root’s key stored in the public key database and then stores the decrypted key in `/etc/.rootkey` for future use. This option is useful if the `/etc/.rootkey` file ever gets out of date or corrupted.
- `-s sizespec` Specify the size of the extended Diffie-Hellman common key disk caches. The `sizespec` can be one of the following forms:
  - `mechtype=size` `size` is an integer specifying the maximum number of entries in the cache, or an integer immediately followed by the letter `M`, denoting the maximum size in MB.
  - `size` This form of `sizespec` applies to all caches.

Note that the des mechanism, `AUTH_DES`, does not use a disk cache.
Files

/etc/.rootkey

/etc/default/keyserv

Contains default settings. You can use command-line options to override these settings.

Notes

The keyserv service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/keyserv:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
**Name**
killall – kill all active processes

**Synopsis**
/usr/sbin/killall \ [signal]

**Description**
killall is used by shutdown(1M) to kill all active processes not directly related to the shutdown procedure.

killall terminates all processes with open files so that the mounted file systems will be unbusied and can be unmounted.

killall sends signal (see kill(1)) to the active processes. If no signal is specified, a default of 15 is used.

The killall command can be run only by the super-user.

Name  kmscfg – configure the PKCS#11 KMS provider

Synopsis  kmscfg
   kmscfg -p[rofile]  Profile_Name
   kmscfg -a[gent] Agent_ID
   kmscfg -i[paddr] Agent_Address
   kmscfg -t[imeout] Transaction_Timeout
   kmscfg -f[ailover] Failover_Limit
   kmscfg -d[iscovery] Discovery_Freq

Description  The kmscfg command is used to initialize the PKCS#11 KMS provider (pkcs11_kms) for use with the Solaris Cryptographic Framework. In order for the KMS provider to communicate with the Oracle Key Manager (OKM), it must have some configuration information available. This configuration data contains information such as the name of the profile to be used, the name of the OKM Agent, the IP address of an OKM appliance (KMA) and some other parameters (see SYNOPSIS).

By default, kmscfg stores the configuration information in /var/user/$USERNAME/kms. This directory will be created if it is not already present. If the configuration is already detected, the user will be given the option to override the existing data. The default location can be overridden by using the KMSTOKEN_DIR environment variable, which must be set prior to invoking kmscfg.

Prior to running kmscfg, the OKM administrator must have performed the required initialization and configuration steps on the appliance itself to setup the individual Profiles and Agents that PKCS11 KMS consumers will use. The instructions for configuring these profiles are available in the Oracle Key Manager Administration Guide on the Oracle website (http://docs.oracle.com).

Once the administrator has configured the KMA, the necessary identification information (profile name, agent ID, IP address) must be provided to be able to run kmscfg and initialize the provider on the Oracle Solaris client.

Options  The options listed below are supported. Note that, if the profile, agent id, or KMA address are not specified on the command line, kmscfg prompts you to provide these items.

   -a Agent_ID
      The user agent ID as configured on the OKM to be used for the KMS token being configured. It is not unusual for the Profile and Agent ID to be the same, for example, MyAgent.

   -d Discovery_Freq
      Frequency in seconds with which the client will try to discover the availability of other KMAs in an OKM cluster. If not specified, Discovery_Freq defaults to 600 seconds (10 minutes).
-t Failover_Limit
   The number of times communications to the KMA can fail before the client gives up. If not
   specified, Failover_Limit defaults to 3.

-1 Agent_Addr
   Address of the KMA. This can be an IPv4 address (xxx.xxx.xxx.xxx) or an IPv6 address. A
   fully qualified host name can also be used, as long as that name can be resolved by the name
   service configured on the client. If an OKM cluster is being used, the address of any
   member of the cluster can be specified.

-p Profile_Name
   A name for the profile to be used for the KMS token being configured. Typically, the profile
   name and the Agent ID will be the same, though they are not required to be.

-t Transaction_Timeout
   Timeout period for individual KMS commands, in seconds. If not specified, this value
   defaults to 10.

Exit Status
After completing the requested operation, kmscfg exits with one of the following status values.

0
   Successful termination.

1
   Failure. The requested operation could not be completed.

Files
/var/user/$USERNAME/kms
   Default KMS token configuration directory.

$(KMSTOKEN_DIR)
   Alternate KMS token configuration directory.

Oracle Key Manager Administration Guide
(http://docs.oracle.com)

Notes
PKCS#11 clients require Oracle Key Manager Software Version 2.4 be installed on the OKM.

If PKCS#11 clients will use the same Agent ID from multiple systems, that agent should be
created without the "One Time Passphrase" flag set. This option will not be available in OKM
clusters with some members running versions of the OKM software prior to 2.4. Please refer
to the OKM Administration Guide for assistance in creating Agents.
OKM Agents must have a Default Key Group assigned prior to being used to create keys with a PKCS#11 client. If a Default Key Group is not assigned to the Agent, operations will fail with a CKR_PIN_INCORRECT error. Please refer to the OKM Administration Guide for assistance in assigning key groups to agents.
kprop – Kerberos database propagation program

**Synopsis**

```
/usr/lib/krb5/kprop [-d] [-f file] [-p port-number]
    [-r realm] [-s keytab] [host]
```

**Description**

`kprop` is a command-line utility used for propagating a Kerberos database from a master KDC to a slave KDC. This command must be run on the master KDC. See the Solaris System Administration Guide, Vol. 6 on how to set up periodic propagation between the master KDC and slave KDCs.

To propagate a Kerberos database, the following conditions must be met:

- The slave KDCs must have an `/etc/krb5/kpropd.acl` file that contains the principals for the master KDC and all the slave KDCs.
- A keytab containing a host principal entry must exist on each slave KDC.
- The database to be propagated must be dumped to a file using `kdb5_util(1M)`.

**Options**

The following options are supported:

- `-d`
  Enable debug mode. Default is debug mode disabled.
- `-f file`
  File to be sent to the slave KDC. Default is the `/var/krb5/slave_datatrans` file.
- `-p port-number`
  Propagate `port-number`. Default is port 754.
- `-r realm`
  Realm where propagation will occur. Default `realm` is the local realm.
- `-s keytab`
  Location of the keytab. Default location is `/etc/krb5/krb5.keytab`.

**Operands**

The following operands are supported:

- `host`
  Name of the slave KDC.

**Examples**

**Example 1** Propagating the Kerberos Database

The following example propagates the Kerberos database from the `/tmp/slave_data` file to the slave KDC `london`. The machine `london` must have a host principal keytab entry and the `kpropd.acl` file must contain an entry for all the KDCs.

```
# kprop -f /tmp/slave_data london
```

**Files**

- `/etc/krb5/kpropd.acl`
  List of principals of all the KDCs; resides on each slave KDC.
- `/etc/krb5/krb5.keytab`
  Keytab for Kerberos clients.
- `/var/krb5/slave_datatrans`
  Kerberos database propagated to the KDC slaves.

Oracle Solaris 11.1 Administration: Security Services
**Name**  
kpropd – Kerberos propagation daemon for slave KDCs

**Synopsis**  
/usr/lib/krb5/kpropd [-d] [-f temp_dbfile] [-F dbfile]  
[-p kdb_util] [-P port_number] [-r realm]  
[-s srv_tabfile] [-S] [-a acl_file]

**Description**  
The kpropd command runs on the slave KDC server. It listens for update requests made by kprop(1M) from the master KDC and periodically requests incremental updates from the master KDC.

When the slave receives a kprop request from the master, kpropd copies principal data to a temporary text file. Next, kpropd invokes kdb5_util(1M) (unless a different database utility is selected) to load the text file in database format.

When the slave periodically requests incremental updates, kpropd updates its principal. ulog file with any updates from the master. kproplog(1M) can be used to view a summary of the update entry log on the slave KDC.

kpropd is not configured for incremental database propagation by default. These settings can be changed in the kdc.conf(4) file:

sunw_dbprop_enable = [true | false] 
Enables or disables incremental database propagation. Default is false.

sunw_dbprop_slave_poll = N[s, m, h] 
Specifies how often the slave KDC polls for any updates that the master might have. Default is 2m (two minutes).

The kprop/<hostname>@<REALM> principal must exist in the slave’s keytab file to enable the master to authenticate incremental propagation requests from the slave. In this syntax, <hostname> is the slave KDC’s host name and <REALM> is the realm in which the slave KDC resides.

**Options**  
The following options are supported:

- **-d**  
  Enable debug mode. Default is debug mode disabled.

- **-f temp_dbfile**  
  The location of the slave's temporary principal database file. Default is /var/krb5/from_master.

- **-F dbfile**  
  The location of the slave's principal database file. Default is /var/krb5/principal.

- **-p kdb_util**  
  The location of the Kerberos database utility used for loading principal databases. Default is /usr/sbin/kdb5_util.

- **-P port_number**  
  Specifies the port number on which kpropd will listen. Default is 754 (service name: krb5_prop).

- **-r realm**  
  Specifies from which Kerberos realm kpropd will receive information. Default is specified in /etc/krb5/krb5.conf.
The location of the service table file used to authenticate the kpropd daemon.

Run the daemon in standalone mode, instead of having inetd listen for requests. Default is non-standalone mode.

The location of the kpropd’s access control list to verify if this server can run the kpropd daemon. The file contains a list of principal name(s) that will be receiving updates. Default is /etc/krb5/kpropd.acl.

/var/krb5/principal Kerberos principal database.
/etc/krb5/kdc.conf KDC configuration information.
/etc/krb5/kpropd.acl List of principals of all the KDCs; resides on each slave KDC.
/var/krb5/from_master Temporary file used by kpropd before loading this to the principal database.

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTETYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/security/kerberos-5</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

The kprop service is managed by the service management facility, smf(5), under the service identifier:

`svc:/network/security/krb5_prop:default`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service’s status can be queried using the svcs(1) command.
kproplog – display the contents of the Kerberos principal update log

**Synopsis**

```bash
/usr/sbin/kproplog [-h | -e num]
```

**Description**

The `kproplog` displays the contents of the Kerberos principal update log to standard output. This command can be used to keep track of the incremental updates to the principal database, which is enabled by default. The `/var/krb5/principal.ulog` file contains the update log maintained by the `kadmind(1M)` process on the master KDC server and the `kpropd(1M)` process on the slave KDC servers. When updates occur, they are logged to this file. Subsequently, any KDC slave configured for incremental updates will request the current data from the master KDC and update their `principal.ulog` file with any updates returned.

The `kproplog` command can only be run on a KDC server by someone with privileges comparable to the superuser. It will display update entries for that server only.

If no options are specified, the summary of the update log is displayed. If invoked on the master, all of the update entries are also displayed. When invoked on a slave KDC server, only a summary of the updates are displayed, which includes the serial number of the last update received and the associated time stamp of the last update.

**Options**

The following options are supported:

- **-h**
  Display a summary of the update log. This information includes the database version number, state of the database, the number of updates in the log, the time stamp of the first and last update, and the version number of the first and last update entry.

- **-e num**
  Display the last `num` update entries in the log. This is useful when debugging synchronization between KDC servers.

- **-v**
  Display individual attributes per update. If more than one `-v` is specified, then very verbose output is displayed. An example of the output generated for one entry:

```
Update Entry
Update serial # : 4
Update operation : Add
Update principal : test@EXAMPLE.COM
Update size : 424
Update committed : True
Update time stamp : Fri Feb 20 23:37:42 2004
Attributes changed : 6
  Principal
  Key data
  Password last changed
  Modifying principal
  Modification time
  TL data
```
**Files**  
/var/krb5/principal.u.log  The update log file for incremental propagation.

**Attributes**  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

**See Also**  
kpasswd(1), gkadmin(1M), kadmin(1M), kadmind(1M), kdb5_util(1M), kprop(1M), kpropd(1M), kadm5.acl(4), kdc.conf(4), attributes(5), kerberos(5)
krb5kdc(1M)

Name  krb5kdc – KDC daemon

Synopsis  /usr/lib/krb5/krb5kdc [-d dbpath] [-r realm] [-m]
            [-k masterenctype] [-M masterkeyname]
            [-p port] [-n] [-x db_args] [-P pid_file]

Description  krb5kdc is the daemon that runs on the master and slave KDCs to process the Kerberos tickets. For Kerberos to function properly, krb5kdc must be running on at least one KDC that the Kerberos clients can access. Prior to running krb5kdc, you must initialize the Kerberos database using kdb5_util(1M). See the Oracle Solaris 11.1 Administration: Security Services for information regarding how to set up KDCs and initialize the Kerberos database.

Options  The following options are supported:

- d dbpath
  Specify the path to the database; default value is /var/krb5.

- k masterenctype
  Specify the encryption type for encrypting the database. The default value is des-cbc-crc.
  des3-cbc-sha1, arcfour-hmac-md5, arcfour-hmac-md5-exp, aes128-cts-hmac-sha1-96, and aes256-cts-hmac-sha1-96 are also valid.

- m
  Specify that the master key for the database is to be entered manually.

- M masterkeyname
  Specify the principal to retrieve the master Key for the database.

- n
  Specify that krb5kdc should not detach from the terminal.

- p port
  Specify the port that will be used by the KDC to listen for incoming requests.

- P pid_file
  Tells the KDC to write its PID (followed by a newline) into pid_file after it starts up. This can be used to identify whether the KDC is still running and to allow init scripts to stop the correct process.

- r realm
  Specify the realm name; default is the local realm name.

- x db_args
  Pass database-specific arguments to kadmin. Supported arguments are for the LDAP plug-in. These arguments are:
  binddn=binddn
    Specifies the DN of the object used by the KDC server to bind to the LDAP server. This object should have the rights to read the realm container, principal container and the subtree that is referenced by the realm. Overrides the ldap_kdc_dn parameter setting in krb5.conf(4).
**bindpwd**

Specifies the password for the above-mentioned **binddn**. It is recommended not to use this option. Instead, the password can be stashed using the **stashrvpw** command of **kdb5_ldap_util**(1M).

**nconns=num**

Specifies the number of connections to be maintained per LDAP server.

**host=ldapuri**

Specifies, by an LDAP URI, the LDAP server to which to connect.

### Files

/var/krb5/principal.db

Kerberos principal database.

/var/krb5/principal.kadm5

Kerberos administrative database. This file contains policy information.

/var/krb5/principal.kadm5.lock

Kerberos administrative database lock file. This file works backwards from most other lock files (that is, **kadmin** will exit with an error if this file does **not** exist).

/etc/krb5/kdc.conf

KDC configuration file. This file is read at startup.

/etc/krb5/kpropd.acl

File that defines the access control list for propagating the Kerberos database using **kprop**.

### Attributes

See **attributes**(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/security/kerberos-5</td>
</tr>
</tbody>
</table>

*Oracle Solaris 11.1 Administration: Security Services*

### Notes

The following signal has the specified effect when sent to the server process using the **kill**(1) command:

**SIGHUP**

**krb5kdc** closes and re-opens log files that it directly opens. This can be useful for external log-rotation utilities such as **logadm**(1M). If this method is used for log file rotation, set the **krb5.conf**(4) **kdc_rotate** period relation to **never**.
### Synopsis

```
ksslcfg create -f pkcs11 -T token_label -C certificate_label
    [-d softtoken_directory] [-p password_file] [-u username]
    [-h ca_certchain_file] [-c ciphersuites]
    [-t ssl_session_cache_timeout] [-z ssl_session_cache_size] [-v] [-x proxy_port] [host] ssl_port

ksslcfg create -f pkcs12 -i cert_and_key_pk12file
    [-p password_file] [-u username] [-c ciphersuites] [-t ssl_session_cache_timeout]
    [-z ssl_session_cache_size] [-v] [-x proxy_port] [host] ssl_port

ksslcfg create -f pem -i cert_and_key_pemfile
    [-p password_file] [-u username] [-c ciphersuites] [-t ssl_session_cache_timeout]
    [-z ssl_session_cache_size] [-v] [-x proxy_port] [host] ssl_port

ksslcfg delete [-v] [host] ssl_port

ksslcfg -V
ksslcfg -?
```

### Description

**ksslcfg** manages SMF instances for the Kernel SSL proxy module. An SSL-enabled web server can use the services of its Kernel SSL proxy to improve the performance of the HTTPS packets processing. It does so by creating an instance of the Kernel SSL service, specifying the SSL proxy port and parameters, and by listening on the proxy port.

The `create` subcommand creates an instance and enables the service for the given address and SSL port.

The `delete` subcommand disables the service for the given address and port, if it is enabled, and deletes the instance from the SMF repository.

**ksslcfg** can be run as root or by other users assigned to the Network Security profile. See `rbac(5)` and `user_attr(4)`.

After **ksslcfg** successfully configures the service in the kernel, the proxy application must be started, or restarted if it is already running.

You must run **ksslcfg** to configure your Kernel SSL proxy before you start your application.

**ksslcfg** allows you to specify an `ssl_port` operand, described under OPERANDS, and, with the `-x` option, a `proxy_port` value. When specified for use with the Kernel SSL proxy, these values cannot also be configured for the Solaris Network Cache and Acceleration (NCA) feature.

The Fault Managed Resource Identifier (FMRI) for the kernel SSL proxy instances is `svc://network/ssl/proxy`. **ksslcfg** creates an instance of that service unique to the
combination of host and SSL port. Instance FMRs for particular proxy entries can be found with `svcs(1)` and used for dependencies of other services. The state of the service instance tracks in-kernel configuration only. It does not reflect the presence or state of the application listening on the proxy port.

**Options**  
The following options are supported:

- `-c ciphersuites`
  Set of ciphers a client is allowed to negotiate in a sorted order. The supported SSLv3 and TLS ciphers are listed below. Note that the names are case-insensitive.

  ```
  rsa_rc4_128_sha
  rsa_rc4_128_md5
  rsa_aes_256_cbc_sha
  rsa_aes_128_cbc_sha
  rsa_3des_ede_cbc_sha
  rsa_des_cbc_sha
  ```

- `-f key_format`
  Uses the certificate/key format specified in `key_format`. The supported options are `pkcs11`, `pkcs12`, and `pem`.

- `-i key_and_certificate_file`
  When `pkcs12` or `pem` is specified with the `-f` option, reads a key and a certificate of the web server from `key_and_certificate_file`. This file can also contain any intermediate CA certificates that form the certificate chain to the root CA for the server certificate. These certificates must follow the server certificate in the file and the order must be bottom up: lowest level CA certificate followed by the next higher level CA certificate, and so on.

- `-C certificate_label`
  PKCS#11 can store multiple certificates in single token. This option enables you to specify a single certificate, identified by `certificate_label`. This label must match the `CKA_LABEL` on the certificate object in the token specified by `-T`. This option is to be used only with `-f pkcs11`.

- `-d softtoken_directory`
  This option is applicable only with the `pkcs11` key format, when the token label is the Sun Software PKCS#11 softtoken. Use this option to override the default location of the PKCS#11 softtoken directory (`$HOME/.sunw`). See `pkcs11_softtoken(5)`.

- `-h ca_certchain_file`
  When `pkcs11` is specified with the `-f` option, reads a set of intermediate CA certificates that form the certificate chain to the root CA for the server certificate (specified with the `-C` option), from `ca_certchain_file`. The file must be in PEM format.

- `-p password_file`
  Obtains the password used to encrypt the private key from `password_file`. When using the `pkcs11` option (see `-f`, above), the password is used to authenticate the user to the PKCS #11 token.
-t \textit{ssl\_session\_cache\_timeout}
  The timeout value, in seconds, for an SSL session. It corresponds to SSL3SessionTimeout of the Sun ONE web server configuration or SSLSessionCacheTimeout of mod_ssl.

-T \textit{token\_label}
  When pkcs11 is specified with -f, uses the PKCS#11 token specified in \textit{token\_label}. Use \texttt{cryptoadm list -v} to display all PKCS#11 tokens available.

-u \textit{username}
  The username of the user who owns the password file. If omitted, the system will try to read the password file as root.

-v
  Verbose mode.

-V
  Displays the version.

-x \textit{proxy\_port}
  The SSL proxy port. The port number is designated exclusively for clear-text HTTP communication between the web server and the kernel SSL proxy module. No external HTTP packets are delivered to this port.

-z \textit{ssl\_session\_cache\_size}
  The maximum number of SSL sessions that can be cached. It corresponds to SSLCacheEntries of the Sun ONE web server configuration. When this option is not specified, the default is 5000 entries.

-?
  Displays the usage of the command.

**Operands**

- \texttt{host}\ [ \texttt{ssl\_port}\ ]
  The address and the port of the web server for which the kernel SSL entry is created. If \texttt{host} is omitted, the entry will be used for all requests that arrived at the \texttt{ssl\_port}, regardless of the destination address. Both a host name and an IP address are acceptable forms for \texttt{host}. \texttt{ssl\_port} is required. Typically, this has a value of 443.

**Examples**

**EXAMPLE 1  Create and Enable a Kernel SSL Instance**

The following command creates and enables a Kernel SSL instance using a certificate and a key in PKCS#11 format.

```
# ksslcfg create -f pkcs11 -T "Sun Software PKCS#11 softtoken" \ 
-C "Server-Cert" -p /some/directory/password -u webservd \ 
-x 8080 www.mysite.com 443
```

```
% svcsv svc:/network/ssl/proxy
STATE  STIME  FMRI
online  Sep_27  svc:/network/ssl/proxy:kssl-www-mysite-com-443
```
**EXAMPLE 2  Create and Enable a Default Instance for All Addresses**

The following command creates and enables a default instance for all addresses from a certificate and key in a pkcs#12 file.

```
# ksslcfg create -x 8888 -f pkcs12 -i /some/directory/keypair.p12 \ 
   -p /some/directory/password -u webservd 443
```

**EXAMPLE 3  Create and Enable an Instance with Specific Cipher Suites**

The following command creates and enables an instance with specific cipher suites.

```
# ksslcfg create -x 8080 -f pem \ 
   -i /some/directory/keypair.pem -p /some/directory/password \ 
   -c "rsa_rc4_128_md5,rsa_rc4_128_sha" \ 
209.249.116.195 443
```

**EXAMPLE 4  Disable and Delete an Instance**

The following command disables and deletes an instance.

```
# ksslcfg delete www.mysite.com 443
```

**EXAMPLE 5  Establishing Dependency of Proxy Application**

The sequence of commands shown below establishes a dependency of a proxy application on a KSSL instance. Note that the proxy application should only be started after the SSL kernel proxy instance has been started.

The following commands establish the dependency of an Apache 2.2 web server. KSSL has been configured to listen on SSL port 443 and a wildcard address.

```
# svccfg -s svc:/network/http:apache22 > addpg kssl dependency
svc:/network/http:apache22> setprop kssl/entities = fmri:svc:/network/\ 
ssl/proxy:kssl-INVADDR_ANY-443
svc:/network/http:apache22> setprop kssl/grouping = astring: require_all
svc:/network/http:apache22> setprop kssl/restart_on = astring: refresh
svc:/network/http:apache22> setprop kssl/type = astring: service
svc:/network/http:apache22> end
```

Following these commands, enable the web server:

```
# svcadm enable svc:/network/http:apache22
```

If the web server was already running, restart it:

```
# svcadm refresh svc:/network/http:apache22
# svcadm restart svc:/network/http:apache22
```
Exit Status  
   0  Successful completion.
   >0  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

Command line options and the utility name are Committed. The command output, the FMRI service name (svc://network/ssl/proxy), and the FMRI instance's name format are Uncommitted

See Also  svcprop(1), svc(1), cryptoadm(1M), svcadm(1M), svccfg(1M), user_attr(4), attributes(5), kssl(5), pkcs11_softtoken(5), rbac(5), smf(5), nca(7d)

Notes  ksslcfg create without an host argument creates an INADDR_ANY smf instance. ksslcfg delete without an host argument deletes only the INADDR_ANY instance. ksslcfg delete needs a host argument to delete any non-INADDR_ANY instance.

On a system with zones(5) installed, the ksslcfg command can be used only in the global zone at this time.
kstat(1M)

Name  kstat – display kernel statistics

Synopsis  kstat [-lpq] [-T u | d ] [-c class] [-m module]
             [-i instance] [-n name] [-s statistic]
             [interval [count]]

kstat [-lpq] [-T u | d ] [-c class]
       [module:instance:name:statistic]...
       [interval [count]]

Description  The kstat utility examines the available kernel statistics, or kstats, on
the system and reports those statistics which match the criteria specified on the
command line. Each matching statistic is printed with its module, instance, and name
fields, as well as its actual value.

Kernel statistics may be published by various kernel subsystems, such as drivers or
loadable modules; each kstat has a module field that denotes its publisher. Since each
module might have countable entities (such as multiple disks associated with the
sd(7D) driver) for which it wishes to report statistics, the kstat also has an instance
field to index the statistics for each entity; kstat instances are numbered starting from
zero. Finally, the kstat is given a name unique within its module.

Each kstat may be a special kstat type, an array of name-value pairs, or raw data. In
the name-value case, each reported value is given a label, which we refer to as the
statistic. Known raw and special kstats are given statistic labels for each of their values
by kstat; thus, all published values can be referenced as module:instance:name:statistic.

When invoked without any module operands or options, kstat will match all defined
statistics on the system. Example invocations are provided below. All times are
displayed as fractional seconds since system boot.

Options  The tests specified by the following options are logically ANDed, and all
matching kstats will be selected. A regular expression containing shell metacharacters
must be protected from the shell by enclosing it with the appropriate quotes.

The argument for the -c, -i, -m, -n, and -s options may be specified as a shell glob
pattern, or a Perl regular expression enclosed in ’/’ characters.

- c class  Displays only kstats that match the specified class. class is a kernel-defined
          string which classifies the “type” of the kstat.
- i instance  Displays only kstats that match the specified instance.
- l  Lists matching kstat names without displaying values.
- m module  Displays only kstats that match the specified module.
- n name  Displays only kstats that match the specified name.
- p  Displays output in parseable format. All example output in this document is
given in this format. If this option is not specified, kstat produces output in a
human-readable, table format.
-q Displays no output, but return appropriate exit status for matches against given criteria.

-s statistic Displays only kstats that match the specified statistic.

-T d | u Displays a time stamp before each statistics block, either in date(1) format (d) or as an alphanumeric representation of the value returned by time(2) (u).

Operands The following operands are supported:

module:instance:name:statistic Alternate method of specifying module, instance, name, and statistic as described above. Each of the module, instance, name, or statistic specifiers may be a shell glob pattern or a Perl regular expression enclosed by ‘’ characters. It is possible to use both specifier types within a single operand. Leaving a specifier empty is equivalent to using the ‘*’ glob pattern for that specifier.

interval The number of seconds between reports.

count The number of reports to be printed.

Examples In the following examples, all the command lines in a block produce the same output, as shown immediately below. The exact statistics and values will of course vary from machine to machine.

EXAMPLE 1 Using the kstat Command

example$ kstat -p -m unix -i 0 -n system_misc -s 'avenrun*'
example$ kstat -p -s 'avenrun*'
example$ kstat -p 'unix:0:system_misc:avenrun*'
example$ kstat -p ':::avenrun*'
example$ kstat -p ':::/^avenrun_\d+min$/'

unix:0:system_misc:avenrun_15min 3
unix:0:system_misc:avenrun_1min 4
unix:0:system_misc:avenrun_5min 2

EXAMPLE 2 Using the kstat Command

example$ kstat -p -m cpu_stat -s 'intr*'
example$ kstat -p cpu_stat:::/^intr/

cpu_stat:0:cpu_stat0:intr 3
cpu_stat:0:cpu_stat0:intrblk 87
cpu_stat:0:cpu_stat0:intrthread 15054222
cpu_stat:1:cpu_stat1:intr 426073
cpu_stat:1:cpu_stat1:intrblk 51
cpu_stat:1:cpu_stat1:intrthread 289668
EXAMPLE 2  Using the kstat Command  (Continued)

```
cpu_stat:2:cpu_stat2:intr  134160
cpu_stat:2:cpu_stat2:intrblk  0
cpu_stat:2:cpu_stat2:intrthread  131
cpu_stat:3:cpu_stat3:intr  196566
cpu_stat:3:cpu_stat3:intrblk  30
cpu_stat:3:cpu_stat3:intrthread  59626
```

EXAMPLE 3  Using the kstat Command

```
example$ kstat -p :::state ':::avenrun*'  
example$ kstat -p :::state :::/~avenrun/
```

```
cpu_info:0:cpu_info0:state  on-line  
cpu_info:1:cpu_info1:state  on-line  
cpu_info:2:cpu_info2:state  on-line  
cpu_info:3:cpu_info3:state  on-line  
unix:0:system_misc:avenrun_15min  4  
unix:0:system_misc:avenrun_1min  10  
unix:0:system_misc:avenrun_5min  3
```

EXAMPLE 4  Using the kstat Command

```
example$ kstat -p 'unix:0:system_misc:avenrun*' 1 3  
```

```
unix:0:system_misc:avenrun_15min  15  
unix:0:system_misc:avenrun_1min  11  
unix:0:system_misc:avenrun_5min  21  
unix:0:system_misc:avenrun_15min  15  
unix:0:system_misc:avenrun_1min  11  
unix:0:system_misc:avenrun_5min  21  
unix:0:system_misc:avenrun_15min  15  
unix:0:system_misc:avenrun_1min  11  
unix:0:system_misc:avenrun_5min  21
```

EXAMPLE 5  Using the kstat Command

```
example$ kstat -p -T d 'unix:0:system_misc:avenrun*' 5 2  
```

```
Thu Jul 22 19:39:50 1999  
unix:0:system_misc:avenrun_15min  12  
unix:0:system_misc:avenrun_1min  0  
unix:0:system_misc:avenrun_5min  11  
```

```
Thu Jul 22 19:39:55 1999  
unix:0:system_misc:avenrun_15min  12  
unix:0:system_misc:avenrun_1min  0  
unix:0:system_misc:avenrun_5min  11  
```
**EXAMPLE 6** Using the `kstat` Command

```bash
example$ kstat -p -T u 'unix:0:system_misc:avenrun*'
932668656
unix:0:system_misc:avenrun_15min 14
unix:0:system_misc:avenrun_1min 5
unix:0:system_misc:avenrun_5min 18
```

**Exit Status** The following exit values are returned:

- 0 One or more statistics were matched.
- 1 No statistics were matched.
- 2 Invalid command line options were specified.
- 3 A fatal error occurred.

**Files** /dev/kstat kernel statistics driver

**Attributes** See `attributes(5)` for descriptions of the following attributes:

**Notes** If the pattern argument contains glob or Perl RE metacharacters which are also shell metacharacters, it will be necessary to enclose the pattern with appropriate shell quotes.
**ktkt_warnd(1M)**

**Name**  
ktkt_warnd – Kerberos warning daemon

**Synopsis**  
/usr/lib/krb5/ktkt_warnd

**Description**  
ktkt_warnd is a daemon on Kerberos clients that can warn users when their Kerberos tickets are about to expire or renew the tickets before they expire. It is invoked by inetd when a ticket-granting ticket (TGT) is obtained for the first time, such as after using the `kinit` command. ktkt_warnd can be configured through per user and system configuration files on the client. In the configuration files, you can specify that you be supplied notice of ticket expiration—through terminal, mail, or syslog—or to renew the TGT.

**Files**  
/etc/krb5/warn.conf Kerberos warning configuration file  
/var/user/$USER/krb-warn.conf Per-user Kerberos warning configuration file

If the user's configuration file does not exist, /etc/krb5/warn.conf will be used.

**Attributes**

</thead>
<tbody>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

**See Also**  
svcs(1), inetadm(1M), inetd(1M), svcadm(1M), warn.conf(4), attributes(5), kerberos(5), smf(5)

**Notes**  
The ktkt_warnd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/security/ktkt_warn:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.
The `labeld` daemon is a system daemon which is started at boot time when Trusted Extensions is enabled. This daemon is started automatically and should not be invoked directly. It does not constitute a programming interface.

To enable Trusted Extensions, enter the following at the command line:

```
% svcadm enable svc:/system/labeld
```

Because Trusted Extensions affects the initialization and operation of zones, all zones must be removed before enabling Trusted Extensions. After enabling, the system should be rebooted to allow Trusted Extensions to come up properly initialized.

Enabling or disabling Trusted Extensions can only be done by a user or role with the `solaris.smf.manage.labels` authorization. (For example, a user or role that has either the Information Security or Object Label Management Rights Profile, or superuser.)

Other configuration steps are needed before using Trusted Extensions functionality. For more information, see the *Solaris Trusted Extensions Installation and Configuration Guide*.

### Attributes

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/trusted</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Uncommitted</td>
</tr>
</tbody>
</table>

### See Also

`srvc(1), svcadm(1M), syslogd(1M), attributes(5), smf(5)`

*Solaris Trusted Extensions Administrator’s Procedures*

### Notes

The `labels(5)` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/labeld:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service’s status can be queried using the `svcs(1)` command.
The `labelit` utility is used to write or display labels on unmounted disk file systems.

### Options

The following options are supported:

- `-F` *FSType*
  
  Specify the `FSType` on which to operate. The `FSType` should either be specified here or be determinable from `/etc/vfstab` by matching the `special` with an entry in the table. If no matching entry is found, the default file system type specified in `/etc/default/fs` will be used.

- `-V`

  Echo complete command line. This option may be used to verify and validate the command line. Additional information obtained using a `/etc/vfstab` lookup is included in the output. The command is not executed.

- `-o` *FSType-specific-options*

  Specify `FSType`-specific options. See the manual page for the `labelit` module specific to the file system type.

### Operands

The following operands are supported. If no operands are specified, `labelit` will display the value of the labels.

- `special`

  The disk partition (for example, `/dev/rdsk/c0t3d0s6`). The device may not be on a remote machine.

- `operands`

  `FSType`-specific operands. Consult the manual page of the `FSType`-specific `labelit` command for detailed descriptions.

### Usage

See `largefile(5)` for the description of the behavior of `labelit` when encountering files greater than or equal to 2 Gbyte (`2^{31}` bytes).

### Exit Status

The following exit values are returned:

- `0`

  Write or display of labels was successful.

- non-zero

  An error occurred.

### Files

- `/etc/vfstab`

  List of default parameters for each file system.

- `/etc/default/fs`

  Default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example:

```
LOCAL=ufs
LOCAL
```

  The default partition for a command if no `FSType` is specified.

### Attributes

See `attributes(5)` for descriptions of the following attributes:
ATTRIBUTES

<table>
<thead>

**Notes**  
This utility may not be supported for all FSTypes.
Name  labelit_hsfs – provide and print labels for hsfs file systems

Synopsis  
/usr/sbin/labelit -F hsfs [generic_options] 
[-o specific_options] special

Description  labelit can be used to provide labels for unmounted CD-ROM images (CD-ROMs may not be labeled, as they are read-only media).

generic_options are options supported by the generic labelit command.

If no specific_options are specified, labelit prints the current value of all label fields.

The special name should be the physical disk section (for example, /dev/dsk/c0d0s6).

Options  
- o  Use one or more of the following name=value pairs separated by commas (with no intervening spaces) to specify values for specific label fields. According to the ISO 9660 specification, only certain sets of characters may be used to fill in these labels. Thus, “d-characters” below refers to the characters ‘A’ through ‘Z’, the digits ‘0’ through ‘9’, and the ‘_’ (underscore) character. “a-characters” below refers to ‘A’ through ‘Z’, ‘0’ through ‘9’, space, and the following characters: '!&()*+,-./:;<=>?_'.

absfile=  Abstract file identifier, d-characters, 37 characters maximum.
applid=  Application identifier, d-characters, 128 characters maximum.
bibfile=  Bibliographic file identifier, d-characters, 37 characters maximum.
copyfile=  Copyright file identifier, d-characters, 128 maximum.
prepid=  Data preparer identifier, d-characters, 128 maximum.
pubid=  Publisher identifier, d-characters, 128 maximum.
sysid=  System identifier, a-characters, 32 maximum.
volid=  Volume identifier, d-characters, 32 maximum.
volsetid=  Volume set identifier, d-characters, 128 maximum.

<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  labelit(1M), volcopy(1M), attributes(5)
The `labelit` command writes labels on an unmounted disk that contains a universal disk file (UDF) system. These labels can be used to identify volumes.

**Options**

The following options are supported:

- `generic_options` Specify `generic_options` supported by the generic `labelit` command. See `labelit(1M)` for descriptions of supported options.

- `-o specific_options` Specify udfs-file-system-specific options in a comma-separated list with no intervening spaces. The following `specific_options` are available:

  - `lvinfo1=string` Specify information to be inserted in the LVInfo1 field of the Implementation Use Volume Descriptor. Information in LVInfo1 is generally used to identify the person creating the file system. The maximum length of the string specified is 35 bytes.

  - `lvinfo2=string` Specify information to be inserted into the LVInfo2 field of the Implementation Use Volume Descriptor. Information in LVInfo2 is generally used to identify the organization responsible for creating the file system. The maximum length of the string specified is 35 bytes.

  - `lvinfo3=string` Specify information to be inserted into the LVInfo3 field of the Implementation Use Volume Descriptor. Information in LVInfo3 is generally used to identify the contact information for the medium. The maximum length of the string specified is 35 bytes.

**Operands**

The following operands are supported:

- `special` Specify `special` as the physical disk slice, for example, `/dev/rdsk/c0t0d0s6`. The device cannot be on a remote machine.

- `fsname` Specify `fsname` as the mount point, (for example, `root`, `u1`, and so forth), of the file system.

- `volume` Specify `volume` as the physical volume name.

If none of the options (`fsname`, `volume`, `specific_options`) is specified, `labelit` prints the current values of `fsname`, `volume`, `LVInfo1`, `LVInfo2` and `LVInfo3`.
**Exit Status**  The following exit values are returned:

0  Successful completion.
non-zero  An error occurred.

**Attributes**  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

**See Also**  labelit(1M), attributes(5)
labelit_ufs(1M)

**Name**
labelit_ufs – provide and print labels for ufs file systems

**Synopsis**
labelit -F ufs [generic_options] special [fsname volume]

**Description**
labelit is used to write labels on unmounted disk file systems. Such labels may be used to uniquely identify volumes and are used by volume-oriented programs such as volcopy(1M).

**Options**
The following option is supported:

- **generic_options**: options supported by the generic labelit command. See labelit(1M).

**Operands**
The following operands are supported:

- **special**: name should be the physical disk section (for example, /dev/dsk/c0d0s6). The device may not be on a remote machine.

- **fsname**: represents the mount point (for example, root, u1, and so on) of the file system.

- **volume**: may be used to represent the physical volume name.

If fsname and volume are not specified, labelit prints the current values of these labels. Both fsname and volume are limited to six or fewer characters.

**Exit Status**
The following exit values are returned:

- **0**: Write or display of labels was successful.

- **non-zero**: An error occurred.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

LatencyTOP is an observability tool that reports statistics about latencies in the system and in applications. The tool reports statistics about where and what kind of latencies are happening in the system and in the applications that are running on the system. The statistics then can be used to improve performance throughput of applications and system, as you remove the identified latencies.

The tool analyzes system activity periodically and displays the data in the output window. Two types of latencies are tracked: an LWP going in and out of sleep and an LWP spinning in order to acquire a synchronization object. The tool uses the Solaris DTrace framework to collect the statistics corresponding to these two scenarios of inactivity of the system and application LWPs.

The output window is divided into two sections. An upper part displays the system-wide statistics, while the lower part displays statistics about individual processes. The user can navigate the list of processes (using the left- and right-arrow keys) and select the list they are interested in. The tool will then display statistics about that selected process in the lower part of the window. If the t or T key is pressed, the tool displays the LWP-specific view of that selected process. The t or T key can be used to toggle between the process-view and the thread-view.

During execution, a user can force a refresh of the analysis by pressing the r or R key. The interval time is restored to the default or to a specified value (if -t was used). To quit the application, the user must press the q or Q key.

Options
The following options are supported:

-f, --feature [no]feature1,[no]feature2,...
Enables/disables features in LatencyTOP. Features can be only one of the following:

[no]filter
Filter large interruptible latencies, for example, sleep. The default is off.

[no]sched
Monitors sched (PID=0). The default is off.

[no]sobj
Monitors synchronize objects. The default is on.

[no]low
Lower overhead by sampling small latencies. Enabling this feature will lower CPU utilization by estimating small latencies statistically. Use it for heavy workloads such as a very busy web server. The default is off.
-h
  Displays the command’s usage.

-k log_level
  Specifies the level of logging in the log file. Valid values are:
  0 none (default)
  1 unknown
  2 all

-l [log_interval]
  Writes data to the log file every log_interval seconds; log_interval must be greater than 60.

-o log_file
  Specifies the log file where output will be written. The default log file is /var/log/latencytop.log.

-s pid=PID | pgid=PGID
  Tracks only the specified process or the specified process group and displays data related only to that process or the process group.

-t interval
  Specifies the interval, in seconds, at which the tool collects statistics from the system. The possible values are between 1 and 60; the default is 5 seconds.

Examples

EXAMPLE 1 Running the Tool

The following command launches the tool with default values for options.

% latencytop

EXAMPLE 2 Setting the Interval

The following command sets the sampling interval to two seconds.

% latencytop -t 2

EXAMPLE 3 Specifying the Log File

The following command sets the log file to /tmp/latencytop.log.

% latencytop -o /tmp/latencytop.log

EXAMPLE 4 Specifying the Log Level

The following command sets the log level to all.

% latencytop -l 2
EXAMPLE 5 Enabling Tracing of Latencies
The following command enables the tracing of latencies caused by synchronization objects.
% latencytop -f sobj

EXAMPLE 6 Displaying Data for a Process Group
The following command displays trace data for processes belonging to Process Group 630.
% latencytop -s pgid=630

Exit Status
0  Successful operation.
1  An error occurred.

Usage You must have DTrace privileges to run LatencyTOP.
**Name**
ldapaddent – create LDAP entries from corresponding /etc files

**Synopsis**
```
ldapaddent [-cpv] [-a authenticationMethod] [-b baseDN]
    [-D bindDN] [-w bind_password] [-j passwdFile] [-f filename]
database
```
```
ldapaddent [-cpv] [-a sasl/GSSAPI] [-b baseDN] [-f filename]
database
```
```
ldapaddent -d [-v] [-a authenticationMethod] [-D bindDN]
    [-w bind_password] [-j passwdFile] database
```
```
ldapaddent [-cpv] -h LDAP_server[:serverPort] [-M domainName]
    [-N profileName] [-P certifPath] [-a authenticationMethod]
    [-b baseDN] [-D bindDN] [-w bind_password] [-f filename]
    [-j passwdFile] database
```
```
ldapaddent [-cpv] -h LDAP_server[:serverPort] [-M domainName]
    [-N profileName] [-P certifPath] [-a authenticationMethod]
    [-b baseDN] [-f filename] database
```
```
ldapaddent -d [-v] -h LDAP_server[:serverPort] [-M domainName]
    [-N profileName] [-P certifPath] [-a authenticationMethod]
    [-b baseDN] [-D bindDN] [-w bind_password] [-j passwdFile]
database
```

**Description**
ldapaddent creates entries in LDAP containers from their corresponding /etc files. This operation is customized for each of the standard containers that are used in the administration of Solaris systems. The `database` argument specifies the type of the data being processed. Legal values for this type are one of aliases, auto_, bootparams, ethers, group, hosts (including both IPv4 and IPv6 addresses), ipnodes (alias for hosts), netgroup, netmasks, networks, passwd, shadow, protocols, publickey, rpc, and services. In addition to the preceding, the `database` argument can be one of the RBAC-related files (see rbac(5)):

- `/etc/user_attr`
- `/etc/security/auth_attr`
- `/etc/security/prof_attr`
- `/etc/security/exec_attr`

By default, ldapaddent reads from the standard input and adds this data to the LDAP container associated with the database specified on the command line. An input file from which data can be read is specified using the `-f` option.

If you specify the `-h` option, ldapaddent establishes a connection to the server indicated by the option in order to obtain a DUAPProfile specified by the `-N` option. The entries will be stored in the directory described by the configuration obtained.

By default (if the `-h` option is not specified), entries will be stored in the directory based on the client’s configuration. To use the utility in the default mode, the Solaris LDAP client must be set up in advance.
The location where entries are to be written can be overridden by using the \texttt{-b} option.

If the entry to be added exists in the directory, the command displays an error and exits, unless the \texttt{-c} option is used.

Although, there is a shadow database type, there is no corresponding shadow container. Both the shadow and the passwd data is stored in the people container itself. Similarly, data from networks and netmasks databases are stored in the networks container.

The user\_attr data is stored by default in the people container. The prof\_attr and exec\_attr data is stored by default in the SolarisProfAttr container.

You must add entries from the passwd database before you attempt to add entries from the shadow database. The addition of a shadow entry that does not have a corresponding passwd entry will fail.

The passwd database must precede the user\_attr database.

For better performance, the recommended order in which the databases should be loaded is as follows:

- passwd database followed by shadow database
- networks database followed by netmasks database
- bootparams database followed by ethers database

Only the first entry of a given type that is encountered will be added to the LDAP server. The \texttt{ldapaddent} command skips any duplicate entries.

**Options**

The \texttt{ldapaddent} command supports the following options:

- \texttt{-a authenticationMethod}
  Specify authentication method. The default value is what has been configured in the profile. The supported authentication methods are:

  simple
  sasl/CRAM-MD5
  sasl/DIGEST-MD5
  sasl/GSSAPI
  tls:simple
  tls:sasl/CRAM-MD5
  tls:sasl/DIGEST-MD5

  Selecting \texttt{simple} causes passwords to be sent over the network in clear text. Its use is strongly discouraged. Additionally, if the client is configured with a profile which uses no authentication, that is, either the credentialLevel attribute is set to anonymous or authenticationMethod is set to none, the user must use this option to provide an authentication method. If the authentication method is sasl/GSSAPI, bindDN and bindPassword is not required and the hosts and ipnodes fields of /etc/nsswitch.conf must be configured as:
hosts: dns files
ipnodes: dns files
See nsswitch.conf(4).

-b baseDN
Create entries in the baseDN directory. baseDN is not relative to the client’s default search base, but rather, it is the actual location where the entries will be created. If this parameter is not specified, the first search descriptor defined for the service or the default container will be used.

-c
Continue adding entries to the directory even after an error. Entries will not be added if the directory server is not responding or if there is an authentication problem.

-d bindDN
Create an entry which has write permission to the baseDN. When used with -d option, this entry only needs read permission.

-d
Dump the LDAP container to the standard output in the appropriate format for the given database.

-f filename
Indicates input file to read in an /etc/ file format.

-h LDAP_server[:serverPort]
Specify an address (or a name) and an optional port of the LDAP server in which the entries will be stored. The current naming service specified in the nsswitch.conf file is used. The default value for the port is 389, except when TLS is specified as the authentication method. In this case, the default LDAP server port number is 636.

The format to specify the address and port number for an IPv6 address is:
[ipv6_addr]:port
To specify the address and port number for an IPv4 address, use the following format:
ipv4_addr:port
If the host name is specified, use the format:
host_name:port

-j passwdFile
Specify a file containing the password for the bind DN or the password for the SSL client’s key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the -w option.

-M domainName
The name of a domain served by the specified server. If not specified, the default domain name will be used.
-N profileName
 Specify the DUAProfile name. A profile with such a name is supposed to exist on the server
 specified by -h option. Otherwise, a default DUADirectory will be used. The default value is
default.

-P certifPath
 The certificate path for the location of the certificate database. The value is the path where
 security database files reside. This is used for TLS support, which is specified in the
 authenticationMethod and serviceAuthenticationMethod attributes. The default is
 /var/ldap.

-p
 Process the password field when loading password information from a file. By default, the
 password field is ignored because it is usually not valid, as the actual password appears in a
 shadow file.

-w bindPassword
 Password to be used for authenticating the bindDN. If this parameter is missing, the
 command will prompt for a password. NULL passwords are not supported in LDAP.

 When you use -w bindPassword to specify the password to be used for authentication, the
 password is visible to other users of the system by means of the ps command, in script files
 or in shell history.

 If you supply “-” (hyphen) as a password, you will be prompted to enter a password.

-v
 Verbose.

Operands
 The following operands are supported:

database
 The name of the database or service name. Supported values are: aliases, auto *,
 bootparams, ethers, group, hosts (including IPv6 addresses), netgroup, netmasks,
 networks, passwd, shadow, protocols, publickey, rpc, and services. Also supported are
 auth_attr, prof_attr, exec_attr, user_attr, and projects.

Examples

**EXAMPLE 1** Adding Password Entries to the Directory Server

The following example shows how to add password entries to the directory server:

```
example# ldapaddent -D "cn=directory manager" -w secret \
             -f /etc/passwd passwd
```

**EXAMPLE 2** Adding Group Entries

The following example shows how to add group entries to the directory server using
sasl/CRAM-MD5 as the authentication method:

```
example# ldapaddent -D "cn=directory manager" -w secret \
             -a "sasl/CRAM-MD5" -f /etc/group group
```
EXAMPLE 3 Adding auto_master Entries
The following example shows how to add auto_master entries to the directory server:
example# ldapaddent -D "cn=directory manager" -w secret \\
- f /etc/auto_master auto_master

EXAMPLE 4 Dumping passwd Entries from the Directory to File
The following example shows how to dump password entries from the directory to a file foo:
example# ldapaddent -d passwd > foo

EXAMPLE 5 Adding Password Entries to a Specific Directory Server
The following example shows how to add password entries to a directory server that you specify:
example# ldapaddent -h 10.10.10.10:3890 \\
- M another.domain.name - N special_duaprofile \\
- D "cn=directory manager" - w secret \\
- f /etc/passwd passwd

Exit Status The following exit values are returned:
0 Successful completion.
>0 An error occurred.

Files /var/ldap/ldap_client_file
/var/ldap/ldap_client_cred
Files containing the LDAP configuration of the client. These files are not to be modified manually. Their content is not guaranteed to be human readable. Use ldapclient(1M) to update these files.

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

Oracle Solaris 11.1 Administration: Security Services
Caution Currently StartTLS is not supported by libldap.so.5, therefore the port number provided refers to the port used during a TLS open, rather than the port used as part of a StartTLS sequence. For example:

```
-h foo:1000 -a tls:simple
```

The preceding refers to a raw TLS open on host foo port 1000, not an open, StartTLS sequence on an unsecured port 1000. If port 1000 is unsecured the connection will not be made.
ldap_cachemgr – LDAP daemon to manage client configuration for LDAP based Network Information Service lookups

Synopsis

```
/usr/lib/ldap/ldap_cachemgr [-l log-file] [-g]
```

Description

The `ldap_cachemgr` daemon is a process that provides an up-to-date configuration cache for LDAP naming services. It is started during multi-user boot.

The `ldap_cachemgr` utility provides caching for all parameters as specified and used by the LDAP naming service clients. The `ldap_cachemgr` utility uses the cache files which are originally created by executing the `ldapclient(1M)` utility, as cold start files. Updates to the cache files take place dynamically if profiles are used to configure the client. See the `init` option to `ldapclient(1M)`.

The `ldap_cachemgr` utility helps improve the performance of the clients that are using LDAP as the Naming service repository. In order for the LDAP naming services to function properly, the `ldap_cachemgr` daemon must be running. `ldap_cachemgr` also improves system security by making the configuration files readable by superuser only.

The cache maintained by this daemon is shared by all the processes that access LDAP Naming information. All processes access this cache through a door call. On startup, `ldap_cachemgr` initializes the cache from the cache files. See `ldapclient(1M)`. Thus, the cache survives machine reboots.

The `ldap_cachemgr` daemon also acts as its own administration tool. If an instance of `ldap_cachemgr` is already running, commands are passed transparently to the running version.

Options

The following options are supported:

- `-g`
  Print current configuration and statistics to standard output. This is the only option executable without superuser privileges.

- `-l log-file`
  Cause `ldap_cachemgr` to use a log file other than the default `/var/ldap/cachemgr.log`.

Examples

**EXAMPLE 1** Stopping and Restarting the `ldap_cachemgr` Daemon

The following example shows how to stop and to restart the `ldap_cachemgr` daemon.

```
example# svcadm disable network/ldap/client
example# svcadm enable network/ldap/client
```

**EXAMPLE 2** Forcing `ldap_cachemgr` to Reread Configuration Files

The following example shows how to force `ldap_cachemgr` to reread the `/var/ldap/ldap_client_file` and `/var/ldap/ldap_client_cred` files.

```
example# pkill -HUP ldap_cachemgr
```
Files
/var/ldap/cachemgr.log
    Default log file.
/var/ldap/ldap_client_file
/var/ldap/ldap_client_cred
    Files containing the LDAP configuration of the client. These files are not to be modified
    manually. Their content is not guaranteed to be human readable. Use ldapclient(1M) to
    update these files.

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/network/nis</td>
</tr>

Notes
The ldap_cachemgr service is managed by the service management facility, smf(5), under the
service identifier:

    svc:/network/ldap/client

Administrative actions on this service, such as enabling, disabling, or requesting restart, can
be performed using svcadm(1M). The service's status can be queried using the svc(1)
command.
**Name**

ldapclient – initialize LDAP client machine or output an LDAP client profile in LDIF format

**Synopsis**

```
/usr/sbin/ldapclient [-v | -q] init [-a profileName=profileName]
    [-a domainName=domain] [-a proxyDN=proxyDN]
    [-a proxyPassword=password]
    [-a authenticationMethod=authenticationMethod]
    [-a enableShadowUpdate=true | false]
    [-a adminDN=adminDN]
    [-a adminPassword=adminPassword]
    [-a certificatePath=path] [-d bindDN] [-w bindPassword]
    [-j passwdFile] [-y passwdFile]
    [-z adminrPasswdFile] LDAP_server[:port_number]
```

```
/usr/sbin/ldapclient [-v | -q] manual [-a attrName=attrVal]
```

```
/usr/sbin/ldapclient [-v | -q] mod [-a attrName=attrVal]
```

```
/usr/sbin/ldapclient [-v | -q] list
```

```
/usr/sbin/ldapclient [-v | -q] uninit
```

```
/usr/sbin/ldapclient [-v | -q] genprofile -a profileName=profileName
    [-a attrName=attrVal]
```

**Description**

The `ldapclient` utility can be used to:

- initialize LDAP client machines
- restore the network service environment on LDAP clients
- list the contents of the LDAP client cache in human readable format.

The `init` form of the `ldapclient` utility is used to initialize an LDAP client machine, using a profile stored on an LDAP server specified by `LDAP_server`. The LDAP client will use the attributes specified in the profile to determine the configuration of the LDAP client. Using a configuration profile allows for easy installation of LDAP client and propagation of configuration changes to LDAP clients. The `ldap_cachemgr(1M)` utility will update the LDAP client configuration when its cache expires by reading the profile. For more information on the configuration profile refer to IETF document *A Configuration Schema for LDAP Based Directory User Agents*.

The `manual` form of the `ldapclient` utility is used to initialize an LDAP client machine manually. The LDAP client will use the attributes specified on the command line. Any unspecified attributes will be assigned their default values. At least one server must be specified in the `defaultServerList` or the `preferredServerList` attributes. The `domainName` attribute must be specified if the client’s `domainName` is not set.

The `mod` form of the `ldapclient` utility is used to modify the configuration of an LDAP client machine that was setup manually. This option modifies only those LDAP client configuration attributes specified on the command line. The `mod` option should only be used on LDAP clients that were initialized using the `manual` option.
Regardless of which method is used for initialization, if a client is to be configured to use a proxy credentialLevel, proxy credentials must be provided using -a proxyDN=proxyDN and -a proxyPassword=proxyPassword options. However, if -a proxyPassword=proxyPassword is not specified, ldapclient will prompt for it. Note that NULL passwords are not allowed in LDAP. If a self credentialLevel is configured, authenticationMethod must be sasl/GSSAPI.

Similarly, if a client is to be configured to enable shadow information update and use a proxy credentialLevel, administrator credentials must be provided using -a adminDN=adminDN and -a adminPassword=adminPassword. However, the shadow information update does not need the administrator credentials if a self credentialLevel is configured.

The naming service-specific configuration properties are stored in the svc:/network/ldap/client SMF service. Modifying the SMF properties directly is not advised. Use this tool instead.

Other configuration might be modified during installation. It will be backed up to /var/ldap/restore. The files that are typically modified during initialization are:

- /etc/nsswitch.conf
- /etc/defaultdomain (if it exists)
- /var/yp/binding/'domainname' (for a NIS [YP] client)

LDAP configuration is managed in location profiles; this affects when and how LDAP configuration is made to persist. Please refer to netcfg(1M) for more information about location profiles, and to the section “Interaction with Location Profiles” below for more details on how LDAP configuration should be managed when automatic network configuration is being used.

ldapclient does not set up a client to resolve hostnames using DNS. It simply copies /etc/nsswitch.ldap to /etc/nsswitch.conf. If you prefer to use DNS for host resolution, please refer to the DNS documentation for information on setting up DNS. See resolv.conf(4). If you want to use sasl/GSSAPI as the authentication method, you have to use DNS for hosts and ipnodes resolution.

The list form of the ldapclient utility is used to list the LDAP client configuration. The output will be human readable. LDAP configuration files are not guaranteed to be human readable. Note that for security reason, the values for adminDN and adminPassword will not be displayed.

The uninit form of the ldapclient utility is used to uninitialize the network service environment, restoring it to the state it was in prior to the last execution of ldapclient using init or manual. The restoration will succeed only if the machine was initialized with the init or manual form of ldapclient, as it uses the backup files created by these options.

The genprofile option is used to write an LDIF formatted configuration profile based on the attributes specified on the command line to standard output. This profile can then be loaded into an LDAP server to be used as the client profile, which can be downloaded by means of the
ldapclient init command. Loading the LDIF formatted profile to the directory server can be done through `ldapadd(1)`, or through any server specific import tool. Note that the attributes proxyDN, proxyPassword, certificatePath, domainName, enableShadowUpdate, adminDN, and adminPassword are not part of the configuration profile and thus are not permitted.

You must have superuser privileges to run the `ldapclient` command, except with the `genprofile` option.

To access the information stored in the directory, clients can either authenticate to the directory, or use an unauthenticated connection. The LDAP client is configured to have a credential level of either anonymous or proxy. In the first case, the client does not authenticate to the directory. In the second case, client authenticates to the directory using a proxy identity for read access, and using an administrator identity for write access if `enableShadowUpdate` is configured. In the third case, client authenticates to the directory using a Kerberos principal that is mapped to an LDAP identity by the LDAP server. Refer to the chapter on implementing security in the *Oracle Solaris Administration: Naming and Directory Services* or your appropriate directory server documentation for identity mapping details.

If a client is configured to use an identity, you can configure which authentication method the client will use. The LDAP client supports the following authentication methods:

```
none
simple
sasl/CRAM-MD5
sasl/DIGEST-MD5
sasl/GSSAPI
tls:simple
tls:sasl/CRAM-MD5
tls:sasl/DIGEST-MD5
```

Note that some directory servers may not support all of these authentication methods. For `simple`, be aware that the bind password will be sent in the clear to the LDAP server. For those authentication methods using TLS (transport layer security), the entire session is encrypted. You will need to install the appropriate certificate databases to use TLS.

As previously mentioned, LDAP configuration is managed in location profiles (refer to `netcfg(1M)` for more information about location profiles). These profiles are either fixed, meaning the network configuration is being managed in the traditional way, or reactive, meaning the network configuration is being managed automatically, reacting to changes in the network environment according to policy rules specified in the profiles.

When a fixed location (there can currently be only one, the `DefaultFixed` location) is active, changes made to the SMF repository—including those made indirectly using tools such as `ldapclient`—will be applied to the location when it is disabled, and thus will be restored if that location is later re-enabled.
When a reactive location is active, changes should not be applied directly to the SMF repository; these changes will not be preserved in the location profile, and will thus be lost if the location is disabled, or if the system’s network configuration, as managed by svc:/network/physical:default and svc:/network/location:default, is refreshed or restarted. Changes should instead be applied to the location itself, using the netcfg(1M) command; this will save the change to the location profile repository, and will also apply it to the SMF repository (if the change is made to the currently active location).

Support for LDAP configuration in a location is currently very limited. The user must specify a server name, in the ldap-nameservice-servers property, from which a complete configuration profile can be obtained. No other parameters may be specified. Further, if LDAP configuration is not included in a location, then the relevant LDAP services will be disabled when the location is enabled.

More sophisticated LDAP configurations can be accommodated by creating a script that issues appropriate ldapclient commands to configure LDAP; this script can then be used to create an ENM profile, which can be enabled/disabled as needed. Please refer to netcfg(1M) for more information about ENM profiles.

 Commands
The following commands are supported:

  init
  Initialize client from a profile on a server.

  manual
  Manually initialize client with the specified attribute values.

  mod
  Modify attribute values in the configuration file after a manual initialization of the client.

  list
  Write the contents of the LDAP client cache to standard output in human readable form.

  uninit
  Uninitialize an LDAP client, assuming that ldapclient was used to initialize the client.

  genprofile
  Generate a configuration profile in LDIF format that can then be stored in the directory for clients to use, with the init form of this command.

 Attributes
The following attributes are supported:

  adminDN
  Specify the Bind Distinguished Name for the administrator identity that is used for shadow information update. This option is required if the credential level is proxy, and enableShadowUpdate is set to true. There is no default value.

  adminPassword
  Specify the administrator password. This option is required if the credential level is proxy, and enableShadowUpdate is set to true. There is no default value.
attributeMap

Specify a mapping from an attribute defined by a service to an attribute in an alternative schema. This can be used to change the default schema used for a given service. The syntax of attributeMap is defined in the profile IETF draft. This option can be specified multiple times. The default value for all services is NULL. In the example,

attributeMap: passwd:uid=employeeNumber

the LDAP client would use the LDAP attribute employeeNumber rather than uid for the passwd service. This is a multivalued attribute.

authenticationMethod

Specify the default authentication method used by all services unless overridden by the serviceAuthenticationMethod attribute. Multiple values can be specified by using a semicolon-separated list. The default value is none. For those services that use credentialLevel and credentialLevel is anonymous, this attribute is ignored. Services such as pam_ldap will use this attribute, even if credentialLevel is anonymous. The supported authentication methods are described above. If the authenticationMethod is sasl/GSSAPI, the hosts and ipnodes of /etc/nsswitch.conf must be configured with DNS support, for example:

hosts: dns files
ipnodes: dns files

bindTimeLimit

The maximum time in seconds that a client should spend performing a bind operation. Set this to a positive integer. The default value is 30.

certificatePath

The certificate path for the location of the certificate database. The value is the path where security database files reside. This is used for TLS support, which is specified in the authenticationMethod and serviceAuthenticationMethod attributes. The default is /var/ldap.

credentialLevel

Specify the credential level the client should use to contact the directory. The credential levels supported are anonymous, proxy, and self. If a proxy credential level is specified, then the authenticationMethod attribute must be specified to determine the authentication mechanism. Also, if the credential level is proxy and at least one of the authentication methods require a bind DN, the proxyDN and proxyPassword attribute values must be set. In addition, if enableShadowUpdate is set to true, the adminDN and adminPassword values must be set. If a self credential level is specified, the authenticationMethod must be sasl/GSSAPI.

defaultSearchBase

Specify the default search base DN. There is no default. The serviceSearchDescriptor attribute can be used to override the defaultSearchBase for given services.
defaultSearchScope=one | sub
Specify the default search scope for the client's search operations. This default can be overridden for a given service by specifying a serviceSearchDescriptor. The default is one level search.

defaultServerList
A space separated list of server names or server addresses, either IPv4 or IPv6. If you specify server names, be sure that the LDAP client can resolve the name without the LDAP name service. You must resolve the LDAP servers' names by using either files or dns. If the LDAP server name cannot be resolved, your naming service will fail.

The port number is optional. If not specified, the default LDAP server port number 389 is used, except when TLS is specified in the authentication method. In this case, the default LDAP server port number is 636.

The format to specify the port number for an IPv6 address is:
.ipv6_addr:port
To specify the port number for an IPv4 address, use the following format:
.ipv4_addr:port
If the host name is specified, use the format:
.host_name:port
If you use TLS, the LDAP server's hostname must match the hostname in the TLS certificate. Typically, the hostname in the TLS certificate is a fully qualified domain name. With TLS, the LDAP server host addresses must resolve to the hostnames in the TLS certificate. You must use files or dns to resolve the host address.

domainName
Specify the DNS domain name. This becomes the default domain for the machine. The default is the current domain name. This attribute is only used in client initialization.

enableShadowUpdate=true | false
Specify whether the client is allowed to update shadow information. If set to true and the credential level is proxy, adminDN and adminPassword must be specified.

followReferrals=true | false
Specify the referral setting. A setting of true implies that referrals will be automatically followed and false would result in referrals not being followed. The default is true.

objectClassMap
Specify a mapping from an objectClass defined by a service to an objectClass in an alternative schema. This can be used to change the default schema used for a given service. The syntax of objectClassMap is defined in the profile IETF draft. This option can be specified multiple times. The default value for all services is NULL. In the example,

.objectClassMap=passwd:posixAccount=unixAccount
the LDAP client would use the LDAP objectclass of unixAccount rather than the posixAccount for the passwd service. This is a multivalued attribute.

**preferredServerList**
Specify the space separated list of server names or server addresses, either IPv4 or IPv6, to be contacted before servers specified by the defaultServerList attribute. If you specify server names, be sure that the LDAP client can resolve the name without the LDAP name service. You must resolve the LDAP servers’ names by using either files or dns. If the LDAP server name cannot be resolved, your naming service will fail.

The port number is optional. If not specified, the default LDAP server port number 389 is used, except when TLS is specified in the authentication method. In this case, the default LDAP server port number is 636.

The format to specify the port number for an IPv6 address is:

```
[ipv6_addr]:port
```

To specify the port number for an IPv4 address, use the following format:

```
ipv4_addr:port
```

If the host name is specified, use the format:

```
host_name:port
```

If you use TLS, the LDAP server’s hostname must match the hostname in the TLS certificate. Typically, the hostname in the TLS certificate is a fully qualified domain name. With TLS, the LDAP server host addresses must resolve to the hostnames in the TLS certificate. You must use files or dns to resolve the host address.

**profileName**
Specify the profile name. For ldapclient init, this attribute is the name of an existing profile which may be downloaded periodically depending on the value of the profileTTL attribute. For ldapclient genprofile, this is the name of the profile to be generated. The default value is default.

**profileTTL**
Specify the TTL value in seconds for the client information. This is only relevant if the machine was initialized with a client profile. If you do not want ldap_cachemgr(1M) to attempt to refresh the LDAP client configuration from the LDAP server, set profileTTL to 0 (zero). Valid values are either zero 0 (for no expiration) or a positive integer in seconds. The default value is 12 hours.

**proxyDN**
Specify the Bind Distinguished Name for the proxy identity. This option is required if the credential level is proxy, and at least one of the authentication methods requires a bind DN. There is no default value.
proxyPassword
Specify client proxy password. This option is required if the credential level is proxy, and at least one of the authentication methods requires a bind DN. There is no default.

searchTimeLimit
Specify maximum number of seconds allowed for an LDAP search operation. The default is 30 seconds. The server may have its own search time limit.

serviceAuthenticationMethod
Specify authentication methods to be used by a service in the form servicename:authenticationmethod, for example:

    pam_ldap:tls:simple

For multiple authentication methods, use a semicolon-separated list. The default value is no service authentication methods, in which case, each service would default to the authenticationMethod value. The supported authentications are described above.

Three services support this feature: passwd-cmd, keyserv, and pam_ldap. The passwd-cmd service is used to define the authentication method to be used by passwd(1) to change the user’s password and other attributes. The keyserv service is used to identify the authentication method to be used by the chkey(1) and newkey(1M) utilities. The pam_ldap service defines the authentication method to be used for authenticating users when pam_ldap(5) is configured. If this attribute is not set for any of these services, the authenticationMethod attribute is used to define the authentication method. This is a multivalued attribute.

serviceCredentialLevel
Specify credential level to be used by a service. Multiple values can be specified in a space-separated list. The default value for all services is NULL. The supported credential levels are: anonymous or proxy. At present, no service uses this attribute. This is a multivalued attribute.

serviceSearchDescriptor
Override the default base DN for LDAP searches for a given service. The format of the descriptors also allow overriding the default search scope and search filter for each service. The syntax of serviceSearchDescriptor is defined in the profile IETF draft. The default value for all services is NULL. This is a multivalued attribute. In the example,

    serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one

the LDAP client would do a one level search in ou=people,dc=a1,dc=acme,dc=com rather than ou=people, defaultSearchBase for the passwd service.

Options
The following options are supported:

- a attrName=attrValue
  Specify attrName and its value. See SYNOPSIS for a complete list of possible attribute names and values.
-D bindDN
  Specifies an entry that has read permission for the requested database.

- j passwdFile
  Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the -w option.

-q
  Quiet mode. No output is generated.

-v
  Verbose output.

-w bindPassword
  Password to be used for authenticating the bind DN. If this parameter is missing, the command will prompt for a password. NULL passwords are not supported in LDAP.

  When you use -w bindPassword to specify the password to be used for authentication, the password is visible to other users of the system by means of the ps command, in script files, or in shell history.

  If you supply "-" (hyphen) as a password, the command will prompt for a password.

- y passwdFile
  Specify a file containing the password for the proxy DN. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the - a proxyPassword option.

-z adminrPasswdFile
  Specify a file containing the password for the adminDN. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the - a adminPassword option.

Operands
  The following operand is supported:

    LDAP_server
      An address or a name for the LDAP server from which the profile will be loaded. The current naming service specified in the nsswitch.conf file is used. Once the profile is loaded, the preferredServerList and defaultServerList specified in the profile are used.

Examples
  EXAMPLE 1 Setting Up a Client By Using the Default Profile Stored on a Specified LDAP Server

  The following example shows how to set up a client using the default profile stored on the specified LDAP server. This command will only be successful if either the credential level in the profile is set to anonymous or the authentication method is set to none.

  example# ldapclient init 172.16.100.1
EXAMPLE 2  Setting Up a Client By Using the simple Profile Stored on a Specified LDAP Server

The following example shows how to set up a client using the simple profile stored on the specified LDAP server. The domain name is set to `xyz.mycompany.com` and the proxyPassword is secret.

```
example# ldapclient init -a profileName=simple \ 
  -a domainName=xyz.mycompany.com \ 
  -a proxyDN=cn=proxyagent,ou=profile,dc=xyz,dc=mycompany,dc=com \ 
  -a proxyPassword=secret \[
    {10}{10}{10}fe80::a00:20ff:fed3:388\]':386
```

EXAMPLE 3  Setting Up a Client Using Only One Server

The following example shows how to set up a client using only one server. The authentication method is set to none, and the search base is `dc=mycompany,dc=com`.

```
example# ldapclient manual -a authenticationMethod=none \ 
  -a defaultSearchBase=dc=mycompany,dc=com \ 
  -a defaultServerList=172.16.100.1
```

EXAMPLE 4  Setting Up a Client Using Only One Server That Does Not Follow Referrals

The following example shows how to set up a client using only one server. The credential level is set to proxy. The authentication method is `sasl/CRAM-MD5`, with the option not to follow referrals. The domain name is `xyz.mycompany.com`, and the LDAP server is running on port number 386 at IP address `172.16.100.1`.

```
example# ldapclient manual \ 
  -a credentialLevel=proxy \ 
  -a authenticationMethod=sasl/CRAM-MD5 \ 
  -a proxyPassword=secret \ 
  -a proxyDN=cn=proxyagent,ou=profile,dc=xyz,dc=mycompany,dc=com \ 
  -a defaultSearchBase=dc=xyz,dc=mycompany,dc=com \ 
  -a domainName=xyz.mycompany.com \ 
  -a followReferrals=false \ 
  -a defaultServerList=172.16.100.1:386
```

EXAMPLE 5  Using genprofile to Set Only the defaultSearchBase and the Server Addresses

The following example shows how to use the genprofile command to set the defaultSearchBase and the server addresses.

```
example# ldapclient genprofile -a profileName=myprofile \ 
  -a defaultSearchBase=dc=eng,dc=sun,dc=com \ 
  -a "defaultServerList=172.16.100.1 172.16.234.15:386" \ 
  > myprofile.ldif
```

EXAMPLE 6  Creating a Profile on IPv6 servers

The following example creates a profile on IPv6 servers.
Creating a Profile on IPv6 servers (Continued)

```bash
example# ldapclient genprofile -a profileName=eng \
    -a credentialLevel=proxy \
    -a authenticationMethod=sasl/DIGEST-MD5 \
    -a defaultSearchBase=dc=eng,dc=acme,dc=com \
    -a "serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one" \
    -a preferredServerList='[fe80::a00:20ff:fea3:388]' \
    -a "defaultServerList='[fec0::111:a00:20ff:feb5:e41]'" \
    > eng.ldif
```

Creating a Profile That Overrides Every Default Value

The following example shows a profile that overrides every default value.

```bash
example# ldapclient genprofile -a profileName=eng \
    -a credentialLevel=proxy -a authenticationMethod=sasl/DIGEST-MD5 \
    -a bindTimeLimit=20 \
    -a defaultSearchBase=dc=eng,dc=acme,dc=com \
    -a "serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one" \
    -a serviceAuthenticationMethod=pam_ldap:tls:simple \
    -a defaultSearchScope=sub \
    -a attributeMap=passwd:uid=employeeNumber \
    -a objectclassMap=passwd:posixAccount=unixAccount \
    -a followReferrals=false -a profileTTL=6000 \
    -a preferredServerList=172.16.100.30 -a searchTimeLimit=30 \
    -a "defaultServerList=172.16.100.1 172.16.100.1 192.168.5.6" > eng.ldif
```

**Exit Status**

The following exit values are returned:

0 The command successfully executed.
1 An error occurred. An error message is output.
2 `proxyDN` and `proxyPassword` attributes are required, but they are not provided.

**Files**

- `/var/ldap/ldap_client cred`
  - Contains the LDAP configuration of the client. These files are not to be modified manually. Their content is not guaranteed to be human readable. Use `ldapclient` to update them.
- `/etc/defaultdomain`
  - System default domain name, matching the domain name of the data in the LDAP servers. See `defaultdomain(4)`.
- `/etc/nsswitch.conf`
  - Configuration file for the name-service switch. See `nsswitch.conf(4)`.
- `/etc/nsswitch.ldap`
  - Sample configuration file for the name-service switch configured with LDAP and files.

defaultdomain(4), nsswitch.conf(4), resolv.conf(4), attributes(5)

Caution

Currently StartTLS is not supported by libldap.so.5, therefore the port number provided
refers to the port used during a TLS open, rather than the port used as part of a StartTLS
sequence. To avoid timeout delays, mixed use of TLS and non-TLS authentication
mechanisms is not recommended.

For example:

    -h foo:1000 -a authenticationMethod=tls:simple

...or:

    defaultServerList= foo:1000
    authenticationMethod= tls:simple

The preceding refers to a raw TLS open on host foo port 1000, not an open, StartTLS sequence
on an unsecured port 1000. If port 1000 is unsecured the connection will not be made.

As a second example, the following will incur a significant timeout delay while attempting the
connection to foo:636 with an unsecured bind.

    defaultServerList= foo:636 foo:389
    authenticationMethod= simple
ldmad – Logical Domains Agents daemon

Synopsis

The ldmad daemon is part of the framework that enables Logical Domain agents to run on a Logical Domain. A Logical Domain agent is a component that interacts with the control domain to provide features or information. ldmad is responsible for running agents on a Logical Domain. ldmad must be enabled to ensure the proper functionality of all features provided by the domain manager on the control domain. The daemon is started at boot time and has no configuration options.

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/ldoms</td>

<td>Unstable</td>
</tr>
</tbody>
</table>

See Also

svcs(1), svcadm(1M), syslog(3C), syslog.conf(4), attributes(5), smf(5)

Oracle VM Server for SPARC 2.2 Administration Guide

Errors

ldmad uses syslog(3C) to report status and error messages. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities. Informational messages are logged with the LOG_INFO priority. The default entries in the /etc/syslog.conf file specify that all ldmad error messages are written to the /var/adm/messages log.

Notes

The ldmad service is managed by the service management facility, smf(5), under the service identifier:

svc:/ldoms/agents:default

Administrative actions on this service, such as enabling, disabling, or requesting restart can be performed using svcadm(1M). The service’s status can be queried using the svcs(1) command.
The `link` and `unlink` commands link and unlink files and directories. Only super-users can use these commands on directories.

Use `link` to create a new file that points to an existing file. The `existing-file` and `new-file` operands specify the existing file and newly-created files. See `OPERANDS`.

Note that the ZFS file system does not support links between directories.

`link` and `unlink` directly invoke the `link(2)` and `unlink(2)` system calls, performing exactly what they are told to do and abandoning all error checking. This differs from the `ln(1)` command. See `ln(1)`.

While linked files and directories can be removed using `unlink`, it is safer to use `rm(1)` and `rmdir(1)` instead. See `rm(1)` and `rmdir(1)`.

The following operands are supported:

- `existing-file` Specifies the name of the existing file to be linked.
- `file` Specifies the name of the file to be unlinked.
- `new-file` Specifies the name of newly created (linked) file.

See `environ(5)` for descriptions of the following environment variables that affect the execution of `link`: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

See `attributes(5)` for descriptions of the following attributes:

Name  llc2_loop – loopback diagnostics to test the driver, adapter and network.

Synopsis  
/usr/lib/llc2/llc2_loop2 [-v] ppa
/usr/lib/llc2/llc2_loop3 ppa sap frames
/usr/lib/llc2/llc2_loop3 ppa type frames
/usr/lib/llc2/llc2_loop4 [-v] ppa

Description

Loop 2  The loop2 test sends a NULL XID frame to the broadcast (all 1's) destination MAC address. The source SAP (Service Access Point) value used is 0x04 (SNA’s SAP). Therefore, if SNA is running on the system, the loop2 test will fail. The destination SAP value is the NULL SAP (0x00). This test finds out who is listening and can receive frames sent out from a node. The verbose (-v) option displays the MAC address of responding nodes. All possible responders may not be displayed, since the loop2 test only waits for responses for 2 seconds, but during this time 50-200 nodes may be displayed. The most likely error is:

Unexpected DLPI primitive x, expected y.

where x = 5 and y = 6. From /usr/include/sys/dlpi.h, the expected return value from one of the DLPI primitives is 6 (DL_OK_ACK), but instead a 5 (DL_ERROR_ACK) was received. This can occur for two reasons:

- The loop2 command was issued to a non-existent PPA (Physical Point of Attachment).
- The SAP (0x04) is already in use (for example, the SNA subsystem is up).

Loop 3  The loop3 test sends 1,495 byte Unnumbered Information (UI) frames to the NULL (all 0's) destination MAC address. This should be used along with data capture either on the local node or another node on the same LAN to verify the transmission of data. The ppa argument specifies the adapter on which to run the test. The ppa is the relative physical position of the adapter and may be ascertained by viewing the adapter configuration (see llc2_config(1)). For Token Ring or Ethernet, specify an even sap value from 2 through 254, or, for Ethernet only, any type value from 1519 (0x05ef) through 65535 (0xffff). It is advised to pick a value that is easily recognized when the data capture output is viewed. frames is the decimal number of 1,495 bytes packets to transmit. The test will only display a message if a failure occurs.

Loop 4  The loop4 test sends a TEST frame (no information field) to the broadcast (all 1's) destination MAC address. The source SAP value used is 0x04 (SNA’s SAP). Therefore, if SNA is running on the system, the loop4 test will fail. The destination SAP value is the NULL SAP (0x00). This test finds out who is listening and can receive frames sent out from a node. The verbose (-v) option displays the MAC address of responding nodes. All possible responders may not be displayed since the loop4 test only waits for responses for 2 seconds, but during this time 50-200 nodes may be displayed. The loop4 test displays information similar to the following example if other nodes are listening and respond (verbose mode):

- Attaching
- Binding
- Sending TEST
- Responders
  1-0000c0c12449
  2-08000e142990
  3-08000e142a51
  4-0000c0450044
  5-0000c0199e46
- Unbinding
- Detaching
  5 nodes responding

The errors displayed are the same as for \texttt{\texttt{\texttt{\texttt{\texttt{llc2_loop}(1M)}}}}.

lldpadm(1M)

**Name**

lldpadm – Link Layer Discovery Protocol administration tool

**Synopsis**

```
lldpadm set-agentprop -p prop[+|-]=value[,...] lldp_agent
lldpadm reset-agentprop -p prop[,...] lldp_agent
lldpadm show-agentprop [-c] -o field[,...] -p prop[,...] [lldp_agent]
lldpadm set-tlvprop -p prop[+|-]=value[,...] tlv_name
lldpadm reset-tlvprop -p prop[,...] tlv_name
lldpadm show-tlvprop [-c] -o field[,...] -p prop[,...] [tlv_name]
lldpadm set-agenttlvprop -p prop[+|-]=value[,...] -a lldp_agent tlv_name
lldpadm reset-agenttlvprop -p prop[,...] -a lldp_agent tlv_name
lldpadm show-agenttlvprop [-c] -o field[,...] -p prop[,...] [-a lldp_agent] [tlv_name]
lldpadm show-agent [-c] [-s] [-v] -o field[,...] [-l|-r] [lldp_agent]
```

**Description**

The `lldpadm` command is used to enable or disable a Link Layer Discovery Protocol (LLDP) agent on a physical datalink. `lldpadm` is also used to configure the behavior of an LLDP agent. The LLDP agent implements the LLDP protocol for a given physical datalink. LLDP is a one-way link layer protocol that allows an IEEE 802 LAN station to advertise the capabilities and current status of the system to other stations attached to the same LAN. The LLDP agent can also receive information about the capabilities and current status of the system associated with a remote station. LLDP agent can either be enabled for transmission only, for reception only, or for both.

Information to be exchanged is packed as a sequence of type, length, and value (TLVs), wherein the type field identifies the type of information, the length field indicates the length of the information field in octets, and the value field contains the information itself.

**Operands**

Each `lldpadm` subcommand operates on one of the following objects:

- **lldp_agent**
  
  An LLDP agent implements the LLDP protocol for a given physical datalink that is connected to IEEE 802 LAN. The only supported physical links are the ones of media type Ethernet. Thus, LLDP can be enabled on all the links displayed in `dladm show-phys` output that are of media type Ethernet. The name of the `lldp_agent` is the name of the datalink itself.

- **tlv_name**
  
  Name of the TLV whose value can be modified. The supported modifiable TLVs are:

  - **syscapab** and **mgmtaddr**. These form Global TLVs that are common to all the LLDP agents on the system.
  - **pfc**, **ets**, and **appln**. Per-LLDP agent TLVs.
lldpadm supports the following subcommands.

```
lldpadm set-agentprop set-ap -p prop[+|-]=value[,...] lldp_agent
```
Sets the value of one or more LLDP agent properties to the value specified. If the property takes multiple values then the value should be specified with a comma as the delimiter. The value is always made persistent and thus will be reapplied on system reboot or llpd(1M) daemon restart. The list of properties supported and each property's possible values can be retrieved using show-agentprop subcommand.

```
-p prop[+|-]=value[,...], -p prop[+|-]=value[,...]
```
A comma-separated list of properties to be set to the specified values. It also provides the following qualifiers to perform add and delete operations in addition to assignment.
+  Adds the given value to the current list of value(s).
-  Removes the given value from the current list of value(s).
=  Makes a new assignment and removes all the current value(s).

See EXAMPLES for more information on how to use the qualifiers.

```
lldpadm reset-agentprop reset-ap -p prop[,...] lldp_agent
```
Resets one or more properties to their default values. The default values for properties can be retrieved using show-agentprop subcommand.

```
-p prop[,...], -p prop[,...]
```
A comma-separated list of properties to reset.

```
lldpadm show-agentprop show-ap [-c] -o field[,...] -p prop[,...] [lldp_agent]
```
Show the current value of one or more properties, either for all of the LLDP agents or for the specified LLDP agent. Several properties of interest can be retrieved at a time by providing comma-separated property names to -p option. If the -p option is not specified, all available properties are displayed.

```
-o field[,...], -o output field[,...]
```
A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. For each LLDP agent, the following fields can be displayed:

AGENT
  The name of the LLDP agent.

PROPERTY
  The name of the property.

PERM
  The read/write permissions of the property. The value shown will be r (read only), w (write only) or rw (read/write).
The current value of the property. If the value is not set, it is shown as --. If it is unknown, the value is shown as ?.

The default value of the property. If the property has no default value, -- is shown.

A comma-separated list of the values the property can have. If the values span a numeric range, min - max might be shown as shorthand. If the possible values are unknown or unbounded, -- is shown.

Display using a stable machine-parsable format. The -o option is required with this option. See "Parsable Output Format", below.

A comma-separated list of properties to display.

For the supported list of agent properties, see "Agent Properties" section below.

Sets the value of one or more TLV properties to the value specified. If the property takes multiple values, the value should be specified with a comma as the delimiter. The value is always persisted and will be reapplied on system reboot or lldpd(1M) daemon restart. The list of properties supported and each property's possible values can be retrieved using show-tlvprop subcommand.

Note – The TLVs modified using this subcommand apply to all the LLDP agents running on the system.

Resets one or more properties to their default values. The default values for properties can be retrieved using show-tlvprop subcommand.

A comma-separated list of properties to reset.

Show the current value of one or more properties, either for all the TLVs or for a specified TLV. Several properties of interest can be retrieved at a time by providing comma-separated property names to -p option. If the -p option is not specified, all available properties are displayed.
- o field[,...], - output field[,...]
A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. For each TLV, the following fields can be displayed:

TLVNAME
The name of the TLV.

PROPERTY
The name of the property.

PERM
The read/write permissions of the property. The value shown will be r (read only), w (write only) or rw (read/write).

VALUE
The current value of the property. If the value is not set, it is shown as -. If it is unknown, the value is shown as ?.

DEFAULT
The default value of the property. If the property has no default value, - - is shown.

POSSIBLE
A comma-separated list of the values the property can have. If the values span a numeric range, min - max might be shown as shorthand. If the possible values are unknown or unbounded, - - is shown.

-c, --parsable
Display using a stable machine-parsable format. The - o option is required with this option. See "Parsable Output Format", below.

-p prop[,...], - prop prop[,...]
A comma-separated list of properties to display.

lldpadm set-agenttlvprop|set-atp - p prop[+]=-value[,...] - a lldp_agent tlv_name
Sets the value of one or more TLV properties to the value specified. The - a option is mandatory and identifies the name of the agent for which the TLV property needs to be set. In this way, the TLV property modification is reflected only on the specified agent. If the property takes multiple values then the value should be specified with a comma as the delimiter. The value is always made persistent and will be reapplied on system reboot or lldpd(1M) daemon restart. The list of properties supported and each property's possible values can be retrieved using show-agenttlvprop subcommand.

-p prop[+]=-value[,...], - prop prop[+]=-value[,...]
See the description of this option under the set-agentprop subcommand, above.

-a lldp_agent, - agent=lldp_agent
The name of the LLDP agent for which TLV properties need to be displayed.
llldadm reset-agenttlvprop

llldadm reset-agenttlvprop

Resets one or more properties to their default values. The -a option is mandatory and
identifies the name of the agent for which the TLV property needs to be reset. The default
values for properties can be retrieved using show-agenttlvprop subcommand.

- p prop[,...] - prop prop[,...]
   A comma-separated list of properties to display.

- a lldp_agent - agent=lldp_agent
   The name of the LLDP agent for which the TLV properties need to be displayed.

llldadm show-agenttlvprop

llldadm show-agenttlvprop

Show the current value of one or more properties, either for all of the TLVs or for a
specified TLV. If a single LLDP agent is not specified (using -a), TLV properties for all
LLDP agents are displayed. Several properties of interest can be retrieved at a time by
providing comma-separated property names to the -p option. If the -p option is not
specified, all available properties are displayed.

- a field[,...] - output field[,...]
   A case-insensitive, comma-separated list of output fields to display. The field name must
   be one of the fields listed below, or the special value all to display all fields. For each
   LLDP agent, the following fields can be displayed:

   AGENT
      The name of the LLDP agent.

   TLVNAME
      The name of the TLV.

   PROPERTY
      The name of the property.

   PERM
      The read/write permissions of the property. The value shown will be r (read only), w
      (write only) or rw (read/write).

   VALUE
      The current value of the property. If the value is not set, it is shown as -. If it is
      unknown, the value is shown as ?.

   DEFAULT
      The default value of the property. If the property has no default value, - - is shown.

   POSSIBLE
      A comma-separated list of the values the property can have. If the values span a
      numeric range, min - max might be shown as shorthand. If the possible values are
      unknown or unbounded, - - is shown.
lldpadm show-agent [-c] [-s] [-v] [-o field,...] [-l | -r] [lldp_agent]

Show the information advertised by the specified LLDP agent or information advertised by the adjacent neighbors to the specified LLDP agent. If no LLDP agent is specified, then the local or remote information will be displayed for all the LLDP agents. The information is displayed as a multi-line output, with each line containing information about a single TLV in the following format:

<Name of the TLV> : <TLV Information expressed as a string>

The following lines can be displayed:

      EVB RKA:
Next Packet Transmission:  [displayed only when \(-l\) is used]
Information Valid Until:   [displayed only when \(-r\) is used]

In preceding output, the ETS parameters are described as follows:

ETS Configured CBS  Indicates whether Credit-Based Shaper is supported.
ETS Configured TCS  Number of Traffic Classes supported.
ETS Configured PAT  Priority Assignment Table.
ETS Configured BAT  Bandwidth Assignment Table.
ETS Configured TSA  Transmission Selection Algorithm supported.
ETS Recommended values Values that will be recommended to the peer.

\(-c,\ --parsable\)
  Display using a stable machine-parsable format. The \(-o\) option is required with this
  option. See "Parsable Output Format", below.

\(-l,\ --local\)
  Displays information advertised by the local LLDP agent. This option is mutually
  exclusive of the \(-r\) option.

\(-r,\ --remote\)
  Displays information advertised by the adjacent neighbors. This option is mutually
  exclusive of the \(-l\) option.
Show the statistics for the specified LLDP agents or for all the LLDP agents on the system. Every LLDP agent maintains statistical counters that are used to count significant events in the transmit and receive state machines. These counters are defined to be 32-bit unsigned integers.

```
-o field[,...], -o output field[,...]
```
A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all` to display all fields. For each TLV, the following fields can be displayed:

**AGENT**
The name of the LLDP agent.

**IFRAMES**
Count of all LLDP frames received by `AGENT`.

**IERR**
Count of all LLDPDUs received with one or more detectable errors.

**IDISCARD**
Count of all LLDPDUs received and then discarded for any of the following reasons:
- incorrectly formed LLDPDUs with respect to the first three mandatory TLVs
- insufficient space to store the incoming LLDPDU

**OFRAMES**
Count of all LLDP frames transmitted by `AGENT`.

**OLENERR**
Count of times the outgoing LLDPDU exceeded the length restrictions of 1500 bytes.

**TLVDISCARD**
Count of all TLVs received and then discarded because the TLVs did not adhere to the TLV usage rules as specified by the standard.

**TLVUNRECOG**
Count of all TLVs received that are not recognized by the LLDP agent.

**AGEOUT**
Count of the times that a neighbor's information has been deleted because of aging.

```
-v, -v verbose
```
Displays detailed information.

**Parsable Output Format**
The `lldpadm` show subcommands have a `-c` option that displays output in a machine-parsable format. The output format is one or more lines of colon (`:`)-delimited fields. The fields displayed are specific to the subcommand used and are listed under the entry for the `-o` option for a given subcommand. Output includes only those fields requested by means of the `--o` option, in the order requested. Note that the `-o all` option, which displays all the fields for a given subcommand, cannot be used with the parsable output option.
When you request multiple fields, any literal colon characters are escaped by a backslash (\) before being output. Similarly, literal backslash characters are also escaped with a backslash. This escape format is parsable by using shell `read(1)` functions with the environment variable set as `IFS=`: Note that escaping is not done when you request only a single field.

### Agent Properties

The following LLDP agent properties are supported:

**mode**

Configures the operation mode of the LLDP agent. Possible values are:

- `txonly`
  
  Enables LLDP for transmission only.

- `rxonly`

  Enables LLDP for receiving only.

- `both`

  Enables LLDP for both transmission and receiving.

- `disable`

  Disables LLDP on the LLDP agent.

Every LLDP packet (LLDPU) transmitted by an LLDP agent contains multiple TLVs. The following four TLVs are mandatory and therefore included in all the LLDPUUs transmitted by an agent configured in the `txonly` or `both` mode:

**CHASSIS ID**

The value transmitted in the Chassis ID TLV is:

- `subtype = 7` (locally assigned)
- `Chassis ID = hostid(1)`

**PORT ID**

The value transmitted in the Port ID TLV is:

- `subtype = 3` (MAC address)
- `Port ID = primary MAC address of the agent`

**TTL**

The duration for which this packet is valid. The default value is 30 seconds.

End of PDU TLV

End of PDU indicator.

Optional TLVs that can be advertised are configured using the following properties:

**basic-tlv**

Configures the Basic Management TLVs that should be advertised by the LLDP agent. The possible values are:

- `portdesc`

Alphanumeric string that identifies the datalink. Value set to the linkname.
sysname
Alphanumeric string that identifies the system. Value set to the output of 'uname -n'.

sysdesc
Alphanumeric string that describes the system. Value set to the output of 'uname -a'.

syscapab
Indicates the systems supported and enabled capabilities.

mgmtaddr
Indicates the IP address of the system that can be used by network management.

dot1-tlv
Configures the IEEE 802.1 Organizationally Specific TLVs that should be advertised by the LLDP agent. The possible values are:

vlanname
Indicates the names and IDs of all the VLANS configured on the datalink.

pvid
Indicates the default VLAN ID associated with the given datalink. It corresponds to the default_tag datalink property that is managed by means of the `dladm(1M)` utility.

linkaggr
Indicates whether underlying datalink is in an aggregation or is capable of being part of an aggregation.

pfc
Indicates whether underlying datalink supports PFC (Priority Flow Control) and the priorities for which the PFC pause frame is enabled. Also indicates whether the local endpoint is willing to negotiate the PFC configuration.

ets-cfg
Indicates the ETS (Enhanced Transmission Selection) configuration on the host when the underlying physical link supports ETS feature. Also indicates whether the local endpoint is willing to negotiate the ETS configuration.

appln
Indicates the priority that will be used by an application.

dot3-tlv
Configures the IEEE 802.3 Organizationally Specific TLVs that should be advertised by the LLDP agent. The possible values are:

max-framesize
Indicates the maximum supported frame size for the underlying datalink.

virt-tlv
Configures the Solaris's Virtualization Specific TLVs that should be advertised by the LLDP agent. The possible values are:
vnic
Indicates the MAC address of the Virtual NIC created on top of the underlying physical link. Also indicates any VLAN id associated with the VNIC. See dladm(1M) for more information on VNIC.

Global TLVs and Their Properties
The following Global TLV properties are supported:

syscapab (TLV name)
This property can one of the following values:
supported
Indicates the supported capabilities on the system. The default supported capabilities are: bridge, router, and station.

enabled
Indicates the enabled capabilities on the system. The enabled capabilities must be a subset of the supported capabilities.

mgmtaddr (TLV name)
This property can have the following value:
ipaddr
The IP address(es), either IPv4 or IPv6, associated with the local LLDP agent that will be used to reach higher layer entities to assist discovery by network management.

Per-Agent TLVs and Their Properties
The following Agent TLV properties are supported:

appln (TLV name)
This property can have the following value:
apt
Configures the Application Priority Table for an Application TLV. One can add or remove entries from this table using the + and - qualifiers. Each entry in the table indicates the application and the priority that will be used for that application. Its value is of the form:
id(selector)/priority
The meaning of the id is determined by the selector field. The selector field can be any one of the following:

- 1 — id indicates an Ethertype (an L2 protocol), therefore id’s value should be greater than 1536
- 2 — id indicates a port number over TCP or SCTP
- 3 — id indicates a port number over UDP or DCCP
- 4 — id indicates a port number over TCP, SCTP, UDP, or DCCP

The priority indicates the priority value (0-7) that will be used for given application.
ets (TLV name)
This property can have the following value:

willing
Indicates whether the host is willing to accept the peer’s ETS recommendation. This property is likely to change in the future.

pfc (TLV name)
This property can have the following value:

willing
Configures the willingness to accept the configuration from the remote peer and change the operational configuration on the host locally for a Priority-based Flow Control TLV. Its value can be on (default) or off. This property is subject to change in future releases.

AUTHORIZATIONS
The following subcommands require solaris.network.ldp authorization:

- set-agentprop
- reset-agentprop
- set-tlvprop
- reset-tlvprop
- set-agenttlvprop
- reset-agenttlvprop

The various show-* subcommands do not need any authorization.

EXAMPLES

EXAMPLE 1  Enabling LLDP Protocol on an LLDP Agent
The following command enables the LLDP protocol on an LLDP agent for both transmission and reception of LLDPDUs.

```
# lldpdm set-agentprop -p mode=both net0
```

EXAMPLE 2  Disabling LLDP Protocol on an LLDP Agent
The following command disables the LLDP protocol on an LLDP agent.

```
# lldpdm set-agentprop -p mode=disable net0
```

EXAMPLE 3  Configuring TLVs
The following command configures transmission of the Port Description and System Name TLV.

```
# lldpdm set-agentprop -p basic-tlv=portdesc,sysname net0
```

The following command configures transmission of a VLAN Name TLV and a Link Aggregation TLV.

```
# lldpdm set-agentprop -p dot1-tlv=vlanname net0
# lldpdm set-agentprop -p dot1-tlv+=linkaggr net0
```
EXAMPLE 3  Configuring TLVs  (Continued)

The following command configures transmission of all dot3-tlv.

```
# lldpadm set-agentprop -p dot3-tlv=all net0
```

All the above lldpadm invocations can be combined into the following, single invocation.

```
# lldpadm set-agentprop -p basic-tlv=portdesc,sysname,\non
   dot1-tlv=vlanname,linkaggr,dot3-tlv=all net0
```

EXAMPLE 4  Disabling Transmission

The following command disables the transmission of all dot1-tlv out of an LLDP agent.

```
# lldpadm set-agentprop -p dot1-tlv=none net0
```

The following command is equivalent to the preceding.

```
# lldpadm reset-agentprop -p dot1-tlv net0
```

EXAMPLE 5  Configuring Enabled Capabilities

The following command configures the enabled capabilities on a system.

```
# lldpadm set-tlvprop -p enabled=router syscapab
```

With this configuration, when an LLDP agent is enabled for advertising a System Capabilities TLV, the adjacent neighbors would learn of the local system's capabilities.

EXAMPLE 6  Configuring a Management Address for Subsequent Advertising

The following command configures the management address that will be advertised by means of the Management Address TLV.

```
# lldpadm set-tlvprop -p ipaddr=192.168.1.2 mgmtaddr
```

Note that this address would be identified as an address associated with the local LLDP agent that will be used to reach higher layer entities to assist discovery by network management.

EXAMPLE 7  Configuring an Application TLV

The following sequence of commands configures the application TLV to advertise the priority that will be used by FCoE.

```
# lldpadm set-agenttlvprop -p apt=8906/1/4 -a net0 appln
# lldpadm show-agenttlvprop -a net0 appln
```

**AGENT**  **TLVNAME**  **PROPERTY**  **PERM**  **VALUE**  **DEFAULT**  **POSSIBLE**

lldpadm(1M)
EXAMPLE 8  Show Local Information Advertised by LLDP Agent

The following commands show, respectively, brief and detailed local information advertised by an LLDP agent.

Brief information:

```
# lldpadm show-agent -l net0
AGENT   CHASSISID   PORTID
net0    004bb87f   00:14:4f:01:77:5d
```

Detailed information:

```
# lldpadm show-agent -lv net0
Agent: net0
    Chassis ID Subtype: Local(7)
    Chassis ID: 004bb87f
    Port ID Subtype: MacAddress(3)
    Port ID: 00:14:4f:01:77:5d
    Port Description: net0
    Time to Live: 81 (seconds)
    System Name: hosta.example.com
    System Description: SunOS 5.11 dcb-clone-x-01-19-11 i86pc
    Supported Capabilities: bridge, router, station
    Enabled Capabilities: router
    Management Address: 192.168.1.2
    Maximum Frame Size: 3000
    Port VLAN ID: --
    VLAN Name/ID: vlan25/25
    VNIC PortID/VLAN ID : --
    Aggregation Information: Capable, Not Aggregated
    PFC Willing: --
    PFC Cap: --
    PFC MBC: --
    PFC Enable: --
    PFC Pending: --
    ETS Configured CBS: 0
    ETS Configured TCS: 8
    ETS Configured PAT: 0,1,2,3,4,5,6,7
    ETS Configured BAT: 70,30,0,0,0,0,0,0
    ETS Configured TSA: 2,2,2,2,2,2,2,2
    ETS Recommended PAT: --
    ETS Recommended BAT: --
    ETS Recommended TSA: --
    Application(s)(ID/Sel/Pri): --
    EVB Mode: Station
    EVB GID (Station): Not Supported
    EVB RRREQ: Not Requested
    EVB RRSTAT: RR Unknown
    EVB GID (Bridge): Not Supported
```
EVB RRCAP: Not Supported
EVB RRCTR: Not Enabled
EVB R: 3
EVB RTE: 20
EVB ROL RWD: Local
EVB RWD: 20
EVB ROL RKA: Local
EVB RKA: 20

Next Packet Transmission: 18 (seconds)

The above ETS-related information indicates that CBS is not supported, 8 Traffic Classes are supported, there is a 1-to-1 mapping between the priority and the Traffic Class, the bandwidth allocation among the Traffic Classes are 70,30, 000000, and the transmission algorithm used for all the Traffic Classes is ETS.

EXAMPLE 9 Show Remote Information about Adjacent Devices for an LLDP Agent

The following commands show, respectively, brief and detailed remote information about adjacent devices for a given LLDP agent.

Brief information:

```
# lldpadm show-agent -r net0
AGENT    SYSTYPE   CHASSISID  PORTID
net0     hostb    0083b390  00:14:4f:01:59:ab
```

Detailed information:

```
# lldpadm show-agent -rv net0
Agent: net0
Chassis ID Subtype: Local(7)
  Chassis ID: 0083b390
Port ID Subtype: MacAddress(3)
  Port ID: 00:14:4f:01:59:ab
Port Description: net0
  Time to Live: 121 (seconds)
System Name: hostb.example.com
System Description: SunOS 5.11 dcb-clone-x-01-19-11 i86pc
Supported Capabilities: bridge, router, station
Enabled Capabilities: router
Management Address: 192.168.1.3
Maximum Frame Size: 3000
Port VLAN ID: --
VLAN Name/ID: vlan25/25
VNIC PortID/VLAN ID : 02:08:20:72:71:31
Aggregation Information: Capable, Not Aggregated
PFC Willing: --
```

Notes
The lldpd(1M) daemon that implements the LLDP protocol must be first enabled before using the lldpd(1M) command. The lldpd daemon is controlled through the service management facility (SMF) service instance:

svc:/network/lldp/default

Use svcadm(1M) to enable this service.
### lldpd(1M)

**Name**  
llpd – Link Layer Discovery Protocol daemon

**Synopsis**  
/usr/lib/llpd  
svc:/network/lldp:default

**Description**  
LLDPd is a system daemon that implements the Link Layer Discovery Protocol as specified in IEEE Std. 802.1AB. The daemon also manages LLDP agents on physical datalinks. Please see lldpadmin(1M) for more information on administering LLDP on LLDP agents.

The lldpd daemon is controlled through the service management facility (SMF) service instance:

svc:/network/lldp:default

This means that svcadm(1M) must be used to start, stop, restart, and refresh this daemon. This daemon is enabled by default. To enable LLDP on any of the physical datalinks, this daemon should be running.

The lldpd daemon is a project private interface and has no user-accessible options.

**Service Properties**  
The following properties control the behavior of LLDP protocol on each of the LLDP agents. These are private properties that are subject to change.

- **msgTxInterval**  
  Indicates the time interval between the transmission of two consecutive LLDPDUs during normal transmission periods. The default value is 30 seconds and the possible values for this property is 1 through 3600.

- **msgFastTx**  
  Indicates the time interval between the transmission of two consecutive LLDPDUs during fast transmission periods. The default value is 1 second and the possible values for this property is 1 through 3600.

  **Note** – Fast transmission of LLDPDUs occur when a new neighbor is detected or some local configuration has changed. During this period LLDPDUs are transmitted at shorter time intervals than during the normal operation. This helps in achieving quick convergence of information.

- **msgTxHold**  
  The value of the TTL in the LLDPDU transmitted by the LLDP agent is determined by multiplying msgTxHold by msgTxInterval. So, if this value is set to 2, then the adjacent stations would wait for twice the msgTxInterval before aging the entries from this station. The default value is 4 and the possible values for this property is 1 through 100.

- **reinitDelay**  
  Indicates the delay before reinitialization of LLDP state machines. The default value is 2 seconds and the possible values for this property is 1 through 100.
txCreditMax
The maximum number of consecutive LLDPDUs that can be transmitted at any time. The
default value is 5 and the possible values for this property is 1 through 10.

txFastInit
Indicates the number of LLDPDUs that are transmitted during a fast transmission period.
The default value is 4 and the possible values for this property is 1 through 8.

snmp
This boolean property turns SNMP support on or off.

Whenever any of the above properties are modified, svcadm(1M) must be used to refresh the
daemon. On refresh, the daemon rereads these service properties and applies the new values.
Note that none of the LLDP agents are restarted on refresh. The only action is that the
configuration is reread.

The following property controls whether LLDP agents should be automatically enabled on all
physical ports on system.

auto-enable-agents

yes
If LLDP is not enabled on any port on the system, enable LLDP on all ports into both
mode. If LLDP is explicitly enabled in rxonly mode, or in txonly mode, or in both
mode on a port, do not automatically enable LLDP on such port. This option is
particularly useful when one wants to deploy LLDP in a large datacenter environment.

force
Regardless of whether LLDP agent is enabled on ports in rxonly mode or txonly mode
or disabled, enable LLDP agents on all ports into the both mode.

no
Do not automatically enable LLDP agents on any port. This option does not mean that it
will disable LLDP agents on all ports. Rather with this value, LLDP is required to be
explicitly enabled on the desired ports. Please see lldpadm(1M) on how to enable LLDP
agent explicitly.

The auto-enable-agents property is set to yes by default, which makes LLDP
automatically enabled in both mode on all physical ports on the system. Whenever this
property gets modified, svcadm(1M) must be used to restart the daemon. Only refresh of
the daemon will not cause the restart of LLDP agents.

Examples

EXAMPLE 1 Enabling the Daemon
The following command enables the lldpd daemon.

```
# svcadm enable network/lldp
# svcsc network/lldp
STATE STIME FMRI
online Jan_26 svc:/network/lldp:default
```
EXAMPLE 2  Disabling the Daemon
The following command disables the lldpd daemon.

# svcadm disable network/lldp
# svcx network/lldp
STATE STIME FMRI
disabled 5:11:35 svc:/network/lldp:default

EXAMPLE 3  Listing All Service Properties
The following command lists all service properties.

# svcprop -p lldp network/lldp:default
lldp/msgFastTx count 1
lldp/msgTxHold count 4
lldp/reinitDelay count 2
lldp/snmp boolean false
lldp/stability astring Evolving
lldp/txCreditMax count 5
lldp/txFastInit count 4
lldp/msgTxInterval count 30

EXAMPLE 4  Modifying the Service Property, Refreshing the Daemon
The following command sequence changes the LLDPDU transmission interval to every 15 seconds.

# svcCfg -s lldp:default setprop lldp/msgTxInterval = 15
# svcadm refresh lldp:default
# svcprop -p lldp/msgTxInterval lldp:default
15

EXAMPLE 5  Modifying auto-enable-agents, Restarting Daemon
The following command sequence modifies the auto-enable-agents property and restarts the LLDP daemon.

# svcCfg -s lldp:default setprop lldp/auto-enable-agents = no
# svcadm restart lldp:default

IEEE Std 802.1AB-2009, *IEEE Standard for Local and Metropolitan Area Networks: Station and Media Access Control Connectivity Discovery*
**Name**  lms – allow applications to access the Intel Active Management Technology

**Synopsis**  lms

**Description**  The Local Manageability Service, lms, allows applications to access the Intel Active Management Technology (Intel AMT) ME (Management Engine) using the local HECI interface. LMS is dependent on the HECI driver.

To use lms, ensure that the Intel AMT Manageability Interface driver is installed and connected to the ME.

lms is intended to be run as a daemon. Messages from the service are sent to the syslog. LMS messages are marked with a source of "LMS".

For an example of how to enable the LMS service using SMF, see EXAMPLES.

**Examples**  EXAMPLE 1  Enabling the LMS service using SMF

The following example enables the LMS service using SMF:

```
svcadm enable network/lms
```

The `locator` command sets or queries the state of the system locator if such a device exists.

Without options, the `locator` command reports the current state of the system.

The privileges required to use this command are hardware dependent. Typically, only the super user can get or set a locator.

The following options are supported:
- `-f` Turns the locator off.
- `-n` Turns the locator on.

**Examples**

**EXAMPLE 1** Using the `locator` Command on a Platform Which Has a System Locator LED

When issued on a platform which has a system locator LED, the following command turns the locator on:

```
# locator -n
```

```
# locator
The 'system' locator is on
```

**EXAMPLE 2** Using the `locator` Command on a Platform Which Does Not Have a System Locator LED

When issued on a platform which does not have a system locator LED, the following command attempts to turn the locator on. The command returns an error message.

```
# locator -n
'system' locator not found
```

**Exit Status**

The following exit values are returned:

0  Successful completion.
1  Invalid command line input.
2  The requested operation failed.

**See Also**

`attributes(5)`
The `lockd` utility is part of the NFS lock manager, which supports record locking operations on NFS files in NFSv2 and NFSv3. See `fcntl(2)` and `lockf(3C)`. The lock manager provides the following two functions:

- It forwards `fcntl(2)` locking requests for NFS mounted file systems to the lock manager on the NFS server.
- It generates local file locking operations in response to requests forwarded from lock managers running on NFS client machines.

State information kept by the lock manager about these locking requests can be lost if the `lockd` is killed or the operating system is rebooted. Some of this information can be recovered as follows. When the server lock manager restarts, it waits for a grace period for all client-site lock managers to submit reclaim requests. Client-site lock managers, on the other hand, are notified by the status monitor daemon, `statd(1M)`, of the restart and promptly resubmit previously granted lock requests. If the lock daemon fails to secure a previously granted lock at the server site, then it sends SIGLOST to a process.

Administrators can make changes to the startup parameters for `lockd` by logging in as root and using the `sharectl(1M)` command.

The `lockd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/nfs/nlockmgr
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

If it is disabled, it will be enabled by `mount_nfs(1M), share_nfs(1M),` and `automountd(1M)` unless its application/auto_enable property is set to false.

The `sharectl(1M)` command is used to manipulate the startup SMF parameters for `lockd`. Currently supported parameters are as follows:

- `lockd.listen_backlog=num`
  Set connection queue length for `lockd` over a connection-oriented transport. The default and minimum value is 32. Equivalent to `-l` option.

- `lockd.servers=num`
  Maximum number of concurrent `lockd` requests. The default is 1024. Equivalent to the `nthreads` operand.
lockd_retransmit_timeout=num
   Retransmit timeout, in seconds, before lockd retries. The default is 5. Equivalent to -t option.

grace_period=num
   Grace period, in seconds, that all clients (both NLM and NFSv4) have to reclaim locks after a server reboot. This parameter also controls the NFSv4 lease interval. The default is 90. Equivalent to -g option.

See EXAMPLES, below.

Options
The following options are supported:

- g graceperiod
   Deprecated in favor of grace_period. Specify the number of seconds that all clients (both NLM and NFSv4) have to reclaim locks after the server reboots. It also controls the NFSv4 lease interval. This option is equivalent to the grace_period property described above.

- l listen_min_backlog
   Specify the listener backlog (listen_min_backlog). listen_min_backlog is the number of connect requests that are queued and waiting to be processed before new connect requests start to get dropped. Equivalent of the lockd_listen_backlog property described above.

- t timeout
   Specify the number of seconds to wait before retransmitting a lock request to the remote server. The default value is 5 seconds. Equivalent of the lockd_retransmit_timeout property described above.

Operands
nthreads
   Specify the maximum number of concurrent threads that the server can handle. This concurrency is achieved by up to nthreads threads created as needed in the kernel. nthreads should be based on the load expected on this server. If nthreads is not specified, the maximum number of concurrent threads will default to 1024. Equivalent of the lockd_servers property described above.

Examples
EXAMPLE 1  Setting a lockd Property
The following command sets lockd_listen_backlog to a new value:

# sharectl set -p lockd_listen_backlog=40 nfs

The lockd_listen_backlog and other lockd properties are described under NOTES, below.

EXAMPLE 2  Getting a lockd Property Value
The following command retrieves the value of the lockd_listen_backlog property.

% sharectl get -p lockd_listen_backlog nfs
lockd_listen_backlog=40
### Attributes

### Notes

The lockd daemon does not need to be running for NFSv4.

The lockd daemon might not exist in a future release of Solaris.
lockfs – change or report filesystem locks

Synopsis
/usr/sbin/lockfs [-adefhnuw] [-c "string"] [file-system] ...

Description
lockfs is used to change and report the status of file system locks. lockfs reports the lock status and unlocks the file systems that were improperly left locked.

Using lockfs to lock a file system is discouraged because this requires extensive knowledge of SunOS internals to be used effectively and correctly.

When invoked with no arguments, lockfs lists the UFS file systems that are locked. If file-system is not specified, and -a is specified, lockfs is run on all mounted, UFS type file systems.

Options
The options are mutually exclusive: w, d, e, h, u, f, n. If you do specify more than one of these options on a lockfs command line, the utility does not protest and invokes only the last option specified. In particular, you cannot specify a flush (-f) and a lock (for example, -w) on the same command line. However, all locking operations implicitly perform a flush, so the -f is superfluous when specifying a lock.

You must be super-user to use any of the following options, with the exception of -a, -f and -v.

The following options are supported.

- a
  Apply command to all mounted, UFS type file systems. file-system is ignored when -a is specified.

- c "string"
  Accept a string that is passed as the comment field. The -c only takes affect when the lock is being set using the -d, -h, -n, -u, or -w options.

- d
  Delete-lock (dlock) the specified file-system. dlock suspends access that could remove directory entries.

- e
  Error-lock (elock) the specified file-system. elock blocks all local access to the locked file system and returns EWOULDBLOCK on all remote access. File systems are elocked by UFS on detection of internal inconsistency. They may only be unlocked after successful repair by fsck, which is usually done automatically (see mount_ufs(1M)). elocked file systems can be unmounted.

- f
  Force a synchronous flush of all data that is dirty at the time fsflush is run to its backing store for the named file system (or for all file systems.)
It is a more reliable method than using `sync(1M)` because it does not return until all possible data has been pushed. In the case of UFS filesystems with logging enabled, the log is also rolled before returning. Additional data can be modified by the time `fsflush` exits, so using one of the locking options is more likely to be of general use.

- **h**
  Hard-lock (`hlock`) the specified file-system. hlock returns an error on every access to the locked file system, and cannot be unlocked. hlocked file systems can be unmounted.

- **n**
  Name-lock (`nlock`) the specified file-system. nlock suspends accesses that could change or remove existing directories entries.

- **u**
  Unlock (`ulock`) the specified file-system. ulock awakens suspended accesses.

- **v**
  Enable verbose output.

- **w**
  Write-lock (`wlock`) the specified file-system. wlock suspends writes that would modify the file system. Access times are not kept while a file system is write-locked.

**Operands**

The following operands are supported.

*file-system*

A list of path names separated by whitespace. Note that `file-system` can be a directory rather than the specific name of a file system, such as `/` or `/usr`. For example, if you specify `/export/home` as an argument to a `lockfs` command and `/export/home` is mounted on the root (/) file system, the `lockfs` command will take effect on the root file system.

**Usage**

See `largefile(5)` for the description of the behavior of `lockfs` when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

**Examples**

**EXAMPLE 1** Using `lockfs -a`

In the following examples, `filesystem` is the pathname of the mounted-on directory (mount point). Locktype is one of “write,” “name,” “delete,” “hard,” or “unlock”. When enclosed in parenthesis, the lock is being set. Comment is a string set by the process that last issued a lock command.

The following example shows the `lockfs` output when only the `-a` option is specified.

example#  /usr/sbin/lockfs -a

<table>
<thead>
<tr>
<th>Filesystem</th>
<th>Locktype</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>/</td>
<td>unlock</td>
<td></td>
</tr>
</tbody>
</table>
### EXAMPLE 1  Using `lockfs -a`  (Continued)

```
/var unlock
```
```
example#  
```

### EXAMPLE 2  Using `lockfs -w`

The following example shows the `lockfs` output when the `-w` option is used to write lock the `/var` file system and the comment string is set using the `-c` option. The `-a` option is then specified on a separate command line.

```
example#  /usr/sbin/lockfs -w -c "lockfs: write lock example" /var
example#  /usr/sbin/lockfs -a
```

<table>
<thead>
<tr>
<th>Filesystem</th>
<th>Locktype</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>/</td>
<td>unlock</td>
<td></td>
</tr>
<tr>
<td>/var</td>
<td>write</td>
<td>lockfs: write lock example</td>
</tr>
</tbody>
</table>

```
example#  
```

### EXAMPLE 3  Using `lockfs -u`

The following example shows the `lockfs` output when the `-u` option is used to unlock the `/var` file system and the comment string is set using the `-c` option.

```
example#  /usr/sbin/lockfs -uc "lockfs: unlock example" /var
example#  /usr/sbin/lockfs /var
```

<table>
<thead>
<tr>
<th>Filesystem</th>
<th>Locktype</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>/var</td>
<td>unlock</td>
<td>lockfs: unlock example</td>
</tr>
</tbody>
</table>

```
example#  
```

### Attributes

# lockstat(1M)

## Name
lockstat – report kernel lock and profiling statistics

## Synopsis
```
lockstat [-ACEHI] [-e event_list] [-i rate]
       [-b |-t | -h | -s depth] [-n nrecords]
       [-l lock [, size]] [-d duration]
       [-f function [, size]] [-T] [-cexamples
       [-o filename] [-x opt [=val]] command [args]
```

## Description
The `lockstat` utility gathers and displays kernel locking and profiling statistics. `lockstat` allows you to specify which events to watch (for example, spin on adaptive mutex, block on read access to rwlock due to waiting writers, and so forth) how much data to gather for each event, and how to display the data. By default, `lockstat` monitors all lock contention events, gathers frequency and timing data about those events, and displays the data in decreasing frequency order, so that the most common events appear first.

`lockstat` gathers data until the specified command completes. For example, to gather statistics for a fixed-time interval, use `sleep(1)` as the command, as follows:

```
example# lockstat sleep 5
```

When the `-I` option is specified, `lockstat` establishes a per-processor high-level periodic interrupt source to gather profiling data. The interrupt handler simply generates a `lockstat` event whose caller is the interrupted PC (program counter). The profiling event is just like any other `lockstat` event, so all of the normal `lockstat` options are applicable.

`lockstat` relies on DTrace to modify the running kernel’s text to intercept events of interest. This imposes a small but measurable overhead on all system activity, so access to `lockstat` is restricted to super-user by default. The system administrator can permit other users to use `lockstat` by granting them additional DTrace privileges. Refer to the Solaris Dynamic Tracing Guide for more information about DTrace security features.

## Options
The following options are supported:

### Event Selection
If no event selection options are specified, the default is `-C`.

- `-A`
  Watch all lock events. `-A` is equivalent to `-CH`.

- `-C`
  Watch contention events.

- `-E`
  Watch error events.

- `-e event_list`
  Only watch the specified events. `event list` is a comma-separated list of events or ranges of events such as 1,4-7,35. Run `lockstat` with no arguments to get a brief description of all events.
-H
   Watch hold events.

- I
   Watch profiling interrupt events.

- i rate
   Interrupt rate (per second) for - I. The default is 97 Hz, so that profiling doesn't run in lockstep with the clock interrupt (which runs at 100 Hz).

-x arg[=val]
   Enable or modify a DTrace runtime option or D compiler option. The list of options is found in dtrace(1M). Boolean options are enabled by specifying their name. Options with values are set by separating the option name and value with an equals sign (=).

-b
   Basic statistics: lock, caller, number of events.

-h
   Histogram: Timing plus time-distribution histograms.

-s depth
   Stack trace: Histogram plus stack traces up to depth frames deep.

-t
   Timing: Basic plus timing for all events [default].

-d duration
   Only watch events longer than duration.

-f func[,size]
   Only watch events generated by func, which can be specified as a symbolic name or hex address. size defaults to the ELF symbol size if available, or 1 if not.

-l lock[,size]
   Only watch lock, which can be specified as a symbolic name or hex address. size defaults to the ELF symbol size or 1 if the symbol size is not available.

-n nrecords
   Maximum number of data records.

-T
   Trace (rather than sample) events [off by default].

-c
   Coalesce lock data for lock arrays (for example, pse_mutex[]).

-D count
   Only display the top count events of each type.
-g  
Show total events generated by function. For example, if foo() calls bar() in a loop, the work done by bar() counts as work generated by foo() (along with any work done by foo() itself). The -g option works by counting the total number of stack frames in which each function appears. This implies two things: (1) the data reported by -g can be misleading if the stack traces are not deep enough, and (2) functions that are called recursively might show greater than 100% activity. In light of issue (1), the default data gathering mode when using -g is -s 50.

-k  
Coalesce PCs within functions.

-o filename  
Direct output to filename.

-P  
Sort data by (count * time) product.

-p  
Parsable output format.

-R  
Display rates (events per second) rather than counts.

-W  
Whichever: distinguish events only by caller, not by lock.

-w  
Wherever: distinguish events only by lock, not by caller.

Display Formats  
The following headers appear over various columns of data.

Count or ops/s  
Number of times this event occurred, or the rate (times per second) if -R was specified.

indv  
Percentage of all events represented by this individual event.

genr  
Percentage of all events generated by this function.

cuml  
Cumulative percentage; a running total of the individuals.

rcnt  
Average reference count. This will always be 1 for exclusive locks (mutexes, spin locks, rwlocks held as writer) but can be greater than 1 for shared locks (rwlocks held as reader).

nsec  
Average duration of the events in nanoseconds, as appropriate for the event. For the profiling event, duration means interrupt latency.
Lock
Address of the lock; displayed symbolically if possible.

CPU+PIL
CPU plus processor interrupt level (PIL). For example, if CPU 4 is interrupted while at PIL 6, this will be reported as cpu[4]+6.

Caller
Address of the caller; displayed symbolically if possible.

EXAMPLE 5  Generated-load Profiling

In the example above, 5% of the samples were in poll(). This tells us how much time was spent inside poll() itself, but tells us nothing about how much work was generated by poll(); that is, how much time we spent in functions called by poll(). To determine that, we use the -g option. The example below shows that although polltest spends only 5% of its time in poll() itself, poll()-induced work accounts for 34% of the load.

Note that the functions that generate the profiling interrupt (lockstat_intr(), cyclic_fire(), and so forth) appear in every stack trace, and therefore are considered to have generated 100% of the load. This illustrates an important point: the generated load percentages do not add up to 100% because they are not independent. If 72% of all stack traces contain both foo() and bar(), then both foo() and bar() are 72% load generators.

### EXAMPLE 6  Gathering Lock Contention and Profiling Data for a Specific Module

In this example we use the `-f` option not to specify a single function, but rather to specify the entire text space of the `sbus` module. We gather both lock contention and profiling statistics so that contention can be correlated with overall load on the module.

```bash
eexample# modinfo | grep sbus
24 102a8b6f b8b4 59 1 sbus (SBus (sysio) nexus driver)
```

```bash
eexample# lockstat -kICE -f 0x102a8b6f,0xb8b4 sleep 10
Adaptive mutex spin: 39 events in 10.042 seconds (4 events/sec)
```

Solaris Dynamic Tracing Guide

Notes  
The profiling support provided by lockstat -I replaces the old (and undocumented) /usr/bin/kgmon and /dev/profile.

Tail-call elimination can affect call sites. For example, if foo()+0x50 calls bar() and the last thing bar() does is call mutex_exit(), the compiler can arrange for bar() to branch to mutex_exit() with a return address of foo()+0x58. Thus, the mutex_exit() in bar() will appear as though it occurred at foo()+0x58.

The PC in the stack frame in which an interrupt occurs can be bogus because, between function calls, the compiler is free to use the return address register for local storage.

When using the -I and -s options together, the interrupted PC will usually not appear anywhere in the stack since the interrupt handler is entered asynchronously, not by a function call from that PC.

The lockstat technology is provided on an as-is basis. The format and content of lockstat output reflect the current Solaris kernel implementation and are therefore subject to change in future releases.
lofiadm(1M)

**Name**  
lofiadm – administer files available as block devices through lofi

**Synopsis**  
/usr/sbin/lofiadm -a | -r file [device]
/usr/sbin/lofiadm -c crypto_algorithm -a file | -r [device]
/usr/sbin/lofiadm -c crypto_algorithm -k raw_key_file
   -a | -r file [device]
/usr/sbin/lofiadm -c crypto_algorithm -T token_key -a | -r file [device]
/usr/sbin/lofiadm -c crypto_algorithm -T token_key
   -k wrapped_key_file -a | -r file [device]
/usr/sbin/lofiadm -c crypto_algorithm -e -a file [device]
/usr/sbin/lofiadm -C algorithm [-s segment_size] file
/usr/sbin/lofiadm -d file | device
/usr/sbin/lofiadm -U file
/usr/sbin/lofiadm [ file | device]
/usr/sbin/lofiadm -r device

**Description**  
lofiadm administrs lofi, the loopback file driver. lofi allows a file to be associated with a block device. That file can then be accessed through the block device. This is useful when the file contains an image of some filesystem (such as a CD-ROM image), because the block device can then be used with the normal system utilities for mounting, checking or repairing file systems. See fsck(1M) and mount(1M).

Use lofiadm to add a file as a loopback device, remove such an association, or display information about the current associations.

Two types of loopback devices can be created: a normal read-write loopback device and a removable loopback device. They differ in the following ways.

Firstly, a file cannot be dissociated from a normal loopback device during its lifetime. By contrast, a file can be dissociated from a removable loopback device, which leaves it as an empty loopback device. Following disassociation, a different file can be associated with it. Note that eject(1) should be used to dissociate a file from a removable device.

Secondly, there is one-to-one mapping between a normal loopback device and its associated file. By contrast, a single file can be associated with multiple removable loopback devices at the same time.

Thirdly, a normal loopback device is writable. A removable loopback device is read-only.

The number of potential lofi devices is limited by the zone.max.lofi rctl, which can be set by means of zonectf(1M) in the global zone. See resource_controllers(5) for a description of zone.max.lofi.
Encryption and compression options are mutually exclusive on the command line. Further, an encrypted file cannot be compressed later, nor can a compressed file be encrypted later.

In the global zone, lofiadm can be used on both the global zone devices and all devices owned by other non-global zones on the system.

**Options** The following options are supported:

- **-a** | **-r** file [device]
  Add file as a normal loopback device, when -a is specified or a removable loopback device, when -r is specified.
  
  If device is not specified, a non-existing device is picked.
  
  If device is specified, lofiadm attempts to assign it to file. If -a is specified, device must not exist or lofiadm will fail. If -r is specified, lofiadm will fail if device exists and is not an empty removable loopback device.

- **-C** {gzip | gzip-N | lzma}
  Compress the file with the specified compression algorithm.
  
  The gzip compression algorithm uses the same compression as the open-source gzip command. You can specify the gzip level by using the value gzip-N where N is 6 (fast) or 9 (best compression ratio). Currently, gzip, without a number, is equivalent to gzip-6 (which is also the default for the gzip command).
  
  *lzma* stands for the LZMA (Lempel-Ziv-Markov) compression algorithm.
  
  Note that you cannot write to a compressed file, nor can you mount a compressed file read/write.
  
  Note that removal by file will fail if multiple devices is currently associated with it. Use removal by device in this case.

- **-d** file | device
  Remove an association by file or device name, if the associated block device is not busy, and deallocates the block device.

- **-s** segment_size
  The segment size to use to divide the file being compressed. segment_size can be an integer multiple of 512.

- **-U** file
  Uncompress a compressed file.

The following options are used when the file is encrypted:

- **-c** crypto_algorithm
  Select the encryption algorithm. The algorithm must be specified when encryption is enabled because the algorithm is not stored in the disk image.
If none of \(-e\), \(-k\), or \(-T\) is specified, `lofiadm` prompts for a passphrase, with a minimum length of eight characters, to be entered. The passphrase is used to derive a symmetric encryption key using PKCS#5 PBKDF2.

\[-k\ \text{raw_key_file} | \text{wrapped_key_file}\]
Path to raw or wrapped symmetric encryption key. If a PKCS#11 object is also given with the \(-T\) option, then the key is wrapped by that object. If \(-T\) is not specified, the key is used raw.

\[-T\ \text{token_key}\]
The key in a PKCS#11 token to use for the encryption or for unwrapping the key file.

If \(-k\) is also specified, \(-T\) identifies the unwrapping key, which must be an RSA private key.

\[-e\]
Generate an ephemeral symmetric encryption key. Note that you cannot use \(-e\) together with \(-r\).

\[-r\ [device]\]
Create an empty removable loopback device. A file can be associated with that device at a later time.

If \(device\) is not specified, a non-existing device is selected.

If \(device\) is specified, `lofiadm` attempts to select it. \(device\) must not exist or \`lofiadm\` will fail.

### Operands
The following operands are supported:

- `crypto_algorithm`
  One of: `aes-128-cbc`, `aes-192-cbc`, `aes-256-cbc`, `des3-cbc`, `blowfish-cbc`.

- `device`
  Display the file name associated with the block device \(device\).

Without arguments, print a list of the current associations. Filenames must be valid absolute pathnames.

When a file is added, it is opened for reading or writing by root. Any restrictions apply (such as restricted root access over NFS). The file is held open until the association is removed. It is not actually accessed until the block device is used, so it will never be written to if the block device is only opened read-only.

Note that the filename might appear as a question mark (?) if it is not possible to resolve the path in the current context (for example, if it is an NFS path in a non-global zone). Or, the filename might appear as a dash (-) if the device is an empty removable loopback device.

- `file`
  Display all block device(s) associated with \(file\).

- `raw_key_file`
  Path to a file of the appropriate length, in bits, to use as a raw symmetric encryption key.
token_key
PKCS#11 token object in the format:

\[ token_name:manufacturer_id:serial_number:key_label \]

All but the key label are optional and can be empty. For example, to specify a token object with only its key label MylofiKey, use:

\[-T \\::\::MylofiKey\]

wrapped_key_file
Path to file containing a symmetric encryption key wrapped by the RSA private key specified by -T.

Examples

**EXAMPLE 1** Mounting an Existing CD-ROM Image

You should ensure that Solaris understands the image before creating the CD. lofi allows you to mount the image and see if it works.

This example mounts an existing CD-ROM image (sparc.iso), of the Red Hat 6.0 CD which was downloaded from the Internet. It was created with the mkisofs utility from the Internet.

Use lofiadm to attach a block device to it:

\[# lofiadm -a /home/mike_s/RH6.0/sparc.iso \\
/dev/lofi/1\]

lofiadm picks the device and prints the device name to the standard output. You can run lofiadm again by issuing the following command:

\[# lofiadm\]

Block Device File Options
/dev/lofi/1 /home/mike_s/RH6.0/sparc.iso -

Or, you can give it one name and ask for the other, by issuing the following command:

\[# lofiadm /dev/lofi/1 \\
/home/mike_s/RH6.0/sparc.iso\]

Use the mount command to mount the image:

\[# mount -F hsfs -o ro /dev/lofi/1 /mnt\]

Check to ensure that Solaris understands the image:

\[# df -k /mnt\]

Filesystem kbytes used avail capacity Mounted on
/dev/lofi/1 512418 512418 0 100% /mnt

\[# ls /mnt\]

./ RedHat/ doc/ ls-lR rr Moved/
../ TRANS.TBL dosutils/ ls-lR.gz sbin@
.buildlog bin@ etc@ misc/ tmp/
Mounting an Existing CD-ROM Image  

(Sold)

COPYING
boot/ images/ mnt/ usr@
README
boot.cat* kernels/ modules/
RPM-PGP-KEY dev@ lib@ proc/

Solaris can mount the CD-ROM image, and understand the filenames. The image was created properly, and you can now create the CD-ROM with confidence.

As a final step, unmount and detach the images:

# umount /mnt
# lofiadm -d /dev/lofi/1
# lofiadm

Block Device File Options

EXAMPLE 2  Making a UFS Filesystem on a File

Making a UFS filesystem on a file can be useful, particularly if a test suite requires a scratch filesystem. It can be painful (or annoying) to have to repartition a disk just for the test suite, but you do not have to. You can newfs a file with lofi

Create the file:

# mkfile 35m /export/home/test

Attach it to a block device. You also get the character device that newfs requires, so newfs that:

# lofiadm -a /export/home/test
/dev/lofi/1
# newfs /dev/lofi/1
newfs: construct a new file system /dev/lofi/1: (y/n)? y
/dev/lofi/1: 71638 sectors in 119 cylinders of 1 tracks, 602 sectors
35.0MB in 8 cyl groups (16 c/g, 4.70MB/g, 2240 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
  32, 9664, 19296, 28928, 38560, 48192, 57824, 67456,

Note that ufs might not be able to use the entire file. Mount and use the filesystem:

# mount /dev/lofi/1 /mnt
# df -k /mnt

Filesystem kbytes used avail capacity Mounted on
/dev/lofi/1 33455 9 30101 1% /mnt
# ls /mnt
./ ../ lost+found/
# umount /mnt
# lofiadm -d /dev/lofi/1

EXAMPLE 3  Creating a PC (FAT) File System on a Unix File

The following series of commands creates a FAT file system on a Unix file. The file is associated with a block device created by lofiadm.
EXAMPLE 3  Creating a PC (FAT) File System on a Unix File  (Continued)

# mkfile 10M /export/test/testfs
# lofiadm -a /export/test/testfs
/dev/lofi/1

Note use of rlofi, not lofi, in following command.
# mkfs -F pcfs -o nodisk,size=20480 /dev/rlofi/1
Construct a new FAT file system on /dev/rlofi/1: (y/n)? y
# mount -F pcfs /dev/lofi/1 /mnt
# cd /mnt
# df -k .

Filesystem kbytes used avail capacity Mounted on
/dev/lofi/1 10142 0 10142 0% /mnt

EXAMPLE 4  Compressing an Existing CD-ROM Image

The following example illustrates compressing an existing CD-ROM image (solaris.iso), verifying that the image is compressed, and then uncompressing it.

# lofiadm -C gzip /export/home/solaris.iso

Use lofiadm to attach a block device to it:

# lofiadm -a /export/home/solaris.iso
/dev/lofi/1

Check if the mapped image is compressed:

# lofiadm

Block Device File Options
/dev/lofi/1 /export/home/solaris.iso Compressed(gzip)
/dev/lofi/2 /export/home/regular.iso -

Unmap the compressed image and uncompress it:

# lofiadm -d /dev/lofi/1
# lofiadm -U /export/home/solaris.iso

EXAMPLE 5  Creating an Encrypted UFS File System on a File

This example is similar to the example of making a UFS filesystem on a file, above.

Create the file:

# mkfile 35m /export/home/test

Attach the file to a block device and specify that the file image is encrypted. As a result of this command, you obtain the character device, which is subsequently used by newfs:

# lofiadm -c aes-256-cbc -a /export/home/secrets
Enter passphrase: My-M0th3r;l0v3_m3+4lw4ys! (not echoed)
Re-enter passphrase: My-M0th3r;l0v3_m3+4lw4ys! (not echoed)
Creating an Encrypted UFS FileSystem on a File  (Continued)

/dev/lofi/1

# newfs /dev/rlofi/1
newfs: construct a new file system /dev/rlofi/1: (y/n)? y
/dev/rlofi/1: 71638 sectors in 119 cylinders of 1 tracks, 602 sectors
35.0MB in 8 cyl groups (16 c/g, 4.70MB/g, 2240 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
32, 9664, 19296, 28928, 38560, 48192, 57824, 67456,

The mapped filesystem shows that encryption is enabled:

# lofiadm
Block Device File Options
/dev/lofi/1 /export/home/secrets Encrypted

Mount and use the filesystem:

# mount /dev/lofi/1 /mnt
# cp moms_secret_*_recipe /mnt
# ls /mnt
./ moms_secret_cookie_recipe moms_secret_soup_recipe
.. moms_secret_fudge_recipe moms_secret_stuffing_recipe
lost+found/ moms_secret_meatloaf_recipe moms_secret_waffle_recipe
# umount /mnt
# lofiadm -d /dev/lofi/1

Subsequent attempts to map the filesystem with the wrong key or the wrong encryption
algorithm will fail:

# lofiadm -c blowfish-cbc -a /export/home/secrets
Enter passphrase: mommy               (not echoed)
Re-enter passphrase: mommy             (not echoed)
lofiadm: could not map file /root/lofi: Invalid argument
# lofiadm
Block Device File Options
#

 Attempts to map the filesystem without encryption will succeed, however attempts to mount
and use the filesystem will fail:

# lofiadm -a /export/home/secrets
/dev/lofi/1
# lofiadm
Block Device File Options
/dev/lofi/1 /export/home/secrets -
# mount /dev/lofi/1 /mnt
mount: /dev/lofi/1 is not this fstype
#
EXAMPLE 6 Manipulating a Removable Loopback Device

The following example illustrates how to create an empty removable loopback device, associate a file with it, and then dissociate the file from the device.

Use lofiadm to create an empty removable loopback device:

```
# lofiadm -r
/dev/lofi/1
```

Verify that the device has been created:

```
# lofiadm
Block Device File Options
/dev/lofi/1 - Removable,Readonly
```

Use lofiadm to associate a file with the device:

```
# lofiadm -r /export/home/solaris.iso /dev/lofi/1
/dev/lofi/1
```

Verify that the association has succeeded:

```
# lofiadm
Block Device File Options
/dev/lofi/1 /export/home/solaris.iso Removable,Readonly
```

Use eject to dissociate the file from the device:

```
# eject /dev/lofi/1
```

Verify that the dissociation succeeded:

```
# lofiadm
Block Device File Options
/dev/lofi/1 - Removable,Readonly
```

Environment Variables See environ(5) for descriptions of the following environment variables that affect the execution of lofiadm: LC_CTYPE, LC_MESSAGES and NLSPATH.

Exit Status The following exit values are returned:

0
  Successful completion.

>0
  An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
Availability system/core-os

See Also eject(1), fsck(1M), mount(1M), mount_ufs(1M), newfs(1M), zonecfg(1M), attributes(5), resource_controls(5), lofi(7D), lofs(7FS)

Notes Just as you would not directly access a disk device that has mounted file systems, you should not access a file associated with a block device except through the lofi file driver. It might also be appropriate to ensure that the file has appropriate permissions to prevent such access.

The abilities of lofiadm, and who can use them, are controlled by the permissions of /dev/lofictl. Read-access allows query operations, such as listing all the associations. Write-access is required to do any state-changing operations, like adding an association. As shipped, /dev/lofictl is owned by root, in group sys, and mode 0644, so all users can do query operations but only root can change anything. The administrator can give users write-access, allowing them to add or delete associations, but that is very likely a security hole and should probably only be given to a trusted group.

When mounting a filesystem image, take care to use appropriate mount options. In particular, the nosuid mount option might be appropriate for UFS images whose origin is unknown. Also, some options might not be useful or appropriate, like logging or forcedirectio for UFS. For compatibility purposes, a raw device is also exported along with the block device. For example, newfs(1M) requires one.

The output of lofiadm (without arguments) might change in future releases.
**Name**
logadm – manage endlessly growing log files

**Synopsis**

```
logadm [-options] logname...
```

**Description**

logadm is a general log rotation tool that is suitable for running from `cron(1M)`.

Without arguments, `logadm` reads the `/etc/logadm.conf` file, and for every entry found in that file checks the corresponding log file to see if it should be rotated. Typically this check is done each morning by an entry in the root's crontab.

If the `logname` argument is specified, `logadm` renames the corresponding log file by adding a suffix so that the most recent log file ends with `.0` (that is, `logfile.0`), the next most recent ends with `.1` (that is, `logfile.1`), and so forth. By default, ten versions of old log files are kept (that is, `logfile.0` through `logfile.9`). At the point when what would be the eleventh file is logged, `logadm` automatically deletes the oldest version to keep the count of files at ten.

`logadm` takes a number of options. You can specify these options on the command line or in the `/etc/logadm.conf` file. The `logadm` command searches `/etc/logadm.conf` for lines of the form `logname options`

`logname`
Identifies an entry in `/etc/logadm.conf`. This can be a name or the pathname of the log file. If you specify a log file, rather than a name, for this field, it must be a fully qualified pathname.

`options`
Identifies command line options exactly as they would be entered on the command line. This allows commonly used log rotation policies to be stored in the `/etc/logadm.conf` file. See EXAMPLES.

If `options` are specified both in `/etc/logadm.conf` and on the command line, those in the `/etc/logadm.conf` file are applied first. Therefore, the command line options override those in `/etc/logadm.conf`.

Log file names specified in `/etc/logadm.conf` may contain filename substitution characters such as `*` and `?`, that are supported by `csh(1)`.

Two options control when a log file is rotated. They are: `-s size -p period`.

When using more than one of these options at a time, there is an implied `and` between them. This means that all conditions must be met before the log is rotated.

If neither of these two options are specified, the default conditions for rotating a log file are: `-s 1b -p 1w`, which means the log file is only rotated if the size is non-zero and if at least 1 week has passed since the last time it was rotated.
By specifying \texttt{-p never} as a rotation condition, any other rotation conditions are ignored and \texttt{logadm} moves on to the expiration of old log files. By specifying \texttt{-p now} as a rotation condition, a log rotation is forced.

Unless specified by the \texttt{-o}, \texttt{-g}, or \texttt{-m} options, \texttt{logadm} replaces the log file (after renaming it) by creating an empty file whose owner, group ID, and permissions match the original file.

Three options control when old log files are expired: \texttt{-A age} \texttt{-C count} \texttt{-S size}. These options expire the oldest log files until a particular condition or conditions are met. For example, the combination \texttt{-C 5} and the \texttt{-S 10m} options expires old log files until there are no more than 5 of the files \textit{and} their combined disk usage is no more than 10 megabytes. If none of these options are specified, the default expiration is \texttt{-C 10} which keeps ten old log files. If no files are to be expired, use \texttt{-C 0} to prevent expiration by default.

\texttt{logadm} stores timestamps in the file \texttt{/var/logadm/timestamps}. For users of previous versions of \texttt{logadm}, the utility automatically moves timestamps from \texttt{/etc/logadm.conf}, their previous repository, to \texttt{/var/logadm/timestamps}.

**Options** The following options are supported:

\textbf{-a post\_command}
Execute the \texttt{post\_command} after renaming the log file. \texttt{post\_command} is passed to \texttt{sh -c}.

Specify \texttt{post\_command} as a valid shell command. Use quotes to protect spaces or shell metacharacters in \texttt{post\_command}.

This option can be used to restart a daemon that is writing to the file. When rotating multiple logs with one \texttt{logadm} command, \texttt{post\_command} is executed only once after all the logs are rotated, not once per rotated log.

\textbf{-A age}
Delete any versions that have not been modified for the amount of time specified by \texttt{age}.

Specify \texttt{age} as a number followed by an \texttt{h} (hours), \texttt{d} (days), \texttt{w} (weeks), \texttt{m} (months), or \texttt{y} (years).

\textbf{-b pre\_command}
Execute \texttt{pre\_command} before renaming the log file. \texttt{pre\_command} is passed to \texttt{sh -c}.

Specify \texttt{pre\_command} as a valid shell command. Use quotes to protect spaces or shell metacharacters in \texttt{pre\_command}.

This option can be used to stop a daemon that is writing to the file. When rotating multiple logs with one \texttt{logadm} command, \texttt{pre\_command} is executed only once before all the logs are rotated, not once per rotated log.

\textbf{-c}
Rotate the log file by copying it and truncating the original logfile to zero length, rather than renaming the file.
-C count
    Delete the oldest versions until there are not more than count files left.

    If no expire options (-A, -C, or -S) are specified, -C 10 is the default. To prevent the default expire rule from being added automatically, specify -C 0.

-e mail_addr
    Send error messages by email to mail_addr.

    As logadm is typically run from cron(1M), error messages are captured by cron and mailed to the owner of the crontab.

    This option is useful if you want the mail regarding error messages to go to another address instead. If no errors are encountered, no mail message is generated.

-E cmd
    Execute cmd to expire the file, rather than deleting the old log file to expire it.

    cmd is passed to sh -c. The file is considered expired after cmd completes. If the old log file is not removed or renamed by the cmd, logadm considers it for expiration the next time that it runs on the specified log file. If present, the keyword $file is expanded in the specified cmd to the name of the file being expired.

    This option is useful for tasks such as mailing old log files to administrators, or copying old log files to long term storage.

-f conf_file
    Use conf_file instead of /etc/logadm.conf.

    This option allows non-root users to keep their own logadm configuration files.

-F timestamp_file
    Use timestamp_file instead of /var/logadm/timestamps to store logadm timestamps.

-g group
    Create a new empty file with the ID specified by group, instead of preserving the group ID of the log file.

    Specify group by name or by numeric group ID, as accepted by chgrp(1).

    This option requires the ability to change file group ownership using the chgrp(1) command.

-h
    Print a help message that describes logadm’s options.

-l
    Use local time rather than the Coordinated Universal Time (UTC) when naming rotated log files (see the discussion of percent sequences in the templates supplied with the -t option).
-m mode
Create a new empty file with the mode specified by mode, instead of preserving the mode of the log file.

Specify mode in any form that is accepted by the chmod(1) command.

-M cmd
Use cmd to rename the log file. If the keyword $file is specified, it is expanded to the name of the log file. Similarly, the keyword $nfile is expanded to the new name of the log file.
The $nfile keyword is only available with commands provided with the -M option. After the command completes, the log file is replaced by the rotate file. The default cmd is "/bin/mv $file$nfile".

-n
Print the actions that the logadm command will perform without actually performing them.

This option is useful for checking arguments before making any changes to the system.

It is important to remember, however, that since log rotating actions are only printed with this option, logadm might not find files that need expiring, but if run without the -n logadm might create a file that needs expiring by performing the log rotating actions. Therefore, if you see no files being expired with the -n option, files still might be expired without it.

-N
Prevent an error message if the specified log file does not exist. Normally, logadm produces an error message if the log file is not found. With -N, if the log file doesn’t exist logadm moves on to the expire rules (if any) and then to the next log file (if any), without creating the empty replacement log file.

-o owner
Create the new empty file with owner, instead of preserving the owner of the log file.

Specify owner in any form that is accepted by the chown(1) command.

-p period
Rotate a log file after the specified time period (period).

Specify period as a number followed by d for days, h for hours, w for weeks, m for months (30 days) or y for years. There are also two special values for period: now and never. “-p now” forces log rotation. “-p never” forces no log rotation.

-P timestamp
Used by logadm to record the last time the log was rotated in /var/logadm/timestamps.

This option uses timestamp to determine if the log rotation period has passed. The format of timestamp matches the format generated by ctime(3C), with quotes around it to protect embedded spaces. timestamp is always recorded in the Coordinated Universal Time (UTC) timezone.
-r
  Remove any entries corresponding to the specified logname from the /etc/logadm.conf.

-R cmd
  Run the cmd when an old log file is created by a log rotation. If the keyword $file is embedded in the specified command, it is expanded to the name of the old log file just created by log rotation.

  This option is useful for processing log file contents after rotating the log. cmd is executed by passing it to $sh -c. When rotating multiple logs with one logadm command, the command supplied with -R is executed once every time a log is rotated. This is useful for post-processing a log file (that is, sorting it, removing uninteresting lines, etc.). The -a option is a better choice for restarting daemons after log rotation.

-s size
  Rotate the log file only if its size is greater than or equal to size.

  Specify size as a number followed by the letter b for bytes, k for kilobytes, m for megabytes, or g for gigabytes.

-S size
  Delete the oldest versions until the total disk space used by the old log files is less than the specified size.

  Specify size as a number followed by the letter b for bytes, k for kilobytes, m for megabytes, or g for gigabytes.

-t template
  Specify the template to use when renaming log files.

  template can be a simple name, such as /var/adm/oldfile, or it can contain special keywords which are expanded by logadm and are in the form $word. Allowed sequences are:

  $basename
    The log file name, without the directory name

  $dirname
    The directory of the file to be rotated

  $domain
    Expands to the output of domainname

  $file
    The full path name of the file to be rotated

  $isa
    Expands to the output of uname -p

  $machine
    Expands to the output of uname -m
The version number, $0$ is most recent, $1$ is next most recent, and so forth

$N$
The same as $n$, but starts at $1$ instead of zero

$nodename$
Expands to the output of `uname -n`

$platform$
Expands to the output of `uname -i`

$release$
Expands to the output of `uname -r`

$secs$
The number of seconds since 00:00:00 UTC, January 1, 1970

$zonename$
Expands to the output of `zonename(1)`. To actually have the dollar sign character in the file name, use $$`. Any percent sequences allowed by `strftime(3C)` are also allowed, for example, `%d` expands to the day of the month. To actually have a percent sign character in the file name, use `%`. Both dollar-sign keywords and percent sequences can appear anywhere in the template. If the template results in a pathname with non-existent directories, they are created as necessary when rotating the log file.

If no `-t` option is specified, the default template is `$file.$n`. Actual rotation of log files, where each version is shifted up until it expires is done using the $n$ keyword. If the template does not contain the $n$ keyword, the log file is simply renamed to the new name and then the expire rules, if any, are applied.

-T pattern
Normally `logadm` looks for a list of old log files by turning the template (specified with the `-t` option) into a pattern and finding existing files whose names match that pattern. The `-T` option causes the given pattern to be used instead.

This option is useful if another program fiddles with the old log file names, like a `cron` job to compress them over time. The pattern is in the form of a pathname with special characters such as `*` and `?` as supported by `csh(1)` filename substitution.

-v
Print information about the actions being executed in verbose mode.

-V
Validate the configuration file.

This option validates that an entry for the specified `logname` exists in the `/etc/logadm.conf` file and is syntactically correct. If `logname` is not specified, all entries in
the configuration file are validated. If a logname argument is specified, the command validates the syntax of that entry. If the entry is found, it is printed and the exit value of the command is true. Otherwise the exit value is false.

-w entryname
Write an entry into the config file (that is, /etc/logadm.conf) that corresponds to the current command line arguments. If an entry already existed for the specified entryname, it is removed first. This is the preferred method for updating /etc/logadm.conf, because it prevents syntax errors. The entryname is an argument to an invocation of logadm. entryname might be chosen as something easy to remember or it can be the pathname of the log file. If a pathname, rather than a name is used, it must be a fully qualified pathname.

If no log file name is provided on a logadm command line, the entry name is assumed to be the same as the log file name. For example, the following two lines achieve the same thing, keeping two copies of rotated log files:

% logadm -c2 -w mylog /my/really/long/log/file/name
% logadm -c2 -w /my/really/long/log/file/name

-z count
Compress old log files after all other commands have been executed. count of the most recent log files are left uncompressed, therefore making the count most recent files easier to peruse. Use count of zero to compress all old logs.

The compression is done with gzip(1) and the resulting log file has the suffix of .gz.

Operands
The following operands are supported:

logname
Identifies the name of the entry in /etc/logadm.conf. If the log file name is specified in the logname field, it is assumed that logname is the same as the actual log file name.

Examples

EXAMPLE 1  Rotating a File and Keeping Previous Versions

The following example rotates the /var/adm/exacct/proc file, keeping ten previous versions in /var/adm/exacct/proc.0 through /var/adm/exacct/proc.9.

Tell logadm to copy the file and truncate it.

% logadm -c /var/adm/exacct/proc

EXAMPLE 2  Rotating syslog

The following example rotates syslog and keeps eight log files. Old log files are put in the directory /var/oldlogs instead of /var/log:

% logadm -c8 -t'/var/oldlogs/syslog.$n' /var/log/syslog
EXAMPLE 3  Rotating /var/adm/sulog and Expiring Based on Age

The following entry in the /etc/logadm.conf file rotates the /var/adm/sulog file and expires any copies older than 30 days.

/var/adm/sulog -A 30d

EXAMPLE 4  Rotating Files and Expiring Based on Disk Usage

The following entry in the /etc/logadm.conf file rotates the /var/adm/sulog file and expires old log files when more than 100 megabytes are used by the sum of all the rotated log files.

/var/adm/sulog -S 100m

EXAMPLE 5  Creating an Entry that Stores the Logfile Name

This example creates an entry storing the logfile name and the fact that we want to keep 20 copies in /etc/logadm.conf, but the -p never means the entry is ignored by the normal logadm run from root's crontab every morning.

% logadm -w locallog /usr/local/logfile -C 20 -p never

Use the following entry on the command line to override the -p never option:

% logadm -p now locallog

EXAMPLE 6  Rotating the apache Error and Access Logs

The following example rotates the apache error and access logs monthly to filenames based on current year and month. It keeps the 24 most recent copies and tells apache to restart after renaming the logs.

This command is run once, and since the -w option is specified, an entry is made in /etc/logadm.conf so the apache logs are rotated from now on.

% logadm -w apache -p 1m -C 24\
   -t '/var/apache/old-logs/$basename.%Y-%m'\
   -a '/usr/apache/bin/apachectl graceful'\
   '/var/apache/logs/*{access,error}_log'

This example also illustrates that the entry name supplied with the -w option doesn't have to match the log file name. In this example, the entry name is apache and once the line has been run, the entry in /etc/logadm.conf can be forced to run by executing the following command:

% logadm -p now apache

Because the expression matching the apache log file names was enclosed in quotes, the expression is stored in /etc/logadm.conf, rather than the list of files that it expands to. This means that each time logadm runs from cron it expands that expression and checks all the log files in the resulting list to see if they need rotating.
EXAMPLE 6  Rotating the apache Error and Access Logs  (Continued)

The following command is an example without the quotes around the log name expression. The shell expands the last argument into a list of log files that exist at the time the command is entered, and writes an entry to /etc/logadm.conf that rotates the files.

logadm -w apache /var/apache/logs/*_log

Files
/etc/logadm.conf
configuration file for logadm command
/var/logadm/timestamps
repository for logging timestamps

Notes
When logadm applies expire conditions (supplied by the -A, -C, and -S options), it deletes files, the oldest first, until the conditions are satisfied. If the template used for naming the old logs contained $n or $N, logadm picks the highest value of $n or $N found in the old log file names first. If the template used is something else, logadm uses the modification time to determine which files to expire first. This may not be the expected behavior if an old log file has been modified since it was rotated.

Depending on log file sizes and number of log files, log file rotations can be very time-consuming.

By default, logadm works in UTC. Therefore, all entries written to the /etc/logadm.conf file (see logadm.conf(4)) will have a UTC timestamp. Users can use the -l option to set logadm to local time.

The -f and -F options can specify the same file, in which case logadm reverts to the same behavior as in prior releases. That is, timestamps are written to the configuration file.
**Name**
logins – list user and system login information

**Synopsis**

```
/usr/bin/logins [-admoprstux] [-g group...
   -l login_name...]
```

**Description**

This command displays information on user, role, and system logins known to the system. Contents of the output is controlled by the command options and can include the following: user, role, or system login; user id number; passwd account field value (user name or other information); primary group name; primary group id; multiple group names; multiple group ids; home directory; login shell; and four password-aging parameters. The default information is the following: login id, user id, primary group name, primary group id, and the account field value. Output is sorted by user id, unless the -t option is specified.

**Options**

Options may be used together. If so, any login that matches any criteria are displayed.

The following options are supported:

- **a**
  Add two password expiration fields to the display. The fields show how many days a password can remain unused before it automatically becomes inactive, and the date that the password expires.

- **d**
  Selects logins with duplicate uids.

- **g group**
  Selects all users belonging to group, sorted by login. Multiple groups can be specified as a comma-separated list. When the -l and -g options are combined, a user is only listed once, even if the user belongs to more than one of the selected groups.

- **l login_name...**
  Selects the requested login. Multiple logins can be specified as a comma-separated list. Depending on the nameservice lookup types set in /etc/nsswitch.conf, the information can come from the /etc/passwd and /etc/shadow files and other nameservices. When the -l and -g options are combined, a user is only listed once, even if the user belongs to more than one of the selected groups.

- **m**
  Displays multiple group membership information.

- **o**
  Formats output into one line of colon-separated fields.

- **p**
  Selects logins with no passwords.

- **r**
  Select all role logins.

- **s**
  Selects all system logins.
-t
Sorts output by login instead of by uid.
-u
Selects all user logins.
-x
Prints an extended set of information about each selected user. The extended information includes home directory, login shell, and password-aging information, each displayed on a separate line. The password information currently consists of password status:

NP
   Account has no password
LK
   Account is locked for UNIX authentication
NL
   Account is a no login account
UP
   This account has not yet been activated by the administrator and cannot be used.
PS
   Account probably has a valid password
UN
   Account password status is unknown. That is, it is not a recognizable hashed password or any of the above entries. See crypt(3C) for valid password hashes.

If the login is passworded, status is followed by the date the password was last changed, the number of days required between changes, and the number of days allowed before a change is required. The password-aging information shows the time interval that the user receives a password expiration warning message (when logging on) before the password expires.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>

**Name**
Ishal – list HAL devices

**Synopsis**
/usr/sbin/lshal [options]

**Description**
The lshal command displays items in the HAL device database.

When invoked without options, lshal defaults to long output (-l). Long output includes all devices and all properties associated with each device.

The -s option lists only UDIs (Unique Device Identifier) for all HAL devices.

The -t option prints the HAL device tree, reflecting parent-child relationships with whitespace indentation.

The -u option limits output to the specified device.

When invoked with -m option, lshal monitors HAL device changes, such as property modification and device addition and removal. This option can be combined with the -u option to monitor a particular device.

**Options**
The following options are supported:

- **-h, --help**
  Show help information.

- **-l, --long**
  Long output.

- **-m, --monitor**
  Monitor device list.

- **-s, --short**
  Short output (display only non-static part of UDI).

- **-t, --tree**
  Tree view.

- **-u, --show udi**
  Show only the specified device.

- **-V, --version**
  Display version number.

**Attributes**

The `luxadm` program is an administrative command that manages the SENA, Sun Fire 880 internal storage subsystem, and individual Fiber Channel Arbitrated Loop (FC_AL) devices. `luxadm` performs a variety of control and query tasks depending on the command line arguments and options used.

The command line must contain a subcommand. The command line may also contain options, usually at least one enclosure name or pathname, and other parameters depending on the subcommand. You need specify only as many characters as are required to uniquely identify a subcommand.

Specify the device that a subcommand interacts with by entering a pathname. For the SENA subsystem, a disk device or enclosure services controller may instead be specified by entering the World Wide Name (WWN) for the device or a port to the device. The device may also be specified by entering the name of the SENA enclosure, and an optional identifier for the particular device in the enclosure. The individual FC_AL devices may be specified by entering the WWN for the device or a port to the device.

Specify the device or controller by either a complete physical pathname or a complete logical pathname.

For SENA, a typical physical pathname for a device is:

```
/devices/sbus@1f,0/SUNW,so@1,0/sf@0,0/ssd@w2200002037000f96,0:a,raw
```

For all SENA IBs (Interface Boards) and Sun Fire 880 SES device controllers on the system, a logical link to the physical paths is kept in the directory `/dev/es`. An example of a logical link is `/dev/es/ibes0`.

The WWN may be used in place of the pathname to select an FC_AL device, SENA subsystem IB, or Sun Fire 880 internal storage subsystem. The WWN is a unique 16 hexadecimal digit value that specifies either the port used to access the device or the device itself. A typical WWN value is:

```
2200002037000f96
```

See NOTES for more information on the WWN formats.

For a disk in a Sun Fire 880 internal storage subsystem, a typical physical pathname is:

```
/devices/pci@0,600000/SUNW,qlc@2/fp@0,0/ssd@w2100002037a6303c,0:a
```

and a typical logical pathname is:

```
/dev/rdsn/c2t8d0s2
```
For individual FC_AL devices, a typical physical pathname is:

/devices/sbus@3.0/SUNW,socal@d,10000/sf@0,0/ssf@000002037049fc3,0:a,raw

and a typical logical pathname is:

/dev/rsk/c1t0d0s2

Enclosure For SENA, a device may be identified by its enclosure name and slotname:

\[ \text{box\_name}[,f\text{slot\_number}] \]
\[ \text{box\_name}[,r\text{slot\_number}] \]

\text{box\_name} is the name of the SENA enclosure, as specified by the \text{enclosure\_name} subcommand. When used without the optional \text{slot\_number} parameter, the \text{box\_name} identifies the SENA subsystem IB.

\text{f} or \text{r} specifies the front or rear slots in the SENA enclosure.

\text{slot\_number} specifies the slot number of the device in the SENA enclosure, 0 - 6 or 0 - 10.

For a Sun Fire 880 internal storage subsystem, a device may also be identified by its enclosure name and slot name. However, there is only one set of disks:

\[ \text{box\_name}[,s\text{slot\_number}] \]

\text{box\_name} is the name of the Sun Fire 880 enclosure, as specified by the \text{enclosure\_name} subcommand. When used without the optional \text{slot\_number} parameter, \text{box\_name} identifies the Sun Fire 880 internal storage subsystem enclosure services device. Use \text{s} to specify the disk slot number in the Sun Fire 880 internal storage subsystem, 0 - 11.

See disks(1M) and devlinks(1M) for additional information on logical names for disks and subsystems.

Options The following options are supported by all subcommands:

- \text{e} Expert mode. This option is not recommended for the novice user.
- \text{v} Verbose mode.

Options that are specific to particular subcommands are described with the subcommand in the \text{USAGE} section.

Operands The following operands are supported:

\text{enclosure}

The \text{box\_name} of the SENA or Sun Fire 880 internal storage subsystem.

\text{fibre\_channel\_HBA\_port}

The path to the host controller port. A typical path is:

/devices/pci@8,600000/pci@1/SUNW,qlc@4/fp@0,0:devctl
pathname
The logical or physical path of a SENA IB, Sun Fire 880 internal storage subsystem, or disk
device. pathname can also be the WWN of a SENA IB, SENA disk, or individual FC_AL
device.

Usage
Subcommands

display enclosure[,dev]...|pathname ...
display -p pathname ...
display -r enclosure[,dev]...|pathname ...
display -v enclosure[,dev]...|pathname ...
  Displays enclosure or device specific data.

Subsystem data consists of enclosure environmental sense information and status for all
subsystem devices, including disks.

Disk data consists of inquiry, capacity, and configuration information.

-p Displays performance information for the device or subsystem specified by
  pathname. This option only applies to subsystems that accumulate performance
  information.

-r Displays error information for the FC_AL device specified by the pathname, or, if
  the path is a SENA, for all devices on the loop. The -r option only applies to SENA
  subsystems and individual FC_AL devices.

-v Displays in verbose mode, including mode sense data.

download [-s] [-f filename_path] enclosure...
  Download the prom image pointed to the SENA subsystem Interface Board unit or the Sun
  Fire 880 internal storage subsystem specified by the enclosure or pathname.

  When the SENA’s download is complete, the SENA will be reset and the downloaded code
  executed. If no filename is specified, the default prom image will be used. The default prom
  image for the SENA is in the directory /usr/lib/locale/C/LC_MESSAGES and is named
  ibfirmware.

  When the Sun Fire 880 internal storage subsystem’s download is complete, the subsystem
  resets and the downloaded code begins execution. The default firmware image for the Sun
  Fire 880 internal storage subsystem is in:
  /usr/platform/SUNW,Sun-Fire-880/lib/images/int_fcbpl_fw.

-s Save. The -s option is used to save the downloaded firmware in the FEPROM. If -s
  is not specified, the downloaded firmware will not be saved across power cycles.

  The -s option does not apply to the Sun Fire 880 internal storage subsystem as it
  always stores downloaded firmware in the flash memory.
When using the -s option, the download subcommand modifies the FEPROM on the subsystem and should be used with caution.

enclosure_name new_name enclosure | pathname
Change the enclosure name of the enclosure or enclosures specified by the enclosure or pathname. The new name (new_name) must be 16 or less characters. Only alphabetic or numeric characters are acceptable. This subcommand applies only to the SENA and the Sun Fire 880 internal storage subsystem.

failover primary | secondary pathname
Select which Sun Storage T3 storage array partner group controller accesses a given logical volume. If primary is specified, the logical volume is accessed through the primary controller. If secondary is specified, the logical volume is accessed through the secondary controller specified by pathname.

fcal_s_download [-f fcode-file]
Download the fcode contained in the file fcode-file into all the FC100/S Sbus Cards. This command is interactive and expects user confirmation before downloading the fcode.

Use fcal_s_download only in single-user mode. Using fcal_s_download to update a host adapter while there is I/O activity through that adapter will cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

- f fcode-file When invoked without the -f option, the current version of the fcode in each FC100/S Sbus card is printed.

fcode_download -p
fcode_download -d dir-name
Locate the installed FC/S, FC100/S, FC100/P, or FC100/2P host bus adapter cards and download the FCode files in dir-name to the appropriate cards. The command determines the correct card for each type of file, and is interactive. User confirmation is required before downloading the FCode to each device.

Use fcode_download to load FCode only in single-user mode. Using fcode_download to update a host adapter while there is I/O activity through that adapter causes the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

- d dir-name Download the FCode files contained in the directory dir-name to the appropriate adapter cards.

- p Prints the current version of FCode loaded on each card. No download is performed.

inquiry enclosure[,dev] . . . | pathname . . .
Display the inquiry information for the selected device specified by the enclosure or pathname.
**insert_device [enclosure, dev ...]**

Assist the user in the hot insertion of a new device or a chain of new devices. Refer to NOTES for limitations on hotplug operations. This subcommand applies only to the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL drives. For the SENA, if more than one enclosure has been specified, concurrent hot insertions on multiple busses can be performed. With no arguments to the subcommand, entire enclosures or individual FC_AL drives can be inserted. For the SENA or the Sun Fire 880 internal storage subsystem, this subcommand guides the user interactively through the hot insertion steps of a new device or chain of devices. If a list of disks was entered it will ask the user to verify the list of devices to be inserted is correct, at which point the user can continue or quit. It then interactively asks the user to insert the disk(s) or enclosure(s) and then creates and displays the logical pathnames for the devices.

**led enclosure, dev ... | pathname ...**

Display the current state of the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

**led_blink enclosure, dev ... | pathname ...**

Requests the subsystem to start blinking the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

**led_off enclosure, dev ... | pathname ...**

Requests the subsystem to disable (turn off) the LED associated with the disk specified by the enclosure or pathname. On a SENA subsystem, this may or may not cause the LED to turn off or stop blinking depending on the state of the SENA subsystem. Refer to the SENA Array Installation and Service Manual (p/n 802-7573). This subcommand only applies to subsystems that support this functionality.

**led_on pathname ...**

Requests the subsystem to enable (turn on) the LED associated with the disk specified by the pathname. This subcommand only applies to subsystems that support this functionality.

**power_off [ -F ] enclosure[, dev ... | pathname ...**

When a SENA is addressed, this subcommand causes the SENA subsystem to go into the power-save mode. The SENA drives are not available when in the power-save mode. When a drive in a SENA is addressed the drive is set to the drive off/unmated state. In the drive off/unmated state, the drive is spun down (stopped) and in bypass mode. This command does not apply to the Sun Fire 880 internal storage subsystem.

- **-F** The force option only applies to the SENA. Instructs luxadm to attempt to power off one or more devices even if those devices are being used by this host (and are, therefore, busy).

*Warning:* Powering off a device which has data that is currently being used will cause unpredictable results. Users should attempt to power off the device normally (without -F) first, only resorting to this option when sure of the consequences of
overriding normal checks.

power_on enclosure[,dev]...
Causes the SENA subsystem to go out of the power-save mode, when this subcommand is addressed to a SENA. When this subcommand is addressed to a drive the drive is set to its normal start-up state. This command does not apply to the Sun Fire 880 internal storage subsystem.

probe [-p]
Finds and displays information about all attached SENA subsystems, Sun Fire 880 internal storage subsystems, and individual FC_AL devices, including the logical pathname, the WWNs, and enclosure names. This subcommand warns the user if it finds different SENAs with the same enclosure names.

- p Includes the physical pathname in the display.

qlgc_s_download [-f fcode-file]
Download the FCode contained in the file fcode-file into all the FC100/P, FC100/2P PCI host adapter cards. This command is interactive and expects user confirmation before downloading the FCode to each device. Only use qlgc_s_download in single-user mode. Using qlgc_s_download to update a host adapter while there is I/O activity through that adapter will cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

- f fcode-file When invoked without the - f option, the current version of the FCode in each FC100/P, FC100/2P PCI card is printed.

release pathname
Release a reservation held on the specified disk. The pathname should be the physical or logical pathname for the disk.

This subcommand is included for historical and diagnostic purposes only.

remove_device [-F] enclosure[,dev]...|pathname...
Assists the user in hot removing a device or a chain of devices. This subcommand can also be used to remove entire enclosures. This subcommand applies to the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL drives. Refer to NOTES for limitations on hotplug operations. For the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL devices, this subcommand guides the user through the hot removal of a device or devices. During execution it will ask the user to verify the list of devices to be removed is correct, at which point the user can continue or quit. It then prepares the disk(s) or enclosure(s) for removal and interactively asks the user to remove the disk(s) or enclosure(s).

For Multi-Hosted disk, the steps taken are:
- Issue the luxadm remove_device command on the first host. When prompted to continue, wait.
- Issue the `luxadm remove_device` command on the secondary hosts. When prompted to continue, wait.
- Continue with the `remove_device` command on the first host. Remove the device when prompted to do so.
- Complete the `luxadm remove_device` command on the additional hosts.
- `-F` Instructs `luxadm` to attempt to hot plug one or more devices even if those devices are being used by this host (and are, therefore, busy or reserved), to force the hotplugging operation.

  Warning: Removal of a device which has data that is currently being used will cause unpredictable results. Users should attempt to hotplug normally (without `-F`) first, only resorting to this option when sure of the consequences of overriding normal hotplugging checks.

- `reserve pathname` Reserve the specified disk for exclusive use by the issuing host. The pathname used should be the physical or logical pathname for the disk.
  This subcommand is included for historical and diagnostic purposes only.

- `set_boot_dev [-y] pathname` Set the boot-device variable in the system PROM to the physical device name specified by `pathname`, which can be a block special device or the pathname of the directory on which the boot file system is mounted. The command normally runs interactively requesting confirmation for setting the default boot-device in the PROM. The `-y` option can be used to run it non-interactively, in which case no confirmation is requested or required.

- `start pathname` Spin up the specified disk(s) in a SENA.

- `stop pathname` Spin down the specified disks in a SENA.

The following subcommands are for expert use only, and are applicable only to the SENA, Sun Fire 880 internal storage subsystem, and fiber channel loops. They should only be used by users that are knowledgeable about the SENA subsystem and fiber channel loops.

If you specify a disk to an expert subcommand that operates on a bus, the subcommand operates on the bus to which the specified disk is attached.

- `-e bypass [-ab] enclosure,dev` Request the enclosure services controller to set the LRC (Loop Redundancy Circuit) to the bypassed state for the port and device specified.
This subcommand supports the following options:

- \texttt{-a} Bypass port \texttt{a} of the device specified.
- \texttt{-b} Bypass port \texttt{b} of the device specified.

\textbf{-e dump\_map fibre\_channel\_HBA\_port}

Display WWN data for a target device or host bus adapter on the specified fibre channel port. If there are no target devices on the specified port, an error is returned.

\textbf{-e enable \{-ab\} enclosure,dev}

Request the enclosure services controller to set the LRC (Loop Redundancy Circuit) to the enabled state for the port and device specified.

This subcommand supports the following options:

- \texttt{-a} Enable port \texttt{a} of the device specified.
- \texttt{-b} Enable port \texttt{b} of the device specified.

\textbf{-e forcelip enclosure[, dev]...|pathname...}

Force the link to reinitialize, using the Loop Initialization Primitive (LIP) sequence. The enclosure or pathname can specify any device on the loop. Use the pathname to specify a specific path for multiple loop configurations.

This is an expert only command and should be used with caution. It will reset all ports on the loop.

\textbf{-e rd\ls enclosure[, dev]...|pathname...}

Read and display the link error status information for all available devices on the loop that contains the device specified by the enclosure or pathname.

\textbf{Other Expert Mode Subcommands}

See \texttt{NOTES} for limitations of these subcommands. They should only be used by users that are knowledgeable about the systems they are managing.
These commands do not apply to the Sun Fire 880 internal storage subsystem.

- `e bus_getstate pathname` Get and display the state of the specified bus.
- `e bus_quiesce pathname` Quiesce the specified bus.
- `e bus_reset pathname` Reset the specified bus only.
- `e bus_resetall pathname` Reset the specified bus and all devices.
- `e bus_unquiesce pathname` Unquiesce the specified bus. The specified device.
- `e dev_getstate pathname` Get and display the state of the specified device.
- `e dev_reset pathname` Reset the specified device.
- `e offline pathname` Take the specified device offline.
- `e online pathname` Put the specified device online.

Examples

**EXAMPLE 1**  Displaying the SENAs and Individual FC_AL Devices on a System
The following example finds and displays all of the SENAs and individual FC_AL devices on a system:

```
example% luxadm probe
```

**EXAMPLE 2**  Displaying a SENA or Sun Fire 880 Internal Storage Subsystem
The following example displays a SENA or Sun Fire 880 internal storage subsystem:

```
example% luxadm display /dev/es/ses0
```

**EXAMPLE 3**  Displaying Two Subsystems
The following example displays two subsystems using the enclosure names:

```
example% luxadm display BOB system1
```

**EXAMPLE 4**  Displaying Information about the First Disk
The following example displays information about the first disk in the front of the enclosure named BOB. Use f to specify the front disks. Use r to specify the rear disks.

```
example% luxadm display BOB,f0
```

**EXAMPLE 5**  Displaying Information on a Sun Fire 880 Internal Storage Subsystem
The Sun Fire 880 internal storage subsystem has only one set of disks. In this case, use s to specify the slot:

```
example% luxadm display BOB,s0
```
EXAMPLE 6  Displaying Information about a SENA disk, an Enclosure, or an Individual FC_AL Drive
The following example displays information about a SENA disk, an enclosure, or an individual FC_AL drive with the port WWN of 2200002037001246:

example% luxadm display 2200002037001246

EXAMPLE 7  Using Unique Characters to Issue a Subcommand
The following example uses only as many characters as are required to uniquely identify a subcommand:

example% luxadm disp BOB

EXAMPLE 8  Displaying Error Information
The following example displays error information about the loop that the enclosure BOB is on:

example% luxadm display -r BOB

EXAMPLE 9  Downloading New Firmware into the Interface Board
The following example downloads new firmware into the Interface Board in the enclosure named BOB (using the default path for the file to download):

example% luxadm download -s BOB

EXAMPLE 10  Displaying Information from the SCSI Inquiry Command
The following example displays information from the SCSI inquiry command from all individual disks on the system, using only as many characters as necessary to uniquely identify the inquiry subcommand:

example% luxadm inq /dev/rdsk/c?t?d?s2

EXAMPLE 11  Hotplugging
The following example hotplugs a new drive into the first slot in the front of the enclosure named BOB:

example% luxadm insert_device BOB,f0

The following example hotplugs a new drive into the first slot in the Sun Fire 880 internal storage subsystem named SF880-1:

example% luxadm insert_device SF880-1,s0

EXAMPLE 12  Running an Expert Subcommand
The following example runs an expert subcommand. The subcommand forces a loop initialization on the loop that the enclosure BOB is on:

example% luxadm -e forcelip BOB
EXAMPLE 13  Using the Expert Mode Hot Plugging Subcommands

An example of using the expert mode hot plugging subcommands to hot remove a disk
follows. See NOTES for hot plugging limitations.

The first step reserves the SCSI device so that it can’t be accessed by way of its second SCSI bus:

```
example# luxadm reserve /dev/rdsk/c1t8d0s2
```

EXAMPLE 14  Taking the Disk to be Removed Offline

The next two steps take the disk to be removed offline then quiesce the bus:

```
exaample# luxadm -e offline /dev/rdsk/c1t8d0s2
example# luxadm -e bus_quiesce /dev/rdsk/c1t8d0s2
```

EXAMPLE 15  Unquiescing the Bus

The user then removes the disk and continues by unquiescing the bus, putting the disk back
online, then unreserving it:

```
exaample# luxadm -e bus_unquiesce /dev/rdsk/c1t8d0s2
example# luxadm -e online /dev/rdsk/c1t8d0s2
example# luxadm release /dev/rdsk/c1t8d0s2
```

Environment Variables  See `environ(5)` for a description of the LANG environment variable that affects the execution of luxadm.

Exit Status  The following exit values are returned:

- 0  Successful completion.
- -1  An error occurred.

Files  `usr/lib/firmware/fc_s/fc_s_fcode`
       `usr/lib/locale/C/LC_MESSAGES/ibfirmware`

Attributes  See `attributes(5)` for descriptions of the following attributes:

```
<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/storage/fc-utilities</td>
</tr>
</tbody>
</table>
```

See Also  `devlinks(1M), disks(1M), attributes(5), environ(5), ses(7D)`

*Oracle Solaris 11.1 Administration: SAN Configuration and Multipathing*

*Oracle Solaris Cluster 3.3 with Fibre Channel JBOD Storage Device Manual*
Notes. Refer to *Tutorial for SCSI use of IEEE Company_ID*, R. Snively, for additional information regarding the IEEE extended WWN. Currently, only some device drivers support hot plugging. If hot plugging is attempted on a disk or bus where it is not supported, an error message of the form:

```
luxadm: can't acquire "PATHNAME": No such file or directory
```

...will be displayed.

You must be careful not to quiesce a bus that contains the root or the /usr filesystems or any swap data. If you do quiesce such a bus a deadlock can result, requiring a system reboot.
**Name**  
mail.local – store mail in a mailbox

**Synopsis**  
/usr/lib/mail.local [-f sender] [-d] recipient

**Description**  
mail.local reads the standard input up to an end-of-file and appends it to each user's mail file (mailbox). This program is intended to be used by sendmail(1M) as a mail delivery agent for local mail. It is not a user interface agent.

Messages are appended to the user's mail file in the /var/mail directory. The user must be a valid user name.

Each delivered mail message in the mailbox is preceded by a "Unix From line" with the following format:

From sender_address time_stamp

The sender_address is extracted from the SMTP envelope address (the envelope address is specified with the -f option).

A trailing blank line is also added to the end of each message.

The mail files are locked with a .lock file while mail is appended.

The mail files are created with mode 660, owner is set to recipient, and group is set to mail. If the "biff" service is returned by getservbyname(3SOCKET), the biff server is notified of delivered mail. This program also computes the Content-Length: header which will be used by the mailbox reader to mark the message boundary.

**Options**  
The following options are supported:

- **-f sender**  
  Specifies the "envelope from address" of the message. This flag is technically optional, but should be used.

- **-d**  
  Specifies the recipient of the message. This flag is also optional and is supported here for backward compatibility. That is, mail.local recipient is the same as mail.local -d recipient.

- **-l**  
  Turn on LMTP mode.

- **-r from**  
  Specify the sender's name (for backward compatibility).

- **-7**  
  Do not advertise 8BITMIME support in LMTP mode.

- **-b**  
  Return a permanent error instead of a temporary error if a mailbox exceeds quota.

**Operands**  
The following operand is supported:

- **recipient**  
  The recipient of the mail message.
TZ  Used to set the appropriate time zone on the timestamp.

Exit Status  The following exit values are returned:

0  Successful operation.

>0  An error occurred.

Files  
/tmp/local.XXXXXX  temporary files
/tmp/lochd.XXXXXX  temporary files
/var/mail/user_name  user's mail file

**makedbm(1M)**

**Name**
makedbm – make a dbm file, or get a text file from a dbm file

**Synopsis**
makedbm [-b] [-l] [-s] [-E] [-i yp_input_file]
   [-o yp_output_name] [-d yp_domain_name]
   [-m yp_master_name] [-S delimiter]
   [-D number_of_delimiters] infile outfile

makedbm [-u dbmfilename]

**Description**
The makedbm utility takes the infile and converts it to a pair of files in ndbm format (see ndbm(3C)), namely outfile.pag and outfile.dir. Each line of the input file is converted to a single dbm record. All characters up to the first TAB or SPACE form the key, and the rest of the line is the data. If a line ends with \ (backslash), the data for that record is continued on to the next line. makedbm does not treat ’#’ (pound-sign) as a special character.

Because makedbm is mainly used in generating dbm files for the NIS name service, it generates a special entry with the key yp_last_modified, which is the date of infile (or the current time, if infile is ‘−1’). The entries that have keys with the prefix yp_ are interpreted by NIS server utilities.

**Options**
The following options are supported:

- **-b**
  Insert the YP_INTERDOMAIN into the output. This key causes ypserv(1M) to use DNS for host name and address lookups for hosts not found in the maps.

- **-d yp_domain_name**
  Create a special entry with the key yp_domain_name.

- **-D number_of_delimiters**
  Specify number_of_delimiters to skip before forming the key.

- **-E**
  Delimiters are escaped.

- **-i yp_input_file**
  Create a special entry with the key yp_input_file.

- **-l**
  Lower case. Convert the keys of the given map to lower case, so that, for example, host name matches succeed independent of upper or lower case distinctions.

- **-m yp_master_name**
  Create a special entry with the key yp_master_name. If no master host name is specified, yp_master_name is set to the local host name.

- **-o yp_output_name**
  Create a special entry with the key yp_output_name.

- **-s**
  Secure map. Accept connections from secure NIS networks only.

- **-S delimiter**
  Specify the delimiter to use instead of the default delimiter for forming the key.

- **-u dbmfilename**
  Undo a dbm file. Prints out the file in text format, one entry per line, with a single space separating keys from values.
Operands

The following operands are supported:

infile Input file for makedbm. If infile is ‘−’ (dash), the standard input is read.

outfile One of two output files in ndbm format: outfile.pag and outfile.dir.

Attributes

makemap(1M)

makemap – create database maps for sendmail

Synopsis

       [-c cache size] [-D comment char] [-e] [-l] [-t delim]
       [-u] mantype mapname

Description

makemap creates the database maps used by the keyed map lookups in sendmail(1M). makemap reads from the standard input and outputs to the specified mapname.

In all cases, makemap reads lines from the standard input consisting of two words separated by whitespace. The first is the database key, the second is the value. The value may contain %n strings to indicated parameter substitution. Literal percents should be doubled (%%). Blank lines and lines beginning with # are ignored.

makemap handles three different database formats. Database format is selected using the maptype parameter. See OPERANDS.

Options

The following options are supported:

- c cache size  Use the specified hash and B-Tree cache size (cache size).
- C file       Use the specified sendmail configuration file (file) for looking up the TrustedUser option.
- d            Allow duplicate keys in the map. This is only allowed on B-Tree format maps. If two identical keys are read, both be inserted into the map.
- D comment char  Use the specified character to indicate a comment (which is ignored) instead of the default of '#'.
- e            Allow empty value (right hand side).
- f            Normally, all upper case letters in the key are folded to lower case. This flag disables that behavior. This is intended to mesh with the -f flag in the K line in sendmail.cf. The value is never case folded.
- l            List supported map types.
- N            Include the null byte that terminates strings in the map. This must match the -N flag in the K line in sendmail.cf
- o            Append to an old file. This allows you to augment an existing file.
- r            Allow replacement of existing keys. Normally makemap complains if you repeat a key, and does not do the insert.
- s            Ignore safety checks on maps being created. This includes checking for hard or symbolic links in world writable directories.
- t delim      Use the specified delimiter (delim) instead of whitespace.

makemap(1M)
Dump (unmap) the content of the database to standard output. Note that, if the \(-\text{t}\) option is also provided, the specified delimiter is used when the content is dumped instead of whitespace.

\(-v\) Verbose print what it is doing.

**Operands**
The following operands are supported:

- `mapname` File name of the database map being created.
- `maptype` Specifies the database format. The following `maptype` parameters are available:
  - `dbm` Specifies DBM format maps.
  - `btree` Specifies B-Tree format maps.
  - `hash` Specifies hash format maps.

masfcnv(1M)

Name
masfcnv – SNMP configuration migration script

Synopsis
/usr/lib/net-snmp/masfcnv [-cimnrs] [-l agentmaster]
    [-p enabledisableerror] [-t noneadd]
    [-u agentmastererror] [-y agentmastererror]
masfcnv [-V]
masfcnv [-?]

Description
The masfcnv script is used to assist the system administrator in migrating an existing set of configuration files for the Sun SNMP Management Agent for Sun Fire and Netra Systems (MASF) to the Systems Management Agent (SMA).

The script accepts as input the currently installed set of MASF and SMA configuration files and outputs a new set of SMA configuration files. Existing SMA configuration files are backed up by appending .bak to the filename. The administrator can choose to output the new configuration to standard output, instead of replacing the current configuration, by specifying the -n option.

The migration script must be run as the superuser. Failure to do so causes the script to exit with an error message. Before running the script you should ensure that both the SMA and MASF agents are not running. If the agents are running they will be shut down by the script.

The migration script installs a new startup script for the MASF agent in /etc/init.d, as well as a backup of the old script. During migration, MASF will be configured as an AgentX subagent of SMA. All migration settings will be migrated to the SMA configuration file.

The migration script aborts if any unrecognized directives are found in either the MASF configuration files or the SMA configuration files. This can be overridden with the -i option. If this option is selected, the behavior is to retain unrecognized directives that were present in the SMA configuration, but remove those present in the MASF configuration.

The migration script then proceeds to migrate access control and trap configuration. As a side effect of running the migration script, the following directives might be expanded by the script into multiple directives with an equivalent interpretation:

- rwcommunity
- rocommunity
- rwuser
- rouser
- trapcommunity
- trapisink
- trap2sink
- informsink
Access control directives are expanded into the equivalent com2sec, group, access and view directives. Existing group names are renamed by prepending a prefix to avoid conflict with any which may already be defined in SMA.

When migrating SNMPv1 or v2c access control, a conflict can occur if both MASF and SMA configuration files have defined access permissions for the same community and source address. The default behavior is to abort with a message, unless a use of the -y option specifies otherwise. If -y agent is specified then the MASF configuration takes precedence. If -y master is specified then the SMA configuration is retained.

When migrating USM configuration (SNMPv3), a conflict can occur if both SMA and MASF configurations define a user with the same securityName. If this occurs, the behavior of the script is determined by the -u option. If -u agent is specified, the configuration of the user defined in the MASF configuration files is the one that is retained. Otherwise, if the -u master option is specified, the use defined in the SMA configuration files is retained.

By default, the migration script attempts to migrate USM users from MASF to SMA. The script determines whether there are any SNMPv3 users present in the SMA configuration and whether the default engineID has been overridden in the SMA configuration files. If neither of these conditions obtain, then the any usmUser statements containing localized authentication keys can be migrated to SMA, along with the MASF engineID. This results in the engineID of the SMA master agent changing.

If the script determines that there are existing SNMPv3 users or a manually configured engineID present in the SMA configuration, only those users defined in createUser statements are transferred. Those users that were defined in usmUser statements are transferred but will have their passwords reset to a random value. You should notify your users of their new password or reset the password yourself by editing the newly-generated configuration file.

The migration script performs a check to determine whether a trap destination defined for MASF is already specified in an existing SMA trapsink, trap2sink or informsink directive. If this is the case, then the directive in the MASF configuration will be discarded to avoid duplicate traps/informs being received.

trapsink, trap2sink and informsink directives specified in the existing SMA configuration are considered valid destinations for MASF traps/informs and will receive them from the MASF subagent after migration.

If the -t none option was specified on the command line, the migration script carries over any remaining MASF trap/inform directives without modification.

If the -t add option was specified (the default), the migration script expands any trapsink, trap2sink, or informsink directives to use the TARGET-MIB and NOTIFICATION-MIB. The TARGET-MIB specifies targets using IP addresses, so it might be desirable to use the -t none option if, for example, the network allocates IP addresses to hostnames dynamically by means of DHCP.
The expanded directives defines filters specific to the MASF agent so that traps from other subagents will not be received by migrated trap destinations. Existing filters present in the SMA configuration are, by default, not modified and might or might not receive MASF traps, depending upon the filters that were originally defined for them.

If the `-l` option is specified, any filters already defined in the TARGET-MIB and the NOTIFICATION-MIB for SMA are extended to include traps from MASF. In the event that a trap destination is already configured in the TARGET-MIB with the same target address and community as an existing MASF trap/inform sink, a conflict will arise.

If `-l agent` was specified and a conflict arises, the migration script uses the target SNMP parameters (that is, the SNMP version and choice of trap/inform) defined by the MASF trap/informsink directive to send traps to this destination. Otherwise, if the `-l master` option was specified, the conflict will be resolved using the target SNMP parameters specified in the SMA configuration.

If the migration script encounters in the MASF configuration file any of the directives listed below and the directives are either not present or differ from the SMA configuration, the script will log a warning message.

- syslocation
- syscontact
- sysname
- sysservices
- agentgroup
- agentuser
- authtrapenable

**Options**

The following options are supported:

- `-?` 
  `---help`       Displays usage information.

- `-c`
  `---no-community`       Do not transfer v1/v2c communities.

- `-i`
  `---ignore-unrecognized-directives`       Continue processing if unrecognized directives are present.

- `-l agent | master`
  `---master-trap-target=agent | master`       If agent is specified, the existing SMA trap targets will be configured to receive traps that were previously sent to destinations for the Sun Fire SNMP agent. If master is specified, the targets will be configured to receive Sun Fire SNMP traps, but existing SNMP target parameters will be used.

Miscellaneous If the migration script encounters in the MASF configuration file any of the directives listed below and the directives are either not present or differ from the SMA configuration, the script will log a warning message.
Do not transfer usm (v3) users.

Run the migration without modifying any files. If an error arises, continue processing. This can be used to determine the likely migration issues.

Indicates whether the port originally used by the Sun Fire SNMP agent should be used by the SMA agent after migration (if the two agents are using different ports). If enable is specified, then the port used by the Sun Fire SNMP agent will also be used by the SMA agent after migration. If disable is specified, the ports used by SMA will not be updated by the migration tool. If the error option is specified and the SMA agent is not already using the same ports as those used by the original Sun Fire SNMP agent, an error is reported and the migration process is terminated. If no option is specified the default behavior is equivalent to the error flag.

Do not transfer trap destinations.

If a user is found in the MASF configuration file that cannot be created in the new configuration because of a change in the engine ID, then output a message indicating that the user could not be migrated (needs to be manually recreated) and continue processing. If this option is not present, the migration tool will consider such a situation as an error and abort.

If none is specified then the script will copy trap directives directly. The administrator might need to manually update the
configuration file to ensure traps are only delivered to their intended destinations. If add is specified, trap filters will be constructed so that traps originating from the original Sun Fire SNMP agent are delivered only to the destinations that originally received them. The default behavior is add.

```
-u agent|master|error
--select-user=agent|master|error
```

Specifies that if a user with the same name is found in both configuration files that the conflict is to be resolved using the specified configuration file as input. Selecting a user from a particular file will also cause the group declaration for that user to be taken from the same file. If agent is specified then the user will be taken from the configuration file for the Sun Fire SNMP Agent. If master is specified, the user will be taken from the SMA configuration. Otherwise, if error is given, the script will terminate. If this option is not present, the default behavior is equivalent to the error flag.

```
-V
--version
```

Display the version of this script.

```
-y agent|master|error
--select-community=agent|master|error
```

Specifies that if a community with the same name is found in both configuration files that the conflict is to be resolved using the specified configuration file as input. If agent is specified then the community will be taken from the configuration file for the Sun Fire SNMP Agent. If master is specified, the community will be taken from the SMA configuration. Otherwise, if error is given, the script will terminate. If this option is not present, the default behavior is equivalent to the error flag.
Examples

EXAMPLE 1  Simplest Case
The command shown below is appropriate for a simple migration. The migration fails if there are any potential conflicts.

# masfcnv

EXAMPLE 2  Migrating Such That MASF Settings Override
To migrate the MASF configuration such that it will always succeed, that MASF settings will override in the event of a conflict with SMA, and that access will still be provided on the original MASF port, enter:

# masfcnv -is -l agent -p enable -u agent -y agent

EXAMPLE 3  Dry Run, Retaining SMA Settings
To attempt a dry run and migrate the configuration such that any conflicts will be resolved by retaining existing SMA settings, enter:

masfcnv -l master -u master -y master

Exit Status

0  Success.
non-zero  A problem occurred during migration.

Files

/etc/sma/snmp/snmpd.conf  SMA configuration files
/var/sma_snmp/snmpd.conf  SMA configuration files
/etc/opt/SUNWmasf/conf/snmpd.conf  MASF configuration files

mdlogd(1M)

Name  mdlogd – Solaris Volume Manager daemon

Synopsis  mdlogd

Description  mdlogd implements a simple daemon that watches the system console looking for messages written by the Solaris Volume Manager. When a Solaris Volume Manager message is detected, mdlogd sends a generic SNMP trap.

To enable traps, you must configure mdlogd into the SNMP framework. See Solaris Volume Manager Administration Guide.

Usage  mdlogd implements the following SNMP MIB:

```
SOLARIS-VOLUME-MGR-MIB DEFINITIONS ::= BEGIN
  IMPORTS
    enterprises FROM RFC1155-SMI
    DisplayString FROM SNMPv2-TC;

  -- Sun Private MIB for Solaris Volume Manager

  sun OBJECT IDENTIFIER ::= { enterprises 42 }
  sunSVM OBJECT IDENTIFIER ::= { sun 104 }

  -- this is actually just the string from /dev/log that
  -- matches the md: regular expressions.
  -- This is an interim SNMP trap generator to provide
  -- information until a more complete version is available.

  -- this definition is a formalization of the old
  -- Solaris DiskSuite mdlogd trap mib.

  svmOldTrapString OBJECT-TYPE
    SYNTAX DisplayString (SIZE (0..255))
    ACCESS read-only
    STATUS mandatory
    DESCRIPTION

Solaris Volume Manager Administration Guide
Name  mdmonitord – daemon to monitor metadevices

Synopsis  /usr/sbin/mdmonitord [-t time_interval]

Description  The mdmonitord utility is part of Solaris Volume Manager. It monitors and checks RAID1 (mirrors), RAID5 and hot spares.

There are two methods for checking:

- At fixed time intervals.
- When a RAID-1 (mirror), RAID-5, or hot spare fails. A failure generates an error event which triggers a check of these metadevices.

Options  The following options are supported:

- -t  Time interval in seconds. The default value is 0, which causes probes to occur only upon an error. If you want to run mdmonitord at a regular interval, a value of 1800 (seconds, every half hour) is recommended as a starting point.

Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Solaris Volume Manager Administration Guide

Notes  Since frequent probes can affect performance, it is recommended that the intervals between probes be limited.

The mdmonitord service is managed by the service management facility, smf(5), under the service identifier:
	svc:/system/mdmonitor

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
**Name**
mdnsd – Multicast DNS daemon

**Synopsis**

`mdnsd [-debug]`

**Description**

`mdnsd` is the daemon program for Multicast DNS and DNS Service Discovery.

The `mdnsd` daemon listens on UDP port 5353 for Multicast DNS Query packets. When it receives a query for which it knows an answer, `mdnsd` issues the appropriate Multicast DNS Reply packet.

The `mdnsd` daemon also performs Multicast DNS Queries on behalf of client processes, and maintains a cache of the replies.

The `mdnsd` daemon has no user-specifiable command-line argument, and users should not run `mdnsd` manually. The `mdnsd` daemon should be managed by the Solaris Management Facility (SMF) and should be administered by the `svcadm(1M)` command using the following fault management resource identifier (FMRI):

`svc:/network/dns/multicast:default`

To examine `mdnsd`'s internal state for debugging and diagnostic purposes, send it a SIGUSR1 signal, and it will then log a snapshot summary of its internal state using the `syslog(3C)` facility. `mdnsd` uses the syslog facility code daemon and info priority level.

**Options**

The `mdnsd` daemon recognizes the following option:

- `-debug`  
  Debug mode. The `mdnsd` daemon sends output to the standard error, and does not run in the background. This option is only intended for debugging the daemon.

**Configuration**

Multicast DNS can be used to look up host names and host addresses by specifying `mdns` as a source for hosts and ipnodes in the name service switch configuration file `nsswitch.conf(4)`. The configuration options for host name and host address queries using Multicast DNS are stored in the SMF repository. This configuration can be modified by the `svccfg(1M)` command using the following fault management resource identifier (FMRI):

`svc:/network/dns/multicast:default`

The configuration options for host name and host address queries using Multicast DNS are stored in a property group named "`nss_mdns_config`". The properties that make up the configuration options are as follows:

- `search`  
  A list of search domains for host name look up. By default, no search domains are included in the configuration. The search list is currently limited to six domains.

- `valid`  
  A list of valid domains checked before Multicast DNS is used to look up the host name or host address for a domain. Domains specified in the search list are always included in the valid list. The valid domain list is currently limited to ten domains.

Please note the above configuration options are Volatile and may change in a future release.

medstat - check the status of mediator hosts for a given diskset

/*usr/sbin/medstat [-q] -s setname
If a specified diskset has been configured for mediators, medstat attempts to contact these
hosts to see if they are accessible and returns the results of the communication.

-q
This optional argument disables the printing of informative text. When used
with -q, medstat still prints error messages and returns a result code.

-s setname Specifies the name of a diskset on which medstat will work.

EXAMPLE 1 Checking diskset
This example checks the mediator hosts for the selected diskset.

# medstat -s relo-red

The name of the diskset is relo-red. The medstat command prints the status for each
mediator host. Additionally, if the mediator quorum is met, either through a “golden”
mediator host or because half+1 of the mediator hosts respond, the exit code is 0. If the
quorum is not met, then the exit code is 1. If no mediator hosts have been configured for the
named diskset, the exit code is 2. The status field will contain one of the following values:
Unreachable, Bad, Fatal, or Ok, where Unreachable indicates an RPC/communication
problem, Bad indicates an error in the mediator data, Fatal indicates any other error
condition, and Ok indicates no error conditions.

/etc/lvm/meddb Contains the mediator data for a host that has been selected as a
mediator host.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE        ATTRIBUTE VALUE
Availability            storage/svm
Interface Stability     Committed

mediator(7D)

Sun Cluster documentation, Solaris Volume Manager Administration Guide
Notes  This command is designed for use in the high availability product.
metaclear – delete active metadevices and hot spare pools

**Synopsis**

```
/usr/sbin/metaclear -h
/usr/sbin/metaclear [-s setname] -a [-f]
/usr/sbin/metaclear component
/usr/sbin/metaclear [-s setname] [-f] metadevice... hot_spare_pool...
/usr/sbin/metaclear [-s setname] -r [-f] metadevice... hot_spare_pool...
/usr/sbin/metaclear [-s setname] -p component
/usr/sbin/metaclear [-s setname] -p metadevice
```

**Description**

The `metaclear` command deletes the specified metadevice or `hot_spare_pool`, or purges all soft partitions from the designated component. Once a metadevice or hot spare pool is deleted, it must be re-created using `metainit` before it can be used again.

Any metadevice currently in use (open) cannot be deleted.

**Options**

Root privileges are required for all of the following options except `-h`.

- `-a` Deletes all metadevices and configured hot spare pools in the set named by `-s`, or the local set by default.
- `-f` Deletes (forcibly) a metadevice that contains a subcomponent in an error state.
- `-h` Displays usage message.
- `-p` Deletes (purges) all soft partitions from the specified metadevice or component.
- `-r` Recursively deletes specified metadevices and hot spare pools, but does not delete metadevices on which others depend.
- `-s setname` Specifies the name of the diskset on which `metaclear` will work. Using the `-s` option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices and/or hot spare pools.

**Operands**

- `metadevice...` Specifies the name(s) of the metadevice(s) to be deleted.
- `component` Specifies the `c*d*t*s*` name(s) of the components containing soft partitions to be deleted.
- `hot_spare_pool...` Specifies the name(s) of the hot spare pools to be deleted. Names for hot spare pools can be any legal file name that is composed of alphanumeric characters, a dash ("-"), an underscore ("_"), or a period ("."). Names must begin with a letter. The words "all" and "none" are reserved and cannot be used.
Examples

**EXAMPLE 1**  Deleting Various Devices

The following example deletes a metadevice named d10.

```
# metaclear /dev/md/dsk/d10
```

The following example deletes all local metadevices and hot spare pools on the system.

```
# metaclear -a
```

The following example deletes a mirror, mymirror, with a submirror in an error state.

```
# metaclear -f mymirror
```

The following example deletes a hot spare pool, hsp001.

```
# metaclear hsp001
```

The following example deletes a soft partition, d23.

```
# metaclear d23
```

The following example purges all soft partitions on the slice c2t3d5s2 if those partitions are not being used by other metadevices or are not open.

```
# metaclear -p c2t3d5s2
```

The following example purges soft partitions from a metadevice.

```
# metaclear -p d2
d3: Soft Partition is cleared
d4: Soft Partition is cleared
d5: Soft Partition is cleared
```

**Exit Status**
The following exit values are returned:

- `0`  Successful completion.
- `>0`  An error occurred.

Solaris Volume Manager Administration Guide
metadb(1M)

Name  metadb – create and delete replicas of the metadevice state database

Synopsis  
/usr/sbin/metadb -h

/usr/sbin/metadb [-s setname]

/usr/sbin/metadb [-s setname] -a [-f] [-k system-file] mddb

/usr/sbin/metadb [-s setname] -a [-f] [-k system-file]
  [-c number] [-l length] slice...

/usr/sbin/metadb [-s setname] -d [-f] [-k system-file] mddb

/usr/sbin/metadb [-s setname] -d [-f] [-k system-file] slice...

/usr/sbin/metadb [-s setname] -i

/usr/sbin/metadb [-s setname] -p [-k system-file]
  [mddb.cf-file]

Description  The metadb command creates and deletes replicas of the metadevice state database. State
database replicas can be created on dedicated slices, or on slices that will later become part of a simple
metadevice (concatenation or stripe) or RAID5 metadevice. Do not place state
database replicas on fabric-attached storage, SANs, or other storage that is not directly
attached to the system and available at the same point in the boot process as traditional SCSI
or IDE drives. See NOTES.

The metadevice state database contains the configuration of all metadevices and hot spare
pools in the system. Additionally, the metadevice state database keeps track of the current
state of metadevices and hot spare pools, and their components. Solaris Volume Manager
automatically updates the metadevice state database when a configuration or state change
occurs. A submirror failure is an example of a state change. Creating a new metadevice is an
example of a configuration change.

The metadevice state database is actually a collection of multiple, replicated database copies.
Each copy, referred to as a replica, is subject to strict consistency checking to ensure
correctness.

Replicated databases have an inherent problem in determining which database has valid and
correct data. To solve this problem, Volume Manager uses a majority consensus algorithm.
This algorithm requires that a majority of the database replicas be available before any of them
are declared valid. This algorithm strongly encourages the presence of at least three initial
replicas, which you create. A consensus can then be reached as long as at least two of the three
replicas are available. If there is only one replica and the system crashes, it is possible that all
metadevice configuration data can be lost.

The majority consensus algorithm is conservative in the sense that it will fail if a majority
consensus cannot be reached, even if one replica actually does contain the most up-to-date
data. This approach guarantees that stale data will not be accidentally used, regardless of the
failure scenario. The majority consensus algorithm accounts for the following: the system will
stay running with exactly half or more replicas; the system will panic when less than half the replicas are available; the system will not reboot without one more than half the total replicas.

When used with no options, the `metadb` command gives a short form of the status of the metadevice state database. Use `metadb -i` for an explanation of the flags field in the output.

The initial state database is created using the `metadb` command with both the `-a` and `-f` options, followed by the slice where the replica is to reside. The `-a` option specifies that a replica (in this case, the initial) state database should be created. The `-f` option forces the creation to occur, even though a state database does not exist. (The `-a` and `-f` options should be used together only when no state databases exist.)

Additional replicas beyond those initially created can be added to the system. They contain the same information as the existing replicas, and help to prevent the loss of the configuration information. Loss of the configuration makes operation of the metadevices impossible. To create additional replicas, use the `metadb -a` command, followed by the name of the new slice(s) where the replicas will reside. All replicas that are located on the same slice must be created at the same time.

To delete all replicas that are located on the same slice, the `metadb -d` command is used, followed by the slice name.

When used with the `-i` option, `metadb` displays the status of the metadevice state databases. The status can change if a hardware failure occurs or when state databases have been added or deleted.

To fix a replica in an error state, delete the replica and add it back again.

The metadevice state database (mddb) also contains a list of the replica locations for this set (local or shared diskset).

The local set mddb can also contain host and drive information for each of the shared disksets of which this node is a member. Other than the diskset host and drive information stored in the local set mddb, the local and shared diskset mdibs are functionality identical.

The mdibs are written to during the resync of a mirror or during a component failure or configuration change. A configuration change or failure can also occur on a single replica (removal of a mdib or a failed disk) and this causes the other replicas to be updated with this failure information.

Options

Root privileges are required for all of the following options except `-h` and `-i`.

The following options can be used with the `metadb` command. Not all the options are compatible on the same command line. Refer to the `SYNOPSIS` to see the supported use of the options.
-a
Attach a new database device. The /kernel/drv/md.conf file is automatically updated with the new information and the /etc/lvm/mddb.cf file is updated as well. An alternate way to create replicas is by defining them in the /etc/lvm/md.tab file and specifying the assigned name at the command line in the form, mddbnn, where nn is a two-digit number given to the replica definitions. Refer to the md.tab(4) man page for instructions on setting up replicas in that file.

-c number
Specifies the number of replicas to be placed on each device. The default number of replicas is 1.

-d
Deletes all replicas that are located on the specified slice. The /kernel/drv/md.conf file is automatically updated with the new information and the /etc/lvm/mddb.cf file is updated as well.

-f
The -f option is used to create the initial state database. It is also used to force the deletion of replicas below the minimum of one. (The -a and -f options should be used together only when no state databases exist.)

-h
Displays a usage message.

-i
Inquire about the status of the replicas. The output of the -i option includes characters in front of the device name that represent the status of the state database. Explanations of the characters are displayed following the replica status and are as follows:

d
replica does not have an associated device ID.

-o
replica active prior to last mddb configuration change

-u
replica is up to date

-l
locator for this replica was read successfully

-c
replica's location was in /etc/lvm/mddb.cf

-p
replica's location was patched in kernel

-m
replica is master, this is replica selected as input
replica does not have device relocation information

tagged data is associated with the replica

replica has device write errors

replica is active, commits are occurring to this

replica had problem with master blocks

replica had problem with data blocks

replica had format problems

replica is too small to hold current database

replica had device read errors

tagged data associated with the replica is not valid

-k system-file
   Specifies the name of the kernel file where the replica information should be written. The default system-file is /kernel/drv/md.conf. This option is for use with the local diskset only.

-l length
   Specifies the size of each replica. The default length is 8192 blocks, which should be appropriate for most configurations. “Replica” sizes of less than 128 blocks are not recommended.

-p
   Specifies updating the system file (md.conf) in the current working directory with entries from the /etc/lvm/mddb.cf file. This option is normally used to update a newly built system before it is booted for the first time. If the system has been built on a system other than the one where it will run, the location of the mdcb.cf on the local machine can be passed as an argument. The system file to be updated can be changed using the -k option. This option is for use with the local diskset only.
-s setname
  Specifies the name of the diskset on which the metadb command will work. Using the -s option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local database replicas.

slice
  Specifies the logical name of the physical slice (partition), such as /dev/dsk/c0t0d0s3.

Examples

EXAMPLE 1  Creating Initial State Database Replicas
  The following example creates the initial state database replicas on a new system.
  # metadb -a -f c0t0d0s7 c0t1d0s3 c1t0d0s7 c1t1d0s3
  The -a and -f options force the creation of the initial database and replicas. You could then create metadevices with these same slices, making efficient use of the system.

EXAMPLE 2  Adding Two Replicas on Two New Disks
  This example shows how to add two replicas on two new disks that have been connected to a system currently running Volume Manager.
  # metadb -a c0t2d0s3 c1t1d0s3

EXAMPLE 3  Deleting Two Replicas
  This example shows how to delete two replicas from the system. Assume that replicas have been set up on /dev/dsk/c0t2d0s3 and /dev/dsk/c1t1d0s3.
  # metadb -d c0t2d0s3 c1t1d0s3
  Although you can delete all replicas, you should never do so while metadevices still exist. Removing all replicas causes existing metadevices to become inoperable.

Files

/etc/lvm/md.db.cf
  Contains the location of each copy of the metadevice state database.

/etc/lvm/md.tab
  Workspace file for metadevice database configuration.

/kernel/drv/md.conf
  Contains database replica information for all metadevices on a system. Also contains Solaris Volume Manager configuration information.

Exit Status

The following exit values are returned:

0
  successful completion

>&0
  an error occurred

Solaris Volume Manager Administration Guide

Notes Replicas cannot be stored on fabric-attached storage, SANs, or other storage that is not directly attached to the system. Replicas must be on storage that is available at the same point in the boot process as traditional SCSI or IDE drives. A replica can be stored on a:

- Dedicated local disk partition
- Local partition that will be part of a volume
- Local partition that will be part of a UFS logging device
metadevadm (1M)

Name
metadevadm – update metadevice information

Synopsis
/usr/sbin/metadevadm [-h] [-n] [-l] [-r] [-s setname]
[-u disk_specifier] [-v]

Description
The metadevadm command facilitates the administration of device ID entries in Solaris Volume Manager. Use this command when the pathname stored in the metadevice state database no longer correctly addresses the device or when a disk drive has had its device ID changed.

This command requires root privileges.

Options
The following options are supported.

- h
Provide a help display.

- l
Specify that metadevadm log to syslog(3C). metadevadm logs to the DAEMON facility at the ERR level by default. See syslog.conf(4) for additional information on changing logging levels.

Use this option anytime. It is most useful in startup scripts and less useful interactively.

- n
Emulate the effect of a command, without making any changes to the system.

- r
Recompute the pathname and disk specifier (including slice) associated with all devices in the metadevice state database if the device supports device IDs. If a device does not support device IDs or the device is not available, then no action is taken for that device.

Use this option when the disk has been moved or readdressed.

This option is run automatically at boot time to detect device ID changes and update the state database.

- s setname
Specify the name of the disk set on which metadevadm works. This option causes the command to perform its administrative function within the specified disk set. Without this option, the command performs its function on devices in the local disk set.

- u disk_specifier
Obtain the device ID associated with the disk_specifier (for example, c1t2d0) of a device and update the metadevice state database. If the device ID has not changed this option does nothing. Use this option when a disk drive has had its device ID changed during a firmware upgrade or due to changing the controller of a storage subsystem.

- v
Execute in verbose mode. This option has no effect when used with -u. Verbose is the default.
Examples

**EXAMPLE 1** Updating Device ID of Disk

The following example updates the device c2t3d0:

```
# metadevadm -u c2t3d0
```

Updating SLVM device relocation information for c2t3d0.
Old device reloc information: id19280192391293123012012010012012091398
New device reloc information: id19380192391293123012012010012012091398

The following example is a variation of the preceding, using the full pathname.

```
# metadevadm -u /dev/dsk/c2t3d0
```

The following example uses the -n option, which means that the command is emulated, but does not take effect. Note that when the -v option is used with -u, -v has no effect (verbose is the default).

```
# metadevadm -u -v -n c2t3d0
```

Updating SLVM device relocation information for c2t3d0.
Old device reloc information: id19280192391293123012012010012012091398
New device reloc information: id19380192391293123012012010012012091398

**EXAMPLE 2** Recomputing Pathnames

In the following example, all device names are valid.

```
# metadevadm -r
```

Disk movement detected.
Updating device names in SLVM.

In the following example, once again device names are valid.

```
# metadevadm -r -v
```

Disk movement detected.
Updating device names in SLVM.
c0t0d0s0 changed to c0t0d1s0 from device relocation information
id12098123lkmklsljaasadkfdjfadkfdjaksd

In the following example, metadevadm detects an invalid device name.

```
# metadevadm -r
```

Invalid device relocation information detected in SLVM.
Please check status of following disk(s): c3t0d0

**Return Values**

The following exit values are returned:

- **0** Command was successful.
- **1** metadevadm encountered an error condition.
An invalid device ID was detected when using the -r option. This is for use in the rc2.d script. See init.d(4).

**Attributes**  See attributes(5) for descriptions of the following attributes:

*Solaris Volume Manager Administration Guide*
Name

metahs – manage hot spares and hot spare pools

Synopsis

/usr/sbin/metahs [-s setname] -a all component
/usr/sbin/metahs [-s setname] -a hot_spare_pool [component]
/usr/sbin/metahs [-s setname] -d hot_spare_pool [component]
/usr/sbin/metahs [-s setname] -d all component
/usr/sbin/metahs [-s setname] -e component
/usr/sbin/metahs [-s setname] -r hot_spare_pool component-old
/usr/sbin/metahs [-s setname] -r all component-old component-new
/usr/sbin/metahs [-s setname] -i [hot_spare_pool]...

Description

The metahs command manages existing hot spares and hot spare pools. It is used to add, delete, enable, and replace components (slices) in hot spare pools. Like the metainit command, the metahs command can also create an initial hot spare pool. The metahs command does not replace a component of a metadevice. This function is performed by the metareplace command.

Hot spares are always in one of three states: available, in-use, or broken. Available hot spares are running and ready to accept data, but are not currently being written to or read from. In-use hot spares are currently being written to and read from. Broken hot spares are out of service and should be repaired. The status of hot spares is displayed when metahs is invoked with the -i option.

Solaris Volume Manager supports storage devices and logical volumes, including hot spares, greater than 1 terabyte (TB) when Solaris 10 is running a 64-bit kernel.

If a system with large volumes or hot spares is rebooted under a 32-bit Solaris 10 kernel, the large volumes are visible through metastat output, but they cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are also unavailable. If a system with large volumes is rebooted under a version of Solaris prior to Solaris 10, Solaris Volume Manager will not start. All large volumes must be removed before Solaris Volume Manager runs under another version of the Solaris Operating Environment.

Options

Root privileges are required for any of the following options except -i.

The following options are supported:

-a all component
Add component to all hot spare pools. all is not case sensitive.

-a hot_spare_pool [component]
Add the component to the specified hot_spare_pool. hot_spare_pool is created if it does not already exist.
-d all component 
Delete component from all the hot spare pools. The component cannot be deleted if it is in the in-use state.

-d hot_spare_pool [component] 
Delete hot_spare_pool, if the hot_spare_pool is both empty and not referenced by a metadevice. If component is specified, it is deleted from the hot_spare_pool. Hot spares in the in-use state cannot be deleted.

-e component 
Enable component to be available for use as a hot spare. The component can be enabled if it is in the broken state and has been repaired.

-i [hot_spare_pool . . .] 
Display the status of the specified hot_spare_pool or for all hot spare pools if one is not specified.

-r all component-old component-new 
Replace component-old with component-new in all hot spare pools which have the component associated. Components cannot be replaced from any hot spare pool if the old hot spare is in the in-use state.

-r hot_spare_pool component-old component-new 
Replace component-old with component-new in the specified hot_spare_pool. Components cannot be replaced from a hot spare pool if the old hot spare is in the in-use state.

-s setname 
Specify the name of the diskset on which metahs works. Using the -s option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local hot spare pools.

Operands  The following operands are supported:

component 
The logical name for the physical slice (partition) on a disk drive, such as /dev/dsk/c0t0d0s2.

hot_spare_pool 
Names for hot spare pools can be any legal file name that is composed of alphanumeric characters, a dash (“-”), an underscore (“_”), or a period.
Names must begin with a letter. The words “all” and “none” are reserved and cannot be used.

Examples

**EXAMPLE 1**  Adding a Hot Spare to a Hot Spare Pool

The following example adds a hot spare /dev/dsk/c0t0d0s7 to a hot spare pool mirror1_pool:

```
# metahs -a mirror1_pool c0t0d0s7
```

When the hot spare is added to the pool, the existing order of the hot spares already in the pool is preserved. The new hot spare is added at the end of the list of hot spares in the hot spare pool specified.

**EXAMPLE 2**  Adding a Hot Spare to All Currently Defined Pools

This example adds a hot spare to the hot spare pools that are currently defined:

```
# metahs -a all c0t0d0s7
```

The keyword all in this example specifies adding the hot spare, /dev/dsk/c0t0d0s7, to all the hot spare pools.

**EXAMPLE 3**  Deleting a Hot Spare

This example deletes a hot spare, /dev/dsk/c0t0d0s7, from a hot spare pool, hsp003:

```
# metahs -d hsp003 c0t0d0s7
```

When you delete a hot spare, the position of the remaining hot spares in the pool changes to reflect the new order. For instance, if in this example /dev/dsk/c0t0d0s7 were the second of three hot spares, after deletion the third hot spare would move to the second position.

**EXAMPLE 4**  Replacing a Hot Spare

This example replaces a hot spare that was previously defined:

```
# metahs -r hsp001 c0t1d0s0 c0t3d0s0
```

In this example, the hot spare /dev/dsk/c0t1d0s0 is replaced by /dev/dsk/c0t3d0s0. The order of the hot spares does not change.

**Exit Status**

The following exit values are returned:

- `0`  Successful completion.
- `>0`  An error occurred.

Solaris Volume Manager Administration Guide

Warnings

Do not create large (>1 TB) volumes if you expect to run the Solaris Operating Environment with a 32-bit kernel or if you expect to use a version of the Solaris Operating Environment prior to Solaris 10.
metaimport – imports disk sets into existing Solaris Volume Manager configurations

Synopsis
metaimport -s setname [-n] [-f] [-v] [disks]...
metaimport -r [-v] [disks]...
metaimport -V
metaimport -?

Description
The metaimport command allows the importing of disk sets, including replicated disk sets, into an existing Solaris Volume Manager configuration. Replicated disk sets are disk sets created using remote replication software.

The default Solaris Volume Manager configuration specifies a maximum number of disk sets that can be configured. The metaimport command fails if importing the disk set would result in exceeding the number of disk sets configured on the system. To increase the number of disk sets allowed on a system, see the Solaris Volume Manager Administration Guide.

Use metaset(1M) or metastat(1M) to view the configuration of the imported set.

You must run metaimport as root.

metaimport requires a functional Solaris Volume Manager configuration before it runs.

Options
The following options are supported:

-f Force the import, even if a quorum of replicas from the imported disk set is not available. This option could result in corrupt configurations and should only be used when metaimport fails with the "Insufficient quorum detected; exiting" error. If only a partial disk set is available, this option might be necessary to successfully import. Some or all data could be corrupted or unavailable when importing a partial set or a set lacking a replica quorum.

-n Does not actually perform the operation, but shows the output or errors that would have resulted from the operation, had it been run.

-r Report on the non-configured disk sets found on the system. If no disk device or LUN is specified, metaimport reports on all non-configured disk sets attached to the system. When the name of one disk is specified, metaimport reports on the disk set (or virtual LUN) containing the specified disk. If two or more disks are specified, metaimport reports on the set (or sets, if they belong to different disk sets) containing the specified disks. If two or more disks are specified, metaimport reports on the set (or sets, if they belong to different disk sets) containing the specified disks.

This option can be used in conjunction with the -v option to give verbose output on each disk set reported.
metainport(1M)

- `s setname` Specify the disk set name to use when importing. The imported disk set will be called `setname`, without regard to the name it may have had on a different system.

- `v` Verbose. Provides detailed information about the metadb replica location and status. It also provides detailed information about the disk set configuration and status similar to the "metastat -c" output.

- `V` Version information.

- `?` Display a help message.

Examples

**EXAMPLE 1  Importing a Disk Set**

The following example creates a disk set called `blue` and identifies `c1t5d0` as a disk containing a state database replica from the disk set being imported.

```
# metaimport -s blue c1t5d0
```

**EXAMPLE 2  Reporting Disk Sets to Import**

The following example scans all disks and LUNs attached to the system and configured as part of the system. It scans for disks that could be part of a disk set to be imported. Components that are already part of the Solaris Volume Manager configuration are ignored.

This use of `metaimport` provides suggested forms of the `metaimport` command to use to actually import the disk sets that have been found. You can specify a component on the command line to reduce the scope of the scan and generate results more quickly.

```
# metaimport -r
```

Exit Status

- `0` Successful completion.
- `>0` An error occurred.

Solaris Volume Manager Administration Guide
metainit(1M)

### Name
metainit – configure metadevices

### Synopsis
```
/usr/sbin/metainit -h

/usr/sbin/metainit [generic options] concat/stripe numstripes width component... [-i interlace]

/usr/sbin/metainit [width component... [-i interlace]]
    [-h hot_spare_pool]

/usr/sbin/metainit [generic options] mirror -m submirror [read_options] [write_options] [pass_num]

/usr/sbin/metainit [generic options] RAID -r component...
    [-i interlace]
    [-h hot_spare_pool] [-k] [-o original_column_count]

/usr/sbin/metainit [generic options] hot_spare_pool [hotspare...]

/usr/sbin/metainit [generic options] metadevice-name

/usr/sbin/metainit [generic options] -a

/usr/sbin/metainit -r
```

### Description
The `metainit` command configures metadevices and hot spares according to the information specified on the command line. Alternatively, you can run `metainit` so that it uses configuration entries you specify in the `/etc/lvm/md.tab` file (see `md.tab(4)`). All metadevices must be set up by the `metainit` command before they can be used.

Solaris Volume Manager supports storage devices and logical volumes greater than 1 terabyte (TB) when a system runs a 64-bit Solaris kernel. Support for large volumes is automatic. If a device greater than 1 TB is created, Solaris Volume Manager configures it appropriately and without user intervention.

If a system with large volumes is rebooted under a 32–bit Solaris kernel, the large volumes are visible through `metastat` output. Large volumes cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are unavailable. If a system with large volumes is rebooted under a version of Solaris prior to the Solaris 9 4/03 release, Solaris Volume Manager does not start. You must remove all large volumes before Solaris Volume Manager runs under an earlier version of the Solaris Operating System.

If you edit the `/etc/lvm/md.tab` file to configure metadevices, specify one complete configuration entry per line. You then run the `metainit` command with either the `-a` option, to activate all metadevices you entered in the `/etc/lvm/md.tab` file, or with the metadevice name corresponding to a specific configuration entry.
metainit does not maintain the state of the volumes that would have been created when metainit is run with both the -a and -n flags. Any volumes in md.tab that have dependencies on other volumes in md.tab are reported as errors when metainit -a -n is run, although the operations might succeed when metainit -a is run. See md.tab(4).

Solaris Volume Manager never updates the /etc/lvm/md.tab file. Complete configuration information is stored in the metadevice state database, not md.tab. The only way information appears in md.tab is through editing it by hand.

When setting up a disk mirror, the first step is to use metainit create a one-on-one concatenation for the named slice. See EXAMPLES.

**Options**
The following options are supported:

**Generic Options**
Root privileges are required for all of the following options except -h.

The following generic options are supported:

- **-f**
  Forces the metainit command to continue even if one of the slices contains a mounted file system or is being used as swap, or if the stripe being created is smaller in size than the underlying soft partition. This option is required when configuring mirrors on swap.

- **-h**
  Displays usage message.

- **-n**
  Checks the syntax of your command line or md.tab entry without actually setting up the metadevice. If used with -a, all devices are checked but not initialized.

- **-r**
  Only used in a shell script at boot time. Sets up all metadevices that were configured before the system crashed or was shut down. The information about previously configured metadevices is stored in the metadevice state database (see metadb(1M)).

- **-s setname**
  Specifies the name of the diskset on which metainit works. Without the -s option, the metainit command operates on your local metadevices and/or hotspares.

**Concat/Stripe Options**
The following concat/stripe options are supported:

- **concat/stripe**
  Specifies the metadevice name of the concatenation, stripe, or concatenation of stripes being defined.

- **numstripes**
  Specifies the number of individual stripes in the metadevice. For a simple stripe, numstripes is always 1. For a concatenation, numstripes is equal to the number of slices. For a concatenation of stripes, numstripes varies according to the number of stripes.
**width**
Specifies the number of slices that make up a stripe. When *width* is greater than 1, the slices are striped.

**component**
The logical name for the physical slice (partition) on a disk drive, such as /dev/dsk/c0t0d0s0. For RAID level 5 metadevices, a minimum of three slices is necessary to enable striping of the parity information across slices.

**-i interlace**
Specifies the interlace size. This value tells Solaris Volume Manager how much data to place on a slice of a striped or RAID level 5 metadevice before moving on to the next slice. *interlace* is a specified value, followed by either 'k' for kilobytes, 'm' for megabytes, or 'b' for blocks. The characters can be either uppercase or lowercase. The *interlace* specified cannot be less than 16 blocks, or greater than 100 megabytes. If *interlace* is not specified, it defaults to 512 kilobytes.

**-h hot_spare_pool**
Specifies the *hot_spare_pool* to be associated with the metadevice. If you use the command line, the hot spare pool must have been previously created by the *metainit* command before it can be associated with a metadevice. Use /-h hspnmm when the concat/striped being created is to be used as a submirror.

Names for hot spare pools can be any legal filename that is composed of alphanumeric characters, a dash (“-”), an underscore (“_”), or a period (“.”). Names must begin with a letter. The words “all” and “none” are reserved and cannot be used.

**Mirror Options**
The following mirror options are supported:

**mirror -m submirror**
Specifies the metadevice name of the mirror. The *-m* indicates that the configuration is a mirror. *submirror* is a metadevice (stripe or concatenation) that makes up the initial one-way mirror. Solaris Volume Manager supports a maximum of four-way mirroring. When defining mirrors, first create the mirror with the *metainit* command as a one-way mirror. Then attach subsequent submirrors using the *metattach* command. This method ensures that Solaris Volume Manager properly syncs the mirrors. (The second and any subsequent submirrors are first created using the *metainit* command.)

**read_options**
The following read options for mirrors are supported:

**-g**
Enables the geometric read option, which results in faster performance on sequential reads.

**-r**
Directs all reads to the first submirror. This should only be used when the devices comprising the first submirror are substantially faster than those of the second mirror. This flag cannot be used with the *-g* flag.
If neither the `-g` nor `-r` flags are specified, reads are made in a round-robin order from all submirrors in the mirror. This enables load balancing across the submirrors.

**write_options**
The following write options for mirrors are supported:

- `-S`
  Performs serial writes to mirrors. The first submirror write completes before the second is started. This can be useful if hardware is susceptible to partial sector failures. If `-S` is not specified, writes are replicated and dispatched to all mirrors simultaneously.

**pass_num**
A number in the range 0-9 at the end of an entry defining a mirror that determines the order in which that mirror is resynced during a reboot. The default is 1. Smaller pass numbers are resynced first. Equal pass numbers are run concurrently. If 0 is used, the resync is skipped. 0 should be used only for mirrors mounted as read-only, or as swap.

**RAID Level 5 Options**
The following RAID level 5 options are available:

- `-r`
  Specifies the name of the RAID level 5 metadevice. The `-r` specifies that the configuration is RAID level 5.

- `-k`
  For RAID level 5 metadevices, informs the driver that it is not to initialize (zero the disk blocks) due to existing data. Only use this option to recreate a previously created RAID level 5 device.

  Use the `-k` option with extreme caution. This option sets the disk blocks to the `OK` state. If any errors exist on disk blocks within the metadevice, Solaris Volume Manager might begin fabricating data. Instead of using the `-k` option, you might want to initialize the device and restore data from tape.

- `-o original_column_count`
  For RAID level 5 metadevices, used with the `-k` option to define the number of original slices in the event the originally defined metadevice was grown. This is necessary since the parity segments are not striped across concatenated devices.

  Use the `-o` option with extreme caution. This option sets the disk blocks to the `OK` state. If any errors exist on disk blocks within the metadevice, Solaris Volume Manager might begin fabricating data. Instead of using the `-o` option, you might want to initialize the device and restore data from tape.

**Soft Partition Options**
The following soft partition options are supported:

- `softpart [-p] [-e] component [-A alignment] size`
  The `softpart` argument specifies the name of the soft partition. The `-p` specifies that the configuration is a soft partition.
The -e specifies that the entire disk specified by component as c*t*d* should be repartitioned and reserved for soft partitions. The specified component is repartitioned such that slice 7 reserves space for system (state database replica) usage and slice 0 contains all remaining space on the disk. Slice 7 is a minimum of 4MB, but can be larger, depending on the disk geometry. The newly created soft partition is placed on slice 0 of the device.

The component argument specifies the disk (c*t*d*), slice (c*t*d*s*), or meta device (d*) from which to create the soft partition. The size argument determines the space to use for the soft partition and can be specified in K or k for kilobytes, M or m for megabytes, G or g for gigabytes, T or t for terabyte (one terabyte is the maximum size), and B or b for blocks (sectors). All values represent powers of 2, and upper and lower case options are equivalent. Only integer values are permitted.

The -A alignment option sets the value of the soft partition extent alignment. This option used when it is important specify a starting offset for the soft partition. It preserves the data alignment between the metadevice address space and the address space of the underlying physical device. For example, a hardware device that does checksumming should not have its I/O requests divided by Solaris Volume Manager. In this case, use a value from the hardware configuration as the value for the alignment. When you use this option in conjunction with a software I/O load, the alignment value corresponds to the I/O load of the application. This prevents I/O from being divided unnecessarily and affecting performance.

The literal all, used instead of specifying size, specifies that the soft partition should occupy all available space on the device.

Hot Spare Pool Options
The following hot spare pool options are supported:

```
hot_spare_pool [ hotspare... ]
```

When used as arguments to the metainit command, hot_spare_pool defines the name for a hot spare pool, and hotspare... is the logical name for the physical slice(s) for availability in that pool. Names for hot spare pools can be any legal file name that is composed of alphanumeric characters, a dash (“-”), an underscore (“_”), or a period (“.”). Names must begin with a letter. The words “all” and “none” are reserved and cannot be used.

md.tab File Options
The following md.tab file options are supported:

```
metadevice-name
```

When the metainit command is run with a metadevice-name as its only argument, it searches the /etc/lvm/md.tab file to find that name and its corresponding entry. The order in which entries appear in the md.tab file is unimportant. For example, consider the following md.tab entry:

```
d0 2 1 c1t0d0s0 1 c2t1d0s0
```

When you run the command metainit d0, it configures metadevice d0 based on the configuration information found in the md.tab file.
-a
Activates all metadevices defined in the md.tab file.

`metainit` does not maintain the state of the volumes that would have been created when `metainit` is run with both the `-a` and `-n` flags. If a device d0 is created in the first line of the md.tab file, and a later line in md.tab assumes the existence of d0, the later line fails when `metainit -an` runs (even if it would succeed with `metainit -a`).

**Examples**

**EXAMPLE 1  Creating a One-on-One Concatenation**

The following command creates a one-on-one concatenation for the root slice. This is the first step you take when setting up a mirror for any other slice that cannot be unmounted. The `-f` option is required to create a volume with an existing file system.

```
# metainit -f d1 1 1 c0t0d0s0
```

The preceding command makes d1 a one-on-one concatenation, using the named slice. You can then enter:

```
# metainit d0 -m d1
```

...to make a one-way mirror of the named slice.

**EXAMPLE 2  Concatenation**

All drives in the following examples have the same size of 525 Mbytes.

This example shows a metadevice, `/dev/md/dsk/d7`, consisting of a concatenation of four slices.

```
# metainit d7 4 1 c0t1d0s0 1 c0t2d0s0 1 c0t3d0s0 1 /dev/dsk/c0t4d0s0
```

The number 4 indicates there are four individual stripes in the concatenation. Each stripe is made of one slice, hence the number 1 appears in front of each slice. The first disk sector in all of these devices contains a disk label. To preserve the labels on devices `/dev/dsk/c0t2d0s0`, `/dev/dsk/c0t3d0s0`, and `/dev/dsk/c0t4d0s0`, the metadisk driver must skip at least the first sector of those disks when mapping accesses across the concatenation boundaries. Because skipping only the first sector would create an irregular disk geometry, the entire first cylinder of these disks is skipped. This allows higher level file system software to optimize block allocations correctly.

**EXAMPLE 3  Stripe**

This example shows a metadevice, `/dev/md/dsk/d15`, consisting of two slices.

```
# metainit d15 1 2 c0t1d0s0 c0t2d0s0 -i 32k
```

The number 1 indicates that one stripe is being created. Because the stripe is made of two slices, the number 2 follows next. The optional `-i` followed by 32k specifies the interlace size as 32 Kbytes. If the interlace size were not specified, the stripe would use the default value of 16
EXAMPLE 3  Stripe  

(Continued)

Kbytes.

EXAMPLE 4  Concatentation of Stripes

This example shows a metadevice, /dev/md/dsk/d75, consisting of a concatenation of two stripes of three disks.

```
# metainit d75 2 3 c0t1d0s0 c0t2d0s0 \ 
  c0t3d0s0 -i 16k \ 
  3 c1t1d0s0 c1t2d0s0 c1t3d0s0 -i 32k
```

On the first line, the -i followed by 16k specifies that the stripe interlace size is 16 Kbytes. The second set specifies the stripe interlace size as 32 Kbytes. If the second set did not specify 32 Kbytes, the set would use the default interlace value of 16 Kbytes. The blocks of each set of three disks are interlaced across three disks.

EXAMPLE 5  Mirroring

This example shows a two-way mirror, /dev/md/dsk/d50, consisting of two submirrors. This mirror does not contain any existing data.

```
# metainit d51 1 1 c0t1d0s0
# metainit d52 1 1 c0t2d0s0
# metainit d50 -m d51
# metattach d50 d52
```

In this example, two submirrors, d51 and d52, are created with the metainit command. These two submirrors are simple concatenations. Next, a one-way mirror, d50, is created using the -m option with d51. The second submirror is attached later using the metattach command. When creating a mirror, any combination of stripes and concatenations can be used. The default read and write options in this example are a round-robin read algorithm and parallel writes to all submirrors.

EXAMPLE 6  Creating a metadevice in a diskset

This example shows a metadevice, /dev/md/dsk/d75, consisting of a concatenation of two stripes within a diskset called set1.

```
# metainit -s set1 d75 2 3 c2t1d0s0 c2t2d0s0 \ 
  c2t3d0s0 -i 32k
# metainit -s set1 d51 1 1 c2t1d0s0
# metainit -s set1 d52 1 1 c3t1d0s0
# metainit -s set1 d50 -m d51
# metattach -s set1 d50 d52
```

In this example, a diskset is created using the metaset command. Metadevices are then created within the diskset using the metainit command. The two submirrors, d51 and d52, are simple concatenations. Next, a one-way mirror, d50, is created using the -m option with
EXAMPLE 6  Creating a metadevice in a diskset  (Continued)

d51. The second submirror is attached later using the metattach command. When creating a
mirror, any combination of stripes and concatenations can be used. The default read and write
options in this example are a round-robin read algorithm and parallel writes to all submirrors.

EXAMPLE 7  RAID Level 5
This example shows a RAID level 5 device, d80, consisting of three slices:

```
# metainit d80 -r c1t0d0s0 c1t1d0s0 c1t3d0s0 -i 20k
```

In this example, a RAID level 5 metadevice is defined using the -r option with an interlace size
of 20 Kbytes. The data and parity segments are striped across the slices, c1t0d0s0, c1t2d0s0,
and c1t3d0s0.

EXAMPLE 8  Soft Partition
The following example shows a soft partition device, d1, built on metadevice d100 and 100
Mbytes (indicated by 100M) in size:

```
# metainit d1 -p d100 100M
```

The preceding command creates a 100 Mbyte soft partition on the d100 metadevice. This
metadevice could be a RAID level 5, stripe, concatenation, or mirror.

EXAMPLE 9  Soft Partition on Full Disk
The following example shows a soft partition device, d1, built on disk c3t4d0:

```
# metainit d1 -p -e c3t4d0 9G
```

In this example, the disk is repartitioned and a soft partition is defined to occupy all 9 Gbytes
of disk c3t4d0s0.

EXAMPLE 10  Soft Partition Taking All Available Space
The following example shows a soft partition device, d1, built on disk c3t4d0:

```
# metainit d1 -p -e c3t4d0 all
```

In this example, the disk is repartitioned and a soft partition is defined to occupy all available
disk space on slice c3t4d0s0.

EXAMPLE 11  Hot Spare
This example shows a two-way mirror, /dev/md/dsk/d10, and a hot spare pool with three hot
spare components. The mirror does not contain any existing data.

```
# metainit hsp001 c2t2d0s0 c3t2d0s0 c1t2d0s0
# metainit d41 1 1 c1t0d0s0 -h hsp001
# metainit d42 1 1 c3t0d0s0 -h hsp001
```
**EXAMPLE 11**  Hot Spare  
(Continued)

```plaintext
# metainit d40 -m d41
# metattach d40 d42
```

In this example, a hot spare pool, hsp001, is created with three slices from three different disks used as hot spares. Next, two submirrors are created, d41 and d42. These are simple concatenations. The `metainit` command uses the `-h` option to associate the hot spare pool hsp001 with each submirror. A one-way mirror is then defined using the `-m` option. The second submirror is attached using the `metattach` command.

**EXAMPLE 12**  Setting the Value of the Soft Partition Extent Alignment

This example shows how to set the alignment of the soft partition to 1 megabyte.

```plaintext
# metainit -s red d13 -p clt3d0s4 -A 1m 4m
```

In this example the soft partition, d13, is created with an extent alignment of 1 megabyte. The `metainit` command uses the `-A` option with an alignment of 1m to define the soft partition extent alignment.

**Files**

/`etc/lvm/md.tab`

Contains list of metadevice and hot spare configurations for batch-like creation.

**Warnings**

This section contains information on different types of warnings.

**Devices and Volumes Greater Than 1 TB**

Do not create large (>1 TB) volumes if you expect to run the Solaris Operating Environment with a 32–bit kernel or if you expect to use a version of the Solaris Operating Environment prior to Solaris 10.

**Multi-Way Mirror**

Do not use the `metainit` command to create a multi-way mirror. Rather, create a one-way mirror with `metainit` then attach additional submirrors with `metattach`. When the `metattach` command is not used, no resync operations occur and data could become corrupted.

If you use `metainit` to create a mirror with multiple submirrors, the following message is displayed:

WARNING: This form of metainit is not recommended.
The submirrors may not have the same data.
Please see ERRORS in metainit(1M) for additional information.

**Truncation of Soft Partitions**

When creating stripes on top of soft partitions it is possible for the size of the new stripe to be less than the size of the underlying soft partition. If this occurs, `metainit` fails with an error indicating the actions required to overcome the failure.

If you use the `-f` option to override this behavior, the following message is displayed:

WARNING: This form of metainit is not recommended.
The stripe is truncating the size of the underlying device.
Please see ERRORS in metainit(1M) for additional information.
When mirroring data in Solaris Volume Manager, transfers from memory to the disks do not all occur at exactly the same time for all sides of the mirror. If the contents of buffers are changed while the data is in-flight to the disk (called write-on-write), then different data can end up being stored on each side of a mirror.

This problem can be addressed by making a private copy of the data for mirror writes, however, doing this copy is expensive. Another approach is to detect when memory has been modified across a write by looking at the dirty-bit associated with the memory page. Solaris Volume Manager uses this dirty-bit technique when it can. Unfortunately, this technique does not work for raw I/O or direct I/O. By default, Solaris Volume Manager is tuned for performance with the liability that mirrored data might be out of sync if an application does a “write-on-write” to buffers associated with raw I/O or direct I/O. Without mirroring, you were not guaranteed what data would actually end up on media, but multiple reads would return the same data. With mirroring, multiple reads can return different data. The following line can be added to /etc/system to cause a stable copy of the buffers to be used for all raw I/O and direct I/O write operations.

```
set md_mirror:md_mirror_wow_flg=0x20
```

Setting this flag degrades performance.

**Exit Status**

The following exit values are returned:

0

Successful completion.

>0

An error occurred.

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>

**Limitations**

Recursive mirroring is not allowed; that is, a mirror cannot appear in the definition of another mirror.

Recursive logging is not allowed; that is, a trans metadevice cannot appear in the definition of another metadevice.

Stripes, concatenations, and RAID level 5 metadevices must consist of slices only.
Mirroring of RAID level 5 metadevices is not allowed.

Soft partitions can be built on raw devices, or on stripes, RAID level 5, or mirrors.

RAID level 5 or stripe metadevices can be built directly on soft partitions.

**Notes**  
Trans metadevices have been replaced by UFS logging. Existing trans devices are not logging—they pass data directly through to the underlying device. See `mount_ufs(1M)` for more information about UFS logging.
metaoffline(1M)

**Name**
metaoffline, metaonline – place submirrors offline and online

**Synopsis**
/usr/sbin/metaoffline -h
/usr/sbin/metaoffline [-s setname] [-f] mirror submirror
/usr/sbin/metaonline -h
/usr/sbin/metaonline [-s setname] mirror submirror

**Description**
The `metaoffline` command prevents Solaris Volume Manager from reading and writing to the submirror that has been taken offline. While the submirror is offline, all writes to the mirror will be kept track of (by region) and will be written when the submirror is brought back online. The `metaoffline` command can also be used to perform online backups: one submirror is taken offline and backed up while the mirror remains accessible. (However, if this is a two-way mirror, data redundancy is lost while one submirror is offline.) The `metaoffline` command differs from the `metadetach` command because it does not sever the logical association between the submirror and the mirror. To completely remove a submirror from a mirror, use the `metadetach` command.

A submirror that has been taken offline will only remain offline until the `metaonline` command is invoked or the system is rebooted.

When the `metaonline` command is used, reading from and writing to the submirror resumes. A resync is automatically invoked to resync the regions written while the submirror was offline. Writes are directed to the submirror during resync. Reads, however, will come from a different submirror. Once the resync operation completes, reads and writes are performed on that submirror. The `metaonline` command is only effective on a submirror of a mirror that has been taken offline.

The `metaoffline` and `metaonline` commands cannot be used on RAID 1 volumes in application-based recovery (ABR) mode.

A submirror that has been taken offline with the `metaoffline` command can only be mounted as read-only.

**Options**
Root privileges are required for all of the following options except `-h`.

- `-f`
  Forces offlineing of submirrors that have slices requiring maintenance.
- `-h`
  Displays usage message.
- `-s setname`
  Specifies the name of the diskset on which `metaoffline` and `metaonline` will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local metadevices.
- `mirror`
  Specifies the metadevice name of the mirror from which the submirror will be either taken offline or put online.
submirror

Specifies the metadevice name of the submirror to be either taken offline or put online.

Examples

EXAMPLE 1  Taking a Submirror Offline

This example takes one submirror, mymirror_sub1, offline from mirror mymirror.

# metaoffline mymirror mymirror_sub1

Exit Status

The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Solaris Volume Manager Administration Guide

Notes

The metaonline and metaoffline commands are not applicable to mirrors in application-based recovery (ABR) mode.
The `metaparam` command is used to display or modify current parameters of metadevices. If just the metadevice is specified as an argument to the `metaparam` command, the current settings are displayed. The `metaparam` command enables most metadevice (volume) parameters to be changed. Only the interlace value cannot be changed by `metaparam`, because it is established when the metadevice is created and cannot be changed thereafter.

Root privileges are required for all of the options.

The following options are supported:

- **-h**
  Displays usage message.

- **-s setname**
  Specify the name of the diskset on which `metaparam` works. Using the `-s` option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices.

**Concat/STRIPE or RAID5 Options**

- **--hot_spare_pool | none**
  Specifies the hot spare pool to be used by a metadevice. If `none` is specified, the metadevice is disassociated with the hot spare pool assigned to it. If the metadevice is currently using a hot spare, then `metaparam` cannot replace the hot spare pool.

- **concat/stripe | RAID**
  Specifies the metadevice name of the concatenation, stripe, or concatenation of stripes, or of the RAID5 metadevice.

**Mirror Options**

- **-r roundrobin | geometric | first**
  Modifies the read option for a mirror. The `-r` option must be followed by either `roundrobin`, `geometric`, or `first`. `roundrobin`, which is the default action under the `metainit` command, specifies reading the disks in a round-robin (load balancing) method. `geometric` allows for faster performance on sequential reads. `first` specifies reading only from the first submirror.

- **-w parallel | serial**
  Modifies the write option for a mirror. The `-w` option must be followed by either `parallel` or `serial`. `parallel`, the default action under the `metainit` command, specifies that all writes are parallel. `serial` specifies that all writes are serial.
-p pass_number
A number from 0 to 9 that specifies the order in which a mirror is resynced during reboot. The default is 1. Smaller pass numbers are resynced first. Equal pass numbers are run concurrently. If 0 is used, the mirror resync is skipped. 0 should only be used for mirrors mounted as read-only, or as swap.

mirror
Specifies the metadevice name of the mirror.

Examples

EXAMPLE 1  Associating Hot Spare Pool with RAID5 Metadevice
This example associates a hot spare pool, user_pool, with a RAID5 metadevice, user_raid.

# metaparam -h user_pool user_raid

EXAMPLE 2  Changing Read Option to Geometric
This example changes the read option on a mirror d50 from the default of roundrobin to geometric.

# metaparam -r geometric d50

Exit Status
The following exit values are returned:

0
Successful completion.

>0
An error occurred.

See Also
mdmonitor(1M), metaclear(1M), metadb(1M), metadetach(1M), metahs(1M), metainit(1M), metaoffline(1M), metaonline(1M), metarecover(1M), metarename(1M), metareplace(1M), metaset(1M), metassist(1M), metastat(1M), metasync(1M), metattach(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), attributes(5), md(7D)

Solaris Volume Manager Administration Guide
**Synopsis**

```bash
/usr/sbin/metarecover [-n] [-v] [-s setname] component -p
```

```bash
/usr/sbin/metarecover [-n] [-v] [-s setname] component -p {-d}
```

```bash
/usr/sbin/metarecover [-n] [-v] [-s setname] component -p {-m}
```

**Description**

The `metarecover` command scans a specified component to look for soft partition configuration information and to regenerate the configuration.

**Options**

The following options are supported:

- `-d`
  
  Recover soft partitions in the metadevice state database from the extent headers on the device. Options `-d` and `-m` are mutually exclusive.

- `-m`
  
  Regenerate the extent headers and reapply them to the underlying device based on the soft partitions listed in the metadevice state database. Options `-d` and `-m` are mutually exclusive.

- `-n`
  
  Do not actually perform the operation. Show the output or errors that would have resulted from the operation, had it been run.

- `-p`
  
  Regenerate soft partitions based on the metadevice state database or extent headers on the underlying device. If neither `-d` nor `-m` are specified, this option compares the soft partition information in the metadevice state database to the extent headers.

- `-s setname`
  
  Specify the name of the diskset on which `metarecover` works. Using the `-s` option causes the command to perform its function within the specified diskset. Without the `-s` option, the `metarecover` command operates on the metadevices and/or hot spare pools in the local diskset.

  This option is required to recover former `sps` from a diskset component or raw-device. `setname` must be identical to the former `setname` in which the `sps` were created. The set numbers, however, seem irrelevant.

- `-v`
  
  Verbose mode, displaying the changes being made.

**Operands**

The following operand is supported:

- `component`
  
  Specifies the `c*t*d*s*` number of the disk or slice containing the partitions, or the device name (for example, `d10`) of the metadevice containing the partitions.

  `component` can be a slice name, component name, `/dev/dsk` path, or `/dev/rdsk` path.
Examples

**EXAMPLE 1**  Updating Metadevice State Database Based on Disk Extent Headers

A disk containing soft partitions is moved from one system to another. The system administrator would like to use the existing soft partitions. metarecover updates the metadevice state database based on the extent headers on the disk.

```
# metarecover -v c0t3d0s2 -p -d
```

**EXAMPLE 2**  Updating Metadevice State Database Based on Incomplete Soft Partition Creation

A system crashes in the middle of creating a new soft partition. The soft partition is in the creating state and the driver does not let that device be opened. metarecover rewrites the extent headers for the partially created soft partition and mark it as Okay.

```
# metarecover -v c0t3d0s2 -p -m
```

**EXAMPLE 3**  Updating Extent Headers Based on Metadevice State Database

Someone accidentally overwrote a portion of a disk leaving extent headers destroyed. metarecover rewrites the extent headers to ensure a valid soft partition configuration, though user data is not recovered.

```
# metarecover -v d5 -m
```

The following example implements the same command using a descriptive name.

```
# metarecover -v myvolume -m
```

**EXAMPLE 4**  Validating Soft Partition Configuration

To validate the existing soft partition configuration, use metarecover with only the -p flag.

```
# metarecover c0t3d0s2 -p
```

**Exit Status**  The following exit values are returned:

- 0      Successful completion.
- >0     An error occurred.

Solaris Volume Manager Administration Guide
Name metarename – rename metadevice or switch layered metadevice names

Synopsis
```
/usr/sbin/metarename [-s setname] metadevice1 metadevice2
/usr/sbin/metarename [-s setname] [-f] -x metadevice1 metadevice2
/usr/sbin/metarename -h
```

Description
There are two ways to use metarename, one with and one without the -x option. The first method (without -x) renames an existing metadevice to a new name. This makes managing the metadevice namespace easier. The metadevice being renamed cannot be mounted or open, nor can the new name already exist. For example, to rename a metadevice that contains a mounted file system, you would first need to unmount the file system.

With the second way to use metarename, using the -x option, metarename switches (exchanges) the names of an existing layered metadevice and one of its subdevices. In Solaris Volume Manager terms, a layered metadevice can be either a mirror or a trans metadevice. The -x option enables you to switch the metadevice names of a mirror and one of its submirrors, or a trans metadevice and its master device.

metarename -x makes it easier to mirror or unmirror an existing stripe or concatenation, and to remove a trans device.

When used to mirror an existing stripe or concatenation, you must stop access to the device. For example, if the device contains a mounted file system, you must first unmount the file system before doing the rename.

You can also use the metarename -x command to untrans a trans metadevice from an existing device. This applies only to the master device. You cannot remove a logging device with metarename. Before you can rename a trans device, you must detach the logging device. Then you must stop access to the trans metadevice itself.

You cannot rename or switch metadevices that are in an error state or that have subcomponents in an error state, or metadevices actively using a hot spare replacement.

You can only switch metadevices that have a direct child/parent relationship. You could not, for example, directly exchange a stripe in a mirror that is a master device with the trans metadevice.

You must use the -f flag when switching members of a trans metadevice.

Only metadevices can be switched, not slices.

Options
The following options are supported:
```
- f       Force the switching of trans metadevice members.
- h       Display a help message.
```
metarename(1M)

-s setname  Specifies the name of the diskset on which metarename will work. Using the -s option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on the local metadevices.

-x  Exchange the metadevice names metadevice1 and metadevice2.

metadevice1  Specifies the metadevice to be renamed or switched.

metadevice2  Specifies the target metadevice name for the rename or switch operation.

Examples

EXAMPLE 1  Renaming a Metadevice

This example renames a metadevice named d10 to account_records. Note that account_records must not exist for the rename to succeed.

# metarename d10 account_records

EXAMPLE 2  Creating a Two-Way Mirror

This example creates a two-way mirror from an existing stripe named d1 with a mounted file system, /home2.

# metainit d2 1 1 c13d0s1
# metainit -f d20 -m d1
# umount /home2
# metarename -x d20 d1
# metattach d1 d2
# mount /home2

First, a second concatenation d2, is created. (d1 already exists.) The metainit command creates a one-way mirror, d20, from d1. Next, you umount the file system and switch d1 for d20, making d1 the top-level device (mirror). You attach the second submirror, d2, to create a two-way mirror. Lastly, you remount the file system.

EXAMPLE 3  Mounting a Mirrored File System on Stripe

This example takes an existing mirror named d1 with a mounted file system, and ends up with the file system mounted on a stripe d1.

# umount /fs2
# metarename -x d1 d20
# metadetach d20 d1
# metaclear -r d20
# mount /fs2

First, you unmount the file system, then switch the mirror d1 and its submirror d20. This makes the mirror into d20. Next, you detach d1 from d20, then delete the mirror d20 and its other submirror. You then remount the file system.
EXAMPLE 4  Deleting a Trans Metadevice
This example deletes a trans metadevice named d10 while its mount point is /myhome. The master device, which is a stripe, is named d2. The logging device, also a stripe, is named d5.

# umount /myhome
# metadetach d10
# metarename -f -x d10 d2
# metaclear d2
# metaclear d5
# fsck /dev/md/dsk/d10
# mount /myhome

You umount the file system first, then detach the trans metadevice's logging device. The trans metadevice is switched with the master device, making the trans metadevice d2 and the underlying stripe d10. You clear the trans metadevice d2 and the logging device d5. d10 must be fsck'd, and then the file system is remounted.

Exit Status  The following exit values are returned:
0    Successful completion.
>0   An error occurred.

Solaris Volume Manager Administration Guide

Limitations  Renaming and exchanging metadevice names can only be used for metadevices. A physical slice cannot be renamed to a metadevice, nor can a metadevice be exchanged with a physical slice name.

Metadevice names are strings of the pattern d<xyz> where xyz is a value between 0 and 8192. You cannot use logical names for metadevices.

Notes  Trans metadevices have been replaced by UFS logging. Existing trans devices are not logging—they pass data directly through to the underlying device. See mount_ufs(1M) for more information about UFS logging.
metareplace(1M)

**Name**
metareplace – enable or replace components of submirrors or RAID5 metadevices

**Synopsis**
```
/usr/sbin/metareplace -h
/usr/sbin/metareplace [-s setname] -e mirror component
/usr/sbin/metareplace [-s setname] mirror component-old component-new
/usr/sbin/metareplace [-s setname] -e RAID component
/usr/sbin/metareplace [-s setname] [-f] RAID component-old component-new
```

**Description**
The `metareplace` command is used to enable or replace components (slices) within a submirror or a RAID5 metadevice.

When you replace a component, the `metareplace` command automatically starts resyncing the new component with the rest of the metadevice. When the resync completes, the replaced component becomes readable and writable. If the failed component has been hot spare replaced, the hot spare is placed in the available state and made available for other hot spare replacements.

Note that the new component must be large enough to replace the old component.

A component may be in one of several states. The **Last Erred** and the **Maintenance** states require action. Always replace components in the **Maintenance** state first, followed by a resync and validation of data. After components requiring maintenance are fixed, validated, and resynced, components in the **Last Erred** state should be replaced. To avoid data loss, it is always best to back up all data before replacing **Last Erred** devices.

**Options**
Root privileges are required for all of the following options except `-h`.

- **-e**
  Transitions the state of component to the available state and resyncs the failed component. If the failed component has been hot spare replaced, the hot spare is placed in the available state and made available for other hot spare replacements. This command is useful when a component fails due to human error (for example, accidentally turning off a disk), or because the component was physically replaced. In this case, the replacement component must be partitioned to match the disk being replaced before running the `metareplace` command.

- **-f**
  Forces the replacement of an errored component of a metadevice in which multiple components are in error. The component determined by the `metastat` display to be in the “Maintenance” state must be replaced first. This option may cause data to be fabricated since multiple components are in error.

- **-h**
  Display help message.

- **-s setname**
  Specifies the name of the diskset on which `metareplace` will work. Using the `-s` option will cause the command to perform its administrative
function within the specified diskset. Without this option, the command will perform its function on local metadevices.

- **mirror** The metadevice name of the mirror.
- **component** The logical name for the physical slice (partition) on a disk drive, such as /dev/dsk/c0t0d0s2.
- **component-old** The physical slice that is being replaced.
- **component-new** The physical slice that is replacing **component-old**.
- **RAID** The metadevice name of the RAID5 device.

**Examples**

**EXAMPLE 1** Recovering from Error Condition in RAID5 Metadevice

This example shows how to recover when a single component in a RAID5 metadevice is errored.

```bash
# metareplace d10 c3t0d0s2 c5t0d0s2
```

In this example, a RAID5 metadevice d10 has an errored component, c3t0d0s2, replaced by a new component, c5t0d0s2.

**EXAMPLE 2** Use of -e After Physical Disk Replacement

This example shows the use of the -e option after a physical disk in a submirror (a submirror of mirror mymirror1, in this case) has been replaced.

```bash
# metareplace -e mymirror1 c1t4d0s2
```

Note: The replacement disk must be partitioned to match the disk it is replacing before running the metareplace command.

**Exit Status** The following exit values are returned:

mdmonitor(1M), metaclear(1M), metadb(1M), metadetach(1M), metahs(1M), metainit(1M), metaoffline(1M), metaonline(1M), metaparam(1M), metarecover(1M),
The `metaset` command administers sets of disks in named disk sets. Named disk sets include any disk set that is not in the local set. While disk sets enable a high-availability configuration, Solaris Volume Manager itself does not actually provide a high-availability environment.

A single-owner disk set configuration manages storage on a SAN or fabric-attached storage, or provides namespace control and state database replica management for a specified set of disks.

In a shared disk set configuration, multiple hosts are physically connected to the same set of disks. When one host fails, another host has exclusive access to the disks. Each host can control a shared disk set, but only one host can control it at a time.

When you add a new disk to any disk set, Solaris Volume Manager checks the disk format. If necessary, it repartitions the disk to ensure that the disk has an appropriately configured reserved slice 7 (or slice 6 on an EFI labelled device) with adequate space for a state database replica. The precise size of slice 7 (or slice 6 on an EFI labelled device) depends on the disk geometry. For traditional disk sets, the slice is no less than 4 Mbytes, and probably closer to 6 Mbytes, depending on where the cylinder boundaries lie. For multi-owner disk sets, the slice is
a minimum of 256 Mbytes. The minimal size for slice 7 might change in the future. This
change is based on a variety of factors, including the size of the state database replica and
information to be stored in the state database replica.

For use in disk sets, disks must have a dedicated slice (six or seven) that meets specific criteria:

- The slice must start at sector 0
- The slice must include enough space for disk label
- The state database replicas cannot be mounted
- The slice does not overlap with any other slices, including slice 2

If the existing partition table does not meet these criteria, or if the -L flag is specified, Solaris
Volume Manager repartitions the disk. A small portion of each drive is reserved in slice 7 (or
slice 6 on an EFI labelled device) for use by Solaris Volume Manager. The remainder of the
space on each drive is placed into slice 0. Any existing data on the disks is lost by
repartitioning.

After you add a drive to a disk set, it can be repartitioned as necessary, with the exception that
slice 7 (or slice 6 on an EFI labelled device) is not altered in any way.

After a disk set is created and metadevices are set up within the set, the metadevice name is in
the following form:

/dev/md/setname[dsk,rdsk]/dnumber

where setname is the name of the disk set, and number is the number of the metadevice
(0-127).

If you have disk sets that you upgraded from Solstice DiskSuite software, the default state
database replica size on those sets is 1034 blocks, not the 8192 block size from Solaris Volume
Manager. Also, slice 7 on the disks that were added under Solstice DiskSuite are
correspondingly smaller than slice 7 on disks that were added under Solaris Volume Manager.

If disks you add to a disk set have acceptable slice 7s (that start at cylinder 0 and that have
sufficient space for the state database replica), they are not reformatted.

Hot spare pools within local disk sets use standard Solaris Volume Manager naming
conventions. Hot spare pools with shared disk sets use the following convention:

setname/hot_spare_pool

where setname is the name of the disk set, and hot_spare_pool is the name of the hot spare pool
associated with the disk set.

Multi-node Environment

To create and work with a disk set in a multi-node environment, root must be a member of
Group 14 on all hosts, or the /.rhost file must contain an entry for all other host names. This
is not required in a SunCluster 3.x environment.
Tagged data

Tagged data occurs when there are different versions of a disk set’s replicas. This tagged data consists of the set owner’s nodename, the hardware serial number of the owner, and the time it was written out to the available replicas. The system administer can use this information to determine which replica contains the correct data.

When a disk set is configured with an even number of storage enclosures and has replicas balanced across them evenly, it is possible that up to half of the replicas can be lost (for example, through a power failure of half of the storage enclosures). After the enclosure that went down is rebooted, half of the replicas are not recognized by SVM. When the set is retaken, the metaset command returns an error of “stale databases”, and all of the metadevices are in a read-only state.

Some of the replicas that are not recognized need to be deleted. The action of deleting the replicas also causes updates to the replicas that are not being deleted. In a dual hosted disk set environment, the second node can access the deleted replicas instead of the existing replicas when it takes the set. This leads to the possibility of getting the wrong replica record on a disk set take. An error message is displayed, and user intervention is required.

Use the -q to query the disk set and the -t, -u, and -y, options to select the tag and take the disk set. See OPTIONS.

Mediator Configuration

SVM provides support for a low-end HA solution consisting of two hosts that share only two strings of drives. The hosts in this type of configuration, referred to as mediators or mediator hosts, run a special daemon, rpc.metamedd(1M). The mediator hosts take on additional responsibilities to ensure that data is available in the case of host or drive failures.

A mediator configuration can survive the failure of a single host or a single string of drives, without administrative intervention. If both a host and a string of drives fail (multiple failures), the integrity of the data cannot be guaranteed. At this point, administrative intervention is required to make the data accessible. See mediator(7D) for further details.

Use the -m option to add or delete a mediator host. See OPTIONS.

Options

The following options are supported:

-a drivename
Add drives or hosts to the named set. For a drive to be accepted into a set, the drive must not be in use within another metadevice or disk set, mounted on, or swapped on. When the drive is accepted into the set, it is repartitioned and the metadevice state database replica (for the set) can be placed on it. However, if a slice 7 (or slice 6 on an EFI labelled device), starts at cylinder 0, is large enough to hold a state database replica, and the slice does not overlap with other slices (including slice 2), then the disk is not repartitioned. Also, a drive is not accepted if it cannot be found on all hosts specified as part of the set. This means that if a host within the specified set is unreachable due to network problems, or is administratively down, the add fails.
Specify a drive name in the form `cnum|num|dnum`. Do not specify a slice number (`snum`). For drives in a Sun Cluster, you must specify a complete pathname for each drive. Such a name has the form:

```
/dev/did/[r]dsk/dnum
```

- `-a | -d | -n mediator_host_list`
  Add (-a) or delete (-d) mediator hosts to the specified disk set. A `mediator_host_list` is the nodename (established by `svc:/system/identity:node smf(5)` service) of the mediator host to be added and (for adding) up to two other aliases for the mediator host. The nodename and aliases for each mediator host are separated only by commas. Up to three mediator hosts can be specified for the named disk set. Specify only the nodename of that host as the argument to `-m` to delete a mediator host.

In a single `metaset` command you can add or delete up to three mediator hosts. See `EXAMPLES`.

- `-A {enable | disable}`
  Specify auto-take status for a disk set. If auto-take is enabled for a set, the disk set is automatically taken at boot, and file systems on volumes within the disk set can be mounted through `/etc/vfstab` entries. Only a single host can be associated with an auto-take set, so attempts to add a second host to an auto-take set or attempts to configure a disk set with multiple hosts as auto-take fails with an error message. Disabling auto-take status for a specific disk set causes the disk set to revert to normal behavior. That is, the disk set is potentially shared (non-concurrently) among hosts, and unavailable for mounting through `/etc/vfstab`.

- `-b`
  Insure that the replicas are distributed according to the replica layout algorithm. This can be invoked at any time, and does nothing if the replicas are correctly distributed. In cases where the user has used the `metadb` command to manually remove or add replicas, this command can be used to insure that the distribution of replicas matches the replica layout algorithm.

- `-C {take | release | purge}`
  Do not interact with the Cluster Framework when used in a Sun Cluster 3 environment. In effect, this means do not modify the Cluster Configuration Repository. These options should only be used to fix a broken disk set configuration.

  `take`
  Take ownership of the disk set but do not inform the Cluster Framework that the disk set is available. This option is not for use with a multi-owner disk set.

  `release`
  Release ownership of the disk set without informing the Cluster Framework. This option should only be used if the disk set ownership was taken with the corresponding `-C take` option. This option is not for use with a multi-owner disk set.
purge
   Remove the disk set without informing the Cluster Framework that the disk set has been
   purged. This option should only be used when the disk set is not accessible and requires
   rebuilding.

   -d drivename
   Delete drives or hosts from the named disk set. For a drive to be deleted, it must not be in
   use within the set. The last host cannot be deleted unless all of the drives within the set are
   deleted. Deleting the last host in a disk set destroys the disk set.

   Specify a drive name in the form cnumtnumdnum. Do not specify a slice number (snum).
   For drives in a Sun Cluster, you must specify a complete pathname for each drive. Such a
   name has the form:

   /dev/did/[r]dsk/dnum

   This option fails on a multi-owner disk set if attempting to withdraw the master node while
   other nodes are in the set.

   -f
   Force one of three actions to occur: takes ownership of a disk set when used with -t; deletes
   the last disk drive from the disk set; or deletes the last host from the disk set. Deleting the
   last drive or host from a disk set requires the -d option.

   When used to forcibly take ownership of the disk set, this causes the disk set to be grabbed
   whether or not another host owns the set. All of the disks within the set are taken over
   (reserved) and fail fast is enabled, causing the other host to panic if it had disk set
   ownership. The metadevice state database is read in by the host performing the take, and
   the shared metadevices contained in the set are accessible.

   You can use this option to delete the last drive in the disk set, because this drive would
   implicitly contain the last state database replica.

   You can use -f option to delete hosts from a set. When specified with a partial list of hosts,
   it can be used for one-host administration. One-host administration could be useful when
   a host is known to be non-functional, thus avoiding timeouts and failed commands. When
   specified with a complete list of hosts, the set is completely deleted. It is generally specified
   with a complete list of hosts to clean up after one-host administration has been performed.

   -h hostname...
   Specify one or more host names to be added to or deleted from a disk set. Adding the first
   host creates the set. The last host cannot be deleted unless all of the drives within the set
   have been deleted. The host name is not accepted if all of the drives within the set cannot be
   found on the specified host. The host name is the nodename established by the
   svc:/system/identity:node smf(5) service.
-j
Join a host to the owner list for a multi-owner disk set. The concepts of take and release, used with traditional disk sets, do not apply to multi-owner sets, because multiple owners are allowed.

As a host boots and is brought online, it must go through three configuration levels to be able to use a multi-owner disk set:
1. It must be included in the cluster nodelist, which happens automatically in a cluster or single-node situation.
2. It must be added to the multi-owner disk set with the -a -h options documented elsewhere in this man page.
3. It must join the set. When the host is first added to the set, it is automatically joined.

On manual restarts, the administrator must manually issue

    metaset -s multinodesetname -j

to join the host to the owner list. After the cluster reconfiguration, when the host reenters the cluster, the node is automatically joined to the set. The metaset - j command joins the host to all multi-owner sets that the host has been added to. In a single node situation, joining the node to the disk set starts any necessary resynchronizations.

-L
When adding a disk to a disk set, force the disk to be repartitioned using the standard Solaris Volume Manager algorithm. See DESCRIPTION.

-l length
Set the size (in blocks) for the metadevice state database replica. The length can only be set when adding a new drive; it cannot be changed on an existing drive. The default (and maximum) size is 8192 blocks, which should be appropriate for most configurations. Replica sizes of less than 128 blocks are not recommended.

-M
Specify that the disk set to be created or modified is a multi-owner disk set that supports multiple concurrent owners.

This option is required when creating a multi-owner disk set. Its use is optional on all other operations on a multi-owner disk set and has no effect. Existing disk sets cannot be converted to multi-owner sets.

-O
Return an exit status of 0 if the local host or the host specified with the -h option is the owner of the disk set.

-P
Purge the named disk set from the node on which the metaset command is run. The disk set must not be owned by the node that runs this command. If the node does own the disk set, the command fails.
If you need to delete a disk set but cannot take ownership of the set, use the \(-P\) option.

\(-q\)
Displays an enumerated list of tags pertaining to “tagged data” that can be encountered during a take of the ownership of a disk set.

This option is not for use with a multi-owner disk set.

\(-r\)
Release ownership of a disk set. All of the disks within the set are released. The metadevices set up within the set are no longer accessible.

This option is not for use with a multi-owner disk set.

\(-s\) setname
Specify the name of a disk set on which\-set works. If no setname is specified, all disk sets are returned.

\(-t\)
Take ownership of a disk set safely. If\-set finds that another host owns the set, this host is not be allowed to take ownership of the set. If the set is not owned by any other host, all the disks within the set are owned by the host on which\-set was executed. The metadevice state database is read in, and the shared metadevices contained in the set become accessible. The \(-t\) option takes a disk set that has stale databases. When the databases are stale,\-set exits with code 66, and prints a message. At that point, the only operations permitted are the addition and deletion of replicas. Once the addition or deletion of the replicas has been completed, the disk set should be released and retaken to gain full access to the data.

This option is not for use with a multi-owner disk set.

\(-u\) tagnumber
Once a tag has been selected, a subsequent take with \(-u\) tagnumber can be executed to select the data associated with the given tagnumber.

\(-w\)
Withdraws a host from the owner list for a multi-owner disk set. The concepts of take and release, used with traditional disk sets, do not apply to multi-owner sets, because multiple owners are allowed.

Instead of releasing a set, a host can issue

\-set \(-s\) multinodesetname \(-w\)

to withdraw from the owner list. A host automatically withdraws on a reboot, but can be manually withdrawn if it should not be able to use the set, but should be able to rejoin at a later time. A host that withdrew due to a reboot can still appear joined from other hosts in the set until a reconfiguration cycle occurs.
metaset -w withdraws from ownership of all multi-owner sets of which the host is a member. This option fails if you attempt to withdraw the master node while other nodes are in the disk set owner list. This option cancels all resyncs running on the node. A cluster reconfiguration process that is removing a node from the cluster membership list effectively withdraws the host from the ownership list.

-"y"

Execute a subsequent take. If the take operation encounters "tagged data," the take operation exits with code 2. You can then run the metaset command with the -q option to see an enumerated list of tags.

Examples

EXAMPLE 1  Defining a Disk Set
This example defines a disk set.
# metaset -s relo-red -a -h red blue

The name of the disk set is relo-red. The names of the first and second hosts added to the set are red and blue, respectively. (The hostname is the nodename established by
svc:/system/identity:node smf service.) Adding the first host creates the disk set. A disk set can be created with just one host, with the second added later. The last host cannot be deleted until all of the drives within the set have been deleted.

EXAMPLE 2  Adding Drives to a Disk Set
This example adds drives to a disk set.
# metaset -s relo-red -a c2t0d0 c2t1d0 c2t2d0 c2t3d0 c2t4d0 c2t5d0

The name of the previously created disk set is relo-red. The names of the drives are c2t0d0, c2t1d0, c2t2d0, c2t3d0, c2t4d0, and c2t5d0. There is no slice identifier ("sx") at the end of the drive names.

EXAMPLE 3  Adding Multiple Mediator Hosts
The following command adds three mediator hosts to the specified disk set.
# metaset -s mydiskset -a -m myhost1,alias1 myhost2,alias2 myhost3,alias3

EXAMPLE 4  Purging a Disk Set from the Node
The following command purges the disk set relo-red from the node:
# metaset -s relo-red -P

EXAMPLE 5  Querying a Disk Set for Tagged Data
The following command queries the disk set relo-red for a list of the tagged data:
# metaset -s relo-red -q

This command produces the following results:
The following command selects a tag and takes the disk set relo-red:

```
# metaset -s relo-red -t -u 2
```

**EXAMPLE 7** Defining a Multi-Owner Disk Set

The following command defines a multi-owner disk set:

```
# metaset -s blue -M -a -h hahost1 hahost2
```

The name of the disk set is blue. The names of the first and second hosts added to the set are

```
hahost1 and hahost2, respectively. The hostname is the nodename established by
svc:/system/identity:node smf(5) service. Adding the first host creates the multi-owner
disk set. A disk set can be created with just one host, with additional hosts added later. The last
host cannot be deleted until all of the drives within the set have been deleted.
```

**Files**

/etc/lvm/md.tab

Contains list of metadevice configurations.

**Exit Status**

The following exit values are returned:

0

Successful completion.

>0

An error occurred.

**Attributes**

*Solaris Volume Manager Administration Guide*
Notes  Disk set administration, including the addition and deletion of hosts and drives, requires all hosts in the set to be accessible from the network.
**Name**  metassist – automated volume creation utility to support Solaris Volume Manager

**Synopsis**  metassist -V

```
metassist -?
```

```
metassist create [-v n] [-c] -F config_file
metassist create [-v n] [-c | -d] -F request_file
metassist create [-v n] [-c | -d] [-f] [-n name] [-p datapaths] [-r redundancy] [-a available [,available,...]] [-u unavailable [,unavailable,...]] -s setname -S size
```

**Description**  The `metassist` command provides assistance, through automation, with common Solaris Volume Manager tasks.

**SUBCOMMANDS**  The following subcommands are supported:

- **create**  The `create` subcommand creates one or more Solaris Volume Manager volumes. You can specify this request on the command line or in a file specified on the command line.

  If you create a volume using the command line, you can specify the characteristics of the volume in terms of the desired quality of service it will provide - its size, the number of redundant copies of the data it contains, the number of data paths by which it is accessible, and whether faulty components are replaced automatically. The diskset in which the volume will reside and the volume’s size must be specified on the command line in this form of the command.

  If you create a volume using a request in a file, you can specify the characteristics of the volume in terms of the quality of service they provide, as on the command line. Alternatively, the file can specify the types and component parts of the volume, (for example, mirrors, stripes, concatenations, and their component slices). The file may also specify volumes partly in terms of their types and partly in terms of their component parts, and may specify the characteristics of more than one volume. All volumes specified in a file must reside in the same diskset, whose name must be specified in the file.

  If you specify the `-c` or `-d` option on the command line, the command runs without creating an actual volume or volumes. Instead, it outputs either a a Bourne shell command script (`-c` option) or a volume configuration (`-d` option). The command script, when run, creates the specified volume or volumes. The volume configuration specifies the volume or volumes in complete detail, naming all their components.

  The input file given on the command line can take one of the following forms:
a volume request, which specifies a request for a volume with explicit attributes and components, or matching a given quality of service

a volume configuration, produced by a previous execution of the command

**Options**

The following option is mandatory if you specify a volume request or volume configuration in a file:

```
-F config_file | request_file
```

Specify the volume request or volume configuration file to process. If `config_file` or `request_file` is `-`, it is read from standard input.

The `-d` option cannot be specified when `inputfile` is a volume configuration file.

The following options are mandatory if you specify a volume request on the command line:

```
-s set
```

Specify the disk set to use when creating volumes. All the volumes and hot spare pools are created in this disk set. If necessary, disks are moved into the diskset for use in the volumes and hot spare pools. If the diskset doesn’t exist the command creates it. This option is required. `metassist` works entirely within a named disk set. Use of the local, or unnamed disk set, is not allowed.

```
-S size
```

Specify the size of the volume to be created. The size argument consists of a numeric value (a decimal can be specified) followed by KB, MB, GB, or TB, indicating kilobytes, megabytes, gigabytes, or terabytes, respectively. Case is ignored when interpreting this option. This option is required.

The following options are optional command line parameters:

```
-a device1, device2, ...
```

Explicitly specify the devices that can be used in the creation of this volume. Named devices may be controllers or disks. Only used when specifying a volume on the command line.

```
-c
```

Output the command script that would implement the specified or generated volume configuration. The command script is not run, and processing stops at this stage.

```
-d
```

Output the volume configuration that satisfies the specified or generated volume request. No command script is generated or executed, and processing stops at this stage.

```
-f
```

Specify whether the volume should support automatic component replacement after a fault. If this option is specified, a mirror is created and its submirrors are associated with a hot spare.

```
-n name
```

Specify the name of the new volume. See `metainit(1M)` for naming guidelines.
Specify the number of required paths to the storage volume. The value of \( n \) cannot be greater than the number of different physical paths and logical paths to attached storage. Only used when specifying a volume on the command line.

Specify the redundancy level (0-4) of the data. The default is 0. Only used when specifying a volume on the command line. If redundancy is 0, a stripe is created. If redundancy is 1 or greater, a mirror with this number of submirrors is created. In this case, the volume can suffer a disk failure on \( n \cdot 1 \) copies without data loss. With the use of hot spares (see the -f option), a volume can suffer a disk failure on \( n+hsps \cdot 1 \) volumes without data loss, assuming non-concurrent failures.

Explicitly specify devices to exclude in the creation of this volume. Named devices can be controllers or disks. You can use this option alone, or to exclude some of the devices listed as available with the -a option, Only used when specifying a volume on the command line.

Specify the level of verbosity. Values from 0 to 2 are available, with higher numbers specifying more verbose output when the command is run. -v 0 indicates silent output, except for errors or other critical messages. The default level is 1.

Display program version information.

Display help information. This option can follow a subcommand for subcommand-specific help.

### Examples

#### EXAMPLE 1  Creating a Mirror
The following example creates a two-way, 36Gb mirror on available devices from controller 1 and controller 2. It places the volume in diskset `mirrorset`.

```bash
# metassist create -r 2 -a c1,c2 -s mirrorset -S 36GB
```

#### EXAMPLE 2  Creating a Mirror with Additional Fault Tolerance
The following example creates a two-way, 36Gb mirror on available devices from controller 1 and controller 2. It provides additional fault tolerance in the form of a hot spare. It places the volume in diskset `mirrorset`.

```bash
# metassist create -f -r 2 -a c1,c2 -s mirrorset -S 36GB
```
EXAMPLE 3  Creating a Three-way Mirror and Excluding Devices

The following example creates a three-way, 180Gb mirror from storage devices on controller 1 or controller 2. It excludes the disks c1t2d0 and c2t2d1 from the volume. It places the volume in diskset mirrorset.

```
metassist create -r 3 -a c1,c2 -u c1t2d0, c2t2d1 \
   -s mirrorset -S 180GB
```

EXAMPLE 4  Determining and Implementing a Configuration

The following example determines and implements a configuration satisfying the request specified in a request file:

```
# metassist create -F request.xml
```

EXAMPLE 5  Determining a Configuration and Saving It in a volume-config File

The following example determines a configuration which satisfies the given request. It saves the configuration in a volume-config file without implementing it:

```
# metassist create -d -F request.xml > volume-config
```

EXAMPLE 6  Determining a Configuration and Saving It in a Shell Script

The following example determines a configuration which satisfies the given request. It saves the configuration in a shell script without implementing it:

```
# metassist create -c -F request.xml > setupvols.sh
```

EXAMPLE 7  Implementing the Given volume-config

The following example implements the given volume-config:

```
# metassist create -F config.xml
```

EXAMPLE 8  Converting the Given volume-config to a Shell Script

The following example converts the given volume-config to a shell script that you can run later:

```
# metassist create -c -F config.xml > setupvols.sh
```

Exit Status  The following exit values are returned:

- 0    Successful completion.
- >0   An error occurred.

Files

- /usr/share/lib/xml/dtd/volume-request.dtd
- /usr/share/lib/xml/dtd/volume-defaults.dtd
- /usr/share/lib/xml/dtd/volume-config.dtd
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>storage/svm</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

See Also  mdmonitor(1M), metaclear(1M), metadb(1M), metadetach(1M), metahs(1M),
           metainit(1M), metaoffline(1M), metaonline(1M), metaparam(1M), metarecover(1M),
           metarename(1M), metareplace(1M), metaset(1M), metastat(1M), metasync(1M),
           metattach(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), volume-config(4),
           volume-request(4), attributes(5), md(7D)

Notes  The quality of service arguments are mutually exclusive with the -F inputfile argument.

When specifying a request file or quality of service arguments on the command line, the
/etc/default/metassist.xml file is read for global and per-disk set defaults.

Characteristics of this file are specified in the DTD, in
/usr/share/lib/xml/dtd/volume-defaults.dtd.

Characteristics of the XML request file are specified in the DTD, in
/usr/share/lib/xml/dtd/volume-request.dtd.

Characteristics of the XML configuration file are specified in the DTD, in
/usr/share/lib/xml/dtd/volume-config.dtd.

This command must be run as root.

This command requires a functional Solaris Volume Manager configuration before it runs.
metastat displays the state of each Solaris Volume Manager RAID-1 volume on the system. The possible states include:

**Okay**
The device reports no errors.

**Needs maintenance**
A problem has been detected. This requires that the system administrator replace the failed physical device. Volumes displaying Needs maintenance have incurred no data loss, although additional failures could risk data loss. Take action as quickly as possible.

**Last erred**
A problem has been detected. Data loss is a possibility. This might occur if a component of a submirror fails and is not replaced by a hot spare, therefore going into Needs maintenance state. If the corresponding component also fails, it would go into Last erred state and, as there is no remaining valid data source, data loss could be a possibility.

**Unavailable**
A device cannot be accessed, but has not incurred errors. This might occur if a physical device has been removed with Solaris Dynamic Reconfiguration (DR) features, thus leaving the Solaris Volume Manager volume unavailable. It could also occur if an array or disk is powered off at system initialization, or if a >1TB volume is present when the system is booted in 32-bit mode.

After the storage has been made available, run the `metastat` command with the `-i` option to update the status of the metadevices. This clears the unavailable state for accessible devices.

See the *Solaris Volume Manager Administration Guide* for instructions on replacing disks and handling volumes in Needs maintenance or Last erred states.
### Options

The following options are supported:

- **-a**
  Display all disk sets. Only metadevices in disk sets that are owned by the current host are displayed.

- **-B**
  Display the current status of all of the 64-bit metadevices and hot spares.

- **-c**
  Display concise output.

  There is one line of output for each metadevice. The output shows the basic structure and the error status, if any, for each metadevice.

  The `-c` output format is distinct from the `-p` output format. The `-p` option does not display metadevice status and is not intended as human-readable output.

- **-D**
  Display the current status of all of the descriptive name metadevices and hotspares.

- **-h**
  Display usage message.

- **-i**
  Check the status of RAID-1 (mirror) volumes, RAID-5 volumes, and hot spares. The inquiry checks each metadevice for accessibility, starting at the top level metadevice. When problems are discovered, the metadevice state databases are updated as if an error had occurred.

- **-p**
  Display the list of active metadevices and hot spare pools in the same format as `md.tab`. See `md.tab(4)`.

  The `-p` output is designed for snapshotting the configuration for later recovery or setup.

- **-q**
  Display the status for metadevices without the device relocation information.

- **-s setname**
  Specify the name of the disk set on which `metastat` works. Using the `-s` option causes the command to perform its administrative function within the specified disk set. Without this option, the command performs its function on metadevices and hot spare pools in the local disk set.

- **-t**
  Display the current status and timestamp for the specified metadevices and hot spare pools. The timestamp provides the date and time of the last state change.

### Operands

The following operands are supported:

- **component**
  Display the status of the component hosting a soft partition, including extents, starting blocks, and block count.

- **hot_spare_pool**
  Display the status of the specified hot spare pool(s).
Display the status of the specified metadevice(s). If a trans metadevice is specified, the status of the master and log devices is also displayed. Trans metadevices have been replaced by UFS logging. See NOTES.

**Examples**

**EXAMPLE 1**  Output Showing Mirror with Two Submirrors

The following example shows the partial output of the `metastat` command after creating a mirror, `opt_mirror`, consisting of two submirrors, `opt_sub1` and `opt_sub2`.

```
# metastat opt_mirror
opt_mirror: Mirror
    Submirror 0: opt_sub1
        State: Okay
    Submirror 1: opt_sub2
        State: Resyncing
        Resync in progress: 15 % done
        Pass: 1
        Read option: roundrobin (default)
        Write option: parallel (default)
        Size: 2006130 blocks
```

**EXAMPLE 2**  Soft Partition on Mirror with Submirror

The following example shows the partial output of the `metastat` command after creating a soft partition, `d3`, on `concat d2`, which is built on a soft partition.

```
# metastat
d2: Concat/Stripe
    Size: 204800 blocks
    Stripe 0:
        Device    Start Block  Dbase State  Hot Spare
        d0         0           No         Okay

d0: Soft Partition
    Component: c0t3d0s0
    Status: Okay
    Size: 204800 blocks
    Extent  Start Block  Block count
        0         129       204800

d3: Soft Partition
    Component: d2
    Status: Okay
    Size: 202752 blocks
    Extent  Start Block  Block count
        0         129       202752
```
EXAMPLE 3  Trans Metadevice

The following example shows the output of the `metastat` command after creating a trans
metadevice.

```
# metastat
d2: Concat/Stripe
  Size: 204800 blocks
  Stripe 0:
    Device  Start Block  Dbase State  Hot Spare
    d0      0           No           Okay

d0: Soft Partition
  Component: c0t3d0s0
  Status: Okay
  Size: 204800 blocks
  Extent  Start Block  Block count
         0           129     204800

d3: Soft Partition
  Component: d2
  Status: Okay
  Size: 202752 blocks
  Extent  Start Block  Block count
         0           129     202752
```

EXAMPLE 4  Multi-owner disk set

The following example shows the output of the `metastat` command with a multi-owner disk
set and application-based mirror resynchronization option. Application-based
resynchronization is set automatically if needed.

```
# metastat -s oban
oban/d100: Mirror
  Submirror 0: oban/d10
    State: Okay
  Submirror 1: oban/d11
    State: Okay
  Pass: 1
  Read option: roundrobin (default)
  Write option: parallel (default)
  Resync option: application based
  Owner: None
  Size: 1027216 blocks (501 MB)

oban/d10: Submirror of oban/d100
  State: Okay
  Size: 1027216 blocks (501 MB)
  Stripe 0:
```
EXAMPLE 4  Multi-owner disk set  (Continued)

<table>
<thead>
<tr>
<th>Device</th>
<th>Start Block</th>
<th>Dbase</th>
<th>State</th>
<th>Reloc</th>
<th>Hot Spare</th>
</tr>
</thead>
<tbody>
<tr>
<td>c1t3d0s0</td>
<td>0</td>
<td>No</td>
<td>Okay</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

oban/d11: Submirror of oban/d100
State: Okay
Size: 1027216 blocks (501 MB)
Stripe 0:

<table>
<thead>
<tr>
<th>Device</th>
<th>Start Block</th>
<th>Dbase</th>
<th>State</th>
<th>Reloc</th>
<th>Hot Spare</th>
</tr>
</thead>
<tbody>
<tr>
<td>c1t4d0s0</td>
<td>0</td>
<td>No</td>
<td>Okay</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Warnings  metastat displays states as of the time the command is entered. It is unwise to use the output of the metastat -p command to create a md.tab(4) file for a number of reasons:

- The output of metastat -p might show hot spares being used.
- It might show mirrors with multiple submirrors. See metainit(1M) for instructions for creating multi-way mirrors using metainit and metattach.
- A slice may go into an error state after metastat -p is issued.

Exit Status  The following exit values are returned:
0       Successful completion.
>0      An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>storage/svm</td>
</tr>
<tr>

Solaris Volume Manager Administration Guide

Notes  Trans metadevices have been replaced by UFS logging. Existing trans devices are not logging—they pass data directly through to the underlying device. See mount_ufs(1M) for more information about UFS logging.
metasync – handle metadevice resync during reboot

Synopsis

/usr/sbin/metasync -h
/usr/sbin/metasync [-s setname] [buffer_size] metadevice
/usr/sbin/metasync [-s setname] -r [buffer_size]
/usr/sbin/metasync -p metadevice
/usr/sbin/metasync -c metadevice

Description

The `metasync` command starts a resync operation on the specified `metadevice`. All components that need to be resynced are resynced. If the system crashes during a RAID5 initialization, or during a RAID5 resync, either an initialization or resync restarts when the system reboots.

Applications are free to access a metadevice at the same time that it is being resynced by `metasync`. Also, `metasync` performs the copy operations from inside the kernel, which makes the utility more efficient.

Use the `-r` option in boot scripts to resync all possible submirrors.

Options

The following options are supported:

- `-c metadevice` Cancels the resync that is in progress on the specified metadevice. The resync will be stopped at its current point and can be resumed by running the “`metasync metadevice`” command. This option only applies to RAID1 volumes.

- `-h` Displays usage message.

- `-p metadevice` Regenerates parity information for RAID5 metadevices.

- `-s setname` Specifies the name of the diskset on which `metasync` will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local metadevices.

- `-r` Specifies that the `metasync` command handle special resync requirements during a system reboot. `metasync -r` should only be invoked from the `svc:/system/mdmonitor` service. The `metasync` command only resyncs those metadevices that need to be resynced. `metasync` schedules all the mirror resynchs according to their pass numbers.

To override the default buffer_size value used by the `svc:/system/mdmonitor` service, you can edit `/etc/system` to specify:

```
set md_mirror:md_resync_bufsz = 2048
```

so that resynchs occur as quickly as possible.
Operands  buffer_size  Specifies the size (number of 512-byte disk blocks) of the internal copy buffer for the mirror resync. The size defaults to 1024 512-byte disk blocks. It can be no more than 2048 blocks. For best performance (quickest completion of the resync), 2048 blocks is the recommended size.

Exit Status  The following exit values are returned:

  0  Successful completion.

  >0  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

Solaris Volume Manager Administration Guide

Notes  The metasync service is managed by the service management facility, smf(5), under the service identifier:
 svc:/system/mdmonitor

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
**Name**
metattach, metadetach – attach or detach a metadevice

**Synopsis**
/usr/sbin/metattach [-h]
/usr/sbin/metattach [-s setname] mirror [metadevice]
/usr/sbin/metattach [-s setname] [-i interlace] concat/stripes component...
/usr/sbin/metattach [-s setname] RAID component...
/usr/sbin/metattach [-s setname] [-A alignment] softpart size | all
/usr/sbin/metadetach [-s setname] [-f] mirror submirror
/usr/sbin/metadetach [-s setname] [-f] trans

**Description**
metattach adds submirrors to a mirror, grows metadevices, or grows soft partitions. Growing metadevices can be done without interrupting service. To grow the size of a mirror or trans, the slices must be added to the submirrors or to the master devices.

Solaris Volume Manager supports storage devices and logical volumes greater than 1 terabyte (TB) when a system runs a 64-bit Solaris kernel. Support for large volumes is automatic. If a device greater than 1 TB is created, Solaris Volume Manager configures it appropriately and without user intervention.

If a system with large volumes is rebooted under a 32-bit Solaris kernel, the large volumes are visible through metastat output. Large volumes cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are also unavailable. If a system with large volumes is rebooted under a version of Solaris prior to the Solaris 9.4/03 release, Solaris Volume Manager does not start. You must remove all large volumes before Solaris Volume Manager runs under an earlier version of the Solaris Operating System.

Solaris Volume Manager supports one-to-four-way mirrors. You can only attach a metadevice to a mirror if there are three or fewer submirrors beneath the mirror. Once a new metadevice is attached to a mirror, metattach automatically starts a resync operation to the new submirror.

metadetach detaches submirrors from mirrors and logging devices from trans metadevices.

When a submirror is detached from a mirror, it is no longer part of the mirror, thus reads and writes to and from that metadevice by way of the mirror are no longer performed through the mirror. Detaching the only existing submirror is not allowed. Detaching a submirror that has slices reported as needing maintenance (by metastat) is not allowed unless the -f (force) flag is used.

metadetach also detaches the logging device from a trans. This step is necessary before you can clear the trans volume. Trans metadevices have been replaced by UFS logging. Existing trans devices are not logging. They pass data directly through to the underlying device. See mount_ufs(1M) for more information about UFS logging.
Detaching the logging device from a busy trans device is not allowed unless the -f (force) flag is used. Even so, the logging device is not actually detached until the trans is idle. The trans is in the Detaching state (metastat) until the logging device is detached.

**Options**

Root privileges are required for all of the following options except -h.

The following options are supported:

- **alignment**
  
  Set the value of the soft partition extent alignment. Use this option when it is important specify a starting offset for the soft partition. It preserves the data alignment between the metadevice address space and the address space of the underlying physical device.

  For example, a hardware device that does checksumming should not have its I/O requests divided by Solaris Volume Manager. In this case, use a value from the hardware configuration as the value for the alignment. When using this option in conjunction with a software I/O load, the alignment value corresponds to the I/O load of the application. This prevents I/O from being divided unnecessarily and affecting performance.

- **f**
  
  Force the detaching of metadevices that have components that need maintenance or are busy. You can use this option only when a mirror is in a maintenance state that can be fixed with metareplace(1M). If the mirror is in a maintenance state that can only be fixed with metasync(1M) (as shown by the output of metastat(1M)), metadetach -f has no effect, because the mirrors must be resynchronized before one of them can be detached.

- **h**
  
  Display a usage message.

- **i interlace**
  
  Specify the interlace value for stripes, where size is a specified value followed by either k for kilobytes, m for megabytes, or b for blocks. The units can be either uppercase or lowercase. If size is not specified, the size defaults to the interlace size of the last stripe of the metadevice. When an interlace size change is made on a stripe, it is carried forward on all stripes that follow.

- **s setname**
  
  Specify the name of the diskset on which the metattach command or the metadetach command works. Using the -s option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices.

**Operands**

The following operands are supported:

- **component**
  
  The logical name for the physical slice (partition) on a disk drive, such as /dev/dsk/c0t0d0s2, being added to the concatenation, stripe, concatenation of stripes, or RAID5 metadevice.

- **concat/stripe**
  
  The metadevice name of the concatenation, stripe, or concatenation of stripes.
The metadevice name of the logging device to be attached to the trans metadevice.

**metadevice**
The metadevice name to be attached to the mirror as a submirror. This metadevice must have been previously created by the `metainit` command.

**mirror**
The name of the mirror.

**RAID**
The metadevice name of the RAID5 metadevice.

**size**
The amount of space to add to the soft partition in K or k for kilobytes, M or m for megabytes, G or g for gigabytes, T or t for terabytes, and B or b for blocks (sectors). All values represent powers of 2, and upper and lower case options are equivalent. Only integer values are permitted. The literal `all` specifies that the soft partition should grow to occupy all available space on the underlying volume.

**softpart**
The metadevice name of the existing soft partition.

**submirror**
The metadevice name of the submirror to be detached from the mirror.

**trans**
The metadevice name of the trans metadevice (not the master or logging device).

### Examples

**EXAMPLE 1** Concatenating a New Slice to a Metadevice

This example concatenates a single new slice to an existing metadevice, `Volume.1`. Afterwards, you would use the `growfs(1M)` command to expand the file system.

```
# metattach Volume.1 /dev/dsk/c0t1d0s2
```

**EXAMPLE 2** Detaching Logging Device from Trans Metadevice

This example detaches the logging device from a trans metadevice `d9`. Notice that you do not have to specify the logging device itself, as there can only be one.

```
# metadetach d9
```

**EXAMPLE 3** Expanding a RAID5 Metadevice

This example expands a RAID5 metadevice, `d45`, by attaching another slice.

```
# metattach d45 /dev/dsk/c3t0d0s2
```

When you add additional slices to a RAID5 metadevice, the additional space is devoted to data. No new parity blocks are allocated. The data on the added slices is, however, included in the overall parity calculations, so it is protected against single-device failure.

**EXAMPLE 4** Expanding a Soft Partition

The following example expands a soft partition, `d42`, attaching all space available on the underlying device.
EXAMPLE 4 Expanding a Soft Partition  (Continued)

# metattach d42 all

When you add additional space to a soft partition, the additional space is taken from any available space on the slice and might not be contiguous with the existing soft partition.

EXAMPLE 5 Adding Space to Two-Way Mirror

This example adds space to a two-way mirror by adding a slice to each submirror. Afterwards, you would use the `growfs(1M)` command to expand the file system.

# metattach d9 /dev/dsk/c0t2d0s5
# metattach d10 /dev/dsk/c0t3d0s5

This example tells the mirror to grow to the size of the underlying devices

# metattach d11

This example increases the size of the UFS on the device so the space can be used.

# growfs -M /export /dev/md/rdsk/d11

EXAMPLE 6 Detaching a Submirror from a Mirror

This example detaches a submirror, d2, from a mirror, d4.

# metadetach d4 d2

EXAMPLE 7 Adding Four Slices to Metadevice

This example adds four slices to an existing metadevice, d9. Afterwards, you would use the `growfs(1M)` command to expand the file system.

# metattach d9 /dev/dsk/c0t1d0s2 /dev/dsk/c0t2d0s2 /dev/dsk/c0t3d0s2 /dev/dsk/c0t4d0s2

EXAMPLE 8 Setting the Value of the Soft Partition Extent Alignment

This example shows how to set the alignment of the soft partition to 1mb when the soft partition is expanded.

# metattach -s red -A 2m d13 1m

**Exit Status**  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Solaris Volume Manager Administration Guide

Warnings

This section provides information regarding warnings for devices greater than 1 TB and for multi-way mirrors.

Devices and Volumes Greater Than 1 TB

Do not create large (>1 TB) volumes if you expect to run the Solaris Operating System with a 32-bit kernel or if you expect to use a version of the Solaris Operating System prior to Solaris 9 4/03.

Multi-Way Mirrors

When a submirror is detached from its mirror, the data on the metadevice might not be the same as the data that existed on the mirror prior to running metadetach. In particular, if the -f option was needed, the metadevice and mirror probably do not contain the same data.

Notes

Trans metadevices have been replaced by UFS logging. Existing trans devices are not logging. They pass data directly through to the underlying device. See mount_ufs(1M) for more information about UFS logging.
mib2mof(1M)

**Name**
mib2mof – generate MOF file(s) from input SNMP MIB file(s)

**Synopsis**

**Description**
The mib2mof utility reads input Management Information Base (MIB) files and produces one or more Managed Object Format (MOF) files. MOF files contain a Common Information Model (CIM) class declaration that represents the MIB for the Solaris Simple Network Management Protocol (SNMP) provider. The SNMP provider allows Web-Based Enterprise Management (WBEM) applications to access SNMP device information.

SNMP scalar variables map to properties in the CIM class. Qualifiers on each property convey the following MIB information for each scalar variable:

- syntax
- read/write access
- OID (Object Identifier)
- description (optional)
- index (if the variable is within a group [sequence] that defines a row)

The syntax of an SNMP scalar variable is represented in a CIM class by the property's CIM datatype. All properties are marked with write access (true or false).

The following table shows how a Solaris SNMP datatype in a MIB maps to a Web-Based Enterprise Management (WBEM) CIM datatype and then to an SNMP datatype used by the WBEM SNMP API:

<table>
<thead>
<tr>
<th>SNMP SMI Datatype</th>
<th>SNMP CIM Ver. Datatype</th>

</table>

The mib2mof utility includes its required Solaris _SNMPmib_core.txt_ file (containing core MIB definitions), installed in /usr/sadm/mof. The mib2mof utility looks first for _mib core_ file in the local directory. If this file is not found in the local directory, mib2mof looks in /usr/sadm/mof.
A MOF file is generated for each SNMP group and table row sequence (that is, the columns in one row) found in the supplied MIBs. (This does not include the core MIB definitions contained in the Solaris_SNMPmib_core.txt file.)

There is no MOF file or property for an SNMP table - all table access is through the rows and columns of the table, and the SNMP variable for the table is marked as inaccessible in the MIB.

The MOF file created contains a CIM class that represents an SNMP group or row and a CIM class to represent a CIM association. The output file name and CIM class is of the format <SNMP_>\<MIB name\>\<Group name\>.mof.

**Options**
The following options are supported:

- `-a` Generate MOF files for all of the input MIB files. If `-a` is not given, a MOF file is generated only for the last file of the input list.

- `-c` Do not use the default Solaris_SNMPmib_core.txt definitions file shipped with the Solaris SNMP Provider for WBEM. If this option is specified, you must specify another MIB_CORE definitions file as one of the input files.

- `-d directory` Generate output MOF files in the specified directory.

- `-h` Show how to invoke mib2mof and list its arguments.

- `-n` Parse the input MIB files without generating any output.

- `-q` Include the DESCRIPTION clause of SNMP OBJECT-TYPE as a qualifier in the generated MOF file.

**Operands**
The following operands are supported:

- `files` List of SNMP MIB files to be converted.

**Exit Status**
The mib2mof utility terminates with exit status 0.

**Attributes**

The \textit{mibiisa} utility is an RFC 1157-compliant SNMP agent. It supports MIB-II as defined in RFC 1213, with Sun extensions under Sun's enterprise number. The MIB (Management Information Base) is both readable and writable. The \textit{mibiisa} utility supports all SNMP protocol operations including GET-REQUEST, GETNEXT-REQUEST, SET-REQUEST, GET-REPLY, and TRAP.

The SMA (Systems Management Agent) is the default SNMP agent in Solaris. MIB-II subagent \textit{mibiisa} does not run by default. To enable \textit{mibiisa}, rename the configuration file from `/etc/snmp/conf/mibiisa.rscc` to `/etc/snmp/conf/mibiisa.rscc`. SMA has the capability to handle any MIB-II requests.

The \textit{mibiisa} utility supports the coldStart, linkUp, linkDown, and authentication traps. The authentication trap may be disabled by a command-line switch, which itself may be overridden by a management station writing to a MIB variable in the standard SNMP MIB group.

The \textit{mibiisa} utility supports four distinct views of the MIB. The view used for any request is determined by the community string contained in that request.

To enhance security, \textit{mibiisa} supports an option to block all writes to the MIB. You can also limit the set of management stations from which the agent will accept requests in the configuration file used when starting the \textit{mibiisa}. See the Security section for more information.

Unless overridden, \textit{mibiisa} uses UDP port 161, the standard SNMP port. The \textit{mibiisa} utility issues traps through the same port on which it receives SNMP requests.

The \textit{mibiisa} utility must run with super-user privileges and is typically started at system startup via `/etc/rc3.d`. \textit{mibiisa} may not be started using \textit{inetd}(1M). When started, \textit{mibiisa} detaches itself from the keyboard, disables all signals except SIGKILL, SIGILL, SIGUSR1, and SIGUSR2, and places itself in the background.

The following options are supported by \textit{mibiisa}:

- \texttt{-a} Disable the generation of authentication traps. However, an SNMP manager may write a value into \texttt{snmpEnableAuthenTraps} to enable or disable authentication traps.

- \texttt{-c config-dir} Specify a directory where it expects \texttt{snmpd.conf} file, on startup. The default directory is `/etc/snmp/conf`.

- \texttt{-d debug-level} Debug. A value of 0 disables all debug and is the default. Levels 1 through 3 represent increasing levels of debug output. When \textit{mibiisa} receives the
signal SIGUSR1, it resets the debug-level to 0. When mibiisa receives the signal SIGUSR2, it increments the debug-level by one.

Debug output is sent to the standard output in effect at the time mibiisa is started. No matter what debug level is in effect, certain significant events are logged in the system log.

-p port Define an alternative UDP port on which mibiisa listens for incoming requests. The default is UDP port 161.
-r Place the MIB into read-only mode.
-t cache-timer By default, information fetched from the kernel is considered to be valid for 45 seconds from the time it is retrieved. This cache lifetime may be altered with this parameter. You cannot set cache-timer to any value less than 1.

Configuration File The snmpd.conf file is used for configuration information. Each entry in the file consists of a keyword followed by a parameter string. The keyword must begin in the first position. Parameters are separated from the keyword and from one another by white space. Case in keywords is ignored. Each entry must be contained on a single line. All text following (and including) a pound sign (#) is ignored. Keywords currently supported are:

- sysdescr The value to be used to answer queries for sysDescr.
- syscontact The value to be used to answer queries for sysContact.
- syslocation The value to be used to answer queries for sysLocation.
- trap The parameter names one or more hosts to receive traps. Only five hosts may be listed.
- system-group-read-community The community name to get read access to the system group and Sun's extended system group.
- system-group-write-community The community name to get write access to the system group and Sun's extended system group.
- read-community The community name to get read access to the entire MIB.
- write-community The community name to get write access to the entire MIB (implies read access).
- trap-community The community name to be used in traps.
- kernel-file The name of the file to use for kernel symbols.
- managers The names of hosts that may send SNMP queries. Only five hosts may be listed on any one line. This keyword may be repeated for a total of 32 hosts.
newdevice

The additional devices which are not built in SNMPD. The format is as follows: newdevice type speed name
where newdevice is the keyword, type is an integer which has to match your schema file, speed is the new device's speed, and name is this new device's name.

An example snmpd.conf file is shown below:

```
sysdescr Sun SNMP Agent, Sun Fire 4800, Company Property Number 123456
syscontact Cliff Claven
syslocation Room 1515, building 1
# system-group-read-community public
system-group-write-community private
# read-community all_public
write-community all_private
# trap localhost
trap-community SNMP-trap
# # kernel-file /vmunix
# managers lvs golden
managers swap
```

**Installation**

The mibiisa utility and its configuration file, snmpd.conf, may be placed in any directory. However for Solaris 2.4 and subsequent releases, use /usr/lib/snmp for mibiisa itself and /etc/snmp/conf for the configuration file. You can modify the configuration file as appropriate. If you make any changes to snmpd.conf file keyword values, you must kill and restart mibiisa for the changes to take effect.

Your /etc/services file (or NIS equivalent) should contain the following entries:

```
snmp 161/udp # Simple Network Mgmt Protocol
snmp-trap 162/udp snmptrap # SNMP trap (event) messages
```

The following is an example for Solaris 2.x and releases compatible with Solaris 2.x, such as Solaris 9:

```
# # Start the SNMP agent
#```
if [ -f /etc/snmp/conf/snmpd.conf -a -x /usr/lib/snmp/mibiisa ];
then
/opt/SUNWconn/snmp/agents/snmpd
echo 'Starting SNMP-agent.'

Security

SNMP, as presently defined, offers relatively little security. The mibiisa utility accepts requests from other machines, which can have the effect of disabling the network capabilities of your computer. To limit the risk, the configuration file lets you specify a list of up to 32 manager stations from which mibiisa will accept requests. If you do not specify any such manager stations, mibiisa accepts requests from anywhere.

The mibiisa utility also allows you to mark the MIB as “read-only” by using the -r option.

mibiisa supports four different community strings. These strings, however, are visible in the configuration file and within the SNMP packets as they flow on the network.

The configuration file should be owned by, and readable only by super-user. In other words the mode should be:

```
−rw−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−− 1 root 2090 Oct 17 15:04 /etc/snmp/conf/snmpd.conf
```

Managers can be restricted based on the community strings. This can be configured by creating an optional secondary configuration file /etc/snmp/conf/mibiisa.acl. To enable such a restriction, add the security line in the /etc/snmp/conf/mibiisa.rsnc file.

An example mibiisa.acl file is as follows:

```
acl = {
    { communities = public
      access = read-only
      managers = xyz
    }
    { communities = private
      access = read-write
      managers = abc,pqrs
    }
}
```

An example mibiisa.rsnc file is as follows:

```
resource =
{
  { registration_file = "/etc/snmp/conf/mibiisa.reg"
    security = "/etc/snmp/conf/mibiisa.acl"
    policy = "spawn"
    type = "legacy"
  }
}
```
This section discusses some of the differences between the mibiisa MIB and the standard MIB-II (as defined in RFC 1213).

The following variables are read-only in the mibiisa MIB:

- sysName
- atIfIndex
- ipDefaultTTL

These variables are read-write in the standard MIB-II.

The mibiisa MIB Address Translation tables support limited write access: only atPhysAddress may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The mibiisa MIB IP Net to Media table supports limited write access: only ipNetToMediaPhysAddress and ipNetToMediaType may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The following variables are read-write in the mibiisa MIB; however, these variables have fixed values. Any new values "set" to them are accepted, but have no effect:

- ipRoutIfIndex
- ipRouteMetric1
- ipRouteMetric2
- ipRouteMetric3
- ipRouteMetric4
- ipRouteType
- ipRouteAge
- ipRouteMask
- ipRouteMetric5

The following mibiisa MIB variable reflects the actual state of the related table entry. "Sets" are accepted but have no effect:

- tcpConnState

The following mibiisa MIB variables are readable, but return a fixed value:

<table>
<thead>
<tr>

### Schema Attributes

The following describes the attributes in the group and table definitions in the `/var/snmp/mib/sun.mib` file.

- **system**
  - **sysDescr** – A textual description of the entity. This value should include the full name and version identification of the system’s hardware type, software operating-system, and networking software. This value must only contain printable ASCII characters. (string[255])
  - **sysObjectID** – The vendor’s authoritative identification of the network management subsystem contained in the entity. This value is allocated within the SMI enterprises subtree (1.3.6.1.4.1) and provides an easy and unambiguous means for determining what type of equipment is being managed. For example, if vendor “Flintstones, Inc.” was assigned the subtree 1.3.6.1.4.1.4242, it could assign the identifier 1.3.6.1.4.1.4242.1.1 to its “Fred Router.” (objectid)
  - **sysUpTime** – Time (in hundredths of a second) since the network management portion of the system was last reinitialized. (timeticks)
  - **sysContact** – The textual identification of the contact person for this managed node, together with information on how to contact this person. (string[255])
  - **sysName** – An administratively-assigned name for this managed node. By convention, this is the node’s fully-qualified domain name. (string[255])
  - **sysLocation** – The physical location of this node (for example, “telephone closet, 3rd floor” (string[255]))
  - **sysServices** – A value indicating the set of services that this entity primarily offers. (int) The value is a sum. This sum initially takes the value zero. Then, for each layer L in the range 1 through 7 for which this node performs transactions, 2 raised to (L - 1) is added to the sum. For example, a node that performs primarily routing functions would have a value of 4
(2**(3-1)). In contrast, a node that is a host offering application services would have a value of 72 (2**(4-1) + 2**(7-1)). Note that in the context of the Internet suite of protocols, values should be calculated accordingly:

<table>
<thead>
<tr>
<th>Layer</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>physical (such as repeaters)</td>
</tr>
<tr>
<td>2</td>
<td>datalink/subnetwork (such as bridges)</td>
</tr>
<tr>
<td>3</td>
<td>internet (such as IP gateways)</td>
</tr>
<tr>
<td>4</td>
<td>end-to-end (such as IP hosts)</td>
</tr>
<tr>
<td>7</td>
<td>applications (such as mail relays)</td>
</tr>
</tbody>
</table>

For systems including OSI protocols, Layers 5 and 6 may also be counted.

**interfaces**

The **interfaces** group reports the number of interfaces handled by the agent.

- **ifNumber** – The number of network interfaces, regardless of their current state, present on this system. (int)
- **ifTable** – A table of interface entries. The number of entries is given by the value of ifNumber.
  - **ifIndex** – A unique value for each interface. Its value ranges between 1 and the value of ifNumber. The value for each interface must remain constant at least from one reinitialization of the entity's network management system to the next reinitialization. (int)
  - **ifDescr** – A textual string containing information about the interface. This string should include the name of the manufacturer, the product name, and the version of the hardware interface. (string[255])
  - **ifType** – The type of interface, distinguished according to the physical/link protocol(s) immediately below the network layer in the protocol stack. (enum)
  - **ifMtu** – The size of the largest datagram that can be sent/received on the interface, specified in octets. For interfaces used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface. (int)
  - **ifSpeed** – An estimate of the interface's current bandwidth in bits-per-second. For interfaces that do not vary in bandwidth, or for those where no accurate estimation can be made, this object should contain the nominal bandwidth. (gauge)
  - **ifHysAddress** – The interface's address at the protocol layer immediately below the network layer in the protocol stack. For interfaces without such an address (for example, a serial line), this object should contain an octet string of zero length. (octet[128])
ifAdminStatus – The desired state of the interface. The testing(3) state indicates that no operational packets can be passed. (enum)

ifOperStatus – The current operational state of the interface. The testing(3) state indicates that no operational packets can be passed. (enum)

ifLastChange – The value of sysUpTime at the time the interface entered its current operational state. If the current state was entered prior to the last reinitialization of the local network management subsystem, then this object contains a zero value. (timeticks)

ifInOctets – The total number of octets received on the interface, including framing characters. (counter) Returns a fixed value of 0.

ifInUcastPkts – The number of subnetwork-unicast packets delivered to a higher-layer protocol. (counter)

ifInNUcastPkts – The number of non-unicast (that is, subnetwork-broadcast or subnetwork-multicast) packets delivered to a higher-layer protocol. (counter) Returns a fixed value of 0.

ifInDiscards – The number of inbound packets chosen to be discarded, even though no errors had been detected to prevent their being deliverable to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

ifInErrors – The number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. (counter)

ifInUnknownProtos – The number of packets received via the interface that were discarded because of an unknown or unsupported protocol. (counter) Returns a fixed value of 0.

ifOutOctets – The total number of octets transmitted out of the interface, including framing characters. (counter) Returns a fixed value of 0.

ifOutUcastPkts – The total number of packets that higher-level protocols requested be transmitted to a subnetwork-unicast address, including those that were discarded or not sent. (counter)

ifOutNUcastPkts – The total number of packets that higher-level protocols requested be transmitted to a non-unicast (that is, a subnetwork-broadcast or subnetwork-multicast) address, including those that were discarded or not sent. (counter) Returns a fixed value of 0.

ifOutDiscards – The number of outbound packets that were chosen to be discarded even though no errors had been detected to prevent their being transmitted. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

ifOutErrors – The number of outbound packets that could not be transmitted because of errors. (counter)
ifOutQLen – The length of the output packet queue (in packets). (gauge)

ifSpecific – A reference to MIB definitions specific to the particular media being used to realize the interface. For example, if the interface is realized by an Ethernet, then the value of this object refers to a document defining objects specific to Ethernet. If this information is not present, its value should be set to the OBJECT IDENTIFIER \( \{ 0 \ 0 \} \), which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)

atTable Address Translation tables contain the NetworkAddress to physical address equivalences. Some interfaces do not use translation tables for determining address equivalences (for example, DDN-X.25 has an algorithmic method). If all interfaces are of this type, then the Address Translation table is empty, that is, has zero entries.

atIfIndex – The interface on which this entry’s equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

atPhysAddress – The media-dependent physical address. (octet[128]) Setting this object to a null string (one of zero length) has the effect of invaliding the corresponding entry in the atTable object. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant atPhysAddress object.

atNetAddress – The NetworkAddress (that is, the IP address) corresponding to the media-dependent physical address. (netaddress)

ip The ip group reports statistics about the Internet Protocol (IP) group.

ipForwarding – The indication of whether this entity is acting as an IP gateway in respect to the forwarding of datagrams received by, but not addressed to, this entity. IP gateways forward datagrams. IP hosts do not—except those source-routed via the host. (enum)

Note that for some managed nodes, this object may take on only a subset of the values possible. Accordingly, it is appropriate for an agent to return a “badValue” response if a management station attempts to change this object to an inappropriate value.

ipDefaultTTL – The default value inserted into the Time-To-Live field of the IP header of datagrams originated at this entity, whenever a TTL value is not supplied by the transport layer protocol. (int)

ipInReceives – The total number of input datagrams received from interfaces, including those received in error. (counter)
ipInHdrErrors — The number of input datagrams discarded due to errors in their IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, errors discovered in processing their IP options, and so on. (counter)

ipInAddrErrors — The number of input datagrams discarded because the IP address in their IP header’s destination field was not a valid address to be received at this entity. This count includes invalid addresses (for example, 0.0.0.0) and addresses of unsupported Classes (for example, Class E). For entities that are not IP Gateways and therefore do not forward datagrams, this counter includes datagrams discarded because the destination address was not a local address. (counter)

ipForwDatagrams — The number of input datagrams for which this entity was not their final IP destination, as a result of which an attempt was made to find a route to forward them to that final destination. In entities that do not act as IP Gateways, this counter will include only those packets that were Source-Routed via this entity, and the Source-Route option processing was successful. (counter)

ipInUnknownProtos — The number of locally-addressed datagrams received successfully but discarded because of an unknown or unsupported protocol. (counter)

ipInDiscards — The number of input IP datagrams for which no problems were encountered to prevent their continued processing, but which were discarded, for example, for lack of buffer space. Note that this counter does not include any datagrams discarded while awaiting reassembly. (counter)

ipInDelivers — The total number of input datagrams successfully delivered to IP user-protocols (including ICMP). (counter)

ipOutRequests — The total number of IP datagrams that local IP user-protocols (including ICMP) supplied to IP in requests for transmission. Note that this counter does not include any datagrams counted in ipForwDatagrams. (counter)

ipOutDiscards — The number of output IP datagrams for which no problem was encountered to prevent their transmission to their destination, but which were discarded (for example, for lack of buffer space). Note that this counter would include datagrams counted in ipForwDatagrams if any such packets met this (discretionary) discard criterion. (counter)

ipOutNoRoutes — The number of IP datagrams discarded because no route could be found to transmit them to their destination. Note that this counter includes any packets counted in ipForwDatagrams which meet this “no-route” criterion. Note that this includes any datagrams that a host cannot route because all its default gateways are down. (counter)

ipReasmTimeout — The maximum number of seconds that received fragments are held while they are awaiting reassembly at this entity. (int)

ipReasmReqds — The number of IP fragments received that needed to be reassembled at this entity. (counter)
**ipReasmOKs** – The number of IP datagrams successfully reassembled. (counter)

**ipReasmFails** – The number of failures detected by the IP reassembly algorithm, for whatever reason: timed out, errors, and the like. Note that this is not necessarily a count of discarded IP fragments since some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received. (counter)

**ipFragOKs** – The number of IP datagrams that have been successfully fragmented at this entity. (counter)

**ipFragFails** – The number of IP datagrams that have been discarded because they needed to be fragmented at this entity but could not be, for example, because their “Don’t Fragment” flag was set. (counter)

**ipFragCreates** – The number of IP datagram fragments that have been generated as a result of fragmentation at this entity. (counter)

**ipRoutingDiscards** – The number of routing entries that were chosen to be discarded even though they were valid. One possible reason for discarding such an entry could be to free-up buffer space for other routing entries. (counter) Returns a fixed value of 0.

**ipAddrTable** is a table of addressing information relevant to this entity's IP addresses.

**ipAdEntAddr** – The IP address to which this entry's addressing information pertains. (netaddress)

**ipAdEntIfIndex** – The index value that uniquely identifies the interface to which this entry is applicable. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

**ipAdEntNetMask** – The subnet mask associated with the IP address of this entry. The value of the mask is an IP address with all the network bits set to 1, and all the hosts bits set to 0. (netaddress)

**ipAdEntBcastAddr** – The value of the least-significant bit in the IP broadcast address used for sending datagrams on the (logical) interface associated with the IP address of this entry. For example, when the Internet standard all-ones broadcast address is used, the value will be 1. This value applies to both the subnet and network broadcasts addresses used by the entity on this (logical) interface. (int) Returns a fixed value of 1.

**ipAdEntReasmMaxSize** – The size of the largest IP datagram that this entity can reassemble from incoming IP fragmented datagrams received on this interface. (int) Returns a fixed value of 65535.

**ipRouteTable** is this entity’s IP Routing table.

**ipRouteDest** – The destination IP address of this route. An entry with a value of 0.0.0.0 is considered a default route. Multiple routes to a single destination can appear in the table, but
access to such multiple entries is dependent on the table-access mechanisms defined by the network management protocol in use. (netaddress)

`ipRouteIfIndex` - The index value that uniquely identifies the local interface through which the next hop of this route should be reached. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

`ipRouteMetric1` - The primary routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s `ipRouteProto` value. If this metric is not used, its value should be set to \(-1\). (int) Returns a fixed value of \(-1\).

`ipRouteMetric2` - An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s `ipRouteProto` value. If this metric is not used, its value should be set to \(-1\). (int) Returns a fixed value of \(-1\).

`ipRouteMetric3` - An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s `ipRouteProto` value. If this metric is not used, its value should be set to \(-1\). (int) Returns a fixed value of \(-1\).

`ipRouteMetric4` - An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s `ipRouteProto` value. If this metric is not used, its value should be set to \(-1\). (int) Returns a fixed value of \(-1\).

`ipRouteNextHop` - The IP address of the next hop of this route. (In the case of a route bound to an interface that is realized via a broadcast media, the value of this field is the agent’s IP address on that interface.) (netaddress)

`ipRouteType` - The type of route. Note that the values direct (3) and indirect (4) refer to the notion of direct and indirect routing in the IP architecture. (enum)

Setting this object to the value invalid (2) has the effect of invalidating the corresponding entry in the `ipRouteTable` object. That is, it effectively dissociates the destination identified with said entry from the route identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant `ipRouteType` object.

`ipRouteProto` - The routing mechanism through which this route was learned. Inclusion of values for gateway routing protocols is not intended to imply that hosts should support those protocols. (enum)

`ipRouteAge` - The number of seconds since this route was last updated or otherwise determined to be correct. Note that no semantics of “too old” can be implied except through knowledge of the routing protocol by which the route was learned. (int) Returns a fixed value of 0.
ipRouteMask – Indicate the mask to be logical-ANDed with the destination address before being compared to the value in the ipRouteDest field. For those systems that do not support arbitrary subnet masks, an agent constructs the value of the ipRouteMask by determining whether the value of the correspondent ipRouteDest field belongs to a class-A, B, or C network, and then using one of:

<table>
<thead>
<tr>
<th>Mask</th>
<th>Network</th>
</tr>
</thead>
<tbody>
<tr>
<td>255.0.0.0</td>
<td>class-A</td>
</tr>
<tr>
<td>255.255.0.0</td>
<td>class-B</td>
</tr>
<tr>
<td>255.255.255.0</td>
<td>class-C</td>
</tr>
</tbody>
</table>

If the value of the ipRouteDest is 0.0.0.0 (a default route), then the mask value is also 0.0.0.0. It should be noted that all IP routing subsystems implicitly use this mechanism. (netaddress)

ipRouteMetric5 – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s ipRouteProto value. If this metric is not used, its value should be set to −1. (int) Returns a fixed value of −1.

ipRouteInfo – A reference to MIB definitions specific to the particular routing protocol responsible for this route, as determined by the value specified in the route’s ipRouteProto value. If this information is not present, its value should be set to the OBJECT IDENTIFIER {0 0}, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)

The ipNetToMediaTable is the IP Address Translation table used for mapping from IP addresses to physical addresses.

ipNetToMediaIfIndex – The interface on which this entry’s equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

ipNetToMediaPhysAddress – The media-dependent physical address. (octet[128])

ipNetToMediaNetAddress – The IPAddress corresponding to the media-dependent physical address. (netaddress)

ipNetToMediaType – The type of mapping. (enum) Returns a fixed value of (3)dynamic. Setting this object to the value invalid(2) has the effect of invalidating the corresponding entry in the ipNetToMediaTable. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant ipNetToMediaType object.
The `icmp` group reports statistics about the ICMP group.

- `icmpInMsgs` – The total number of ICMP messages that the entity received. Note that this counter includes all those counted by `icmpInErrors`. (counter)
- `icmpInErrors` – The number of ICMP messages that the entity received but determined as having ICMP-specific errors (bad ICMP checksums, bad length, and the like.). (counter)
- `icmpInDestUnreachs` – The number of ICMP Destination Unreachable messages received. (counter)
- `icmpInTimeExcds` – The number of ICMP Time Exceeded messages received. (counter)
- `icmpInParmProbs` – The number of ICMP Parameter Problem messages received. (counter)
- `icmpInSrcQuenchs` – The number of ICMP Source Quench messages received. (counter)
- `icmpInRedirects` – The number of ICMP Redirect messages received. (counter)
- `icmpInEchos` – The number of ICMP Echo (request) messages received. (counter)
- `icmpInEchoReps` – The number of ICMP Echo Reply messages received. (counter)
- `icmpInTimestamps` – The number of ICMP Timestamp (request) messages received. (counter)
- `icmpInTimestampReps` – The number of ICMP Timestamp Reply messages received. (counter)
- `icmpInAddrMasks` – The number of ICMP Address Mask Request messages received. (counter)
- `icmpInAddrMaskReps` – The number of ICMP Address Mask Reply messages received. (counter)
- `icmpOutMsgs` – The total number of ICMP messages that this entity attempted to send. Note that this counter includes all those counted by `icmpOutErrors`. (counter)
- `icmpOutErrors` – The number of ICMP messages that this entity did not send due to problems discovered within ICMP, such as a lack of buffers. This value should not include errors discovered outside the ICMP layer, such as the inability of IP to route the resultant datagram. In some implementations there may be no types of errors that contribute to this counter’s value. (counter)
- `icmpOutDestUnreachs` – The number of ICMP Destination Unreachable messages sent. (counter)
- `icmpOutTimeExcds` – The number of ICMP Time Exceeded messages sent. (counter)
- `icmpOutParmProbs` – The number of ICMP Parameter Problem messages sent. (counter)
icmpOutSrcQuenchs – The number of ICMP Source Quench messages sent. (counter)

icmpOutRedirects – The number of ICMP Redirect messages sent. For a host, this object will always be zero, since hosts do not send redirects. (counter)

icmpOutEchos – The number of ICMP Echo (request) messages sent. (counter)

icmpOutEchoReps – The number of ICMP Echo Reply messages sent. (counter)

icmpOutTimestamps – The number of ICMP Timestamp (request) messages sent. (counter)

icmpOutTimestampReps – The number of ICMP Timestamp Reply messages sent. (counter)

icmpOutAddrMasks – The number of ICMP Address Mask Request messages sent. (counter)

icmpOutAddrMaskReps – The number of ICMP Address Mask Reply messages sent. (counter)

tcp The tcp group reports statistics about the TCP group.

tcpRtoAlgorithm – The algorithm used to determine the timeout value used for retransmitting unacknowledged octets. (enum)

tcpRtoMin – The minimum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is rsre(3), an object of this type has the semantics of the LBOUND quantity described in RFC 793. (int)

tcpRtoMax – The maximum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is rsre(3), an object of this type has the semantics of the UBOUND quantity described in RFC 793. (int)

tcpMaxConn – The limit on the total number of TCP connections that the entity can support. In entities where the maximum number of connections is dynamic, this object should contain the value –1. (int)

tcpActiveOpens – The number of times that TCP connections have made a direct transition to the SYN-SENT state from the CLOSED state. (counter)

tcpPassiveOpens – The number of times that TCP connections have made a direct transition to the SYN-RCVD state from the LISTEN state. (counter)

tcpAttemptFails – The number of times that TCP connections have made a direct transition to the CLOSED state from either the SYN-SENT state or the SYN-RCVD state, plus the number of times TCP connections have made a direct transition to the LISTEN state from the SYN-RCVD state. (counter)
tcpEstabResets – The number of times TCP connections have made a direct transition to the CLOSED state from either the ESTABLISHED state or the CLOSE-WAIT state. (counter)

tcpCurrEstab – The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT. (gauge)

tcpInSegs – The total number of segments received, including those received in error. This count includes segments received on currently established connections. (counter)

tcpOutSegs – The total number of segments sent, including those on current connections but excluding those containing only retransmitted octets. (counter)

tcpRetransSegs – The total number of segments retransmitted - that is, the number of TCP segments transmitted containing one or more previously transmitted octets. (counter)

tcpInErrs – The total number of segments received in error (for example, bad TCP checksums). (counter)

tcpOutRsts – The number of TCP segments sent containing the RST flag. (counter)

tcpConnTable – A table containing TCP connection-specific information.

tcpConnState – The state of this TCP connection. (enum)

The only value that may be set by a management station is deleteTCB(12). Accordingly, it is appropriate for an agent to return a “badValue” response if a management station attempts to set this object to any other value.

If a management station sets this object to the value deleteTCB(12), then this has the effect of deleting the TCB (as defined in RFC 793) of the corresponding connection on the managed node. This results in immediate termination of the connection.

As an implementation-specific option, an RST segment may be sent from the managed node to the other TCP endpoint. (Note, however, that RST segments are not sent reliably.)

tcpConnLocalAddress – The local IP address for this TCP connection. For a connection in the listen state that is willing to accept connections for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)

tcpConnLocalPort – The local port number for this TCP connection. (int)

tcpConnRemAddress – The remote IP address for this TCP connection. (netaddress)

tcpConnRemPort – The remote port number for this TCP connection. (int)

udp – The UDP group reports statistics about the UDP group.

udpInDatagrams – The total number of UDP datagrams delivered to UDP users. (counter) Returns a fixed value of 0.
udpNoPorts – The total number of received UDP datagrams for which there was no application at the destination port. (counter) Returns a fixed value of 0.

udpInErrors – The number of received UDP datagrams that could not be delivered for reasons other than the lack of an application at the destination port. (counter)

udpOutDatagrams – The total number of UDP datagrams sent from this entity. (counter) Returns a fixed value of 0.

udpTable The udpTable is a table containing UDP listener information.

udpLocalAddress – The local IP address for this UDP listener. For a UDP listener that is willing to accept datagrams for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)

udpLocalPort – The local port number for this UDP listener. (int)

snmp The snmp group reports statistics about the SNMP group.

snmpInPkts – The total number of Messages delivered to the SNMP entity from the transport service. (counter)

snmpOutPkts – The total number of SNMP Messages passed from the SNMP protocol entity to the transport service. (counter)

snmpInBadVersions – The total number of SNMP Messages delivered to the SNMP protocol entity that were for an unsupported SNMP version. (counter)

snmpInBadCommunityNames – The total number of SNMP Messages delivered to the SNMP protocol entity that used a SNMP community name not known to said entity. (counter)

snmpInBadCommunityUses – The total number of SNMP Messages delivered to the SNMP protocol entity, which represented an SNMP operation not allowed by the SNMP community named in the Message. (counter)

snmpInASNParseErrs – The total number of ASN.1 or BER errors encountered by the SNMP protocol entity when decoding received SNMP Messages. (counter)

snmpInTooBigs – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “tooBig.” (counter)

snmpInNoSuchNames – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “noSuchName.” (counter)

snmpInBadValues – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “badValue.” (counter)
snmpInReadOnlys – The total number valid SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is "readOnly." It should be noted that it is a protocol error to generate an SNMP PDU that contains the value "readOnly" in the error-status field. This object is provided as a means of detecting incorrect implementations of the SNMP. (counter)

snmpInGenErrs – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is "genErr." (counter)

snmpInTotalReqVars – The total number of MIB objects successfully retrieved by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs. (counter)

snmpInTotalSetVars – The total number of MIB objects successfully altered by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs. (counter)

snmpInGetRequests – The total number of SNMP Get-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpInGetNexts – The total number of SNMP Get-Next PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpInSetRequests – The total number of SNMP Set-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpInGetResponses – The total number of SNMP Get-Response PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpInTraps – The total number of SNMP Trap PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpOutTooBigs – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is "tooBig." (counter)

snmpOutNoSuchNames – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status is "noSuchName." (counter)

snmpOutBadValues – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is "badValue." (counter)

snmpOutGenErrs – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is "genErr." (counter)

snmpOutGetRequests – The total number of SNMP Get-Request PDUs which have been generated by the SNMP protocol entity. (counter)

snmpOutGetNexts – The total number of SNMP Get-Next PDUs generated by the SNMP protocol entity. (counter)
**snmpOutSetRequests** – The total number of SNMP Set-Request PDUs generated by the SNMP protocol entity. (counter)

**snmpOutGetResponses** – The total number of SNMP Get-Response PDUs generated by the SNMP protocol entity. (counter)

**snmpOutTraps** – The total number of SNMP Trap PDUs generated by the SNMP protocol entity. (counter)

**snmpEnableAuthenTraps** – Indicates whether the SNMP agent process is permitted to generate authentication-failure traps. The value of this object overrides any configuration information. As such, it provides a means whereby all authentication-failure traps may be disabled. (enum)

Note that this object must be stored in non-volatile memory, so that it remains constant between reinitializations of the network management system.

The following are Sun-specific group and table definitions.

**sunSystem**

The `sunSystem` group reports general system information.

- **agentDescr** – The SNMP agent’s description of itself. (string[255])
- **hostID** – The unique Sun hardware identifier. The value returned is four byte binary string. (octet[4])
- **motd** – The first line of `/etc/motd`. (string[255])
- **unixTime** – The UNIX system time. Measured in seconds since January 1, 1970 UTC. (counter)

**sunProcessTable**

The `sunProcessTable` table reports UNIX process table information.

- **psProcessID** – The process identifier for this process. (int)
- **psParentProcessID** – The process identifier of this process’s parent. (int)
- **psProcessSize** – The combined size of the data and stack segments (in kilobytes.) (int)
- **psProcessCpuTime** – The CPU time (including both user and system time) consumed so far. (int)
- **psProcessState** – The run-state of the process. (octet[4])

<table>
<thead>
<tr>
<th>R</th>
<th>Runnable</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>Stopped</td>
</tr>
<tr>
<td>P</td>
<td>In page wait</td>
</tr>
</tbody>
</table>
D Non-interruptable wait
S Sleeping (less than 20 seconds)
I Idle (more than 20 seconds)
Z Zombie

psProcessWaitChannel – Reason process is waiting. (octet[16])
psProcessTTY – Terminal, if any, controlling this process. (octet[16])
psProcessUserName – Name of the user associated with this process. (octet[16])
psProcessUserID – Numeric form of the name of the user associated with this process. (int)
psProcessName – Command name used to invoke this process. (octet[64])
psProcessStatus – Setting this variable will cause a signal of the set value to be sent to the process. (int)

The sunHostPerf group reports hostperf information.

rsUserProcessTime – Total number of timeticks used by user processes since the last system boot. (counter)
rSNiceModeTime – Total number of timeticks used by “nice” mode since the last system boot. (counter)
rSSystemProcessTime – Total number of timeticks used by system processes since the last system boot. (counter)
rSIdleModeTime – Total number of timeticks in idle mode since the last system boot. (counter)
rSDiskXfer1 – Total number of disk transfers since the last boot for the first of four configured disks. (counter)
rSDiskXfer2 – Total number of disk transfers since the last boot for the second of four configured disks. (counter)
rSDiskXfer3 – Total number of disk transfers since the last boot for the third of four configured disks. (counter)
rSDiskXfer4 – Total number of disk transfers since the last boot for the fourth of four configured disks. (counter)

rsVPagesIn – Number of pages read in from disk. (counter)
rsVPagesOut – Number of pages written to disk. (counter)
rsVSwapIn – Number of pages swapped in. (counter)
rsVSwapOut – Number of pages swapped out. (counter)
rsVInt – Number of device interrupts. (counter)
rsIfInPackets – Number of input packets. (counter)
rsIfOutPackets – Number of output packets. (counter)
rsIfInErrors – Number of input errors. (counter)
rsIfOutErrors – Number of output errors. (counter)
rsIfCollisions – Number of output collisions. (counter)

**Files**

/etc/snmp/conf/snmpd.conf configuration information
/etc/snmp/conf/mibiisa.acl access control file
/var/snmp/mib/sun.mib standard SNMP MIBII file

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/network/snmp/mibiisa</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Obsolete</td>
</tr>
</tbody>
</table>

**See Also**

inetd(1M), select(3C), recvfrom(3SOCKET), sendto(3SOCKET), attributes(5), gld(7D)

**Diagnostics**

*cannot dispatch request*  The proxy cannot dispatch the request. The rest of the message indicates the cause of the failure.

*select(3C) failed*  A select(3C) call failed. The rest of the message indicates the cause of the failure.

*sendto(3SOCKET) failed*  A sendto(3SOCKET) call failed. The rest of the message indicates the cause of the failure.

*recvfrom(3SOCKET) failed*  A recvfrom(3SOCKET) call failed. The rest of the message indicates the cause of the failure.

*no response from system*  The SNMP agent on the target system does not respond to SNMP requests. This error might indicate that the
SNMP agent is not running on the target system, the target system is down, or the network containing the target system is unreachable.

**response too big**
The agent could not fit the results of an operation into a single SNMP message. Split large groups or tables into smaller entities.

**missing attribute**
An attribute is missing from the requested group.

**bad attribute type**
An object attribute type received from the SNMP agent that does not match the attribute type specified by the proxy agent schema. The rest of the message indicates the expected type and received type.

**cannot get sysUpTime**
The proxy agent cannot get the variable `sysUpTime` from the SNMP agent.

**sysUpTime type bad**
The variable `sysUpTime` received from the SNMP agent has the wrong data type.

**unknown SNMP error**
An unknown SNMP error was received.

**bad variable value**
The requested specified an incorrect syntax or value for a set operation.

**variable is read only**
The SNMP agent did not perform the set request because a variable to set may not be written.

**general error**
A general error was received.

**cannot make request PDU**
An error occurred building a request PDU.

**cannot make request varbind list**
An error occurred building a request variable binding list.

**cannot parse response PDU**
An error occurred parsing a response PDU.
request ID - response ID mismatch

The response ID does not match the request ID.

string contains non-displayable characters

A displayable string contains non-displayable characters.

cannot open schema file

An error occurred opening the proxy agent schema file.

cannot parse schema file

The proxy agent couldn't parse the proxy agent schema file.

cannot open host file

An error occurred opening the file associated with the `na.snmp.hostfile` keyword in `/etc/snmp/conf/snmpd.conf`

cannot parse host file

The proxy agent was unable to parse the file associated with the `na.snmp.hostfile` keyword in `/etc/snmp/conf/snm.conf`.

attribute unavailable for set operations

The set could not be completed because the attribute was not available for set operations.

**Bugs**

The `mibiisa` utility returns the wrong interface speed for the SBUS FDDI interface (for example, "bf0").

The `mibiisa` utility does not return a MAC address for the SBUS FDDI interface (for example, "bf0").

Process names retrieved from `mibiisa` contain a leading blank space.

When you change attribute values in the system group with an SNMP set request, the change is effective only as long as `mibiisa` is running. `mibiisa` does not save the changes to `/etc/snmp/conf/snmpd.conf`.

---

**mibiisa(1M)**

System Administration Commands - Part 2 1557
The \texttt{mkbootmedia} utility takes \textit{media-root} (the root of an on-disk Solaris install media) as input and creates a bootable Solaris ISO image in the file \texttt{iso}, using \texttt{mkisofs(8)}. The file can then be burned onto a CD/DVD with utilities such as \texttt{cdrw(1)} or \texttt{cdrecord(1)}. (Neither \texttt{mkisofs(8)} nor \texttt{cdrecord(1)} are SunOS man pages.)

\textbf{Caution} – The directory tree \texttt{media-root} must contain the file \texttt{boot/grub/stage2_eltorito}, which will be written to the media boot sectors. This file will be modified with some boot information, thus it must be writable. If necessary, first save a copy prior to running this utility.

### Options

The following options are supported:

- \texttt{-l \textit{label}}  
  Sets \textit{label} as the label/volume name of the ISO image.

- \texttt{-v}  
  Verbose. Multiple -v options increase verbosity.

### Operands

The following operands are supported:

- \texttt{media-root}  
  Top-level directory of an on-disk Solaris install media.

- \texttt{iso}  
  Name of the output file which will contain the resulting ISO image.

### Examples

\textbf{EXAMPLE 1}  
Creating an ISO Image and Burning a CD/DVD

The following commands create an ISO image from the content of s10u1 and burn the image to a CD/DVD.

\begin{verbatim}
# /usr/bin/mkbootmedia s10u1 s10u1.iso
# /usr/bin/cdrw -i s10u1.iso
\end{verbatim}

\texttt{mkisofs(8), \texttt{(8)/usr/share/man/man8/mkisofs.8}}, in the SUNWfsman package (not a SunOS man page)
The `mkdevalloc` command writes to standard out a set of `device_allocate(4)` entries describing the system’s framebuffer, audio, and removable media devices.

The `mkdevalloc` command is used by the device allocation service:

```
svc:/system/device/allocate:default
```

...to create or update the `device_allocate(4)` file. The device allocation service is managed by `smf(5)` and described in `device_allocate(1M)`.

Entries are generated based on the device special files found in `/dev`. For the different categories of devices, the `mkdevalloc` command checks for the following files under `/dev`:

- **audio** `/dev/audio`, `/dev/audioctl`, `/dev/sound/...
- **tape** `/dev/rst*`, `/dev/nrst*`, `/dev/rmt/...
- **removable disk** `/dev/sr*`, `/dev/nsr*`, `/dev/dsk/c0t?d0s?`, `/dev/rdsk/c0t?d0s?
- **frame buffer** `/dev/fb`

All entries set the `device-minimum` and `device-maximum` fields to the hex representations of `ADMIN_LOW` and `ADMIN_HIGH`, respectively. The `device-authorization` field is set to `solaris.device.allocate`, except for the framebuffer entry, where it is set to `*`. The `device-name`, `device-type` and `device-clean` fields are set to the following values:

```
device-name device-type device-clean
audio   audio   audio   audio_clean_wrapper
tape    mag_tape_0,1,...   st   st_clean
floppy  floppy_0,1,...   fd   disk_clean
removable disk  cdrom_0,1,...   sr   disk_clean
frame buffer  framebuffer   fb   /bin/true
```

### Notes
`mkdevalloc` might not be supported in a future release of the Solaris operating system.
The `mkdevmaps` command writes to standard out a set of `device_maps(4)` entries describing the system's framebuffer, audio, and removable media devices.

The `mkdevmaps` command is used by the device allocation service:

```
svc:/system/device/allocate:default
```

...to create or update the `device_maps(4)` file. The device allocation service is managed by `smf(5)` and described in `device_allocate(1M)`.

Entries are generated based on the device special files found in `/dev`. For the different categories of devices, the `mkdevmaps` command checks for the following files under `/dev`:

- **audio** /dev/audio, /dev/audioctl, /dev/sound/...
- **tape** /dev/rst*, /dev/nrst*, /dev/rmt/...
- **removable disk** /dev/dsk/c0t?d0s?, /dev/rdsk/c0t?d0s?
- **frame buffer** /dev/fb

**Notes** `mkdevmaps` might not be supported in a future release of the Solaris operating system.
Name  mkfifo – make FIFO special file

Synopsis  /usr/bin/mkfifo [-m mode] path...

Description  The mkfifo utility creates the FIFO special files named by its argument list. The arguments are taken sequentially, in the order specified; and each FIFO special file is either created completely or, in the case of an error or signal, not created at all.

If errors are encountered in creating one of the special files, mkfifo writes a diagnostic message to the standard error and continues with the remaining arguments, if any.

The mkfifo utility calls the library routine mkfifo(3C), with the path argument is passed as the path argument from the command line, and mode is set to the equivalent of a=rw, modified by the current value of the file mode creation mask umask(1).

Options  The following option is supported:

- **m mode**   Set the file permission bits of the newly-created FIFO to the specified mode value. The mode option-argument will be the same as the mode operand defined for the chmod(1) command. In <symbolic mode> strings, the op characters + and − will be interpreted relative to an assumed initial mode of a=rw.

Operands  The following operand is supported:

- **file**   A path name of the FIFO special file to be created.

Usage  See largefile(5) for the description of the behavior of mkfifo when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

Environment Variables  See environ(5) for descriptions of the following environment variables that affect the execution of mkfifo: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status  The following exit values are returned:

- **0**   All the specified FIFO special files were created successfully.
- **>0**   An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

Name  mkfile – create a file

Synopsis  mkfile [-nv] size [t | g | k | b | m] filename...

Description  mkfile creates one or more files that are suitable for use as NFS-mounted swap areas, or as local swap areas. When a root user executes mkfile(), the sticky bit is set and the file is padded with zeros by default. When non-root users execute mkfile(), they must manually set the sticky bit using chmod(1). The default size is in bytes, but it can be flagged as terabytes, gigabytes, kilobytes, blocks, or megabytes, with the t, g, k, b, or m suffixes, respectively. Suffixes can be uppercase or lowercase.

Options  -n  Create an empty filename. The size is noted, but disk blocks are not allocated until data is written to them. Files created with this option cannot be swapped over local UFS mounts.

- v  Verbose. Report the names and sizes of created files.

Exit Status  The following exit values are returned:

  0  Success.

>0  An error occurred.

Usage  See largefile(5) for the description of the behavior of mkfile when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

Attributes  See attributes(5) for descriptions of the following attributes:

<table>

mkfs – construct a filesystem

**Synopsis**

```bash
mkfs [-F FSType] [generic_options]
    [-o FSType-specific_options] raw_device_file
    [operands]
```

**Description**

The **mkfs** utility constructs a file system on the `raw_device_file` by calling the specific **mkfs** module indicated by `-F FSType`.

**Note:** ufs file systems are normally created with the **newfs** command.

- **generic_options** are independent of file system type. **FSType-specific_options** is a comma-separated list of `keyword=value` pairs (with no intervening spaces), which are **FSType**-specific. **raw_device_file** specifies the disk partition on which to write the file system. It is required and must be the first argument following the **specific_options** (if any). **operands** are **FSType**-specific. See the **FSType**-specific manual page of **mkfs** (for example, **mkfs_ufs**) for a detailed description.

**Options**

The following are the generic options for **mkfs**:

- **-F** Specify the **FSType** to be constructed. If `-F` is not specified, the **FSType** is determined from `/etc/vfstab` by matching the `raw_device_file` with a `vfstab` entry, or by consulting the `/etc/default/fs` file.

- **-V** Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided and adding to them information derived from `/etc/vfstab` or `/etc/default/fs`. This option may be used to verify and validate the command line.

- **-m** Return the command line which was used to create the file system. The file system must already exist. This option provides a means of determining the command used in constructing the file system.

- **-o** Specify **FSType**-specific options. See the manual page for the **mkfs** module specific to the file system type.

**Usage**

See **largefile** for the description of the behavior of **mkfs** when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

**Files**

- `/etc/default/fs` Default file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: `LOCAL=ufs`

  ```
  LOCAL The default partition for a command if no FSType is specified.
  ```

  `/etc/vfstab` List of default parameters for each file system
Attributes

Manual pages for the FSType-specific modules of mkfs.

Notes

This command might not be supported for all FSTypes.

You can use lofiadm to create a file that appears to a mkfs command as a raw device. You can then use a mkfs command to create a file system on that device. See lofiadm(1M) for examples of creating a UFS and a PC (FAT) file system (using mkfs_ufs(1M) and mkfs_pcfs(1M)) on a device created by lofiadm.
The `pcfs-specific module of `mkfs` constructs a File Allocation Table (FAT) on removable media (JAZ disk, ZIP disk, PCMCIA card), a hard disk, or a file (see NOTES). FATs are the standard MS-DOS and Windows file system format.

`mkfs` for `pcfs` determines an appropriate FAT size for the medium, then it installs an initial boot sector and an empty FAT. A sector size of 512 bytes is used. `mkfs` for `pcfs` can also install the initial file in the file system (see the `pcfs-specific -o i` option). This first file can optionally be marked as read-only, system, and/or hidden.

If you want to construct a FAT with `mkfs` for `pcfs` on a medium that is not formatted, you must first perform a low-level format on the medium with `format(1M)`. The media must also be partitioned with the `fdisk(1M)` utility. Note that all existing data on a disk partition, if any, is destroyed when a new FAT is constructed.

`generic_options` are supported by the generic `mkfs` command. See `mkfs(1M)` for a description of these options.

`raw_device_file` indicates the device on which to write unless the `-o N` option has been specified, or if the `-V` or `-m` generic options are passed from the generic `mkfs` module.

### Options

See `mkfs(1M)` for the list of supported generic options.

The following options are supported:

- `-o FSType_specific_options`
  
  Specify `pcfs` file system-specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored.

- `=label`
  
  Label the media with volume label. The volume label is restricted to 11 uppercase characters.

- `filename`
  
  Install `filename` as the boot loader in the file system’s boot sector. If you don’t specify a boot loader, an MS-DOS boot loader is installed. The MS-DOS boot loader requires specific MS-DOS system files to make a disk bootable. See NOTES for more information.

- `fat=n`
  
  The size of a FAT entry. Currently, 12, 16, and 32 are valid values. The default is 16.

- `h`
  
  Mark the first file installed as a hidden file. The `-i` option must also be specified.
hidden=n
Set the number of hidden sectors to n. This is the number of sectors on the physical disk preceding the start of the volume (which is the boot sector itself). This defaults to a computed value (based on the fdisk table) for disks. This option may be used only in conjunction with the nofdisk option.

i=filename
Install filename as the initial file in the new file system. The initial file's contents are guaranteed to occupy consecutive clusters at the start of the files area. When creating bootable media, a boot program should be specified as the initial file.

nofdisk
Do not attempt to find an fdisk table on the medium. Instead rely on the size option for determining the partition size. By default, the created FAT is 16 bits and begins at the first sector of the device. This origination sector can be modified with the hidden option (-h).

nsect=n
The number of sectors per track on the disk. If not specified, the value is determined by using a dkio(7I) ioctl to get the disk geometry.

ntrack=n
The number of tracks per cylinder on the disk. If not specified, the value is determined by using a dkio(7I) ioctl to get the disk geometry.

N
No execution mode. Print normal output, but do not actually write the file system to the medium. This is most useful when used in conjunction with the verbose option.

r
Mark the first file installed as read-only. The -i option must also be specified.

reserve=n
Set the number of reserved sectors to n. This is the number of sectors in the volume, preceding the start of the first FAT, including the boot sector. The value should always be at least 1, and the default value is exactly 1.

s
Mark the first file installed as a system file. The -i option must also be specified.

size=n
The number of sectors in the file system. If not specified, the value is determined from the size of the partition given in the fdisk table.

spc=n
The size of the allocation unit for space within the file system, expressed as a number of sectors. The default value depends on the FAT entry size and the size of the file system.

v
Verbose output. Describe, in detail, operations being performed.
The device on which to build the FAT.

mkfs_pcfs supports MBR (Master Boot Record) partitions and GPT (GUID Partition Table) partitions. GPT is part of the EFI (Extensible Firmware Interface) standard. For both x86 and SPARC, for a GPT-labeled disk, you can specify the partition using the logical device pathname with no suffix, for example, /dev/rdsk/c0t0d0s0. In GPT, this corresponds to the first partition on the disk.

On x86 for MBR partitions, you can specify the proper partition using the logical device pathname corresponding to the partition. For example, /dev/rdsk/c0t0d0p1 corresponds to first partition in the MBR, or /dev/rdsk/c0t0d0p5 corresponds to first logical partition in the extended partition. Alternatively, using a suffix is also acceptable. For example, in /dev/rdsk/c0t0d0p0:c, mkfs_pcfs recognizes :c as the first partition that can accept a FAT file system.

For removable media with MBR partitions on SPARC, you need to specify a disk device name with a suffix to indicate the proper partition. For example, in the name /dev/rdsk/c0t0d0s2:c, the :c suffix indicates that the partition can accept the new FAT.

For a file, raw_device_file is the block device name returned by lofiadm(1M).

Examples

The media in these examples must be formatted before running mkfs for pcfs. See DESCRIPTION for more details.

**EXAMPLE 1**  Creating a FAT File System on a Disk

The following command creates a FAT file system on the second fdisk partition of a disk attached to an x86 based system:

```
mkfs -F pcfs /dev/rdsk/c0d0p0:d
```

**EXAMPLE 2**  Creating a FAT File System on a ZIP Disk

The following command creates a FAT file system on a ZIP disk located on a SPARC based system:

```
mkfs -F pcfs /dev/rdsk/c0t4d0s2:c
```

**EXAMPLE 3**  Creating a FAT File System on a JAZ Disk

The following command creates a FAT file system on a JAZ disk located on a SPARC based system and overrides the sectors/track and tracks/cylinder values obtained from the device's controller:

```
mkfs -F pcfs -o nsect=32,ntrack=64 /dev/rdsk/c0t3d0s2:c
```

Notes You can use lofiadm to create a file that appears to a mkfs command (for example, mkfs_pcfs or mkfs_ufs) as a raw device. You can then use a mkfs command to create a file system on that device. See lofiadm(1M) for examples of creating a UFS and a PC (FAT) file system on a device created by lofiadm.
**Name**  
mkfs_udfs – construct a udfs file system

**Synopsis**  
mkfs -F udfs [generic_options] [-o specific_options] raw_device_file
[size]

**Description**  
This is the universal disk format file system (udfs) -specific module of the mkfs command. mkfs constructs a udfs file system with a root directory.

**Options**  
See mkfs(1M) for the list of supported generic_options.

The following options are supported:

- `-o specific_options`  
  Specify a udfs-specific option. Specify udfs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored.

The following specific_options are available:

- `N`  
  Print the file system parameters without actually creating the file system.

- `label=string`  
  Specify the label to be written into the volume header structures. Specify string as the name of the label. If string is not specified, a default string is generated in the form of *NoLabel*.

**Operands**  
The following operands are supported:

- `raw_device_file`  
  Specify the disk partition on which to write.

- `size`  
  Specify the number of 512-byte blocks in the file system.

**Attributes**  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/file-system/udfs</td>
</tr>
</tbody>
</table>

**See Also**  
fsck(1M), mkfs(1M), attributes(5)

**Diagnostics**  
not currently a valid file system

The specified device does not contain a valid udfs file system.

Invalid size: larger than the partition size

Number of blocks given as parameter to create the file system is larger than the size of the device specified.

`is mounted can’t mkfs`
Device is in use, cannot create file system when the device is in use.

Negativesize

Negative size parameter provided is invalid.

sector size must be between 512, 8192 bytes

Sector size given is not in the valid range.

Volume integrity sequence descriptors too long
File set descriptor too long.

Not enough space to create volume integrity sequence or file set descriptor.

mkfs: argument out of range

One of the arguments is out of range.

mkfs: bad numeric arg

One of the arguments is potentially a bad numeric.

Notes You can use lofiadm to create a file that appears to a mkfs command (for example, mkfs_pcfs or mkfs_ufs) as a raw device. You can then use a mkfs command to create a file system on that device. See lofiadm(1M) for examples of creating a UFS and a PC (FAT) file system on a device created by lofiadm.
mkfs_ufs(1M)

Name
mkfs_ufs – construct a UFS file system

Synopsis
mkfs -F ufs [generic_options] [-o FSType_specific_options] raw_device_file
[size]

Description
The UFS-specific module of mkfs builds a UFS file system with a root directory and a
lost+found directory (see fsck(1M)).

The UFS-specific mkfs is rarely run directly. Use the newfs(1M) command instead.

raw_device_file indicates the disk partition on which to create the new file system. If the -o N,
-V, or -m options are specified, the raw_device_file is not actually modified. size specifies the
number of disk sectors in the file system, where a disk sector is usually 512 bytes. This
argument must follow the raw_device_file argument and is required (even with -o N), unless
the -V or -m generic options are specified.

generic_options are supported by the generic mkfs command. See mkfs(1M) for a description
of these options.

Options
The following generic options are supported:

- m   Print the command line that was used to create the existing file system.
- V   Print the current mkfs command line.

Options
The following UFS-specific options are supported:

- o   Use one or more of the following values separated by commas (with no intervening
spaces) to specify UFS-specific options:

  apc=n   The number of alternate sectors per cylinder to reserve for bad block
          replacement for SCSI devices only. The default is 0.

  This option is not applicable for disks with EFI labels and is ignored.

  bsize=n   The logical block size of the file system in bytes, either 4096 or 8192.
          The default is 8192. The sun4u architecture does not support the
          4096 block size.

  calcbinsb Sends to stdout a binary (machine-readable) version of the
          superblock that would be used to create a file system with the
          specified configuration parameters.

  calcsb   Sends to stdout a human-readable version of the superblock that
          would be used to create a file system with the specified configuration
          parameters.

  cgsize=n   The number of cylinders per cylinder group, ranging from 16 to 256.
          The default is calculated by dividing the number of sectors in the file
          system by the number of sectors in a gigabyte. Then, the result is
          multiplied by 32. The default value is always between 16 and 256.
The per-cylinder-group meta data must fit in a space no larger than what is available in one logical file system block. If too large a cgsize is requested, it is changed by the minimum amount necessary.

`fragsize=n` The smallest amount of disk space in bytes that can be allocated to a file. `fragsize` must be a power of 2 divisor of `bsize`, where:

```
bsize / fragsize is 1, 2, 4, or 8.
```

This means that if the logical block size is 4096, legal values for `fragsize` are 512, 1024, 2048, and 4096. When the logical block size is 8192, legal values are 1024, 2048, 4096, and 8192. The default value is 1024.

For file systems greater than 1 terabyte or for file systems created with the `mtb=y` option, `fragsize` is forced to match block size (`bsize`).

`free=n` The minimum percentage of free space to maintain in the file system between 0% and 99%, inclusively. This space is off-limits to users. Once the file system is filled to this threshold, only the superuser can continue writing to the file system.

The default is `((64 Mbytes/partition size) * 100)`, rounded down to the nearest integer and limited between 1% and 10%, inclusively.

This parameter can be subsequently changed using the `tunefs(1M)` command.

`gap=n` Rotational delay. This option is obsolete in the Solaris 10 release. The value is always set to 0, regardless of the input value.

`maxcontig=n` The maximum number of logical blocks, belonging to one file, that are allocated contiguously. The default is calculated as follows:

```
maxcontig = disk drive maximum transfer size / disk block size
```

If the disk drive's maximum transfer size cannot be determined, the default value for `maxcontig` is calculated from kernel parameters as follows:

If `maxphys` is less than `ufs_maxmaxphys`, which is typically 1 Mbyte, then `maxcontig` is set to `maxphys`. Otherwise, `maxcontig` is set to `ufs_maxmaxphys`.

You can set `maxcontig` to any positive integer value.

The actual value will be the lesser of what has been specified and what the hardware supports.
You can subsequently change this parameter by using `tunefs(1M)`.

`mtb=y`  
Set the parameters of the file system to allow eventual growth to over a terabyte in total file system size. This option sets `fragsize` to be the same as `bsize`, and sets `nbpi` to 1 Mbyte, unless the `-i` option is used to make it even larger. If you explicitly set the `fragsize` or `nbpi` parameters to values that are incompatible with this option, the user-supplied value of `fragsize` or `nbpi` is ignored.

`N`  
Print out the file system parametersthat would be used to create the file system without actually creating the file system.

`nbpi=n`  
The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the number of inodes to create.

This value should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used. To create more inodes, a smaller number should be given. The default is 2048.

The number of inodes can increase if the file system is expanded with the `growfs` command.

`nrpos=n`  
The number of different rotational positions in which to divide a cylinder group. The default is 8.

This option is not applicable for disks with EFI labels and is ignored.

`nsect=n`  
The number of sectors per track on the disk. The default is 32.

This option is not applicable for disks with EFI labels and is ignored.

`ntrack=n`  
The number of tracks per cylinder on the disk. The default is 16.

This option is not applicable for disks with EFI labels and is ignored.

`opt=s | t`  
The file system can either be instructed to try to minimize the time spent allocating blocks, or to try to minimize the space fragmentation on the disk. The default is `time`.

This parameter can be subsequently changed with the `tunefs(1M)` command.

`rps=n`  
The rotational speed of the disk, in revolutions per second. The default is 60.

Note that you specify `rps` for `mkfs` and `rpm` for `newfs`.

This option is not applicable for disks with EFI labels and is ignored.
Alternatively, parameters can be entered as a list of space-separated values (without keywords) whose meaning is positional. In this case, the -o option is omitted and the list follows the size operand. This is the way newfs passes the parameters to mkfs.

**Operands**  The following operands are supported:

- `raw_device_file`  The disk partition on which to write.

**Attributes**  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

**See Also**  fsck(1M), mkfs(1M), newfs(1M), tunefs(1M), dir_ufs(4), attributes(5), ufs(7FS)

**Diagnostics**  The following error message typically occurs with very high density disks. On such disks, the file system structure cannot encode the proper disk layout information. However, such disks have enough onboard intelligence to make up for any layout deficiencies, so there is no actual impact on performance. The warning that performance might be impaired can be safely ignored.

```
Warning: insufficient space in super block for rotational layout tables with nsect sblock.fs_nsect and ntrak sblock.fs_ntrak. (File system performance may be impaired.)
```

The following error message occurs when the disk geometry results in a situation where the last truncated cylinder group cannot contain the correct number of data blocks. Some disk space is wasted.

```
Warning: inode blocks/cyl group (grp) >= data blocks (num) in last cylinder
```

If there is only one cylinder group and if the above condition holds true, mkfs fails with the following error:

```
File system creation failed. There is only one cylinder group and that is not even big enough to hold the inodes.
```

The following error message occurs when the best calculated file system layout is unable to include the last few sectors in the last cylinder group. This is due to the interaction between how much space is used for various pieces of meta data and the total blocks available in a cylinder group. Modifying nbsp and cpg might reduce this number, but it is rarely worth the effort.

```
Warning: num sector(s) in last cylinder group unallocated
```

**Notes**  You can use lofiadm to create a file that appears to the mkfs command (for example, mkfs_pcfs or mkfs_ufs) as a raw device. You can then use the mkfs command to create a file system on that device. See lofiadm(1M) for examples of creating a UFS and a PC (FAT) file system on a device created by lofiadm.
Both the block and character devices, such as devices in /dev/dsk and /dev/rdsk, must be available prior to running the `mkfs` command.
Name  mknod – make a special file

Synopsis  mknod name b major minor
          mknod name c major minor
          mknod name p

Description  mknod makes a directory entry for a special file.

Options  The following options are supported:
          b  Create a block-type special file.
          c  Create a character-type special file.
          p  Create a FIFO (named pipe).

Operands  The following operands are supported:
          major  The major device number.
          minor  The minor device number; can be either decimal or octal. The assignment of major device numbers is specific to each system. You must be the super-user to use this form of the command.
          name   A special file to be created.

Usage  See largefile(5) for the description of the behavior of mknod when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  ftp(1), mknod(2), symlink(2), attributes(5), largefile(5)

Notes  If mknod(2) is used to create a device, the major and minor device numbers are always interpreted by the kernel running on that machine.

With the advent of physical device naming, it would be preferable to create a symbolic link to the physical name of the device (in the /devices subtree) rather than using mknod.
**Synopsis**

```
mkntfs [options] device [number_of_sectors]
```

**Description**

The `mkntfs` utility is used to create an NTFS file system on a device, usually a disk partition, or file. The `device` operand is the special file corresponding to the device; for example, `/dev/dsk/c0d0p0`. The `number-of-sectors` operand is the number of blocks on the device. If omitted, `mkntfs` automatically figures the file system size.

**Options**

Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

Options are divided among basic, advanced, output, and help options, as listed below.

**Basic Options**

- `-C`, `--enable-compression`
  Enable compression on the volume.
- `-f`, `--fast` or `-q`, `--quick`
  Perform quick (fast) format. This option skips both zeroing of the volume and bad sector checking.
- `-L`, `--label string`
  Set the volume label for the filesystem to `string`.
- `-n`, `--no-action`
  Causes `mkntfs` to not actually create a file system, but display what it would do if it were to create a file system. All formatting steps are carried out except the actual writing to the device.

**Advanced Options**

- `-c`, `--cluster-size bytes`
  Specify the size of clusters in bytes. Valid cluster size values are powers of two, with at least 256, and at most 65536, bytes per cluster. If omitted, `mkntfs` uses 4096 bytes as the default cluster size.

  Note that the default cluster size is set to be at least equal to the sector size, as a cluster cannot be smaller than a sector. Also, note that values greater than 4096 have the side effect that compression is disabled on the volume. This is due to limitations in the NTFS compression algorithm used by Windows.
- `-F`, `--force`
  Force `mkntfs` to run, even if the specified device is not a block special device, or appears to be mounted.
-H, --heads num
Specify the number of heads. The maximum is 65535 (0xffff). If omitted, mkntfs attempts to determine the number of heads automatically. If that fails a default of 0 is used. Note that specifying num is required for Windows to be able to boot from the created volume.

-I, --no-indexing
Disable content indexing on the volume. This option is only meaningful on Windows 2000 and later. Windows NT 4.0 and earlier ignore this, as they do not implement content indexing.

-p, --partition-start sector
Specify the partition start sector. The maximum is 4294967295 (2^32-1). If omitted, mkntfs attempts to determine sector automatically. If that fails, a default of 0 is used. Note that specifying sector is required for Windows to be able to boot from the created volume.

-S, --sectors-per-track num
Specify the number of sectors per track. The maximum is 65535 (0xffff). If omitted, mkntfs attempts to determine the number of sectors-per-track automatically and if that fails a default of 0 is used. Note that sectors-per-track is required for Windows to be able to boot from the created volume.

-s, --sector-size bytes
Specify the size of sectors in bytes. Valid sector size values are 256, 512, 1024, 2048, and 4096. If omitted, mkntfs attempts to determine the sector-size automatically. If that fails, a default of 512 bytes per sector is used.

-T, --zero-time
Fake the time to be 00:00:00 UTC, Jan 1, 1970, instead of the current system time. This can be useful for debugging purposes.

-z, --mft-zone-multiplier num
Set the master file table (MFT) zone multiplier, which determines the size of the MFT zone to use on the volume. The MFT zone is the area at the beginning of the volume reserved for the MFT, which stores the on-disk inodes (MFT records). It is noteworthy that small files are stored entirely within the inode; thus, if you expect to use the volume for storing large numbers of very small files, it is useful to set the zone multiplier to a higher value. Although the MFT zone is resized on the fly as required during operation of the NTFS driver, choosing an optimal value reduces fragmentation. Valid values are 1, 2, 3, and 4. The values have the following meaning:

<table>
<thead>
<tr>
<th>MFT zone multiplier</th>
<th>MFT zone size (% of volume size)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>12.5% (default)</td>
</tr>
<tr>
<td>2</td>
<td>25.0%</td>
</tr>
<tr>
<td>3</td>
<td>37.5%</td>
</tr>
<tr>
<td>4</td>
<td>50.0%</td>
</tr>
</tbody>
</table>
Output Options

- `-debug`
  Includes the verbose output from the `-v` option, as well as additional output useful for debugging `mkntfs`.

- `-q, --quiet`
  Verbose execution. Errors are written to stderr, no output to stdout occurs at all. Useful if `mkntfs` is run in a script.

- `-v, --verbose`
  Verbose execution.

Help Options

- `-h, --help`
  Show a list of options with a brief description of each one.

- `-l, --license`
  Display the `mkntfs` licensing information and exit.

- `-V, --version`
  Display the `mkntfs` version number and exit.

Attributes

See `attributes(5)` for descriptions of the following attributes:

Authors

`mkntfs` was written by Anton Altiparmakov, Richard Russon, Erik Sornes and Szabolcs Szakacsits.
Name  mkpwdict – maintain password-strength checking database

Synopsis  

/usr/bin/mkpwdict [-s dict1,...,dictN]  

[-d destination-path]

Description  The mkpwdict command adds words to the dictionary-lookup database used by  
pam_authtok_check(5) and passwd(1).

Files containing words to be added to the database can be specified on the command-line  
using the -s flag. These source files should have a single word per line, much like  
/usr/share/lib/dict/words.

If -s is omitted, mkpwdict will use the value of DICTIONLIST specified in  
/etc/default/passwd (see passwd(1)).

The database is created in the directory specified by the -d option. If this option is omitted,  
mkpwdict uses the value of DICTIONDBDIR specified in /etc/default/passwd (see passwd(1)).  
The default location is /var/passwd.

Options  The following options are supported:

- -s  Specifies a comma-separated list of files containing words to be added to the  
dictionary-lookup database.

- -d  Specifies the target location of the dictionary-database.

Files  /etc/default/passwd  See passwd(1).

/var/passwd  default destination directory

modinfo – display information about loaded kernel modules

/usr/sbin/modinfo [-c] [-w] [-i module-id]

The `modinfo` utility displays information about the loaded modules. The format of the information is as follows:

```
Id Loadaddr Size Info Rev Module Name
```

where `Id` is the module ID, `Loadaddr` is the starting text address in hexadecimal, `Size` is the size of text, data, and bss in hexadecimal bytes, `Info` is module specific information, `Rev` is the revision of the loadable modules system, and `ModuleName` is the filename and description of the module.

The module specific information is the block and character major numbers for drivers, the system call number for system calls, and unspecified for other module types.

The following options are supported:

```
-c
-i module-id
-w
```

**Options**

- `-c`     Display the number of instances of the module loaded and the module's current state.
- `-i module-id` Display information about this module only.
- `-w`      Do not truncate module information at 80 characters.

**Examples**

**EXAMPLE 1** Displaying the Status of a Module

The following example displays the status of module 2:

```
example% modinfo -i 2
Id     Loadaddr  Size  Info  Rev  Module Name
2      ff08e000  1734  -     1    swapgeneric (root and swap configuration)
```

**EXAMPLE 2** Displaying the Status of Kernel Modules

The following example displays the status of some kernel modules:

```
example% modinfo
Id     Loadaddr  Size  Info  Rev  Module Name
2      ff08e000  1734  -     1    swapgeneric
4      ff07a000  3bc0  -     1    specs (filesystem for specs)
6      ff07dbc0  2918  -     1    TS (time sharing sched class)
7      ff0804d8  49c   -     1    TS_DPTBL (Time sharing dispatch table)
8      ff04a000  24a30 2     1    ufs (filesystem for ufs)
9      ff080978  c640  226   1    rpcmod (RPC syscall)
9      ff080978  c640  -     1    rpcmod (rpc interface str mod)
10     ff08cfe8  2031c  -     1    ip (IP Streams module)
10     ff08cfe8  2031c  2     1    ip (IP Streams device)
```

modinfo(1M)
EXAMPLE 3 Using the -c Option

Using the modinfo command with the -c option displays the number of instances of the module loaded and the module's current state.

```
example% modinfo -c
```

**See Also** modload(1M), modunload(1M), attributes(5)
modload(1M)

Name  modload – load a kernel module

Synopsis  modload [-p] [-e exec_file] filename

Description  The modload command loads the loadable module filename into the running system.

filename is an object file produced by ld -r. If filename is an absolute pathname then the file
specified by that absolute path is loaded. If filename does not begin with a slash (/), then the
path to load filename is relative to the current directory unless the -p option is specified.

The kernel’s modpath variable can be set using the /etc/system file. The default value of the
kernel’s modpath variable is set to the path where the operating system was loaded. Typically
this is /kernel/usr/kernel.

For example, the following command looks for ./drv/foo:

exemple# modload drv/foo

The following command looks for /kernel/drv/foo and then /usr/kernel/drv/foo:

exemple# modload -p drv/foo

Options  The following options are supported:

- e exec_file  Specify the name of a shell script or executable image file that is executed after
the module is successfully loaded. The first argument passed is the module ID
(in decimal). The other argument is module specific. The module specific
information is: the block and character major numbers for drivers, the system
call number for system calls, or, for other module types, the index into the
appropriate kernel table. See modinfo(1M)

- p  Use the kernel’s internal modpath variable as the search path for the module.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTETYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

modldr(9S), modlinkage(9S), modlstrmod(9S), module_info(9S)

Writing Device Drivers

Notes  Use add_drv(1M) to add device drivers, not modload. See Writing Device Drivers for
procedures on adding device drivers.
modunload (1M)

**Name**
modunload – unload a module

**Synopsis**
modunload -i module_id [-e exec_file]

**Description**
`modunload` unloads a loadable module from the running system. The `module_id` is the ID of the module as shown by `modinfo(1M)`. If ID is 0, all modules that were autoloaded which are unloadable, are unloaded. Modules loaded by `modload(1M)` are not affected.

**Options**
The following options are supported:

- `-e exec_file` Specify the name of a shell script or executable image file to be executed before the module is unloaded. The first argument passed is the module id (in decimal). There are two additional arguments that are module specific. For loadable drivers, the second argument is the driver major number. For loadable system calls, the second argument is the system call number. For loadable exec classes, the second argument is the index into the execsw table. For loadable filesystems, the second argument is the index into the vfs table. For loadable streams modules, the second argument is the index into the fmodsw table. For loadable scheduling classes, the second argument is the index into the class array. Minus one is passed for an argument that does not apply.

- `-i module_id` Specify the module to be unloaded.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

**See Also**
`modinfo(1M), modload(1M), update_drv(1M), attributes(5)`

**Notes**
The `modunload` command is often used on driver modules to force the system to reread the associated driver configuration file. While this works in the current Solaris release, it is not the supported way to reread the configuration file and is not guaranteed to work in future releases. The supported way for rereading driver configuration file is through the `update_drv(1M)` command.
**Name**
mofcomp – compile MOF files into CIM classes

**Synopsis**
/usr/sadm/bin/mofcomp [-c cimom_hostname] [-h]
[-j filename] [-n namespace] [-o dirname]
[-x] file

**Description**
The `mofcomp` utility is executed during installation to compile managed object format (MOF) files that describe the Common Information Model (CIM) and Solaris Schemas into the CIM Object Manager Repository, a central storage area for management data. The CIM Schema is a collection of class definitions used to represent managed objects that occur in every management environment. The Solaris Schema is a collection of class definitions that extend the CIM Schema and represent managed objects in a typical Solaris operating environment.

The `mofcomp` utility must be run as root or equivalent privileges, or as a user with write access to the namespace in which you are compiling. When performing a privileged operation, you must enter the `-u` or `-u` and `-p` options, which are described below.

MOF is a language for defining CIM classes and instances. MOF files are ASCII text files that use the MOF language to describe CIM objects. A CIM object is a computer representation or model of a managed resource, such as a printer, disk drive, or CPU.

Many sites store information about managed resources in MOF files. Because MOF can be converted to Java, Java applications that can run on any system with a Java Virtual Machine can interpret and exchange this information. You can also use the `mofcomp` utility to compile MOF files at any time after installation.

**Options**
The following options are supported:

- `-c cimom_hostname`
  Specify a remote system running the CIM Object Manager.

- `-C`
  Run the compiler set with the class option, which updates a class if it exists, and returns an error if the class does not exist. If you do not specify this option, the compiler adds a CIM class to the connected namespace, and returns an error if the class already exists.

- `-h`
  List the arguments to the `mofcomp` utility.

- `-I`
  Run the compiler set with the instance option, which updates an instance if it exists, and returns an error if the instance does not exist. If you do not specify this option, the compiler adds a CIM instance to the connected namespace, and returns an error if the instance already exists.

- `-j filename`
  Generate Java Beans and Java Interfaces to manage the CIM instances related to the CIM classes in the MOF being compiled.
The contents of filename are:

```
PACKAGE=Java package name
IMPORTS=import1:...:importN
<EXCEPTIONS=exception1:...:exceptionN
```

PACKAGE is a valid Java package name to include in all generated Java source. IMPORTS is an optional colon separated list of valid Java classes to be imported in all generated Java source. EXCEPTIONS is an optional colon separated list of valid Java exceptions to be thrown by the methods in all generated Java source.

```
-n namespace
```
Requests that the compiler load the MOF file into the namespace specified as namespace. The default namespace (root\cimv2) is used unless this switch is used or a #pragma namespace (namespace) statement appears in the MOF file. If both the -n namespace switch and the #pragma namespace construct are used, all namespaces are created, but the objects are created only in the #pragma namespaces.

```
-o dirname
```
Run compiler in standalone mode, without the CIM Object Manager. Specify dirname as the directory in which the compiler output is to be stored. In this mode, the CIM Object Manager need not be running.

```
-p password
```
Specify a password for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both -p and -u, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify -u but not -p, so that the compiler will prompt for the password.

```
-Q
```
Run the compiler set with the qualifier types option, which updates a qualifier type if it exists, and returns an error if the qualifier type does not exist. If you do not specify this option, the compiler adds a CIM qualifier type to the connected namespace, and returns an error if the qualifier type already exists.

```
-u username
```
Specify user name for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both -p and -u, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify -u but not -p, so that the compiler will prompt for the password.

```
-v
```
Run the compiler in verbose mode, which displays compiler messages.

```
-version
```
Display the version of the MOF compiler.
-x
   Generate XML documents for the CIM classes defined in the input MOF file.

**Operands**  The following operands are supported:

*file*
   The pathname of the file to be compiled.

**Exit Status**  The `mofcomp` utility exits with 0 upon success and a positive integer upon failure.

**Files**  MOF files are installed in `/usr/sadm/mof`.

**Attributes**  See `attributes(5)` for descriptions of the following attributes:

**See Also**  `init.wbem(1M), mofreg(1M), wbemadmin(1M), wbemlogviewer(1M), attributes(5), wbem(5)`
Name  mofreg – register MOF classes with WBEM services

Synopsis  /usr/sadm/bin/mofreg -r tag file
          /usr/sadm/bin/mofreg -s
          /usr/sadm/bin/mofreg -u tag [file]

Description  The mofreg command is used by package and patch install scripts, or by any applications that wish to register managed object format (MOF) classes with Sun The Web-Based Enterprise Management (WBEM) services.

The WBEM services daemon (Common Information Model or CIM object manager) processes at start up the files that are specified by mofreg commands. Files are processed in the order that the individual mofreg commands are executed.

As an alternative to using the mofreg command, MOFs can be registered or unregistered by manipulating directories in /var/sadm/wbem/logr. Instead of running the mofreg -r tag file version fo the command you can create a directory named tag under /var/sadm/wbem/logr/preReg and copy file to the tag directory.

Similarly, instead of running the mofreg -u tag [file] command, you can create a directory named tag under /var/sadm/wbem/logr/preUnreg and copy the optional file to the tag directory.

The entries are processed in increasing order of last modification time of the tag directories. If you issue mofreg commands in rapid succession, the timestamps might be the same. If you have a situation where the timestamp order is critical, you can place appropriate sleeps between the successive registration or unregistration operations. As with the mofreg command, processing is done at next restart or by using the -s option.

This alternative mechanism is typically used in package install scripts which do not have access to /usr, and therefore do not have access to the mofreg command. This case arises when packages are installed for diskless clients.

Options  The following options are supported:

- r tag file  The file argument is the actual MOF registration file. Its form is identical to the MOF syntax as defined by the Distributed Management Task Force (DMTF). The only difference is the addition of the following 3 new pseudo-pragmas, which are variations of the namespace pragma. The name of file cannot end in .unreg.

    #pragma namespace("__create")
    #pragma namespace("__delete")
    #pragma namespace("__modify")

    These three pragmas are used specify if the elements following the pragmas should be created, deleted, or modified by the CIM object manager. The "__delete" pragma can currently only be applied for a mofreg - u command.
The *tag* argument is a unique string that specifies the identity of the registry action. This tag can be set to the package name or the patch number if the *mofreg* script is being invoked through packages/patches, though any tag can be specified.

Errors and warnings that are encountered when the CIM object manager handles the *mofreg* script are logged. Processing of the *mofreg* script stops at the first error. Specific warnings include:

- **Element already defined** - the element already exists and cannot be created.
- **Element not found** - the element does not exist and cannot be modified.

The error conditions are:

- **Key modification** - A class cannot be modified if its keys are being changed.
- **Other mod compilation errors**.

- **-s**
  Forces the CIM object manager to immediately process outstanding registry requests, instead of at the next restart. This currently requires Java.

- **-u tag [file]**
  Undoes the operations performed during *mofreg*.

The *tag* argument must correspond to the value set during the original *mofreg* invocation. If no *mofreg* was done with the original *tag*, the command does not succeed.

If required, an *unreg* file can be specified. If no *unreg* file is specified, the CIM object manager automatically undoes the actions of the registry. Any class created by the registry process is removed and any classes modified by the registry revert to the old state.

The *mofreg* command does not take care of cases where packages and patches make conflicting changes to classes. This should be taken care of by the standard patch and package conflict resolution.

**Exit Status** The following exit values are returned:

- **0**  Successful completion.
- **1**  An error occurred. The reason for error is displayed.

<td></td>
<td>If the ‘auto-boot?’ NVRAM parameter is set to ‘false’ when the workstation is powered on, the system does not attempt to boot and the monitor issues its prompt. If ‘auto-boot’ is set to ‘true’, the system initiates the boot sequence. The boot sequence can be aborted by simultaneously pressing two keys on the system's keyboard: L1 and A (on older keyboards), or Stop and A (on newer keyboards). Either a lower case a or an upper case A works for the keyboard abort sequence. If a console has been attached by way of one of the system’s serial ports then the abort sequence can be accomplished by sending a BREAK. See tip(1).</td>
</tr>
<tr>
<td></td>
<td>When the NVRAM ‘security-mode’ parameter has been turned on, or when the value of the ‘sunmon-compat?’ parameter is true, then the OpenBoot monitor displays the message: Type b (boot), c (continue), or n (new command mode) and the &gt; prompt appears.</td>
</tr>
<tr>
<td><strong>Openboot Prom Usage</strong></td>
<td>Some of the more useful commands that can be issued from OpenBoot's ok prompt are described here. Refer to the OpenBoot 2.x Command Reference Manual book for a complete list of commands.</td>
</tr>
<tr>
<td><strong>Help</strong></td>
<td>Help for various functional areas of the OpenBoot monitor can be obtained by typing help. The help listing provides a number of other key words which can then be used in the help command to provide further details.</td>
</tr>
<tr>
<td><strong>NVRAM Parameters</strong></td>
<td>Each workstation contains one or more NVRAM devices which contains unique system ID information, as well as a set of user-configurable parameters. The NVRAM parameters allow the user a certain level of flexibility in configuring the system to act in a given manner under a specific set of circumstances.</td>
</tr>
<tr>
<td></td>
<td>See eeprom(1M) for a description of the parameters and information regarding setting the parameters from the OS level.</td>
</tr>
</tbody>
</table>
The following commands can be used at the OpenBoot monitor to access the NVRAM parameters.

printenv  
Used to list the NVRAM parameters, along with their default values and current values.

setenv pn pv  
Used to set or modify a parameter. The pn represents the parameter name, and pv represents the parameter value.

set-default pn  
Used to set an individual parameter back to its default value.

set-defaults  
Used to reset all parameters to their default values. (Note that ’set-defaults’ only affects parameters that have assigned default values.)

Security Parameters  
Newer OpenBoot monitors contain user interfaces that support the storage and listing of keys for later use by client programs.

list-security-keys  
Lists the names of keys currently stored on a machine.

set-security-key keyname [ keydata ]  
Stores key data keydata in a key named keyname. Actual key data can be up to 32 bytes in length. The maximum length of keyname is 64 bytes, which allows for the hex-formatted ASCII used to present the key data. If keydata is not present, keyname and its corresponding data is deleted.

Hardware Checks and Diagnostics  
The following commands are available for testing or checking the system’s hardware. If the ’diag-switch?’ NVRAM parameter is set to true when the system is powered on, then a Power-On Self Test (POST) diagnostic is run, if present, sending its results messages to the system’s serial port A. Not all of the commands shown are available on all workstations.

test-all  
Run the diagnostic tests on each device which has provided a self-test.

test /memory  
Run the main memory tests. If the NVRAM parameter ’diag-switch?’ is set to true, then all of main memory is tested. If the parameter is false then only the amount of memory specified in the ’selftest-#megs’ NVRAM parameter is tested.

test net  
Test the network connection for the on-board network controller.

watch-net  
Monitor the network attached to the on-board net controller.

watch-net-all  
Monitor the network attached to the on-board net controller, as well as the network controllers installed in SBus slots.

watch-clock  
Test the system’s clock function.
System Information

The following commands are available for displaying information about the system. Not all commands are available on all workstations.

- `banner` Display the power-on banner.
- `.enet-addr` Display the system’s Ethernet address.
- `.idprom` Display the formatted contents of the IDPROM.
- `module-info` Display information about the system’s processor(s).
- `probe-scsi` Identify the devices attached to the on-board SCSI controller.
- `probe-scsi-all` Identify the devices attached to the on-board SCSI controller as well as those devices which are attached to SBus SCSI controllers.
- `show-disks` Display a list of the device paths for installed SCSI disk controllers.
- `show-displays` Display a list of the device paths for installed display devices.
- `show-nets` Display a list of the device paths for installed Ethernet controllers.
- `show-sbus` Display list of installed SBus devices.
- `show-tapes` Display a list of the device paths for installed SCSI tape controllers.
- `show-ttys` Display a list of the device paths for tty devices.
- `.traps` Display a list of the SPARC trap types.
- `.version` Display the version and date of the OpenBoot PROM.

Emergency Commands

These commands must be typed from the keyboard, they do not work from a console which is attached by way of the serial ports. With the exception of the Stop-A command, these commands are issued by pressing and holding down the indicated keys on the keyboard immediately after the system has been powered on. The keys must be held down until the monitor has checked their status. The Stop-A command can be issued at any time after the console display begins, and the keys do not need to be held down once they’ve been pressed. The Stop-D, Stop-F and Stop-N commands are not allowed when one of the security modes has been set. Not all commands are available on all workstations.

- **Stop (L1)** Bypass the Power-On Self Test (POST). This is only effective if the system has been placed into the diagnostic mode.
- **Stop-A (L1-A)** Abort the current operation and return to the monitor’s default prompt.
- **Stop-D (L1-D)** Set the system’s ‘diag-switch?’ NVRAM parameter to ‘true’, which places the system in diagnostic mode. POST diagnostics, if present, are run, and the messages are displayed by way of the system’s serial port A.
- **Stop-F (L1-F)** Enter the OpenBoot monitor before the monitor has probed the system for devices. Issue the ‘fexit’ command to continue with system initialization.
Stop-N (L1-N)  Causes the NVRAM parameters to be reset to their default values. Note that not all parameters have default values.

Line Editor Commands  The following commands can be used while the monitor is displaying the ok prompt. Not all of these editing commands are available on all workstations.

- CTRL-A  Place the cursor at the start of line.
- CTRL-B  Move the cursor backward one character.
- ESC-B   Move the cursor backward one word.
- CTRL-D  Erase the character that the cursor is currently highlighting.
- ESC-D   Erase the portion of word from the cursor’s present position to the end of the word.
- CTRL-E  Place the cursor at the end of line.
- CTRL-F  Move the cursor forward one character.
- ESC-F   Move the cursor forward one word.
- CTRL-H  Erase the character preceding the cursor (also use Delete or Back Space)
- ESC-H   Erase the portion of the word which precedes the cursor (use also CTRL-W)
- CTRL-K  Erase from the cursor’s present position to the end of the line.
- CTRL-L  Show the command history list.
- CTRL-N  Recall the next command from the command history list
- CTRL-P  Recall a previous command from the command history list.
- CTRL-Q  Quote the next character (used to type a control character).
- CTRL-R  Retype the current line.
- CTRL-U  Erase from the cursor’s present position to the beginning of the line.
- CTRL-Y  Insert the contents of the memory buffer into the line, in front (to the left) of the cursor.

nvramrc  The nvramrc is an area of the system’s NVRAM where users may store Forth programs. The programs which are stored in the nvramrc are executed each time the system is reset, provided that the ‘use-nvramrc?’ NVRAM parameter has been set to ‘true’. Refer to the OpenBoot 2.x Command Reference Manual book for information on how to edit and use the nvramrc.

Restricted Monitor  The command ‘old-mode’ is used to move OpenBoot into a restricted monitor mode, causing the > prompt to be displayed. Only three commands are allowed while in the restricted monitor; the ‘go’ command (to resume a program which was interrupted with the
Stop-A command), the 'n' command (to return to the normal OpenBoot monitor), and boot commands. The restricted monitor's boot commands approximate the older SunMON monitor's boot command syntax. If a 'security-mode' has been turned on then the restricted monitor becomes the default monitor environment. The restricted monitor may also become the default environment if the 'sunmon-compat?' NVRAM parameter is set to true. Not all workstations have the 'sunmon-compat?' parameter.

The following commands are available systems with older SunMON-based PROM:

- `+` or `-` Increment or decrement the current address and display the contents of the new location.

- `^C` source destination n
  (caret-C) Copy, byte-by-byte, a block of length n from the source address to the destination address.

- `^I` program
  (caret-I) Display the compilation date and location of program.

- `^T` virtual_address
  (caret-T) Display the physical address to which virtual_address is mapped.

- `b [ ! ] [ device [ (c, u, p ) ] ] [ pathname ] [ arguments_list ]
  b[?]

  Reset appropriate parts of the system and bootstrap a program. A '! ' (preceding the device argument) prevents the system reset from occurring. Programs can be loaded from various devices (such as a disk, tape, or Ethernet). 'b' with no arguments causes a default boot, either from a disk, or from an Ethernet controller. 'b?' displays all boot devices and their devices.

  device one of
  le   Lance Ethernet
  ie   Intel Ethernet
  sd   SCSI disk, CDROM
  st   SCSI 1/4– or 1/2–inch tape
  fd   Diskette
  id   IPIdisk
  mt   Tape Master 9-track 1/2–inch tape
  xd   Xylogics 7053 disk
  xt   Xylogics 1/2–inch tape
  xy   Xylogics 440/450 disk
A controller number (0 if only one controller),
A unit number (0 if only one driver), and
A partition.
A pathname for a program such as /stand/diag.
A list of up to seven arguments to pass to the program being booted.
Resume execution of a program. When given, virtual_address is the address at which execution resumes. The default is the current PC. Registers are restored to the values shown by the d, and r commands.
Display (dump) the state of the processor. The processor state is observable only after:
- An unexpected trap was encountered.
- A user program dropped into the monitor (by calling abortent).
- The user manually entered the monitor by typing L1−A or BREAK.
The display consists of the following:
- The special registers: PSR, PC, nPC, TBR, WIM, and Y
- Eight global registers
- 24 window registers (8 in, 8 local, and 8 out), corresponding to one of the 7 available windows. If a Floating-Point Unit is on board, its status register along with 32 floating-point registers are also shown.
Display the indicated window_number, which can be any value between 0 and 6, inclusive. If no window is specified and the PSR’s current window pointer contains a valid window number, registers from the window that was active just prior to entry into the monitor are displayed. Otherwise, registers from window 0 are displayed.
Open the 16-bit word at virtual_address (default zero). The address is interpreted in the address space defined by the s command. See the a command for a description of action.
Fill the bytes, words, or long words from virtual_address1 (lower) to virtual_address2 (higher) with the constant, pattern. The size argument can take one of the following values:
- byte format (the default)
- word format
- long word format
For example, the following command fills the address block from 0x1000 to 0x2000 with the word pattern, 0xABCD:

\[ f \ 1000 \ 2000 \ ABCD \ W \]

\[ g \ [vector] \ [argument] \]
\[ g \ [virtual_address] \ [argument] \]

Goto (jump to) a predetermined or default routine (first form), or to a user-specified routine (second form). The value of argument is passed to the routine. If the vector or virtual_address argument is omitted, the value in the PC is used as the address to jump to.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor’s g command, set the variable *romp->v_vector_cmd to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied vector according to the format supplied in argument. This format can be one of:

\[ \%x \] hexadecimal
\[ \%d \] decimal

\[ g0 \]
Force a panic and produce a crash dump when the monitor is running as a result of the system being interrupted,

\[ g4 \]
(Sun-4 systems only) Force a kernel stack trace when the monitor is running as a result of the system being interrupted,

\[ h \]
Display the help menu for monitor commands and their descriptions. To return to the monitor’s basic command level, press ESCAPE or q before pressing RETURN.

\[ i \ [cache_data_offset] \ [action] \]
Modify cache data RAM command. Display and/or modify one or more of the cache data addresses. See the a command for a description of action.

\[ j \ [cache_tag_offset] \ [action] \]
Modify cache tag RAM command. Display and/or modify the contents of one or more of the cache tag addresses. See the a command for a description of action.

\[ k \ [reset_level] \]
Reset the system, where reset_level is:

0 Reset VMEbus, interrupt registers, video monitor (Sun-4 systems). This is the default.
1 Software reset.
Power-on reset. Resets and clears the memory. Runs the EPROM-based diagnostic self test, which can take several minutes, depending upon how much memory is being tested.

Display the system banner.

Open the long word (32 bit) at memory address \textit{virtual_address} (default zero). The address is interpreted in the address space defined by the \texttt{s} command (below). See the \texttt{a} command for a description of \textit{action}.

Open the segment map entry that maps \textit{virtual_address} (default zero). The address is interpreted in the address space defined by the \texttt{s} command. See the \texttt{a} command for a description of \textit{action}.

Disable, enable, or invalidate the cache, respectively.

Open the byte location specified by \textit{virtual_address} (default zero). The address is interpreted in the address space defined by the \texttt{s} command. See the \texttt{a} command for a description of \textit{action}.

Open the page map entry that maps \textit{virtual_address} (default zero) in the address space defined by the \texttt{s} command. See the \texttt{a} command for a description of \textit{action}.

Open the EEPROM \texttt{eeprom_offset} (default zero) in the EEPROM address space. All addresses are referenced from the beginning or base of the EEPROM in physical address space, and a limit check is performed to insure that no address beyond the EEPROM physical space is accessed. This command is used to display or modify configuration parameters, such as: the amount of memory to test during self test, whether to display a standard or custom banner, if a serial port (A or B) is to be the system console, etc. See the \texttt{a} command for a description of \textit{action}.

Display and/or modify one or more of the IU or FPU registers. A hexadecimal \texttt{register_number} can be one of:

\begin{verbatim}
0x00–0x0f   window(0,i0)–window(0,i7), window(0,i0)–window(0,i7)
0x16–0x1f   window(1,i0)–window(1,i7), window(1,i0)–window(1,i7)
\end{verbatim}
Register numbers can only be displayed after an unexpected trap, a user program has entered the monitor using the `abortent` function, or the user has entered the monitor by manually typing `L1`–`A` or `BREAK`.

If a `register_type` is given, the first register of the indicated type is displayed. `register_type` can be one of:

- `f`  floating-point
- `g`  global
- `s`  special

If `w` and a `window_number` (0–6) are given, the first in-register within the indicated window is displayed. If `window_number` is omitted, the window that was active just prior to entering the monitor is used. If the PSR’s current window pointer is invalid, window 0 is used.

`s`  [asi]

Set or display the Address Space Identifier. With no argument, `s` displays the current Address Space Identifier. The `asi` value can be one of:

- `0x2`  control space
- `0x3`  segment table
- `0x4`  Page table
- `0x8`  user instruction
- `0x9`  supervisor instruction
- `0xa`  user data
- `0xb`  supervisor data
- `0xc`  flush segment
Flush page
Flush context
Cache data

With no arguments, display the current I/O device characteristics including: current input device, current output device, baud rates for serial ports A and B, an input-to-output echo indicator, and virtual addresses of mapped UART devices. With arguments, set or configure the current I/O device. With the u argument (uu...), set the I/O device to be the virtual_address of a UART device currently mapped.

Echo can be either e to enable input to be echoed to the output device, or ne, to indicate that input is not echoed.

Port Assign the indicated port to be the current I/O device. Port can be one of:
- a serial port A
- b serial port B
- k the workstation keyboard
- s the workstation screen

Baud rate Any legal baud rate.

Options can be any combination of:
- i input
- o output
- u UART
- e echo input to output
- ne do not echo input
- r reset indicated serial port (a and b ports only)

If either a or b is supplied, and no options are given, the serial port is assigned for both input and output. If k is supplied with no options, it is assigned for input only. If s is supplied with no options, it is assigned for output only.

V virtual_address1 virtual_address2 [size]
Display the contents of virtual_address1 (lower) virtual_address2 (higher) in the format specified by size:
- b byte format (the default)
w  word format
l  long word format

Enter return to pause for viewing; enter another return character to resume the display. To terminate the display at any time, press the space bar.

For example, the following command displays the contents of virtual address space from address 0x1000 to 0x2000 in word format:

```
v 1000 2000 w
```

Set the execution vector to a predetermined or default routine. Pass `virtual_address` and `argument` to that routine.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's `w` command, set the variable `*romp->v_vector_cmd` to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied `vector` according to the format supplied in `argument`. This format can be one of:

- `%x` hexadecimal
- `%d` decimal

```
Display a menu of extended tests. These diagnostics permit additional testing of such things as the I/O port connectors, video memory, workstation memory and keyboard, and boot device paths.
```

```
y  c  context_number

Display context number.
```

```
y  p|s  context_number virtual_address

Flush the indicated context, context page, or context segment.
```

```
c  flush context context_number
```

```
flush the page beginning at virtual_address within context context_number
```

```
s  flush the segment beginning at virtual_address within context context_number
```

OpenBoot 2.x Command Reference Manual
mount(1M)

Name

mount, umount – mount or unmount file systems and remote resources

Synopsis

mount [-p | -v]
   mount [-F FSType] [generic_options] [-o specific_options]
           [special | mount_point]
   mount [-F FSType] [generic_options] [-o specific_options]
           [-O] special mount_point
   mount -a [-F FSType] [-V] [current_options]
           [-o specific_options] [mount_point]...
   umount [-f] [-V] [-o specific_options] special | mount_point
   umount -a [-f] [-V] [-o specific_options] [mount_point]...

Description

mount attaches a file system to the file system hierarchy at the mount_point, which is the
pathname of a directory. If mount_point has any contents prior to the mount operation, these
are hidden until the file system is unmounted.

umount unmounts a currently mounted file system, which may be specified either as a
mount_point or as special, the device on which the file system resides.

The table of currently mounted file systems can be found by examining the mounted file
system information file. This is provided by a file system that is usually mounted on
/etc/mnttab. The mounted file system information is described in mnttab(4). Mounting a file
system adds an entry to the mount table; a umount removes an entry from the table.

When invoked with both the special and mount_point arguments and the -F option, mount
validates all arguments except for special and invokes the appropriate FSType-specific mount
module. If invoked with no arguments, mount lists all the mounted file systems recorded in the
mount table, /etc/mnttab. If invoked with a partial argument list (with only one of special or
mount_point, or with both special or mount_point specified but not FSType), mount will search
/etc/vfstab for an entry that will supply the missing arguments. If no entry is found, and the
special argument starts with /, the default local file system type specified in /etc/default/fs
will be used. Otherwise the default remote file system type will be used. The default remote file
system type is determined by the first entry in the /etc/dfs/fstypes file. After filling in
missing arguments, mount will invoke the FSType-specific mount module.

For file system types that support it, a file can be mounted directly as a file system by specifying
the full path to the file as the special argument. In such a case, the nosuid option is enforced. If
specific file system support for such loopback file mounts is not present, you can still use
lofiadm(1M) to mount a file system image. In this case, no special options are enforced.

Only a user with sufficient privilege (at least PRIV_SYS_MOUNT) can mount or unmount file
systems using mount and umount. However, any user can use mount to list mounted file systems
and resources.
Options

-F FSType
Used to specify the FSType on which to operate. The FSType must be specified or must be
determinable from /etc/vfstab, or by consulting /etc/default/fs or
/etc/dfs/fstypes.

-a [mount_points...]  
Perform mount or umount operations in parallel, when possible.

If mount points are not specified, mount will mount all file systems whose /etc/vfstab
"mount at boot" field is yes. If mount points are specified, then /etc/vfstab "mount at
boot" field will be ignored.

If mount points are specified, umount will only umount those mount points. If none is
specified, then umount will attempt to umount all file systems in /etc/mnttab, with the
exception of certain system required file systems: /, /usr, /var, /var/adm, /var/run,
/proc, /dev/fd and /tmp.

-f
Forcibly umount a file system.

Without this option, umount does not allow a file system to be umounted if a file on the file
system is busy. Using this option can cause data loss for open files; programs which access
files after the file system has been unmounted will get an error (EIO).

-p
Print the list of mounted file systems in the /etc/vfstab format. Must be the only option
specified. See BUGS.

-v
Print the list of mounted file systems in verbose format. Must be the only option specified.

-V
Echo the complete command line, but do not execute the command. umount generates a
command line by using the options and arguments provided by the user and adding to
them information derived from /etc/mnttab. This option should be used to verify and
validate the command line.

generic_options
Options that are commonly supported by most FSType-specific command modules. The
following options are available:

-m
Mount the file system without making an entry in /etc/mnttab.

-g
Globally mount the file system. On a clustered system, this globally mounts the file
system on all nodes of the cluster. On a non-clustered system this has no effect.
Specify FSType-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the FSType-specific module of the command. (See mount_ufs(1M).) When you use -o with a file system that has an entry in /etc/vfstab, any mount options entered for that file system in /etc/vfstab are ignored.

The following options are supported:

- **devices | nodevices**
  - Allow or disallow the opening of device-special files. The default is devices.
  - If you use nosuid in conjunction with devices, the behavior is equivalent to that of nosuid.

- **exec | noexec**
  - Allow or disallow executing programs in the file system. Allow or disallow mmap(2) with PROT_EXEC for files within the file system. The default is exec.

- **loop**
  - Ignored for compatibility.

- **nbmand | nonbmand**
  - Allow or disallow non-blocking mandatory locking semantics on this file system. Non-blocking mandatory locking is disallowed by default.
  - If the file system is mounted with the nbmand option, then applications can use the fcntl(2) interface to place non-blocking mandatory locks on files and the system enforces those semantics. If you enable this option, it can cause standards conformant applications to see unexpected errors.

To avoid the possibility of obtaining mandatory locks on system files, do not use the nbmand option with the following file systems:

- `/`
- `/usr`
- `/etc`
- `/var`
- `/proc`
- `/dev`
- `/devices`
- `/system/contract`
- `/system/object`
- `/etc/mnttab`
- `/etc/dfs/sharetab`

Do not use the remount option to change the nbmand disposition of the file system. The nbmand option is mutually exclusive of the global option. See -g.
Specify read-only or read-write. The default is `rw`.

<table>
<thead>
<tr>
<th>setuid</th>
<th>nosetuid</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow or disallow setuid or setgid execution. The default is setuid.</td>
<td></td>
</tr>
</tbody>
</table>

If you specify setuid in conjunction with nosetuid, the behavior is the same as nosuid.

nosuid is equivalent to nosetuid and nodevices. When suid or nosuid is combined with setuid or nosetuid and devices or nodevices, the most restrictive options take effect.

This option is highly recommended whenever the file system is shared by way of NFS with the `root=` option. Without it, NFS clients could add setuid programs to the server or create devices that could open security holes.

<table>
<thead>
<tr>
<th>suid</th>
<th>nosuid</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow or disallow setuid or setgid execution. The default is suid. This option also allows or disallows opening any device-special entries that appear within the filesystem.</td>
<td></td>
</tr>
</tbody>
</table>

nosuid is equivalent to nosetuid and nodevices. When suid or nosuid is combined with setuid or nosetuid and devices or nodevices, the most restrictive options take effect.

This option is highly recommended whenever the file system is shared using NFS with the `root=` option, because, without it, NFS clients could add setuid programs to the server, or create devices that could open security holes.

<table>
<thead>
<tr>
<th>rstchown</th>
<th>norstchown</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow or disallow restricted chown. If the file system is mounted with rstchown, the owner of the file is prevented from changing the owner ID of the file. If the file system is mounted with norstchown, the user can permit ownership changes for files they own. Only the super-user or a user with appropriate privilege can arbitrarily change owner IDs.</td>
<td></td>
</tr>
</tbody>
</table>

-0
Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error "device busy".

- r
Mount the file system read-only.

**Examples**

**EXAMPLE 1** Mounting and Unmounting a DVD Image Directly

The following commands mount and unmount a DVD image.
EXAMPLE 1  Mounting and Unmounting a DVD Image Directly  (Continued)

```
# mount -F hsfs /images/solaris.iso /mnt/solaris-image
# umount /mnt/solaris-image
```

Usage  See largefile(5) for the description of the behavior of mount and umount when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

Files  

/etc/mnttab
Table of mounted file systems.

/etc/default/fs
Default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs

LOCAL:
The default partition for a command if no FSType is specified.

/etc/vfstab
List of default parameters for each file system.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  lofiadm(1M), mount_hsfs(1M), mount_nfs(1M), mount_pcfs(1M), mount_smbfs(1M), mount_tmpfs(1M), mount_udfs(1M), mount_ufs(1M), mountall(1M), umountall(1M), fcntl(2), mmap(2), mnttab(4), vfstab(4), attributes(5), largefile(5), privileges(5), lofs(7FS), pcfs(7FS)

Notes  If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Bugs  The mount -p output is incorrect for cachefs.
mountall(1M)

Name
mountall, umountall — mount, unmount multiple file systems

Synopsis
mountall [-F FSType] [-l | -r] [file_system_table]

unmountall [-k] [-s] [-F FSType] [-l | -r] [-n] [-Z]

Description
mountall is used to mount file systems specified in a file system table. The file system table
must be in vfstab(4) format. If no file_system_table is specified, /etc/vfstab is used. If – is
specified as file_system_table, mountall reads the file system table from the standard input.

mountall mounts only those file systems with the mount at boot field set to yes in the
file_system_table.

For each file system in the file system table, the following logic is executed: if there exists a
file/usr/lib/fs/FSType/fsckall, where FSType is the type of the file system, save that file
system in a list to be passed later, and all at once, as arguments to the
/usr/lib/fs/FSType/fsckall script. The /usr/lib/fs/FSType/fsckall script checks all of
the file systems in its argument list to determine whether they can be safely mounted. If no
/usr/lib/fs/FSType/fsckall script exists for the FSType of the file system, the file system is
individually checked using fsck(1M). If the file system does not appear mountable, it is fixed
using fsck before the mount is attempted. File systems with a – entry in the fsckdev field are
mounted without first being checked.

umountall causes all mounted file systems in the current zone except root, /usr, /var,
/var/adm, /var/run, /proc, and /dev/fd to be unmounted. If the FSType is specified,
mountall and umountall limit their actions to the FSType specified. There is no guarantee
that umountall unmounts busy file systems, even if the -k option is specified.

Options
The following options are supported:

-F Specify the FSType of the file system to be mounted or unmounted.

-h host Unmount all file systems listed in /etc/mnttab that are remote-mounted from
host.

-k Use the fuser -k mount-point command. See the fuser(1M) for details. The -k
option sends the SIGKILL signal to each process using the file. As this option
spawns kills for each process, the kill messages might not show up immediately.
There is no guarantee that umountall unmounts busy file systems, even if the -k
option is specified.

-l Limit the action to local file systems.

-n List the actions that would be performed for the specified options, but do not
actually execute these actions. Repeating the command without the -n option
executes the listed actions, assuming that the /etc/mnttab file has not changed in
the interval prior to repeating the command.

-r Limit the action to remote file system types.
mountall(1M)

-s  Do not perform the umount operation in parallel.
-Z  Apply the action(s) only to the file systems mounted in non-global zones. By default, mountall unmounts only file systems mounted in the current zone. Option -Z is ignored if used in a non-global zone.

Files  
/etc/mnttab
   Mounted file system table
/etc/vfstab
   Table of file system defaults
/usr/lib/fs/FSType/fsckall
   Script called by mountall to perform the file system check of all file systems of type FSType

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>

fsck(1M), fuser(1M), mount(1M), mnttab(4), vfstab(4), attributes(5)

Diagnostics  No messages are printed if the file systems are mountable and clean.

Error and warning messages come from fsck(1M) and mount(1M).

Notes  At this time, NFS is the only remote file system supported by the -l, -r, and -h options.
mountd – server for NFS mount requests and NFS access checks

**Synopsis**

```
/usr/lib/nfs/mountd [-v] [-r]
```

**Description**

`mountd` is an RPC server that answers requests for NFS access information and file system mount requests. It reads the file `/etc/dfs/sharetab` to determine which file systems are available for mounting by which remote machines. See `sharetab(4)`. `nfsd` running on the local server will contact `mountd` the first time an NFS client tries to access the file system to determine whether the client should get read-write, read-only, or no access. This access can be dependent on the security mode used in the remote procedure call from the client. See `share_nfs(1M)`.

The command also provides information as to what file systems are mounted by which clients. This information can be printed using the `showmount(1M)` command.

The `mountd` daemon is automatically invoked by `share(1M)`.

Only super user can run the `mountd` daemon.

**SMF Management**

Since `mountd` must be running for `nfsd` to function properly, `mountd` is automatically started by the `svc:/network/nfs/server` service.

Startup SMF parameters for `mountd` can be manipulated using the `sharectl(1M)` command. The currently supported parameters are:

- `server_versmax=num`
- `server_versmin=num`
  
  The NFS server only uses NFS versions in the range specified by these variables. Valid values or versions are: 2, 3, and 4. If one or both of these parameters are left unset, the default minimum version is 2, while the default maximum version is 4.

- `showmount_info=[full | none]`
  
  If the value of this property is `none`, the following rules apply:
  - A client can see only the shares that it is allowed to access.
  - A client cannot see access lists for the shares defined at server.
  - A client cannot see remote mounts from the server done by other clients.

  If the value is `full`, these rules do not apply. The default value is `full`.

  For example, to place the restrictions specified above for users of `showmount(1M)`, enter:

  ```
  # sharectl set -p showmount_info=none nfs
  % sharectl get -p showmount_info nfs
  showmount_info=none
  ```

**Options**

The options shown below are supported for NFSv2/v3 clients. They are not supported for Solaris NFSv4 clients.

- `-r` Reject mount requests from clients. Clients that have file systems mounted will not be affected.
-v  Run the command in verbose mode. Each time `mountd` determines what access a client should get, it will log the result to the console, as well as how it got that result.

Files  `/etc/dfs/sharetab`  shared file system table

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/file-system/nfs</td>
</tr>
</tbody>
</table>

See Also: mount_nfs(1M), nfsd(1M), share(1M), share_nfs(1M), sharectl(1M), showmount(1M), sharetab(4), attributes(5)

Notes  Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.
Name  
mount_hsfs – mount hsfs file systems

Synopsis  
mount -F hsfs [generic_options]
    [-o FSType-specific_options] [-O ] special | mount_point

     
mount -F hsfs [generic_options]
    [-o FSType-specific_options] [-O] special mount_point

Description  

mount attaches an ISO 9660 filesystem (the High Sierra file system, hsfs, is a draft predecessor to ISO 9660, so the name reflects the filesystem's history) to the file system hierarchy at the mount_point, which is the pathname of a directory. If mount_point has any contents prior to the mount operation, these are hidden until the file system is unmounted.

If mount is invoked with special or mount_point as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the FSType-specific_options; see mount(1M) for more details.

The hsfs file system supports direct mounting of files containing the file system as well as block devices. See mount(1M) and lofiadm(1M).

A file system conforming to ISO 9660 can contain extensions that allow it to overcome limitations of the original ISO 9660:1988 (version 1) standard. The following types of extensions are supported by hsfs:

Rock Ridge extensions

This is the preferred type of extension as it allows file attributes, name length, and types equivalent to those on other UNIX-style filesystems. Example of supported features are device special files, POSIX permissions, symbolic links, and filenames of up to 255 bytes in length. Rock Ridge extensions also remove the ISO9660:1988 restriction on maximum nesting depth for directories (eight levels). hsfs automatically detects the presence of Rock Ridge extensions and uses them, unless mount options are specified to disable the use of Rock Ridge or to use a different extension.

ISO9660:1999 (version 2) extensions

The first version of ISO9660, released in 1988, supported only uppercase ASCII filenames of no more than 31 characters in length. ISO9660 version 2, released in 1999, provides an extension that allows filenames of at least 207 bytes that can use UTF-8 characters and removes the limitation on the nesting depth for directories. Unlike Rock Ridge, it does not provide support for UNIX-style file types and file attributes. hsfs automatically detects this extension and will use it for filename lookup if no Rock Ridge extensions are found on the media.

Joliet extensions

The Joliet extension was devised by Microsoft to allow Unicode (UCS-2) long filenames with CDROM-based media. It allows filename lengths of up to 110 Unicode characters and does not support UNIX-style file types and attributes. hsfs falls back to using Joliet if such an extension is present and neither Rock Ridge nor ISO9660 version 2 extensions are found.
If filenames are longer than the 64 UCS-2 characters officially allowed by Microsoft (that is, 110 Unicode characters), they can translate to up to 330 UTF-8 octets. Filenames that translate to more than 255 UTF-8 octets will be truncated.

**Options**  
*generic_options*

See `mount(1M)` for the list of supported options.

- `-o`

Specify `hsfs` file system specific options. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

  `global | noglobal`

  If `global` is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If `noglobal` is specified, the mount will not be globally visible. The default behavior is `noglobal`.

  `ro`

  Mount the file system read-only. This option is required.

  `rr | nrr`

  Enable (`rr`) or disable (`nrr`) the use of Rock Ridge. `rr` is the default and need not be specified. If you use `nrr` and Rock Ridge extensions are present in the file system, ignore them and search for other available extensions or fall back to plain ISO9660.

  `vers2 | novers2`

  Enable or disable the use of ISO9660 version 2 extensions. If `vers2` is specified and ISO9660 version 2 extensions are available, `hsfs` will use ISO9660 version 2 even if the file system contains the preferred Rock Ridge extensions as well. If `novers2` is specified, it will fall back to using either Joliet extensions or plain ISO9660 even if ISO9660 version 2 extensions are available.

  `joliet | nojoliet`

  Enable or disable the use of Joliet extensions. If `joliet` is specified and Joliet extensions are available, `hsfs` will use them even if the file system contains the preferred Rock Ridge and/or ISO9660 version 2 extensions. If `nojoliet` is specified, it will fall back to using plain ISO9660.

  `nottaildot`

  File names on High Sierra file systems consist of a proper name and an extension separated by a `.` (dot) character. By default, the separating dot is always considered part of the file's name for all file access operations, even if there is no extension present. Specifying `nottaildot` makes it optional to specify the trailing dot to access a file whose name lacks an extension.

**Exceptions:** This option is effective only on file systems for which Rock Ridge, ISO9660 version 2 or Joliet extensions are not active, either because they are not present on the CD-ROM, or they have been deliberately disabled via the `nrr`, `novers2` and `nojoliet` option. If either extension is active, `hsfs` quietly ignores this option.
nomapcase

File names on High Sierra/ISO9660 CD-ROMs with no extensions present should be
uppercase characters only. By default, hsfs maps file names read from a non-Rock
Ridge disk to all lowercase characters. nomapcase turns off this mapping. The
exceptions for no-trail-dot discussed above apply to nomapcase.

-O

Overlay mount. Allow the file system to be mounted over an existing mount point, making
the underlying file system inaccessible. If a mount is attempted on a preexisting mount
point without setting this flag, the mount will fail, producing the error: device busy.

Examples

EXAMPLE 1 Mounting and Unmounting a DVD Image Directly

The following commands mount and unmount a DVD image.

# mount -F hsfs /images/solaris.iso /mnt/solaris-image
# umount /mnt/solaris-image

Notes

If the directory on which a file system is to be mounted is a symbolic link, the file system is
mounted on the directory to which the symbolic link refers, rather than on top of the symbolic
link itself.
mount_nfs – mount remote NFS resources

Synopsis

mount [-F nfs] [generic_options] [-o specific_options] [-O] resource

mount [-F nfs] [generic_options] [-o specific_options] [-O] mount_point

mount [-F nfs] [generic_options] [specific_options] resource mount_point

Description

The mount utility attaches a named resource to the file system hierarchy at the pathname location mount_point, which must already exist. If mount_point has any contents prior to the mount operation, the contents remain hidden until the resource is once again unmounted.

mount_nfs starts the lockd(1M) and statd(1M) daemons if they are not already running.

If the resource is listed in the /etc/vfstab file, the command line can specify either resource or mount_point, and mount consults /etc/vfstab for more information. If the -F option is omitted, mount takes the file system type from /etc/vfstab.

If the resource is not listed in the /etc/vfstab file, then the command line must specify both the resource and the mount_point.

host can be an IPv4 or IPv6 address string. As IPv6 addresses already contain colons, enclose host in a pair of square brackets when specifying an IPv6 address string. Otherwise the first occurrence of a colon can be interpreted as the separator between the host name and path, for example, [1080::8:800:200C:417A]:tmp/file. See inet(7P) and inet6(7P).

host:pathname

Where host is the name of the NFS server host, and pathname is the path name of the directory on the server being mounted. The path name is interpreted according to the server’s path name parsing rules and is not necessarily slash-separated, though on most servers, this is the case.
	nfs://host[:port]/pathname

This is an NFS URL and follows the standard convention for NFS URLs as described in NFS URL Scheme, RFC 2224. See the discussion of URL’s and the public option under NFS FILE SYSTEMS for a more detailed discussion.

host:pathname nfs://host[:port]/pathname

host:pathname is a comma-separated list of host:pathname.

See the discussion of replicated file systems and failover under NFS FILE SYSTEMS for a more detailed discussion.

hostlist pathname

hostlist is a comma-separated list of hosts.

See the discussion of replicated file systems and failover under NFS FILE SYSTEMS for a more detailed discussion.
The `mount` command maintains a table of mounted file systems in `/etc/mnttab`, described in `mnttab(4)`.

`mount_nfs` supports both NFSv3 and NFSv4 mounts. The default NFS version is NFSv4.

**SMF Management**

The NFS client service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/nfs/client:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

**Options**

See `mount(1M)` for the list of supported `generic_options`. See `share_nfs(1M)` for a description of server options.

- `-o specific_options`
  
  Set file system specific options according to a comma-separated list with no intervening spaces.

  `acdirmax=n`

  Hold cached attributes for no more than `n` seconds after directory update. The default value is 60.

  `acdirmin=n`

  Hold cached attributes for at least `n` seconds after directory update. The default value is 30.

  `acregmax=n`

  Hold cached attributes for no more than `n` seconds after file modification. The default value is 60.

  `acregmin=n`

  Hold cached attributes for at least `n` seconds after file modification. The default value is 3.

  `actimeo=n`

  Set `min` and `max` times for regular files and directories to `n` seconds. See “File Attributes,” below, for a description of the effect of setting this option to 0.

  See "Specifying Values for Attribute Cache Duration Options," below, for a description of how `acdirmax`, `acdirmin`, `acregmax`, `acregmin`, and `actimeo` are parsed on a `mount` command line.

- `bg | fg`

  If the first attempt fails, retry in the background, or, in the foreground. The default is `fg`.
forcedirectio|noforcedirectio
If forcedirectio is specified, then for the duration of the mount, forced direct I/O is used. If the filesystem is mounted using forcedirectio, data is transferred directly between client and server, with no buffering on the client. If the filesystem is mounted using noforcedirectio, data is buffered on the client. forcedirectio is a performance option that is of benefit only in large sequential data transfers. The default behavior is noforcedirectio.

grpid
By default, the GID associated with a newly created file obeys the System V semantics; that is, the GID is set to the effective GID of the calling process. This behavior can be overridden on a per-directory basis by setting the set-GID bit of the parent directory; in this case, the GID of a newly created file is set to the GID of the parent directory (see open(2) and mkdir(2)). Files created on file systems that are mounted with the grpid option obey BSD semantics independent of whether the set-GID bit of the parent directory is set; that is, the GID is unconditionally inherited from that of the parent directory.

hard|soft
Continue to retry requests until the server responds (hard) or give up and return an error (soft). The default value is hard. Note that NFSv4 clients do not support soft mounts.

intr|nointr
Allow (do not allow) keyboard interrupts to kill a process that is hung while waiting for a response on a hard-mounted file system. The default is intr, which makes it possible for clients to interrupt applications that can be waiting for a remote mount.

lock
Use local locking (no lock manager). Note that this is a private interface.

noac
Suppress data and attribute caching. The data caching that is suppressed is the write-behind. The local page cache is still maintained, but data copied into it is immediately written to the server.

nocto
Do not perform the normal close-to-open consistency. When a file is closed, all modified data associated with the file is flushed to the server and not held on the client. When a file is opened the client sends a request to the server to validate the client’s local caches. This behavior ensures a file’s consistency across multiple NFS clients. When nocto is in effect, the client does not perform the flush on close and the request for validation, allowing the possibility of differences among copies of the same file as stored on multiple clients.

This option can be used where it can be guaranteed that accesses to a specified file system are made from only one client and only that client. Under such a condition, the effect of nocto can be a slight performance gain.
port=n
The server IP port number. The default is NFS_PORT. If the port option is specified, and
if the resource includes one or more NFS URLs, and if any of the URLs include a port
number, then the port number in the option and in the URL must be the same.

posix
Request POSIX.1 semantics for the file system. Requires a mount version 2 mountd(1M)
on the server. See standards(5) for information regarding POSIX.

proto=netid | rdma
By default, the transport protocol that the NFS mount uses is the first available RDMA
transport supported both by the client and the server. If no RDMA transport is found,
then it attempts to use a TCP transport or, failing that, a UDP transport, as ordered in
the /etc/netconfig file. If it does not find a connection oriented transport, it uses the
first available connectionless transport.

Use this option to override the default behavior.

proto is set to the value of netid or rdma. netid is the value of the network_id field entry
in the /etc/netconfig file.

The UDP protocol is not supported for NFS version 4. If you specify a UDP protocol
with the proto option, NFS version 4 is not used.

public
The public option forces the use of the public file handle when connecting to the NFS
server. The resource specified might not have an NFS URL. See the discussion of URLs
and the public option under NFS FILE SYSTEMS for a more detailed discussion.

quota | noquota
Enable or prevent quota(1M) to check whether the user is over quota on this file system;
if the file system has quotas enabled on the server, quotas are still checked for operations
on this file system.

remount
Remounts a read-only file system as read-write (using the rw option). This option
cannot be used with other -o options, and this option works only on currently mounted
read-only file systems.

retrans=n
Set the number of NFS retransmissions to n. The default value is 5. For
connection-oriented transports, this option has no effect because it is assumed that the
transport performs retransmissions on behalf of NFS.

retry=n
The number of times to retry the mount operation. The default for the mount command
is 10000.
The default for the automounter is 0, in other words, do not retry. You might find it useful to increase this value on heavily loaded servers, where automounter traffic is dropped, causing unnecessary server not responding errors.

\texttt{rsize=n}

Set the read buffer size to a maximum of \( n \) bytes. The default value is 1048576 when using connection-orientated transports with version 3 or version 4 of the NFS protocol, and 32768 when using connection-less transports. The default can be negotiated down if the server prefers a smaller transfer size. "Read" operations may not necessarily use the maximum buffer size. When using version 2, the default value is 32768 for all transports.

\texttt{sec=mode}

Set the security mode for NFS transactions. If \texttt{sec=} is not specified, then the default action is to use \texttt{AUTH_SYS} over NFS version 2 mounts, use a user-configured default auth over NFS version 3 mounts, or to negotiate a mode over version 4 mounts.

The preferred mode for NFS version 3 mounts is the default mode specified in \texttt{/etc/nfssec.conf} (see \texttt{nfssec.conf(4)}) on the client. If there is no default configured in this file or if the server does not export using the client's default mode, then the client picks the first mode that it supports in the array of modes returned by the server. These alternatives are limited to the security flavors listed in \texttt{/etc/nfssec.conf}.

NFS version 4 mounts negotiate a security mode when the server returns an array of security modes. The client attempts the mount with each security mode, in order, until one is successful.

Only one mode can be specified with the \texttt{sec=} option. See \texttt{nfssec(5)} for the available mode options.

\texttt{secure}

This option has been deprecated in favor of the \texttt{sec=dh} option.

\texttt{timeo=n}

Set the NFS timeout to \( n \) tenths of a second. The default value is 11 tenths of a second for connectionless transports, and 600 tenths of a second for connection-oriented transports. This value is ignored for connectionless transports. Such transports might implement their own timeouts, which are outside the control of NFS.

\texttt{vers=NFS version number}

By default, the version of NFS protocol used between the client and the server is the highest one available on both systems. The default maximum for the client is version 4. This can be changed by setting \texttt{client_versmax} to a valid version number (2, 3, or 4). Use the \texttt{sharectl(1M)} command to manipulate the \texttt{client_versmax} property. If the NFS server does not support the client's default maximum, the next lowest version attempted until a matching version is found.
wsize=n
Set the write buffer size to a maximum of \( n \) bytes. The default value is 1048576 when using connection-orientated transports with version 3 or version 4 of the NFS protocol, and 32768 when using connection-less transports. The default can be negotiated down if the server prefers a smaller transfer size. "Write" operations may not necessarily use the maximum buffer size. When using version 2, the default value is 32768 for all transports.

xattr|noxattr
Allow or disallow the creation and manipulation of extended attributes. The default is xattr. See fsattr(5) for a description of extended attributes.

-O
Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error "device busy."

Nfs File Systems
Background versus Foreground
File systems mounted with the bg option indicate that mount is to retry in the background if the server’s mount daemon (mountd(1M)) does not respond. mount retries the request up to the count specified in the retry=n option. (Note that the default value for retry differs between mount and automount. See the description of retry, above.) Once the file system is mounted, each NFS request made in the kernel waits timeo=n tenths of a second for a response. If no response arrives, the time-out is multiplied by 2 and the request is retransmitted. When the number of retransmissions has reached the number specified in the retrans=n option, a file system mounted with the soft option returns an error on the request; one mounted with the hard option prints a warning message and continues to retry the request.

Hard versus Soft
File systems that are mounted read-write or that contain executable files should always be mounted with the hard option. Applications using soft mounted file systems can incur unexpected I/O errors, file corruption, and unexpected program core dumps. The soft option is not recommended.

Authenticated requests
The server can require authenticated NFS requests from the client. sec=dh authentication might be required. See nfssec(5).

URLs and the public option
If the public option is specified, or if the resource includes and NFS URL, mount attempts to connect to the server using the public file handle lookup protocol. See WebNFS Client Specification, RFC 2054. If the server supports the public file handle, the attempt is successful; mount does not need to contact the server’s rpcbind(1M) and the mountd(1M) daemons to get the port number of the mount server and the initial file handle of pathname, respectively. If the NFS client and server are separated by a firewall that allows all outbound connections through specific ports, such as NFS_PORT, then this enables NFS operations
through the firewall. The public option and the NFS URL can be specified independently or together. They interact as specified in the following matrix:

<table>
<thead>
<tr>
<th>Resource Style</th>
<th>host:pathname</th>
<th>NFS URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>public option</td>
<td>Force public file handle and fail mount if not supported.</td>
<td>Force public file handle and fail mount if not supported.</td>
</tr>
<tr>
<td></td>
<td>Use Native paths.</td>
<td>Use Canonical paths.</td>
</tr>
<tr>
<td>default</td>
<td>Use MOUNT protocol.</td>
<td>Try public file handle with Canonical paths. Fall back to MOUNT protocol if not supported.</td>
</tr>
</tbody>
</table>

A Native path is a path name that is interpreted according to conventions used on the native operating system of the NFS server. A Canonical path is a path name that is interpreted according to the URL rules. See *Uniform Resource Locators (URL)*, RFC 1738. See "Examples," below, for uses of Native and Canonical paths.

Replicated filesystems and failover

*resource* can list multiple read—only file systems to be used to provide data. These file systems should contain equivalent directory structures and identical files. The file systems can be specified either with a comma—separated list of *host:/pathname* entries and/or NFS URL entries, or with a comma—separated list of hosts, if all file system names are the same. If multiple file systems are named and the first server in the list is down, failover uses the next alternate server to access files. If the read—only option is not chosen, replication is disabled. File access, for NFS versions 2 and 3, is blocked on the original if NFS locks are active for that file.

File Attributes

To improve NFS read performance, files and file attributes are cached. File modification times get updated whenever a write occurs. However, file access times can be temporarily out-of-date until the cache gets refreshed.

The attribute cache retains file attributes on the client. Attributes for a file are assigned a time to be flushed. If the file is modified before the flush time, then the flush time is extended by the time since the last modification (under the assumption that files that changed recently are likely to change soon). There is a minimum and maximum flush time extension for regular files and for directories. Setting *actimeo=n* sets flush time to *n* seconds for both regular files and directories.

Setting *actimeo=0* disables attribute caching on the client. This means that every reference to attributes is satisfied directly from the server though file data is still cached. While this
guarantees that the client always has the latest file attributes from the server, it has an adverse effect on performance through additional latency, network load, and server load.

Setting the noac option also disables attribute caching, but has the further effect of disabling client write caching. While this guarantees that data written by an application is written directly to a server, where it can be viewed immediately by other clients, it has a significant adverse effect on client write performance. Data written into memory-mapped file pages (mmap(2)) are not written directly to this server.

The attribute cache duration options are acdirmax, acdirmin, acregmax, acregmin, and actimeo, as described under OPTIONS. A value specified for actimeo sets the values of all attribute cache duration options except for any of these options specified following actimeo on a mount command line. For example, consider the following command:

```
example# mount -o actimeo=1000 server:/path /localpath
```

Because actimeo is the last duration option in the command line, its value (1000) becomes the setting for all of the duration options, including acdirmax. Now consider:

```
example# mount -o actimeo=1000,acdirmax=10 server:/path /localpath
```

Because the acdirmax option follows actimeo on the command line, it is assigned the value specified (10). The remaining duration options are set to the value of actimeo (1000).

### Examples

**EXAMPLE 1**  Mounting an NFS File System

To mount an NFS file system:

```
example# mount serv:/usr/src /usr/src
```

This is an example of the use of a native path.

**EXAMPLE 2**  Mounting An NFS File System Read-Only With No suid Privileges

To mount an NFS file system read-only with no suid privileges:

```
example# mount -r -o nosuid serv:/usr/src /usr/src
```

**EXAMPLE 3**  Mounting An NFS File System Over Version 2, with the UDP Transport

To mount an NFS file system over version 2, with the UDP transport:

```
example# mount -o vers=2,proto=udp serv:/usr/src /usr/src
```

**EXAMPLE 4**  Mounting an NFS File System Using An NFS URL

To mount an NFS file system using an NFS URL (a canonical path):

```
example# mount nfs://serv/usr/man /usr/man
```
EXAMPLE 5  Mounting An NFS File System Forcing Use Of The Public File Handle
To mount an NFS file system and force the use of the public file handle and an NFS URL (a canonical path) that has a non 7–bit ASCII escape sequence:
example# mount -o public nfs://serv/usr/%A0abc /mnt/test

EXAMPLE 6  Mounting an NFS File System Using a Native Path
To mount an NFS file system using a native path (where the server uses colons (":" as the component separator) and the public file handle:
example# mount -o public serv:C:doc:new /usr/doc

EXAMPLE 7  Mounting a Replicated Set of NFS File Systems with the Same Pathnames
To mount a replicated set of NFS file systems with the same pathnames:
example# mount serv-a,serv-b,serv-c:/usr/man /usr/man

EXAMPLE 8  Mounting a Replicated Set of NFS File Systems with Different Pathnames
To mount a replicated set of NFS file systems with different pathnames:
example# mount serv-x:/usr/man,serv-y:/var/man,nfs://serv-z/man /usr/man

Callaghan, Brent, NFS URL Scheme, RFC 2224, October 1997.

Notes

An NFS server should not attempt to mount its own file systems. See `lofs(7FS)`.

If the directory on which a file system is to be mounted is a symbolic link, the file system is
mounted on the directory to which the symbolic link refers, rather than being mounted on top
of the symbolic link itself.

SunOS 4.x used the `biod` maintenance procedure to perform parallel read-ahead and
write-behind on NFS clients. SunOS 5.x made `biod` obsolete with multi-threaded processing,
which transparently performs parallel read-ahead and write-behind.

Since the root (`/`) file system is mounted read-only by the kernel during the boot process, only
the `remount` option (and options that can be used in conjunction with `remount`) affect the root
(`/`) entry in the `/etc/vfstab` file.
mount_pcfs(1M)

Name  
mount_pcfs – mount pcfs file systems

Synopsis  
mount -F pcfs [generic_options]
           [-o FSType-specific_options] special | mount_point
mount -F pcfs [generic_options]
           [-o FSType-specific_options] special mount_point

Description  
mount attaches an MS-DOS file system (pcfs) to the file system hierarchy at the mount_point, which is the pathname of a directory. If mount_point has any contents prior to the mount operation, these are hidden until the file system is unmounted.

The pcfs file system supports direct mounting of files containing the file system as well as block devices. See mount(1M) and lofiadm(1M).

If mount is invoked with special or mount_point as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the FSType-specific_options; see mount(1M) for more details.

The special argument is a special device file type, which is:

A DOS logical drive on a hard disk expressed as device-name:logical-drive, where device-name specifies the special block device-file for the whole disk and logical-drive is either a drive letter (c through z) or a drive number (1 through 24). Examples are /dev/dsk/c0t0d0p0: c and /dev/dsk/c0t0d0p0: 1.

The special device file type must have a formatted MS-DOS file system with either a 12-bit, 16-bit, or 32-bit File Allocation Table.

Options  
generic_options
See mount(1M) for the list of supported options.

-o
Specify pcfs file system-specific options. The following options are supported:

clamptime|noclamptime
File timestamps in pcfs cover a range between January 1st 1980 and December 31st 2027. This is not equal to the range of time_t on Unix for either 32-bit or 64-bit applications. In particular, 32-bit applications fail with EOVERFLOW errors on the stat(2) system call when timestamps beyond the range of 32-bit time_t are encountered. In order to prevent such spurious failures, pcfs by default clamps timestamps to the common subset of possible pcfs timestamps and the range available to 32-bit applications in Unix. The clamptime mount option therefore is active by default. If you want access to the full range of possible timestamps on pcfs, mount the file system with the noclampmtime mount option. Note that if noclampmtime is used, only 64-bit applications will have access to timestamps beyond January 19th 2038, 03:14:06 UTC; 32-bit applications will encounter EOVERFLOW errors.
foldcase | nofoldcase
Force uppercase characters in filenames to lowercase when reading them from the filesystem. This is for compatibility with the previous behavior of pcfs. The default is nofoldcase.

hidden | nohidden
Allow or disallow listing of files with hidden or system bits set. Option hidden is the default. When nohidden is effect, hidden and system files are neither visible nor accessible. Note that PCFS in previous releases of the Solaris operating system used the nohidden option as the default.

atime | noatime
Enable or disable write access timestamps on DOS-formatted media. Default for fixed disks is atime, while for removable media noatime is used. The latter default is so that writes to flash-based media ("memory sticks") can be minimized, to prolong lifetime.

timezone=timezone
Timestamps on DOS-formatted media are recorded in the local time of the recording system. This can cause confusion when accessing removable media in which the recording and receiving system use different time zones. Use this option to force media timestamps to be interpreted for a specific time zone. The mount_pcfs command converts the given time zone name into a numerical offset that is passed to the pcfs kernel module, using the same rules as described in environ(5) for the TZ environment variable. By default, the timezone value is taken from the TZ environment variable.

owner={username|user_id}
Specifies the owner for the contents of the file system. The value can either be a character-string for a user name, or an integer value for the user ID. The default owner is the user ID of current process.

group={groupname|group_id}
Specifies the group ID for the contents of the file systems. The value can either be a character-string for a group name, or an integer value for the group ID. The default group is the group ID of the mounting process.

mask=user_mask
Specifies the mask used for setting maximum access permissions on contents of the file system. The user_mask is an octal value, a bitmask, where each bit represents the permissions that should be disabled. The default user_mask is the file mode creation mask of the mounting process.

See Intro(2) for more information on masks.

Notes If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.
mount_smbfs, umount_smbfs – mount and unmount a shared resource from an SMB file server

**Synopsis**

```
/usr/sbin/mount [-F smbfs] [generic-options] [-o name=value] [-0] resource

/usr/sbin/mount [-F smbfs] [generic-options] [-o name=value] [-0] mount-point

/usr/sbin/mount [-F smbfs] [generic-options] [-o name=value] [-0] resource mount-point

/usr/sbin/umount [-F smbfs] [generic-options] mount-point
```

**Description**

The `mount` utility attaches a named resource, `resource`, to the file system hierarchy at the path name location, `mount-point`, which must already exist.

If `mount-point` has any contents prior to the `mount` operation, those contents remain hidden until the resource is unmounted. An authorized user with the `SYS_MOUNT` privilege can perform a `mount` operation. Also, a user can perform SMBFS mount operations on a directory the user owns.

If the resource is listed in the `/etc/vfstab` file, you can specify either `resource` or `mount-point` as the `mount` command will consult the `/etc/vfstab` file for more information. If the `-F` option is omitted, `mount` takes the file system type from the entry in the `/etc/vfstab` file.

If the resource is not listed in the `/etc/vfstab` file, the command line must specify both `resource` and `mount-point`.

The `umount` utility detaches a mounted file system from the file system hierarchy. An authorized user with the `SYS_MOUNT` privilege can perform a `umount` operation. Also, a user can perform SMBFS unmount operations on a directory the user owns.

The `network/smb/client` service must be enabled to successfully mount an SMB share. This service is enabled by default.

To enable the service, enter the following `svcadm(1M)` command:

```
# svcadm enable network/smb/client
```

**Operands**

The `mount` command supports the following operands:

```
resource //server/share
```

The name of the resource to be mounted. In addition to its name, you can specify the following information about the resource:

- `server` is the DNS or NetBIOS name of the remote computer.
- `share` is the resource name on the remote server.

You can also specify the user account. See the "Options" section.
The `mount` command can read a password from standard input for the user account. If the password is not provided, `mount` first attempts to use the password stored by the `smbadm add-key` command (if any). If that password fails to authenticate, the `mount_smbfs` command prompts you for a password if standard input is a TTY.

**mount-point**

The path to the location where the file system is to be mounted or unmounted. The `mount` command maintains a table of mounted file systems in the `/etc/mnttab` file. See the `mnttab(4)` man page.

**Options**

See the `mount(1M)` man page for the list of supported `generic-options`.

- `-o name=value` or `-o name`
  
  Sets the file system-specific properties. You can specify more than one name-value pair as a list of comma-separated pairs. No spaces are permitted in the list. The properties are as follows:

  acdirmax=n
  
  Hold cached attributes for no more than n seconds after directory update. The default value is 60.

  acdirmin=n
  
  Hold cached attributes for at least n seconds after directory update. The default value is 30.

  acregmax=n
  
  Hold cached attributes for no more than n seconds after file modification. The default value is 60.

  acregmin=n
  
  Hold cached attributes for at least n seconds after file modification. The default value is 3.

  actimeo=n
  
  Set minimum and maximum times for regular files and directories to n seconds. See “File Attributes,” below, for a description of the effect of setting this option to 0.

  See “Specifying Values for Attribute Cache Duration Options,” below, for a description of how `acdirmax`, `acdirmin`, `acregmax`, `acregmin`, and `actimeo` are parsed on a `mount` command line.

  `dirperms=octaltriplet`

  Specifies the permissions to be assigned to directories. The value must be specified as an octal triplet, such as 755. The default value for the directory mode is taken from the `fileperms` setting, with execute permission added where `fileperms` has read permission.

  Note that these permissions have no relation to the rights granted by the SMB server.
domain=value
  Specifies the name of the workgroup or the Windows domain in which the username is defined. If the domain name is not specified, the default system's SMB domain is used.

fileperms=octaltriplet
  Specifies the permissions to be assigned to files. The value must be specified as an octal triplet, such as 644. The default value is 700.

  Note that these permissions have no relation to the rights granted by the SMB server.

gid=groupid
  Assigns the specified group ID to files. The default value is the group ID of the directory where the volume is mounted.

intr|nointr
  Enable (or disable) cancellation of smbfs(7FS) I/O operations when the user interrupts the calling thread (for example, by hitting Ctrl-C while an operation is underway). The default is intr (interruption enabled), so cancellation is normally allowed.

noac
  Suppress attribute caching. Local stat(2) calls always request attributes from the SMB server.

noprompt
  Suppresses the prompting for a password when mounting a share. This property enables you to permit anonymous access to a share. Anonymous access does not require a password.

  The mount operation fails if a password is required, the noprompt property is set, and no password is stored by the smbadm add-key command.

uid=userid
  Assigns the specified user ID to files. The default value is the owner ID of the directory where the volume is mounted.

user=value
  Specifies the remote user name. If user is omitted, the logged-in user ID is used.

xattr|noxattr
  Enable (or disable) Solaris Extended Attributes in this mount point. This option defaults to xattr (enabled Extended Attributes), but note: if the SMB server does not support SMB “named streams”, smbfs(7FS) forces this option to noxattr. When a mount has the noxattr option, attempts to use Solaris Extended attributes fail with EINVAL.

-O
  Overlays mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error “device busy.”
To improve smbfs performance, file attributes are cached. File modification times get updated whenever any local modifications occur. However, file access times can be temporarily out-of-date until the cache gets refreshed.

The attribute cache retains file attributes on the client. Attributes for a file are assigned a time to be flushed. If the file is modified before the flush time, then the flush time is extended by the time since the last modification (under the assumption that files that changed recently are likely to change soon). There is a minimum and maximum flush time extension for regular files and for directories. Setting actimeo=n sets flush time to n seconds for both regular files and directories.

Setting actimeo=n disables attribute caching on the client. This means that every reference to attributes is satisfied directly from the server. While this guarantees that the client always has the latest file attributes from the server, it has an adverse effect on performance through additional latency, network load, and server load.

Setting the noac option also disables attribute caching. When smbfs is enhanced to support writing caching, this option will have the further effect of disabling that write caching.

The attribute cache duration options are acdirmax, acdirmin, acregmax, acregmin, and actimeo, as described under OPTIONS, above. A value specified for actimeo sets the values of all attribute cache duration options except for any of these options specified following actimeo on a mount command line. For example, consider the following command:

```
# mount -F smbfs -o acdirmax=10,actimeo=1000 //server/share /mountpoint
```

Because actimeo is the last duration option in the command line, its value (1000) becomes the setting for all of the duration options, including acdirmax. Now consider:

```
# mount -F smbfs -o actimeo=1000,acdirmax=10 //server/share /mountpoint
```

Because the acdirmax option follows actimeo on the command line, it is assigned the value specified (10). The remaining duration options are set to the value of actimeo (1000).

Examples

**EXAMPLE 1  Mounting an SMBFS Share**

The following example shows how to mount the /tmp share from the nano server in the SALES workgroup on the local /mnt mount point. You must supply the password for the root user to successfully perform the mount operation.

```
# mount -F smbfs -o user=root,domain=SALES //nano.sfbay/tmp /mnt
Password:
```

**EXAMPLE 2  Verifying That an SMBFS File System Is Mounted**

The following example shows how to mount the /tmp share from the nano server on the local /mnt mount point. You must supply the password for the root user to successfully perform the mount operation.

```
# mount -F smbfs -o user=root,domain=SALES //nano.sfbay/tmp /mnt
Password:
```
EXAMPLE 2  Verifying That an SMBFS File System Is Mounted  (Continued)

```bash
# mount -F smbfs -o user=root //nano.sfbay/tmp /mnt
Password:
```

You can verify that the share is mounted in the following ways:

■ View the file system entry in the `/etc/mnttab` file.
  ```bash
  # grep mnt /etc/mnttab
  //nano.sfbay/tmp /mnt smbfs dev=4900000 1177097833
  ```

■ View the output of the `mount` command.
  ```bash
  # mount | grep mnt
  mnt on //nano.sfbay/tmp read/write/setuid/devices/dev=4900000 on
  Tue Apr 20 13:37:13 2010
  ```

■ View the output of the `df /mnt` command.
  ```bash
  # df /mnt
  /mnt (//nano.sfbay/tmp): 3635872 blocks -1 files
  ```

Obtain information about the mounted share by viewing the output of the `df -k /mnt` command.

```bash
# df -k /mnt
Filesystem kbytes used avail capacity Mounted on
//nano.sfbay/tmp 1882384 64448 1817936 4% /mnt
```

EXAMPLE 3  Unmounting an SMB Share

This example assumes that an SMB share has been mounted on the `/mnt` mount point. The following command line unmounts the share from the mount point.

```bash
# umount /mnt
```

**Files**

- `/etc/mnttab`
  Table of mounted file systems.

- `/etc/dfs/fstypes`
  Default distributed file system type.

- `/etc/vfstab`
  Table of automatically mounted resources.

- `/var/smb/smbfspasswd`
  Stores per-user settings for the Solaris SMB client.

**Attributes**

See the `attributes(5)` man page for descriptions of the following attributes:
The Solaris SMB client always attempts to use gethostbyname() to resolve host names. If the host name cannot be resolved, the SMB client uses NetBIOS name resolution (NBNS). The Solaris SMB client permits the use of NBNS to enable Solaris SMB clients in Windows environments to work without additional configuration.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than being mounted on top of the symbolic link itself.
mount_tmpfs(1M)

Name  
mount_tmpfs – mount tmpfs file systems

Synopsis  
mount [-F tmpfs] [-o specific_options] [-O] special mount_point

Description  
tmpfs is a memory based file system which uses kernel resources relating to the VM system and page cache as a file system.

mount attaches a tmpfs file system to the file system hierarchy at the pathname location mount_point, which must already exist. If mount_point has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (mode, owner, and group) of the root of the tmpfs filesystem are inherited from the underlying mount_point, provided that those attributes are determinable. If not, the root's attributes are set to their default values.

The special argument is usually specified as swap but is in fact disregarded and assumed to be the virtual memory resources within the system.

Options  
-o specific_options  Specify tmpfs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

- size=sz The sz argument controls the size of this particular tmpfs file system. If the argument has a 'k' suffix, the number will be interpreted as a number of kilobytes. An 'm' suffix will be interpreted as a number of megabytes. No suffix is interpreted as bytes. In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical pagesize of the system.

- xattr | noxattr Allow or disallow the creation and manipulation of extended attributes. The default is xattr. See fsattr(5) for a description of extended attributes.

-0 Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error device busy.

Files  
/etc/mtab   Table of mounted file systems

Attributes  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>
See Also  mount(1M), mkdir(2), mount(2), open(2), umount(2), mnttab(4), attributes(5), fsattr(5),
            tmpfs(7FS)

Notes  If the directory on which a file system is to be mounted is a symbolic link, the file system is
mounted on the directory to which the symbolic link refers, rather than on top of the symbolic
link itself.
mount -F udfs \[
generic_options
\] \[-o specific_options\]
\[-O\]
special | mount_point

The mount utility attaches a udfs file system to the file system hierarchy at the mount_point, which is the pathname of a directory. If mount_point has any contents prior to the mount operation, these are hidden until the file system is unmounted.

If mount is invoked with either special or mount_point as the only arguments, mount searches /etc/vfstab to fill in the missing arguments, including the specific_options. See mount(1M).

The udfs file system supports direct mounting of files containing the file system as well as block devices. See mount(1M) and lofiadm(1M).

If special and mount_point are specified without any specific_options, the default is rw.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Options

See mount(1M) for the list of supported generic_options.

The following options are supported:

- \[o specific_options\]
  Specify udfs file system specific options in a comma-separated list with no intervening spaces. The following specific_options are available:

  \[m\]
  Mount the file system without making an entry in /etc/mnttab.

  \[remount\]
  Remount the file system as read-write. The option is used in conjunction with the rw option.

  A file system mounted read-only can be remounted as read-write. This option fails if the file system is not currently mounted.

- \[O\]
  Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error device busy.
Files
/etc/mnttab
   Table of mounted file systems
/etc/vfstab
   List of default parameters for each file system

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/file-system/udfs</td>
</tr>
</tbody>
</table>

See Also fsck(1M), fsck_udfs(1M), lofiadm(1M), mount(1M), mountall(1M), mount(2), mnttab(4), vfstab(4), attributes(5)

Diagnostics
   not super user
       The command is run by a non-root user. Run as root.
   no such device
       The device name specified does not exist.
   not a directory
       The specified mount point is not a directory.
   is not an udfs file system
       The device specified does not contain a udf 1.50 file system or the udfs file system module is not available.
   is already mounted
       The specified device is already in use.
   not a block device
       The device specified is not a block device. Use block device to mount.
   write-protected
       The device is read-only.
   is corrupted. needs checking
       The file system is in an inconsistent state. Run fsck.

Notes
Copy-protected files can be stored on DVD-ROM media using Universal Disk Format (UDF). Reading these copy-protected files is not possible as this involves an authentication process. Unless an authentication process between the host and the drive is completed, reading these copy-protected files after mounting and before the authentication process, returns an error.
The `mount` utility attaches a ufs file system to the file system hierarchy at the `mount_point`, which is the pathname of a directory. If `mount_point` has any contents prior to the `mount` operation, these are hidden until the file system is unmounted.

The ufs file system supports direct mounting of files containing the file system as well as block devices. See `mount(1M)` and `lofiadm(1M)`.

If `mount` is invoked with `special` or `mount_point` as the only arguments, `mount` will search `/etc/vfstab` to fill in the missing arguments, including the `specific_options`. See `mount(1M)`.

If `special` and `mount_point` are specified without any `specific_options`, the default is `rw`.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

See `mount(1M)` for the list of supported `generic_options`.

The following options are supported:

- `-o specific_options`
  Specify ufs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

  - `dfratime | nodfratime`
    By default, writing access time updates to the disk may be deferred (`dfratime`) for the file system until the disk is accessed for a reason other than updating access times. `nodfratime` disables this behavior.

    If power management is enabled on the system, do not set `nodfratime` unless `noatime` is also set. If you set `nodfratime` without setting `noatime`, the disk is spun up every time a file within a file system on the disk is accessed - even if the file is not modified.

  - `forcedirectio | noforcedirectio`
    If `forcedirectio` is specified and supported by the file system, then for the duration of the `mount`, forced direct I/O will be used. If the filesystem is mounted using `forcedirectio`, data is transferred directly between user address space and the disk. If the filesystem is mounted using `noforcedirectio`, data is buffered in kernel address space when data is transferred between user address space and the disk. `forcedirectio` is a performance option that is of benefit only in large sequential data transfers. The default behavior is `noforcedirectio`. 

---

**Name**
mount_ufs – mount ufs file systems

**Synopsis**

```markdown
mount -F ufs [generic_options] [-o specific_options]
   [-O] special | mount_point
```

```markdown
mount -F ufs [generic_options] [-o specific_options]
   [-O] special mount_point
```

**Description**

The `mount` utility attaches a ufs file system to the file system hierarchy at the `mount_point`, which is the pathname of a directory. If `mount_point` has any contents prior to the `mount` operation, these are hidden until the file system is unmounted.

The ufs file system supports direct mounting of files containing the file system as well as block devices. See `mount(1M)` and `lofiadm(1M)`.

If `mount` is invoked with `special` or `mount_point` as the only arguments, `mount` will search `/etc/vfstab` to fill in the missing arguments, including the `specific_options`. See `mount(1M)`.

If `special` and `mount_point` are specified without any `specific_options`, the default is `rw`.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

See `mount(1M)` for the list of supported `generic_options`.

The following options are supported:

- `-o specific_options`
  Specify ufs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

  - `dfratime | nodfratime`
    By default, writing access time updates to the disk may be deferred (`dfratime`) for the file system until the disk is accessed for a reason other than updating access times. `nodfratime` disables this behavior.

    If power management is enabled on the system, do not set `nodfratime` unless `noatime` is also set. If you set `nodfratime` without setting `noatime`, the disk is spun up every time a file within a file system on the disk is accessed - even if the file is not modified.

  - `forcedirectio | noforcedirectio`
    If `forcedirectio` is specified and supported by the file system, then for the duration of the `mount`, forced direct I/O will be used. If the filesystem is mounted using `forcedirectio`, data is transferred directly between user address space and the disk. If the filesystem is mounted using `noforcedirectio`, data is buffered in kernel address space when data is transferred between user address space and the disk. `forcedirectio` is a performance option that is of benefit only in large sequential data transfers. The default behavior is `noforcedirectio`. 

---

System Administration Commands - Part 2 1639
global | noglobal
If global is specified and supported on the file system, and the system in question is part
of a cluster, the file system will be globally visible on all nodes of the cluster. If noglobal
is specified, the mount will not be globally visible. The default behavior is noglobal.

intr | nointr
Allow (do not allow) keyboard interrupts to kill a process that is waiting for an
operation on a locked file system. The default is intr.

largefiles | nolargefiles
If nolargefiles is specified and supported by the file system, then for the duration of
the mount it is guaranteed that all regular files in the file system have a size that will fit in
the smallest object of type off_t supported by the system performing the mount. The
mount will fail if there are any files in the file system not meeting this criterion. If
largefiles is specified, there is no such guarantee. The default behavior is largefiles.

If nolargefiles is specified, mount will fail for ufs if the file system to be mounted has
contained a large file (a file whose size is greater than or equal to 2 Gbyte) since the last
invocation of fsck on the file system. The large file need not be present in the file system
at the time of the mount for the mount to fail; it could have been created previously and
destroyed. Invoking fsck (see fsck_ufs(1M)) on the file system will reset the file system
state if no large files are present. After invoking fsck, a successful mount of the file
system with nolargefiles specified indicates the absence of large files in the file system;
an unsuccessful mount attempt indicates the presence of at least one large file.

logging | nologging
If logging is specified, then logging is enabled for the duration of the mounted file
system. Logging is the process of storing transactions (changes that make up a complete
UFS operation) in a log before the transactions are applied to the file system. Once a
transaction is stored, the transaction can be applied to the file system later. This prevents
file systems from becoming inconsistent, therefore reducing the possibility that fsck
might run. And, if fsck is bypassed, logging generally reduces the time required to
reboot a system.

The default behavior is logging for all UFS file systems.

The log is allocated from free blocks in the file system, and is sized approximately 1
Mbyte per 1 Gbyte of file system, up to a maximum of 256 Mbytes. The log size may be
larger (up to a maximum of 512 Mbytes) dependent upon the number of cylinder
groups present in the file system.

Logging is enabled on any UFS file system, including root (/), except under the
following conditions:
  - When logging is specifically disabled.
  - If there is insufficient file system space for the log. In this case, the following message
    is displayed and file system is still mounted:
mount_ufs(1M)

# mount /dev/dsk/c0t4d0s0 /mnt
/mnt: No space left on device
Could not enable logging for /mnt on /dev/dsk/c0t4d0s0.

The log created by UFS logging is continually flushed as it fills up. The log is totally
flushed when the file system is unmounted or as a result of the lockfs -f command.

m

Mount the file system without making an entry in /etc/mnttab.

noatime
By default, the file system is mounted with normal access time (atime) recording. If
noatime is specified, the file system will ignore access time updates on files, except when
they coincide with updates to the ctime or mtime. See stat(2). This option reduces disk
activity on file systems where access times are unimportant (for example, a Usenet news
spool).

noatime turns off access time recording regardless of dfratime or nodfratime.

The POSIX standard requires that access times be marked on files. -noatime ignores
them unless the file is also modified.

nosec
By default, Access Control Lists (ACLs) are supported on a mounted UFS file system.
Use this option to disallow the setting or any modification of an ACL on a file within a
mounted UFS file system. See getfacl(1) for background on ACLs.

onerror = action
This option specifies the action that UFS should take to recover from an internal
inconsistency on a file system. Specify action as panic, lock, or umount. These values
cause a forced system shutdown, a file system lock to be applied to the file system, or the
file system to be forcibly unmounted, respectively. The default is panic.

quota
Quotas are turned on for the file system.

remount
Remounts a file system with a new set of options. All options not explicitly set with
remount revert to their default values.

rq
Read-write with quotas turned on. Equivalent to rw, quota.

xattr | noxattr
Allow or disallow the creation and manipulation of extended attributes. The default is
xattr. See fsattr(5) for a description of extended attributes.

-O
Overlay mount. Allow the file system to be mounted over an existing mount point, making
the underlying file system inaccessible. If a mount is attempted on a pre-existing mount
point without setting this flag, the mount will fail, producing the error "device busy".

**Examples**

**Example 1**  Turning Off (and On) Logging

The following command turns off logging on an already mounted file system. The subsequent command restores logging.

```bash
# mount -F ufs -o remount,nologging /export
# (absence of message indicates success)
# mount -F ufs -o remount,logging /export
```

In the preceding commands, the `-F ufs` option is not necessary.

**Files**

/etc/mnttab

- table of mounted file systems

/etc/vfstab

- list of default parameters for each file system

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

**See Also**

getfacl(1), fsck(1M), fsck_ufs(1M), lofiadm(1M), mount(1M), mountall(1M), fcntl(2), mount(2), stat(2), mnttab(4), vfstab(4), attributes(5), fsattr(5), largefile(5)

**Notes**

Since the root (`/`) file system is mounted read-only by the kernel during the boot process, only the remount option (and options that can be used in conjunction with remount) affect the root (`/`) entry in the `/etc/vfstab` file.
The `mpathadm` command enables multipathing discovery and management. The `mpathadm` command is implemented as a set of subcommands, many with their own options, that are described in the section for that subcommand. Options not associated with a particular subcommand are described under OPTIONS. The `mpathadm` subcommands operate on a *direct-object*. These are described in this section for each subcommand. The *direct-objects*, *initiator-port*, *target-port*, and *logical-unit* in the subcommands are consistent with SCSI standard definitions.

The `mpathadm` command supports the following subcommands, which are described in detail in subsections that follow.

- **list**
  Display a list of discovered instances for a given object.
- **show**
  Display information about a given object instance.
- **modify**
  Modify properties of an object.
- **enable**
  Enable an object.
- **disable**
  Disable an object.
- **failover**
  Cause target port group failover for a logical-unit.
- **override**
  Set a path to be used over other paths on a logical-unit.

The `mpathadm` subcommands operate on a *direct-object*. These are described in this section for each subcommand.

### list Subcommand

The syntax for the `list` subcommand is:

```
# mpathadm list direct-object [operands...]
```

The `list` subcommand displays data for following direct-objects:

- **mpath-support [mpath-support-name, ...]**
  List the multipathing support that can be administered by this CLI. This presents itself in the form of a library name registered through the MPAPI framework. If no `mpath-support-name` is specified, all registered multipathing support libraries will be displayed.

- **initiator-port [initiator-port-name, ...]**
  List the initiator ports that are discovered on this system. If no `initiator-port-name` is specified, all discovered initiator ports are displayed.

- `{logical-unit | lu} [options] [logical-unit-name, ...]`
  List the information on multipath logical units. If no `logical-unit-name` is specified, all discovered logical-units will be displayed.
Options for list logical-unit are as follows:

- `-n, --name name`  
  Return the logical unit name that is associated with the given name string. This name can be extracted from the output of the `mpathadm show lu` command.

- `-t, --target-port target-port-name`  
  Return the list of logical units names that are associated with the given `target-port-name`.

**show Subcommand**

The syntax for the `show` subcommand is:

```
# mpathadm show direct-object [operands...]
```

The `show` subcommand displays detailed information for following the direct-objects:

- `mpath-support [mpath-support-name, ...]`  
  Show the detailed information on the given `mpath-support-name` if the name exists. If the given `mpath-support-name` supports only a limited set of device products, the list of device products will be listed as part of the output.

- `initiator-port initiator-port-name[,initiator-port-name, ...]`  
  Show the detailed information for the given `initiator-port-name`.

- `{logical-unit | lu} [logical-unit-name, ...]`  
  Display the detailed information on multipath logical unit(s), including path and target port group information. Note that the name property in the logical unit information represents the identifier for this LUN, derived from the hardware, and used by this system. If the name is derived from SCSI Inquiry Vital Product Data (VPD) page 83h, the name type property represents an associated identifier type defined by the SCSI standards.

**modify Subcommand**

The syntax for the `modify` subcommand is:

```
# mpathadm modify direct-object [options] [operands...]
```

The `modify` subcommand modifies characteristics of the following direct-objects:

- `mpath-support [options] mpath-support-name,...`  
  Configuration management of an `mpath-support`. Options to modify `mpath-support` are as follows:

  - `Set autofallback applicable` only when `mpath-support` provides auto fallback support.

  - `Set autoprobe applicable` only when `mpath-support` provides auto probing support.

  - `Change loadbalance type`  
    The loadbalance type is one of the
supported types listed in the show
mpath-support output.

{logical-unit | lu} [options] logical-unit-name, ...

Configuration management of a
logical unit. Options to modify
logical-unit are as follows:

Set autofailback Applyable only
when mpath-support provides auto
failback support

Set autocpoprobe Applyable only
when mpath-support provides auto
probing support.

Set loadbalance Applyable only
when load
balance configuration is supported at
the logical unit level.

enable Subcommand    The syntax for the enable subcommand is:

    # mpathadm enable [options]

    The enable subcommand supports the following direct-objects to be enabled:

    path -i initiator-port-name -t target-port-name
    -l logical-unit-name

    The path that consists of the specified
    initiator port, target port, and logical
    unit will be enabled.

disable Subcommand    The syntax for the disable subcommand is:

    # mpathadm disable [options]

    The disable subcommand supports the following direct-objects to be disabled:

    path -i initiator-port-name -t target-port-name
    -l logical-unit-name

    The path that consists of the specified
    initiator port, target port, and logical
    unit will be disabled.

failover Subcommand   The syntax for the failover subcommand is:

    # mpathadm failover direct-object [operand]

    The failover subcommand supports failover for the following direct-objects:

    {logical-unit | lu} logical-unit-name

    The target port group will failover when the given
    logical-unit is asymmetric and supports explicit
state change. The currently active target port group will be changed to the standby state and the standby target port group will be active.

override Subcommand

The syntax for the override subcommand is:

```
# mpathadm override [options]
```

The override subcommand controls whether or not the following direct-objects override another:

```
path [-i initiator-port-name -t target-port-name] -l logical-unit-name
```

Cause a path that consists of the specified initiator port, target port, and logical unit to override other paths on the logical unit. Once a path overrides other paths, the mpath-support uses only that path regardless of any other path selection configuration. The -c option cancels the setting. The path that consists of the specified initiator port, target port, and logical unit will be disabled.

Options for override path are as follows:

```
-i, --initiator-port initiator-port-name
   Represent the initiator port element of a path. Options -t and -l must also be included.
-t, --target-port target-port-name
   Represent the target port element of a path. Options -i and -l must also be included.
-l, --logical-unit logical-unit
   Represent the logical unit element of a path. Options -i and -t must also be included.
-c, --cancel
   Cancels overriding setting for the given logical unit. Option -l must also be included.
```

Options

The following options are supported:

```
-V, --version
   Display the version information.
-?, --help
   Display context help. Can be used following an mpathadm command with no arguments, following a subcommand, or following a subcommand direct-object combination. Responds with help information appropriate for your entry. For example, if you enter:

# mpathadm add mpath-support-help

... mpathadm responds with a display of the options available for that combination of subcommand and direct-object.
```
**Examples**

**EXAMPLE 1**  Obtaining a List of Multipathing Support

The following command uses the `list` subcommand to list all currently registered `mpath-support` libraries.

```
# mpathadm list mpath-support
mpath-support: libmpscsi_vhci.so
```

**EXAMPLE 2**  Displaying the Properties of a Particular Multipathing Support

The following command uses the `show` subcommand to display the properties for a currently registered `mpath-support` library.

```
# mpathadm show mpath-support libmpscsi_vhci.so
mpath-support: libmpscsi_vhci.so
  Vendor: Sun Microsystems
  Driver Name: scsi_vhci
  Default Load Balance: round-robin
  Supported Load Balance Types:
    round-robin
    logical-block
  Allows To Activate Target Port Group Access: yes
  Allows Path Override: no
  Supported Auto Failback Config: 1
  Auto Failback: on
  Failback Polling Rate (current/max): 0/0
  Supported Auto Probing Config: 0
  Auto Probing: NA
  Probing Polling Rate (current/max): NA/NA
  Supported Devices:
    Vendor: SUN
    Product: T300
    Revision:
    Supported Load Balance Types:
      round-robin
    Vendor: SUN
    Product: T4
    Revision:
    Supported Load Balance Types:
      round-robin
```

**EXAMPLE 3**  Obtaining a List of Initiator Ports Discovered Through the mpath-support Libraries

The following command uses the `list initiator-port` subcommand to display a list of initiator ports discovered by the currently registered `mpath-support` libraries.

```
# mpathadm list initiator-port
Initiator-Port: iqn.1986-03.com.sun:01:080020b7ac2b.437a3b3e,400002a0000
Initiator-Port: 200000173018713
Initiator-Port: 200000173818713
```
Displaying the Properties of a Particular Initiator Port

The following command uses the `show initiator-port` subcommand to display the properties of a particular initiator port discovered using the `list initiator-port` subcommand in an example above.

```
# mpathadm show initiator-port 2000000173018713
initiator-port: 2000000173018713
  Transport Type: Fibre Channel
  OS device File: devices/pci@1f,4000/pci@2/SUNW,qlca@5/fp@0,0:fc
```

Displaying the Properties of a Particular Logical Unit

The following command uses the `show logical-unit` subcommand to display the properties of the logical unit with the specified name.

```
# mpathadm show lu /dev/rdsk/c4t60003BA27D2120004204AC2B000DAB00d0s2
Logical Unit: /dev/rdsk/c4t60003BA27D2120004204AC2B000DAB00d0s2
  mpath-support libmpscsi_vhci.so
  Vendor: SUN
  Product: T4
  Revision: 0301
  Name Type: SCSI Inquiry VPD Page 83 type 3
  Name: 60003ba27d2120004204ac2b000dab00
  Asymmetric: yes
  Current Load Balance: round-robin
  Logical Unit Group ID: NA
  Auto Failback: on
  Auto Probing: NA

Paths:
  Initiator Port Name: 2000000173018713
  Target Port Name: 20030003ba27d212
  Override Path: NA
  Path State: OK
  Disabled: no

  Initiator Port Name: 20030003ba27d095
  Target Port Name: 2000000173018713
  Override Path: NA
  Path State: OK
  Disabled: no

Target Port Group:
  ID: 2
  Explicit Failover: yes
  Access State: standby
  Target Ports:
    Name: 20030003ba27d212
EXAMPLE 5  Displaying the Properties of a Particular Logical Unit  (Continued)

Relative ID: 0

ID: 5
Explicit Failover: yes
Access State: active
Target Ports
   Name: 20030003ba27d095
   Relative ID: 0

EXAMPLE 6  Enabling a Path

The following command uses the enable path subcommand to enable the path with the specified initiator port, target port, and logical unit.

```
# mpathadm enable path -i 2000000173018713 -t 20030003ba27d095 \ 
   -l /dev/rdsk/c4t60003BA27D2120004284AC2B000DAB00d8s2
```

EXAMPLE 7  Modifying mpath-support To Turn On autofailback

```
# mpathadm modify mpath-support -a on libmpscsi_vhci.so
```

mpstat (1M)

Name
mpstat – report per-processor or per-processor-set statistics

Synopsis
/usr/bin/mpstat [-amq] [-A core|soc|bins] [-k keys] [-o num]
[ interval [ count]]

Description
The mpstat command reports processor statistics in tabular form. Each row of the table represents the activity of one processor. The first table summarizes all activity since boot. Each subsequent table summarizes activity for the preceding interval. All values are rates listed as events per second unless otherwise noted.

During execution of the kernel status command, the state of the kernel can change. If relevant, a state change message is included in the mpstat output, in one of the following forms:

<<processor 3 moved from pset: -1 to: 1>>
<<pset destroyed: 1>>
<<pset created: 1>>
<<processors added: 1, 3>>
<<processors removed: 1, 3>>

The mpstat command reports the following information:

CPU | SET | COR | SOC | BIN

CPU
Processor ID for which statistics are shown, when the -a and -A options are omitted.

SET
Processor set ID for which statistics are aggregated, for the -a option.

COR
Core ID for which statistics are aggregated, for the -A core option.

SOC
Socket ID for which statistics are aggregated, for the -A soc option.

BIN
Bin ordinal for which statistics are aggregated, for the -A bins option.

minf
minor faults

mjf
major faults

xcal
inter-processor cross-calls

intr
interrupts
ithr
interrupts as threads (not counting clock interrupt)

csw
context switches

icsw
involuntary context switches

migr
thread migrations (to another processor)

smtx
spins on mutexes (lock not acquired on first try)

srxw
spins on readers/writer locks (lock not acquired on first try)

syscl
system calls

usr
percent user time

sys
percent system time

wt
the I/O wait time is no longer calculated as a percentage of CPU time, and this statistic will always return zero.

idl
percent idle time

size
number of processors in the requested processor set

set
processor set membership of each CPU

**Options**
The following options are supported:

-a
Aggregate output by processor set. Sort the output by set. The default output is sorted by CPU number.

-A core
Aggregate CPU output by core ID. Data rows having the same core ID are aggregated into one row. The columns are replaced with subtotals, by default. The -m option prints column averages, instead.

The -A option is incompatible with the -a option for aggregating by processor set.
-A soc
Aggregate CPU output by socket ID. Data rows having the same socket ID are aggregated into one row. The columns are replaced with subtotals, by default. The -m option prints column averages, instead.

The -A option is incompatible with the -a option for aggregating by processor set.

-A bins
Aggregate the rows into bins within each sampling period, grouping them in the order in which they appear, and aggregate over rows for each bin. The -k option may be used to change the row order prior to the binning step. The size column prints the number of CPUs in each bin. The BIN column replaces the CPU column and prints the ordinal of each bin.

Aggregation by ID (-A core|soc) is processed before sorting (-k). Grouping by bins (-A bins) is done next. Finally, the number of output lines printed per interval may be limited by -o.

The -A option is incompatible with the -a option for aggregating by processor set.

-I statfile
Replay data previously saved in statfile. Create data files for replay by specifying -O. This option is especially useful for analyzing statistics on machines with large numbers of CPUs. The file may be reprocessed multiple times using different sorting and aggregation options.

The -I option is incompatible with an interval and count specification.

Read from the standard input if the file name is -- (hyphen).

-k key1,...
Sort rows within each sampling period from highest to lowest by key1, then key2, and so on. Each key may be any of the column headers such as xca1, int r, sys, and so forth.

-m
Print the arithmetic mean value rather than the sum when the -a or -A options are used to aggregate data over multiple CPUs.

-o num
Print only the first num rows within each sampling period, after applying sorting and aggregation options.

-O statfile
Save all data to statfile. This data may be replayed at a later time using -I.

Write to the standard output if the file name is -- (hyphen).

The purpose of -O is to capture all available data. It is incompatible with the data reduction options: -a, -A, -k, -m, -o, -p, and -P.
-p
Report processor set membership of each CPU. Sort the output by set. The default output is sorted by CPU number.

-P set
Display only those processors in the specified set.

-q
Suppress messages related to state changes.

-T u | d
Specify u for a printed representation of the internal representation of time. See time(2).
Specify d for standard date format. See date(1).

interval
Report once each interval seconds.

count
Only print count reports.

Examples
On displays of 80–character width, example output below wraps by one to seven characters. By making a window wider, you can eliminate this wrap.

EXAMPLE 1 Using mpstat to Generate User and System Operation Statistics
The following command generates processor statistics over a five–second interval in two reports. The command shows the processor set membership of each CPU. The default output is sorted by CPU number, aggregated by processor set, for user (usr) and system (sys) operations.

```
example% mpstat -ap 5 2
```

```
SET minf mjf xcal intr ithr csw icsw migr smtx srw syscl usr sys wt idl sze
0  6  0  355  291  190  22  0  0  0  0  43  0  2  0  43  1
1 24  17  534  207  200  70  1  0  2  0  600  4  1  0  84  2
2 19  7  353  325  318  44  0  0  5  0  345  1  1  0  94  3
3 36  2  149  237  236  14  0  0  4  0  97  0  0  0  98  2
```

```
SET minf mjf xcal intr ithr csw icsw migr smtx srw syscl usr sys wt idl sze
0  1  0  18  0  12  0  15  0  81  1
1 0  69  1955 230  200  313  33  4  1  9  7086  4  10  0  19  2
2 0  46  686  314  300  203  11  0  5  4  5287  36  6  0  28  3
3 0  14  386  384  0  0  0  0  0  0  100  2
```

EXAMPLE 2 Displaying CPUs That Meet Filter Requirement
The following command displays the three CPUs with the highest intr rates.

```
example% mpstat -k intr -o 3
```

```
CPU minf mjf xcal intr ithr csw icsw migr smtx srw syscl usr sys wt idl
56 1143  5 975  4238  82  465  74  53 124  0 198163 42 17 0 41
```
EXAMPLE 2  Displaying CPUs That Meet Filter Requirement  (Continued)

123 1189  6 1315 1030  890  461  65  53  122  0 24383  27  12  0  62
 4 1184  5 1040  149  70  502  73  55  113  0 82039  31  13  0  56

EXAMPLE 3  Aggregating Multiple CPUs into Quartiles

The following command aggregates 256 CPUs into quartiles by sys time.

example% mpstat -A 4 -k sys
BIN minf mjf xcal intr ithr csw icsw smtx srw syscl usr sys wt idl sze
0  18  0  5811  7105  1 22154 17  9529 1176  0  72  1  79  0  19  64
1  0  0  4624 1006 12 1321 42  418  73  0 3591 36  37  0  27  64
2 1195  5 1056  92  10 526  74  56 104  0 45876 27  12  0  61  64
3  0  0  2 18  8 10  0  0  0  0  1  0  0  0 100  64

EXAMPLE 4  Saving Statistics for Later Reprocessing

The following command saves statistics for later reprocessing and aggregates by core ID on a
machine with eight CPUs per core.

example% mpstat -O /tmp/t1; mpstat -I /tmp/t1 -A core
COR minf mjf xcal intr ithr csw icsw smtx srw syscl usr sys wt idl sze
514  0  0 124  45  0 21  0 3  1  0  0  0  3  97  8
521  0  0 16  5  0  1  0  0  0  0  0  0  0  0 100  8
528  0  0 11  5  0  3  0  0  0  0  0  0  0  0 100  8
535  0  0  7  4  0  1  0  0  0  0  0  0  0  0 100  8
542  0  0  7  4  0  1  0  0  0  0  0  0  0  0 100  8
549  0  0 10  4  0  1  0  0  0  0  0  0  0  0 100  8
556  0  0 10  5  0  1  0  0  0  0  0  0  0  0 100  8
563  0  0  8  4  0  1  0  0  0  0  0  0  0  0 100  8

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

Invocation is evolving. Human readable output is unstable.

See Also  sar(1), date(1), iostat(1M), sar(1M), vmstat(1M), time(2), attributes(5)

Notes  The sum of CPU utilization might vary slightly from 100 due to rounding errors in the
production of a percentage figure.
The total time used for CPU processing is the sum of usr and sys output values, reported for user and system operations. The idl value reports the time that the CPU is idle for any reason other than pending disk I/O operations.

Run the iostat command with the -x option to report I/O service times in svc_t output. The iostat utility also reports the same wt, user (us), and system (sy) statistics. See iostat(1M) for more information.

When executing in a zone and if the pools facility is active, mpstat(1M) will only provide information for those processors which are a member of the processor set of the pool to which the zone is bound.
msgid – generate message IDs

**Synopsis**  
/usr/sbin/msgid

**Description**  
The `msgid` utility generates message IDs.

A message ID is a numeric identifier that uniquely identifies a message. Although the probability of two distinct messages having the same ID is high, this can be greatly reduced with the appropriate priority or facility.level designator (see `syslogd(1M)`). Specifically, the message ID is a hash signature on the message’s unexpanded format string, generated by `STRLOG_MAKE_MSGID()` as defined in `<sys/strlog.h>`.

`syslogd(1M)` is a simple filter that takes strings as input and produces those same strings, preceded by their message IDs, as output. Every message logged by `syslogd(1M)` includes the message ID. The message ID is intended to serve as a small, language-independent identifier.

**Examples**

**EXAMPLE 1**  Using the msgid command to generate a message ID

The following example uses the `msgid` command to generate a message ID for the `echo` command.

```
example# echo hello | msgid
205790 hello
example#
```

**EXAMPLE 2**  Using the msgid command to Generate a Message Catalog

The following example uses the `msgid` command to enumerate all of the messages in the binary `zfs`, on an x86 machine, to generate a message catalog.

```
example# strings /kernel/fs/amd64/zfs | msgid
... 726970 stride_hits 766819 stride_misses 929857 reclaim_successes 412490 reclaim_failures 234331 streams_resets 737841 streams_noresets 471619 bogus_streams 878613 onloan_read_buf ...
```

**Attributes**

Name  mvdir – move a directory

Synopsis  /usr/sbin/mvdir dirname name

Description  mvdir moves directories within a file system. dirname must be a directory. If name does not exist, it will be created as a directory. If name does exist, and is a directory, dirname will be created as name/dirname. dirname and name may not be on the same path; that is, one may not be subordinate to the other. For example:

example% mvdir x/y x/z

is legal, but

example% mvdir x/y/x/y/z

is not.

Operands  

dirname  The name of the directory that is to be moved to another directory in the filesystem.

name  The name of the directory into which dirname is to be moved. If name does not exist, it will be created. It may not be on the same path as dirname.

Usage  See largefile(5) for the description of the behavior of mvdir when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status  

0  Successful operation.

>0  Operation failed.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  mkdir(1), mv(1), attributes(5), largefile(5)
### Name
named, in.named – Internet domain name server

### Synopsis
named [-f | -g | -s] [-c config-file] [-d debug-level] [-m flag]
   [-n #cpus] [-p port] [-S #max-socks] [-t directory]
   [-u user] [-x cache-file] [-4 | -6]

### Description
The named utility is a Domain Name System (DNS) server, part of the BIND 9 distribution from ISC. For more information on the DNS, see RFCs 1033, 1034, and 1035.

When invoked without arguments, named reads the default configuration file /etc/named.conf, reads any initial data, and listens for queries.

in.named is a link to named.

### Options
The following options are supported:

- **-4**
  Use only IPv4 transport. By default, both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

- **-6**
  Use only IPv6 transport. By default, both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

- **-c config-file**
  Use config-file as the configuration file instead of the default /etc/named.conf. To ensure that reloading the configuration file continues to work after the server has changed its working directory due to a possible directory option in the configuration file, config-file should be an absolute pathname.

- **-d debug-level**
  Set the daemon’s debug level to debug-level. Debugging traces from named become more verbose as the debug level increases.

- **-f**
  Run the server in the foreground (that is, do not run as a daemon).

- **-g**
  Run the server in the foreground and force all logging to stderr.

- **-m flag**
  Turn on memory usage debugging flags. Possible flags are usage, trace, and record, size, and mctx. These correspond to the ISC_MEM_DEBUGXXX flags described in <isc/mem.h>.

- **-n #cpus**
  Create #cpus worker threads to take advantage of multiple CPUs. If not specified, named will try to determine the number of CPUs present and create one thread per CPU. If it is unable to determine the number of CPUs, a single worker thread will be created.

- **-p port**
  Listen for queries on port port. If not specified, the default is port 53.
**-S** `#max-socks`

Allow `named` to use up to `#max-socks` sockets.

This option should be unnecessary for the vast majority of users. The use of this option could even be harmful, because the specified value might exceed the limitation of the underlying system API. It therefore should be set only when the default configuration causes exhaustion of file descriptors and the operational environment is known to support the specified number of sockets. Note also that the actual maximum number is normally a little smaller than the specified value because `named` reserves some file descriptors for its internal use.

**-s**

Write memory usage statistics to `stdout` on exit.

This option is mainly of interest to BIND 9 developers and might be removed or changed in a future release.

**-t** `directory`

Change the root directory using `chroot(2)` to `directory` after processing the command line arguments, but before reading the configuration file.

This option should be used in conjunction with the `-u` option, as chrooting a process running as root does not enhance security on most systems; the way `chroot()` is defined allows a process with root privileges to escape a `chroot` jail.

**-u** `user`

Set the real user ID using `setuid(2)` to `user` after completing privileged operations, such as creating sockets that listen on privileged ports.

**-V**

Report the version number and build options, and exit.

**-v**

Report the version number and exit.

**-x** `cache-file`

Load data from `cache-file` into the cache of the default view.

Do not use this option. It is of interest only to BIND 9 developers and might be removed or changed in a future release.

---

### Extended Description

**SMF Properties**

This section describes additional attributes of `named`.

When starting `named` from the service management facility, `smf(5)`, `named` configuration is read from the service configuration repository. Use `svccprop(1)` to list the properties and `svccfg(1M)` to make changes.

The following application configuration properties are available to administrators:
options/server
Specifies the server executable to be used instead of the default server, /usr/sbin/named.

options/configuration_file
Specifies the configuration file to be used instead of the default, /etc/named.conf. A directory option might be specified in the configuration file. To ensure that reloading the configuration file continues to work in such a situation, configuration_file should be specified as an absolute pathname. This pathname should not include the chroot_dir pathname. This property is the equivalent of the -c option.

options/ip_interfaces
Specifies over which IP transport, IPv4 or IPv6, BIND will transmit. Possible values are IPv4 or IPv6. Any other setting assumes all, the default. This property is the equivalent of command line option -4 or -6.

options/listen_on_port
Specifies the default UDP and TCP port to be used for listening to DNS requests. This property is the equivalent of the command line option -p port.

options/debug_level
Specifies the default debug level. The default is 0, which means no debugging. The higher the number the more verbose debug information becomes. Equivalent of the command line option -d debug_level.

options/threads
Specifies the number of CPU worker threads to create. The default of 0 causes named to try and determine the number of CPUs present and create one thread per CPU. Equivalent of command line option -n #cpus.

options/chroot_dir
Specifies the directory to be used as the root directory after processing SMF properties and the command line arguments but before reading the configuration file. Use this property when using a chroot(2) environment. Synonymous to command line option -t pathname.

When using chroot(2), named is unable to disable itself when receiving rndc(1M) stop or halt commands. Instead, you must use the svcadm(1M) disable command.

In the event of a configuration error originating in one of the above SMF application options, named displays a message providing information about the error and the parameters that need correcting. The process then exits with exit code SMF_EXIT_ERR_CONFIG.

At startup, in the event of an error other than a configuration error, named exits with exit code SMF_EXIT_ERR_FATAL. Both of this code and SMF_EXIT_ERR_CONFIG cause the start method, smf_method(5), to place the service in the maintenance state, which can be observed with the svcs(1) command svcs -x.

In addition to the properties listed above, the following property can be used to invoke named as a user other than root:
start/user

Specifies the identity of the user that is invoking named. See smf_method(5) and chroot(2).

Note that the user must have solaris.smf.manage.bind authorization. Without this role
the named will be unable to manage its SMF FMRI and named will automatically be restarted
by the SMF after an rndc(1M) stop or halt command. See EXAMPLES for a sequence of
commands that establishes the correct authorization.

SIGNALS

In routine operation, signals should not be used to control the nameserver; rndc(1M) should
be used instead.

SIGHUP

Force a reload of the server.

SIGINT, SIGTERM

Shut down the server.

The result of sending any other signals to the server is undefined.

The named configuration file is too complex to describe in detail here. A list of configuration
options is provided in the named.conf man page shipped with the BIND 9 distribution. A
complete description is provided in the BIND 9 Administrator Reference Manual.

Examples

EXAMPLE 1 Configuring named to Transmit Only over IPv4 Networks

The following command sequence configures named such that it will transmit only over IPv4
networks.

```
# svcfg -s svc:network/dns/server:default setprop \
> options/ip_interfaces=IPv4
# svcadm refresh svc:network/dns/server:default
```

EXAMPLE 2 Listing Current Configuration File and Setting an Alternative File

The following sequence of commands lists the current named configuration file and sets an
alternative file.

```
# svcprop -p options/configuration_file dns/server:default /etc/named.conf
# svcfg -s dns/server:default setprop \
> options/configuration_file=/var/named/named.conf
# svcadm refresh dns/server:default
# svcprop -p options/configuration_file dns/server:default \
/var/named/named.conf
```

EXAMPLE 3 Establishing Appropriate Authorization for named

To have named start with the solaris.smf.manage.bind authorization, perform the steps
shown below.

Add the user dnsadmin to the solaris.smf.manage.bind role:
EXAMPLE 3 Establishing Appropriate Authorization for named (Continued)

# usermod -A solaris.smf.manage.bind dnsadmin
Observe effect of command:
# tail -1 /etc/user_attr
dnsadmin:::type=normal;auths=solaris.smf.manage.bind

Modify the service properties:

# svccfg
svc:/> select svc:/network/dns/server:default
svc:/network/dns/server:default> setprop start/user = dnsadmin
svc:/network/dns/server:default> setprop start/group = dnsadmin
svc:/network/dns/server:default> exit
# svcadm refresh svc:/network/dns/server:default
# svcadm restart svc:/network/dns/server:default

Because only root has write access to create the default process-ID file, /var/run/named/named.pid, named must be configured to use an alternative path for the user dnsadmin. Here is an example of how to accomplish this:

# mkdir /var/named/tmp
# chown dnsadmin /var/named/tmp

Shown below is what you must add to named.conf to make use of the directory created above.

# head /etc/named.conf
options {
  directory "/var/named";
  pid-file "/var/named/tmp/named.pid";
};

Files
/etc/named.conf
  default configuration file

/var/run/named/named.pid
  default process-ID file

named-checkconf -- named configuration file syntax checking tool

**Synopsis**

```bash
named-checkconf [-hjvz] [-t directory] filename
```

**Description**
The `named-checkconf` utility checks the syntax, but not the semantics, of a specified configuration file.

**Options**
The following options are supported:

- `-h`
  Display the usage summary and exit.

- `-j`
  When loading a zonefile, read the journal if it exists.

- `-t directory`
  Change the root directory to `directory` so that include directives in the configuration file are processed as if run by a named configuration whose root directory has been similarly changed.

- `-v`
  Print the version of the `named-checkconf` program and exit.

- `-z`
  Perform a test load of the master zones found in `named.conf`.

**Operands**
The following operands are supported:

- `filename`
  The name of the configuration file to be checked. If not specified, it defaults to `/etc/named.conf`.

**Exit Status**

- `0`
  No errors were detected.

- `1`
  An error was detected.

**Attributes**

named-checkzone(1M)

Name
named-checkzone, named-compilezone — zone file validity checking or converting tool

Synopsis
named-checkzone [-Ddhjqv] [-c class] [-F format] [-f format]
   [-i mode] [-k mode] [-M mode] [-n mode]
   [-o filename] [-s mode] [-s style] [-t directory]
   [-W mode] [-w directory] zonename filename

named-compilezone [-Ddjqv] [-c mode] [-c class] [-F format]
   [-f format] [-i mode] [-k mode] [-m mode] [-n mode]
   [-o filename] [-s style] [-t directory]
   [-W mode] [-w directory] zonename filename

Description
The named-checkzone utility checks the syntax and integrity of a zone file. It performs the same checks as named(1M) does when loading a zone. The named-checkzone utility is useful for checking zone files before configuring them into a name server.

named-compilezone is similar to named-checkzone, differing in that it always dumps the zone contents to a specified file in a specified format. Additionally, it applies stricter check levels by default, since the dump output will be used as an actual zone file loaded by named(1M). Unless manually specified otherwise, the check levels must be at least as strict as those specified in the named configuration file.

Options
For either or both utilities, the following options are supported:

- c class
  Specify the class of the zone. If not specified, “IN” is assumed.

- D
  Dump zone file in canonical format.

- d
  Enable debugging.

- F format
  Specify the format of the output file specified. Possible formats are text (default) and raw. For named-checkzone, this does not cause any effects unless it dumps the zone contents.

- f format
  Specify the format of the zone file. Possible formats are text (default) and raw.

- h
  Display usage message for named-checkzone.

- i mode
  Perform post-load zone integrity checks. Possible modes are full (default), full-sibling, local, local-sibling, and none.

  Mode full checks that MX records refer to the A or AAAA record (both in-zone and out-of-zone hostnames). Mode local checks only MX records that refer to in-zone hostnames.
Mode **full** checks that SRV records refer to the A or AAAA record (both in-zone and out-of-zone hostnames). Mode **local** checks only SRV records that refer to in-zone hostnames.

Mode **full** checks that delegation NS records refer to A or AAAA record (both in-zone and out-of-zone hostnames). It also checks that glue address records in the zone match those advertised by the child. Mode **local** checks only NS records that refer to in-zone hostnames or check that some required glue exists, that is, when the nameserver is in a child zone.

Mode **full-sibling** and **local-sibling** disable sibling glue checks, but are otherwise the same as **full** and **local**, respectively.

Mode **none** disables the checks.

**-k mode**

Perform "check-name" checks with the specified failure mode. Possible modes are **fail** (default for named-compilezone), **warn** (default for named-checkzone) and **ignore**.

**-j**

Read the journal, if it exists, when loading the zone file.

**-M mode**

Check if an MX record refers to a CNAME. Possible modes are **fail**, **warn** (default) and **ignore**.

**-m mode**

Specify whether MX records should be checked to see if they are addresses. Possible modes are **fail**, **warn** (default) and **ignore**.

**-n mode**

Specify whether NS records should be checked to see if they are addresses. Possible modes are **fail** (default for named-compilezone), **warn** (default for named-checkzone) and **ignore**.

**-o filename**

Write zone output to **filename**. If **filename** is `-` (a hyphen), then write to standard out. The hyphen mandatory for named-compilezone

**-q**

Run in quiet mode, reporting only the exit status.

**-S mode**

Check if a SRV record refers to a CNAME. Possible modes are **fail**, **warn** (default) and **ignore**.

**-s style**

Specify the style of the dumped zone file. Possible styles are **full** (default) and **relative**. The **full** format is most suitable for processing automatically by a separate script. The **relative** format is more human-readable and is thus suitable for editing by hand. For
named-checkzone this option does not cause any effects unless it dumps the zone contents. It also has no effect if the output format is not text.

- t directory
  chroot to directory so that include directives in the configuration file are processed as if run by a similarly chrooted named.

- v
  Print the version of the named-checkzone program and exit.

- W mode
  Specify whether to check for non-terminal wildcards. Non-terminal wildcards are almost always the result of a failure to understand the wildcard matching algorithm (RFC 1034). Possible modes are warn (default) and ignore.

- w directory
  chdir to directory so that relative filenames in master file $INCLUDE directives work. This is similar to the directory clause in named.conf.

Operands The following operands are supported:

filename
  The name of the zone file.

zonename
  The domain name of the zone being checked.

Exit Status

0
  No errors were detected.

1
  An error was detected.

ncacnfdd – Solaris Network Cache and Accelerator (NCA) configuration daemon

```
/usr/lib/inet/ncacnfdd [-al ] interface1 [interface2 ...]
```

**Description**

Use the `ncacnfdd` utility to set up NCA on a system. At boot time, the `ncakmod` initialization script reads in `nca.if(4)` to determine on which interface(s) NCA should run. `ncacnfdd` then sets up the interface.

`ncacnfdd` also operates as a daemon if the `nca_active` key is set to enabled in `ncakmod.conf(4)` file. In this case, `ncacnfdd` will continue as a daemon after all the NCA interfaces have been set up, listening for routing changes. The changes are then passed to NCA to control which interface NCA should use to make active outgoing TCP connections.

**Options**

The following options are supported:

- `-a` Enable active connections.
- `-l` Enable logging.

**Files**

`/etc/nca/ncakmod.conf`

**Attributes**

`ncakmod(1), nca.if(4), ncakmod.conf(4), attributes(5), nca(7d)`
ncheck(1M)

Name
ncheck – generate a list of path names versus i-numbers

Synopsis
ncheck [-F FSType] [-V] [generic_options]
[-o FSType-specific_options] [special]...

Description
ncheck with no options generates a path-name versus i-number list of all files on special. If
special is not specified on the command line the list is generated for all specialis in /etc/vfstab
which have a numeric fsckpass. special is the raw device on which the file system exists.

Options
-F Specify the FSType on which to operate. The FSType should either be
specified here or be determinable from /etc/vfstab by finding an entry
in the table that has a numeric fsckpass field and an fsckdev that
matches special.

-V Echo the complete command line, but do not execute the command. The
command line is generated by using the options and arguments provided
by the user and adding to them information derived from /etc/vfstab.
This option may be used to verify and validate the command line.

generic_options
Options that are commonly supported by most FSType-specific
command modules. The following options are available:

- i i-list Limit the report to the files on the i-list that follows. The i-list
must be separated by commas with no intervening spaces.

- a Print the names “.” and “..” which are ordinarily suppressed.

- s Report only special files and files with set-user-ID mode. This
option may be used to detect violations of security policy.

- o Specify FSType-specific_options in a comma separated (without spaces)
list of suboptions and keyword-attribute pairs for interpretation by the
FSType-specific module of the command.

Usage
See largefile(5) for the description of the behavior of ncheck when encountering files
greater than or equal to 2 Gbyte (2^31 bytes).

Files
/etc/vfstab list of default parameters for each file system

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also
vfstab(4), attributes(5), largefile(5) Manual pages for the FSType-specific modules of
ncheck
Notes  This command may not be supported for all FSTypes.
ncheck_ufs(1M)

Name  ncheck_ufs – generate pathnames versus i-numbers for ufs file systems

Synopsis  ncheck -F ufs [generic_options] [-o m] [special]...

Description  ncheck -F ufs generates a pathname versus i-number list of files for the ufs file system residing on special. Names of directory files are followed by ‘/’.

Options  See ncheck(1M) for the list of generic_options supported.

- o  Specify ufs file system specific options. The available option is:

- m  Print mode information.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTETYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  ff(1M), ncheck(1M), attributes(5)

Diagnostics  When the file system structure is improper, ‘??’ denotes the “parent” of a parentless file and a pathname beginning with ‘.’ . ‘.’ denotes a loop.
Name  ndd – get and set driver configuration parameters

Synopsis  ndd [-set] driver parameter [value]

Description  ndd gets and sets selected configuration parameters in some kernel drivers. Currently, ndd only supports the drivers that implement the TCP/IP Internet protocol family. Each driver chooses which parameters to make visible using ndd. Since these parameters are usually tightly coupled to the implementation, they are likely to change from release to release. Some parameters may be read-only.

Note – It is strongly encouraged that you use ipadm(1M), rather than ndd, to modify or retrieve TCP/IP Internet protocols. The current ndd command will be made obsolete in a future release, replaced by ipadm(1M). Please see NOTES for more information.

If the ndd - set option is omitted, ndd queries the named driver, retrieves the value associated with the specified parameter, and prints it. If the - set option is given, ndd passes value, which must be specified, down to the named driver which assigns it to the named parameter.

By convention, drivers that support ndd also support a special read-only parameter named “?” which can be used to list the parameters supported by the driver.

Examples  EXAMPLE 1  Getting Parameters Supported By The TCP Driver

To see which parameters are supported by the TCP driver, use the following command:

example% ndd /dev/tcp \\?

The parameter name “?” may need to be escaped with a backslash to prevent its being interpreted as a shell meta character.

The following command sets the value of the parameter ip_forwarding in the dual stack IP driver to zero. This disables IPv4 packet forwarding.

example% ndd -set /dev/ip ip Forwarding 0

Similarly, in order to disable IPv6 packet forwarding, the value of parameter ip6_forwarding

example% ndd -set /dev/ip6 ip6_forwarding 0

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  dladm(1M), ipadm(1M), ioctl(2), attributes(5), nca(7d), arp(7P), ip(7P), ip6(7P), tcp(7P), udp(7P)
```plaintext
Notes  The parameters supported by each driver may change from release to release. Like programs that read /dev/kmem, user programs or shell scripts that execute ndd should be prepared for parameter names to change.

The ioctl() command that ndd uses to communicate with drivers is likely to change in a future release. User programs should avoid making dependencies on it.

The use of ndd to administer Layer 2 (Data Link layer) drivers is strongly discouraged as this capability is to be obsoleted in a future release, replaced by dladm(1M). Please refer to the driver-specific man page in section 7D of the SunOS man pages.

The use of ndd to administer the drivers that implement the TCP/IP Internet protocol family (IP/TCP/SCTP/UDP/ICMP) is strongly discouraged as this capability is to be obsoleted in a future release, replaced by ipadm. Please see ipadm(1M) for instructions for modifying and retrieving supported protocol properties.

The meanings of many ndd parameters make sense only if you understand how the driver is implemented.
```
ndmpadm – administer Network Data Management Protocol activities

Synopsis
/usr/sbin/ndmpadm [-? ] subcommand [options] [direct-object]

Description
The ndmpadm command can be used to query the ndmpd(1M) daemon to get the status of active sessions, terminate a session, query backup devices, and set or get the current NDMP (Network Data Management Protocol) service variables and properties. ndmpadm is implemented as a set of subcommands, many with their own direct object, which are described in the section for a given subcommand. Certain subcommands support options, which are described along with the subcommand.

The ndmpadm command supports the following subcommands:

disable
    Disable the specified authentication password handling.

enable
    Enable the specified authentication password handling.

get
    Get the value of an NDMP configuration property.

kill-sessions
    Terminate an active session.

set
    Set the value of an NDMP configuration property.

show-devices
    Get a list of tape devices connected to the server.

show-sessions
    Display the details of active NDMP sessions.

Options
The following option is supported:
-?    Display a list of all subcommands and options.

Sub-commands
The ndmpadm command supports the subcommands described below.

disable Subcommand
The syntax for the disable subcommand is:

# ndmpadm disable -a auth-type

This subcommand disables the authentication type specified by auth-type for an NDMP client's remote access. Valid values for auth-type are cram-md5 or cleartext.

enable Subcommand
The syntax for the enable subcommand is:

# ndmpadm enable -a auth-type -u username
This subcommand prompts for the user's password twice for confirmation and activates the specified authentication type with the given username and password for NDMP client access. Valid values for auth-type are cram-md5 or cleartext.

get Subcommand
The syntax for the get subcommand is:

```
# ndmpadm get [-p] [property] [-p] property=value...
```

The property names are the same as used for the set subcommand and are described below. If you do not specify a property, the get subcommand returns all configuration properties.

kill-sessions Subcommand
The kill-sessions subcommand allows you to terminate the session number ID.

The syntax for the kill-sessions subcommand is:

```
# ndmpadm kill-sessions ID
```

set Subcommand
The syntax for the set subcommand is:

```
# ndmpadm set [-p] property=value [-p] property=value...
```

The properties you can set with the set subcommand are described in the ndmp(4) man page.

show-devices Subcommand
The syntax for the show-devices subcommand is:

```
# ndmpadm show-devices
```

This subcommand lists the name, vendor, serial number, and other information about the current tape drive and libraries connected to the system.

show-sessions Subcommand
The show-sessions subcommand displays details of a session. The syntax for the show-sessions subcommand is:

```
# ndmpadm show-sessions [-i tape,scsi,data,mover] [ID]
```

The show-sessions subcommand supports the following arguments:

- `-i tape,scsi,data,mover` Identify a type of interface about which to obtain data. If no interface is specified, show-sessions displays information for all types of interfaces.

- `ID` Identifies a particular session about which to display data. If no ID is specified, show-sessions displays data for all sessions.

Examples

**EXAMPLE 1** Obtaining the Status of All NDMP Connections

The following command obtains status on all connections.

```
# ndmpadm show-devices
```
EXAMPLE 2 Obtaining the Status of Certain Types of Connections
The following command obtains status on tape and SCSI interfaces.

```
# ndmpadm show-sessions -i scsi,tape
```

EXAMPLE 3 Limiting Protocol Version
The following command limits the use of the NDMP protocol to version 3.

```
# ndmpadm set -p version=3
```

EXAMPLE 4 Obtaining Current Version Number
The following command obtains the version number of the currently running NDMP.

```
# ndmpadm get -p version
```

EXAMPLE 5 Disconnecting a Specific Session
The command shown below disconnects session 5. The session number was previously obtained from an ndmpadm show-sessions command.

```
# ndmpadm kill-session 5
```

EXAMPLE 6 Obtaining the Values for All NDMP Properties
The following command obtains the values for all NDMP properties.

```
# ndmpadm get
```

EXAMPLE 7 Enabling CRAM-MD5 Authentication
The following command enables CRAM-MD5 authentication.

```
# ndmpadm enable -a cram-md5 -u admin
Enter new password:******
Re-enter password:******
```

EXAMPLE 8 Disabling Clear Text Password Authentication
The following command disabled clear text password authentication.

```
# ndmpadm disable -a cleartext
```

Exit Status

0   Successful completion.

1   An error occurred, such as the ndmpd daemon is not running, that prevented ndmpadm from contacting the demon.

2   Invalid command-line options were specified.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/storage/ndmp</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

See Also  dump(1), tar(1), ndmpd(1M), ndmpstat(1M), svccfg(1M), syslogd(1M), ndmp(4),
          attributes(5), smf(5)

Notes  The ndmpd(1M) daemon is managed by the service management facility (smf(5)), under the
        service identifier:

        svc:/system/ndmpd

        Administrative actions on this service, such as setting and getting a property can be
        alternatively performed using svccfg(1M). For example to enable Direct Access Recovery
        (DAR) mode:

        # svccfg -s svc:/system/ndmpd
        svc:/system/ndmpd> setprop ndmpd/dar-support = yes

        ...and to get the list of properties:

        # svccfg -s svc:/system/ndmpd
        svc:/system/ndmpd> listprop
ndmpd – Network Data Management Protocol daemon

```
/usr/lib/ndmp/ndmpd
```

**Description**
The `ndmpd` daemon handles client Network Data Management Protocol (NDMP) requests. NDMP is an open, enterprise-wide, network-based data management protocol used for backup and recovery. The `ndmpd` daemon enables users to manage data backup and recovery using Data Management Application (DMA) clients. The NDMP protocol is used to coordinate data movement and control between a DMA and an NDMP server or between two NDMP servers.

By default, `ndmpd` is disabled.

**Exit Status**

- **0** Successful completion.
- **1** An error occurred that prevented the `ndmpd` daemon from initializing, such as failure to fork a process, mutex initialization.
- **2** Invalid command-line options were specified.

**Files**

- `/usr/lib/ndmp/ndmpd`
  Network data management protocol server binary.
- `/var/ndmp/ndmp.log`
  Network data management protocol log messages file. This file is deleted upon reboot.
- `/var/ndmp/dumpdates`
  A text file that stores information about the date and the level of dump backups.

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/storage/ndmp</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

**See Also**
`svcs(1), ndmpadm(1M), svcadm(1M), svccfg(1M), syslogd(1M), ndmp(4), attributes(5), smf(5)`

**Notes**
The `ndmpd` daemon is managed by the service management facility (`smf(5)`), under the service identifier:

```
svc:/system/ndmpd:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
**ndmpstat**

**Name**  
ndmpstat – show NDMP backup progress statistics

**Synopsis**  
ndmpstat [tapes] [interval [count]]

**Description**  
The `ndmpstat` utility reports Network Data Management Protocol (NDMP) statistics, among which are NDMP worker threads, disk IO, tape IO, files operation, performance, and backup activity.

`ndmpstat` reports the aggregate statistics for all tapes and disks. In order to obtain statistics for specific tape devices, the tape device name should be passed as argument to the utility.

When invoked, `ndmpstat` begins its display with a one-line summary of the NDMP daemon activity since the NDMP service was invoked.

**Display Fields**  
The fields in `ndmpstat` output are described as follows:

- **wthr**  
  Report the number of worker threads in each of the four following states:
  - `r`  
    the number of worker threads running
  - `w`  
    the number of blocked worker threads that are waiting for resources such as I/O and paging
  - `b`  
    the number of backup operations currently running
  - `r`  
    the number of restore operations currently running

- **file**  
  Report on usage of filesystem.
  - `rd`  
    the number of files being read
  - `wr`  
    the number of files being written

- **disk**  
  Report the number of disk operations per interval.
  - `rd`  
    the number of disk blocks being read
  - `wr`  
    the number of disk blocks being written
tape
  Report the number of tape operations per interval. There are slots for up to four tapes, labeled with a single number. The number indicates the name of the device under /dev/rmt.
    rd
      the number of tape blocks being read
    wr
      the number of tape blocks being written

bytes
  Report the number of bytes transferred. This is the aggregate value of both tape and disk devices. The number is in kilobytes.
    rd
      the number of kilobytes being read
    wr
      the number of kilobytes being written

perf
  Displays a rough estimate of performance of the backup/restore operation in megabytes per second.
    bk
      backup performance
    rs
      restore performance

prcnt
  Display the comparative usage of resources, in percent.
    dsk
      disk I/O time
    tpe
      tape I/O time
    otr
      other time (memory or idle)

See EXAMPLES.

Operands
  The following operands are supported:
    count
      Specifies the number of times that the statistics display is repeated.
    tape
      Specifies which tapes are to be given priority in the output. A command line is limited to a maximum of four tape devices. A common tape name is /dev/rmt/n, where n is an integer.
interval  Specifies the number of seconds over which ndmpstat summarizes activity. The
specified interval remains in effect till the command is terminated.

Examples  EXAMPLE 1  Using ndmpstat

The following command displays a summary of NDMP daemon activity at five-second
intervals.

```bash
example% ndmpstat 5
wthr file disk tape bytes perf prcnt
 r w b r rd wr rd wr rd wr rd wr rd wr rd wr rd wr bk rs dsk tpe otr
 1 0 3 6 50 9 1250 0 32544 4455 42335 3234 5 4 20 40 40
 1 0 0 1 1 0 128 0 0 128 64 64 1 0 0 80 20
 1 0 0 1 2 0 128 0 0 64 0 1 0 80 0 20
 1 0 0 1 1 0 128 0 0 64 0 1 0 80 0 20
 1 0 0 1 3 0 128 0 0 64 0 0 0 80 0 20
 1 0 0 1 1 0 128 0 0 128 64 64 1 0 0 80 20
^C
example%
```

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

Invocation is evolving. Human readable output is unstable.

See Also  iostat(1M), mpstat(1M), ndmpd(1M), ndmpadm(1M), attributes(5)

Notes  Performance numbers are not accurate and are rounded up at the MB/sec. boundary.
The `netadm` utility is used to administer network profiles and interact with the NWAM daemon.

There are three types of network profiles: Network Configuration Profiles (NCPs), Locations, and External Network Modifiers (ENMs).

At any given time, there is one active NCP and one active Location on a system. Enabling a different NCP or Location (with activation-mode `manual`) will implicitly disable the current active NCP or Location. The current Location (if its activation-mode is `manual`) can also be disabled, though the effect of this will be to “turn off” some aspects of the system’s networking capabilities, such as name services. Explicitly disabling an NCP is not permitted, as that would effectively shut down the basic network connectivity of the system. An NCP is only disabled implicitly when a different NCP is enabled.

Conversely, there can be zero or more active ENMs at any given time. Thus enabling or disabling one ENM has no effect on other active ENMs.

Enabling and disabling of individual NCUs is also allowed; the specified NCU must be part of the currently active NCP, and must have its activation mode set to `manual`. If an NCU class is not specified, all NCUs (one link and/or one interface) with the given name will be enabled or disabled.

Enabling and disabling of objects is performed asynchronously. Thus, the request to enable or disable can succeed, while the action itself fails. A failure of this sort will be reflected in the object state; `maintenance` state indicates that the last action taken failed. Note that enabling NCPs and locations in particular can be time-consuming, depending on the configuration. Completion can be verified by checking the state of the appropriate SMF service (`svc:network/physical:default` for NCPs, and `svc:network/location:default` for locations). The state of the individual NCUs that make up an NCP may also be verified with the `netadm list` command.

There are two system-defined NCPs: DefaultFixed, and Automatic. The DefaultFixed NCP represents a manually configured network environment, while Automatic is the default
NWAM-managed environment, which attempts to configure all connected physical interfaces using DHCP. You can use `netcfg(1M)` to create additional NWAM-managed NCPs.

**Sub-commands**

The following subcommands are supported:

- **enable [ -p profile-type ] [ -c ncu-class ] profile-name**
  Enable the specified profile. If the profile name is not unique, the profile type must be specified to identify the profile to be enabled. If the profile type is NCU and the name is not unique (that is, there is both a link and interface NCU with the same name), both NCUs will be enabled, unless the `-c` option is used to specify the NCU class. Profile type must be one of ncp, ncu, loc, or enm; NCU class must be one of phys or ip.

- **disable [ -p profile-type ] [ -c ncu-class ] profile-name**
  Disable the specified profile. If the profile name is not unique, the profile type must be specified to identify the profile to be disabled. If the profile type is NCU and the name is not unique (that is, there is both a link and interface NCU with the same name), both NCUs will be disabled, unless the `-c` option is used to specify the NCU class. Profile type must be one of ncu, loc, or enm; NCU class must be one of phys or ip.

- **list [ -x ] [ -p profile-type ] [ -c ncu-class ] [ profile-name ]**
  List all available profiles and their current state. If a particular profile is specified by name, list only the current state of that profile. If the profile name is not unique, all profiles with the given name will be listed; or the profile type and/or NCU class can be included to identify a specific profile. If only a type is provided, list all profiles of that type. Listing the active NCP will include the NCUs that make up that NCP.

  The `-x` option causes the `list` subcommand to display a fourth column of output, headed AUXILIARY STATE, after the first three column headings in the default display, TYPE, PROFILE, and STATE. The AUXILIARY STATE column shows why a profile is in a given state.

Possible STATE values are:

- **disabled**
  A manually-activated profile that has not been activated.

- **offline**
  A conditionally- or system-activated profile that has not been activated. It might not be active because its conditions have not been satisfied; or it might be that another profile has more specific conditions that are met and has been activated instead (in the case of profile types that must be activated one at a time, such as Locations).

- **online**
  A conditionally- or system-activated profile whose conditions have been met and that has been successfully activated; or a manually-activated profile that has been successfully activated at the request of the user.

- **maintenance**
  Activation of the profile was attempted, but failed.
The profile represents a valid configuration object for which no action has yet been taken.

The profile represents a configuration object not present in the system; for example, an NCU corresponding to a physical link that has been removed.

Listen for stream of events from the NWAM daemon and display them.

Initiate a wireless scan on link linkname.

Select a wireless network to connect to from scan results on link linkname. Prompts for selection, WiFi key, and so forth, if necessary.

Display a usage message with short descriptions for each subcommand.

**Examples**

**EXAMPLE 1** Enabling a User-Specified Location

The following command enables a user-specified location.

```
# netadm enable -p loc office
```

Disabled loc 'home'.
Enabled loc 'office'

**EXAMPLE 2** Disabling an ENM

The following command disables an ENM.

```
# netadm disable -p enm myvpn
```

Disabled enm 'myvpn'.

**EXAMPLE 3** Listing All NCPs

The following command lists all NCPs.

```
# netadm list -xp ncp
```

<table>
<thead>
<tr>
<th>TYPE</th>
<th>PROFILE</th>
<th>STATE</th>
<th>AUXILIARY STATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ncp</td>
<td>Automatic</td>
<td>disabled</td>
<td>disabled by administrator</td>
</tr>
<tr>
<td>ncp</td>
<td>User</td>
<td>online</td>
<td>active</td>

EXAMPLE 5  Forcing a Scan
The following command forces a scan on the wireless interface wp10.

```
# netadm scan-wifi wp10
```

EXAMPLE 6  Selecting a WiFi Network
The following command selects a WiFi network that is broadcasting its ESSID.

```
# netadm select-wifi wp10
```

```
1: ESSID testing BSSID 0:40:96:29:e9:d8
2: ESSID sunwifi BSSID 0:b:e:9f:b5:80
3: ESSID sunwifi BSSID 0:b:e:85:26:c0
4: ESSID sunwifi BSSID 0:b:e:49:2f:80
5: Other

Choose WLAN to connect to [1-5]: 2
```

EXAMPLE 7  Selecting a WiFi Network (Alternative)
The following command selects a WiFi network that is not broadcasting its ESSID.

```
# netadm select-wifi wp10
```

```
1: ESSID testing BSSID 0:40:96:29:e9:d8
2: ESSID sunwifi BSSID 0:b:e:9f:b5:80
3: ESSID sunwifi BSSID 0:b:e:85:26:c0
4: ESSID sunwifi BSSID 0:b:e:49:2f:80
5: ESSID sunwifi BSSID 0:b:e:49:62:c0
6: Other

Choose WLAN to connect to [1-6]: 6
```

Enter WLAN name: oraclewifi
```
1: None
2: WEP
3: WPA
```

Enter security mode: 2
```
Enter WLAN key for ESSID oraclewifi: 123456
```
```
Enter key slot [1-4]: 1
```

```

netcfg – create and modify network configuration profiles

**Synopsis**

netcfg

```bash
netcfg [ -d ] [ -f command-file ]
netcfg help [ subcommand ]
```

**Description**

The `netcfg` utility manipulates system network configuration profiles. `netcfg` can be invoked interactively, with an individual subcommand, or by specifying a command file that contains a series of subcommands.

The `netcfg` utility operates on several different types of configuration profiles:

- Network Configuration Profiles (NCPs)
- Locations
- External Network Modifiers (ENMs)
- Known WLANs

For more details on these profile types, refer to the “Profiles” section.

`netcfg` commands are performed within a scope. There are three scopes: global, profile, and NCP. When `netcfg` is invoked without any arguments, the editing session begins in the global scope. In the global scope, NCPs, Location and ENM profiles, and Known WLAN entries are available to operate on. Selecting an NCP will move the editing session to the NCP scope; from there, individual Network Configuration Units (NCUs) may be created or selected to move into the profile scope. Also, at the global scope, selecting or creating a Location, ENM, or Known WLAN will move the editing session to the profile scope.

Within a given profile scope, profile properties may be viewed and modified.

In interactive mode, changes are not stored to persistent storage until `commit` is invoked. `commit` is implicitly invoked at "end" or "exit", or can be explicitly invoked by the user. When `commit` is invoked, the entire profile is committed. In order to maintain the consistency of persistent storage, the `commit` operation includes a verify step; if verification fails, the `commit` also fails. If an implicit `commit` fails, the user will be given the option of ending or exiting without committing the current changes, or remaining in the current scope to make further changes.

**Profiles**

The NWAM service manages network configuration by storing desired property values in profiles. It then determines which profile should be active at a given time, depending on current network conditions, and activates that profile. In addition to the Network Configuration Profiles (NCPs) discussed in the previous section, `nwadm` also manages Location and ENM profiles.
An NCP specifies the configuration of the local network components, including all datalinks and interfaces. These components are collectively referred to as Network Configuration Units, or NCUs.

NCPs are either ‘reactive’ or ‘fixed’. Reactive NCPs include policy rules which determine when each NCU should be enabled. The policy may be set up such that the network configuration can change in response to changes in the network conditions. Fixed NCPs do not include these policy rules; their configuration is fully applied at the time the NCP is enabled, and will not be changed by the system, regardless of any failures encountered or changes in the network state.

A single fixed NCP, called \texttt{DefaultFixed}, is created by the system. On a newly installed system, this NCP will contain any network configuration that was created during installation, either during an interactive install or with a profile applied during Automated Installation. If no network configuration was specified during system installation, the \texttt{DefaultFixed} NCP will initially be empty.

The system also creates a single reactive NCP. The Automatic NCP is created and managed by \texttt{nwamd}, and cannot be modified by the user. This NCP consists of one link NCU and one interface NCU for each physical link present in the system. As links are added or removed from the system, their corresponding NCUs are added or removed from the Automatic NCP. The policy implemented in this NCP is to prefer wired links over wireless, and to plumb IP on all connected wired links, or one wireless link if no wired links are connected.

The Automatic NCP should not be modified by the user. It is managed by the system to match the current set of links and a specific configuration policy; the system may make change at any time which could overwrite or interfere with changes made by the user. If modifications are desired, a copy may be created and then modified; refer to the \texttt{create} subcommand and its \texttt{-t} option.

Finally, the user can create any number of additional reactive NCPs. These NCPs are managed entirely by the user; NCUs must be added or removed explicitly, and it is possible to add NCUs that do not map to any link currently installed in the system, or to remove NCUs that do map to a link present in the system. The user can determine the policy for these NCPs.

There must always be one active NCP. The active NCP on a newly installed system is determined by the installation method; it will either be the Automatic NCP (in the case of a LiveCD install or an Automated Install with a custom profile specifying the active NCP) or the \texttt{DefaultFixed} for other installation methods. The system will never change the active NCP. The user can do this at any time using the GUI or the \texttt{netadm(1M)} command.

A Location specifies system-wide network configuration, including name services, domain, IP Filter, and IPsec configuration.

External Network Modifiers are, as the name suggests, applications external to the NWAM service that can modify and/or create network configuration. \texttt{nwamd} activates or deactivates an ENM depending on conditions that are specified as part of the ENM profile. Alternatively, the user might choose to manually activate/deactivate ENMs as needed.
While Location profiles allow a specific set of network-related services to be configured automatically based on current network conditions, that set of services is limited. ENMs provide additional flexibility, allowing the user to specify changes to SMF service properties and/or state, or any other system settings, to be applied under specific conditions.

Properties

netcfg supports the following types of properties:

- NCP properties
- NCU properties
- properties of interface NCU
- properties common to all link NCU
- location properties
- ENM properties
- known WLAN properties

These properties are described in the following subsections.

NCP Properties

Each NCP has a single, read-only property.

management-type: enumerated value: fixed | reactive

Determines the way in which the NCP is managed by the system. Fixed NCPs have all configuration applied at the time the NCP is activated, with no subsequent system intervention. Reactive NCPs are more actively managed, with nwadm enforcing policy rules that determine when each link or interface should be configured.

The user cannot set or change the value of this property. All NCPs created using netcfg will have management-type set to reactive. There is only one fixed NCP, called DefaultFixed, which is created by the system.

NCU Properties

The following properties are common to all NCU.

type: enumerated value: link | interface

Specifies the NCU type, either link or interface. The value is implicitly determined based on the specified class.

class: enumerated value: phys for link NCU; ip for interface NCU

Specifies the NCU class.

parent: string: name of parent NCP

Specifies the NCP of which this NCU is a component.

The type, class, and parent properties are set when the NCU is created and cannot be changed later.

enabled: boolean: true | false

If the activation-mode is manual, the enabled property reflects the NCU’s current state. This property is read-only; it is changed indirectly by enabling or disabling the NCU using netadm(1M).

The default value is true.
| Properties of Interface NCUs | ip-version: list of enumerated values: ipv4 | ipv6 |
|-----------------------------|------------------------------------------|
|                             | The version(s) of IP that should be used on this NCU. |
|                             | The default value is ipv4, ipv6. |
|                             | ipv4-addrsrc: list of enumerated values: dhcp | static |
|                             | Identifies the source of IPv4 addresses assigned to this NCU; multiple values may be assigned. If one of the values assigned is static, the ipv4-addr property must include at least one IPv4 address to be assigned to the NCU. |
|                             | The default value is dhcp. |
|                             | ipv4-addr: list of IPv4 address(es) |
|                             | One or more IPv4 addresses to be assigned to this NCU. |
|                             | ipv4-default-route: IPv4 address |
|                             | The IPv4 address of the default router; if this property is set, a default route for IPv4 traffic will be associated with this interface when it is brought up. |
| Properties Common to All LINK NCUs | activation-mode: enumerated value: manual | prioritized |
|                             | The type of trigger for automatic activation of this NCU. |
|                             | The default value is manual. |
|                             | priority-group: uint64: group priority number |
|                             | If activation-mode is set to prioritized, this property specifies the priority group to which this NCU belongs. A group consists of one or more NCUs; smaller numbers are higher priority. The highest priority group that is determined to be available will be activated by nwamdi(1M), and will remain so until it is no longer available, or until a higher priority group becomes available. |
|                             | priority-mode: enumerated value: exclusive | shared | all |
|                             | If activation-mode is set to prioritized, this property specifies the mode used to determine availability and activation behavior for a priority group. |
exclusive

At least one NCU must be available to make the group available, and only one NCU will be activated. If more than one member NCU is available, \texttt{nwmadm(1M)} will randomly choose one to activate.

shared

At least one NCU must be available to make the group available; all available NCUs will be activated.

all

All group member NCUs must be available to make the group available; all member NCUs will be activated.

\textbf{mac-address: string: 48-bit MAC address}

The MAC address assigned to this link. By default, NWAM will request the factory-assigned or default MAC address for the link; set a different value here to override that selection.

\textbf{autopush: string: modules to be pushed over the link}

Identifies a list of modules that should be automatically pushed over the link when it is opened. The string may contain more than one module name; module names are separated by the single character "." (period).

\textbf{mtu: string: MTU size for this link}

This property will be automatically set to the default MTU for the physical link; that value may be overridden by setting this property to a different value.

Note that the range of allowed MTU values depends on the underlying hardware. Because NCUs may be created before the underlying hardware is present with driver attached, it is not possible to verify the value set at the time the NCU is edited. If an NCU fails to activate because of an invalid MTU size, this will be indicated in the system log, and the NCU will be placed in maintenance state.

\begin{tabular}{|l|}
\hline
\textbf{Location Properties} & \textbf{activation-mode: enumerated value: manual | system | conditional-all | conditional-any} \\
\hline
 & The type of trigger for automatic activation of this location. \\
\hline
 & The default value is manual. \\
\hline
\end{tabular}

\textbf{enabled: boolean: true | false}

If the activation-mode is manual, the enabled property reflects the location’s current state. This property is read-only; it is changed indirectly by enabling or disabling the location using \texttt{netadm(1M)}.

The default value is false.

\textbf{conditions: list of strings: conditional expressions}

If activation-mode is set to conditional-all or conditional-any, this property specifies the test to determine whether this location should be activated. The conditional
expression is made up of a sequence of conditions that can be assigned a boolean value, such as “advertised-domain is sun.com” or “ip:bge0 is not active.” The format of these expressions is defined in the “Condition Expressions” section, below. If multiple conditions are specified, either all must be true to meet the activation requirements (when activation-mode is conditional-all) or any one may be true (when activation-mode is conditional-any).

Note the distinction between advertised-domain and system-domain. The advertised domain is learned by means of external communication, such as the DNSmain or NISmain advertised by a DHCP server. This attribute is useful for conditional activation of locations; for example, if the advertised domain is mycompany.com, activate the “work” location. The system domain is the domain which is currently assigned to the system; that is, it is the value returned by the domainname(1M) command. This attribute is useful for conditional activation of ENMs, as it will only become true after a location has been activated and the system is configured for that particular domain.

default-domain: string: system domain name
   The domain name that should be applied to the system; this domain name will be used by NIS and LDAP.

nameservices: enum value list: files | dns | nis | ldap
   Specifies the name services that should be configured, such as DNS, NIS, and LDAP.

nameservices-config-file: string: path to nsswitch.conf file
   Specifies the nsswitch.conf file to be used. This property must always have a value. If the nameservices property specifies a single name service, this property will, by default, contain /etc/nsswitch.nameservice for the name service specified in the nameservices property; this value can be changed by the user. If the nameservices property identifies more than one name service, the user must specify an additional value for this property.

dns-nameservice-configsrc: enum value list: manual | dhcp
   Specifies the source(s) that should be used to obtain configuration information for the DNS name service. If manual is included, the remaining dns-nameservice-* properties will be used.

dns-nameservice-domain: string: domain name

dns-nameservice-servers: string list: name server address(es)

dns-nameservice-search: string list: domain search string

dns-nameservice-sortlist: string list: IP address, netmask pair(s)

dns-nameservice-options: string list: resolver variable(s) to be modified
   If DNS is one of the configured name services and manual is one of its configuration sources, these properties specify its configuration parameters. Only the servers property is required; search and domain are mutually exclusive and only one can be specified, which will override the domain provided by the DHCP server if dhcp is also used. The format of these values are the same as the respective options in resolv.conf(4).
nis-nameservice-configsrc: enum value list: manual | dhcp
   Specifies the source(s) that should be used to obtain configuration information for the NIS
ame service. If manual is included, the remaining nis-nameservice-* properties will be used.

nis-nameservice-servers: string list: name server address(es)
   If NIS is one of the configured name services and manual is one of its configuration sources,
   this property specifies its server address. If this property is not specified, the NIS client will
   be started in broadcast mode.

ldap-nameservice-configsrc: enum value list: manual
   Specifies the source that should be used to obtain configuration information for the LDAP
   name service. manual is currently the only option for LDAP; thus the ldap-nameservice-*
   properties must be provided to complete LDAP configuration.

ldap-nameservice-servers: string list: name server address(es)
   If LDAP is one of the configured name services, this property specifies its server address.
   This property is required, and it is expected that the specified server will have a client
   profile which will be used to complete client configuration.

nfsv4-domain: string: domain name to be used for NVSv4
   Specifies the NVSv4 domain to be used. If this value is unspecified, the name service
domain will be used.

ipfilter-config-file: string: path to ipfilter IPv4 configuration file
ipfilter-v6-config-file: string: path to ipfilter IPv6
ipnat-config-file: string: path to ipnat configuration file
ippool-config-file: string: path to ippool configuration file
   These properties each specify the path to the rules file for a component of the ipfilter(5)
configuration. If a given config-file property is set, the corresponding IP filter
component will be enabled, reading configuration from the specified file.

ike-config-file: string: path to IKE configuration file
   Specifies the IKE configuration file. If a value is specified, the svc:/network/ipsec/ike
service will be enabled, reading configuration from the specified file.

ipsec-policy-config-file: string: path to IPsec policy configuration file
   Specifies the IPsec policy configuration file. If a value is specified, the
svc:/network/ipsec/policy service will be enabled, reading configuration from the
specified file.

ENMProperties
   activation-mode: enumerated value: manual | conditional-all | conditional-any
   The type of trigger for automatic activation of this ENM.

   The default value is manual.
enabled: boolean: true | false
If the activation-mode is manual, the enabled property reflects the ENM’s current state. This property is read-only; it is changed indirectly by enabling or disabling the ENM using netadm(1M).

The default value is false.

conditions: list of strings: conditional expressions
If activation-mode is set to conditional-all or conditional-any, this property specifies the test to determine whether or not this ENM should be activated. The conditional expression is made up of a sequence of conditions that can be assigned a boolean value, such as “system-domain is sun.com” or “ip:bge0 is not active.” The format of these expressions is defined in the “Condition Expressions” section below. If multiple conditions are specified, either all must be true to meet the activation requirements (when activation-mode is conditional-all) or any one may be true (when activation-mode is conditional-any).

Note the distinction between advertised-domain and system-domain. The advertised domain is learned by means of external communication, such as the DNSdomain or NISdomain advertised by a DHCP server. This attribute is useful for conditional activation of locations; for example, if the advertised domain is mycompany.com, activate the “work” location. The system domain is the domain which is currently assigned to the system; that is, it is the value returned by the |domainname|(I) command. This attribute is useful for conditional activation of ENMs, as it will only become true after a location has been activated and the system configured for that particular domain.

fmri: string: service FMRI
If this ENM is implemented as an SMF service, this property identifies that service. If this property is specified, the ENM will be activated by enabling the service and deactivated by disabling the service.

start: string: start command
If this ENM is not implemented as an SMF service, this property identifies the command that should beexec’ed to start or activate the ENM. This property will be ignored if the FMRI property is set.

stop: string: stop command
If this ENM is not implemented as an SMF service, this property identifies the command that should beexec’ed to stop/deactivate the ENM. This property will be ignored if the FMRI property is set.

bssids: list of strings: WLAN BSSID(s) (AP MAC addresses)
If a specific Access Point should be preferred over others with the same name/ESSID, this property allows the AP’s BSSID to be specified.

priority: uint64: a numeric priority value
The relative priority of this WLAN; a smaller number represents higher priority.
Note that this number can be changed if subsequent changes to the set of Known WLAN objects require such a change. For example, consider a system that is configured with two Known WLAN objects, wlanA and wlanB. wlanA has priority 1, and wlanB has priority 2. A new Known WLAN, wlanC, is created and assigned priority 2. In this case, the complete list will be updated such that wlanA has priority 1, wlanC has priority 2, and wlanB has priority 3. No two WLANs can have the same priority value, so the addition of wlanC at priority 2 forces wlanB to be shifted down in priority. If any additional WLANs existed at lower priorities than wlanB, they would be shifted accordingly.

**keyslot**: uint64; the key slot to be used for this WLAN

If the WLAN uses an encryption mode that supports multiple key slots, the slot to place the key can be specified in this property. If unspecified, slot 1 is used by default.

**keyname**: list of strings; Secure object name(s)

Allows the user to associate secure objects created using `dladm(1M)` with Known WLANs.

### Condition Expressions

Locations and ENMs can be activated based on a set of user-specified conditions. The following table summarizes the syntax of those condition expressions.

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Object</th>
<th>Condition</th>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>ncp</td>
<td>ncu</td>
<td>enm</td>
<td>loc</td>
</tr>
</tbody>
</table>

**Options**

The following options are not associated with any particular `netcfg` subcommand:

- `-d`
  - Removes all configuration before reading subcommands from the command file (see following option).

- `-f command_file`
  - Reads and executes `netcfg` subcommands from `command_file`.

### Sub-commands

The following subcommands are supported.

- `cancel`
  - End the current profile specification without committing the current changes to persistent storage, and pop up to the next higher scope.
This subcommand is valid in the NCP and profile scopes.

**clear prop-name**
Clear the value for the specified property.

This subcommand is valid in the profile scope.

**commit**
Commit the current profile to persistent storage. Because a configuration must be correct to be committed, this operation automatically performs a verify on the object as well. The commit operation is attempted automatically upon leaving the current scope (with either the `end` or `exit` subcommand).

This subcommand is valid in the profile scope.

Note that, in non-interactive mode, a commit is not required, as the commit is implicit for any subcommand that changes a value.

**create [ -t template ] object-type [ class ] object-name**
Create an in-memory profile of the specified type and name. The `-t template` option specifies that the new object should be identical to `template`, where `template` is the name of an existing object of the same type. If the `-t` option is not used, the new object is created with default values. For NCPs, only a “user” NCP can be created.

This subcommand is valid in the global and NCP scopes.

**destroy [ -a | object-type [ class ] object-name ]**
Remove all or the specified profile from memory and persistent storage. This action is immediate; it does not need to be committed. A destroyed object cannot be reverted.

This subcommand is valid in the global and NCP scopes if a specific object is specified; the `-a` option is only valid in the global scope.

**end**
End the current profile specification, and pop up to the next higher scope. The current object is verified and committed before ending; if either the verify or commit fails, an appropriate error message is issued and the user is given the opportunity to end without committing the current changes, or to remain in the current scope and continue editing.

This subcommand is valid in any scope.

**exit**
Exit the netcfg session. The current profile is verified and committed before ending; if either fails, an appropriate error message is issued and the user is given the opportunity to exit without committing the current changes, or to remain in the current scope and continue editing.

This subcommand is valid in any scope.
export [-d] [-f output-file] [ object-type [ class ] object-name ]
Print the current configuration at the current or specified scope to standard out, or to a file
specified with the -f option. The -d option generates a destroy -a as the first line of
output. This subcommand produces output in a form suitable for use in a command file.
System created objects, including the Automatic NCP and the Automatic, NoNet, and User
locations, cannot be exported.
This subcommand is limited in that it can only export configuration that can be created
using the netcfg command; an NCP may contain NCU's or NCU properties that can only
be set using ipadm(1M) or dladm(1M). This sort of configuration will be omitted from what
is output by the export subcommand.
This subcommand is valid in any scope.

get [-V] prop-name
Get the current (in-memory) value of the specified property. By default, both the property
name and value are printed; if the -V option is specified, only the property value is
displayed.
This subcommand is valid in the profile scope.

help [ subcommand ]
Display general help or help about a specific subcommand.
This subcommand is valid in any scope.

list [-a] [ object-type [ class ] object-name ]
List all profiles, property-value pairs and resources that exist at the current or specified
scope. When listing properties of an object, the default behavior is to only list properties
that apply to the specified configuration. That is, if listing an IP NCU for which
ipv4 - addr src is dhcp, the ipv4 - addr property will not be listed. Including the -a option
will result in all properties being listed, whether or not they apply to the current settings.
This subcommand is valid in any scope.

revert
Delete any current changes to the current profile and revert to the values from persistent
storage.
This subcommand is valid in the profile scope.

select object-type [ class ] object-name
Select one of the profiles available at the current scope level and jump down into that
object's scope. The selected object will be loaded into memory from persistent storage.
This subcommand is valid in the global and NCP scopes.

set prop-name=value1 [,value2 ...]
Set the current (in-memory) value of the specified property. If performed in
non-interactive mode, the change is also committed to persistent storage.
The delimiter for values of multi-valued properties is "", (comma). If any of the individual values in such a property contains a comma, it must be escaped (that is, written as \,). Commas within properties that can only have a single value are not interpreted as delimiters and need not be escaped.

This subcommand is valid in the profile scope.

verify
Verify that the current in-memory object has a valid configuration.

This subcommand is valid in the profile scope.

walkprop [-a]
Walk each property associated with the current profile. For each property, the name and current value are displayed, and a prompt is given to allow the user to change the current value.

The delimiter for values of multi-valued properties is "", (comma). If any of the individual values in such a property contains a comma, it must be escaped (that is, written as \,). Commas within properties that can only have a single value are not interpreted as delimiters and need not be escaped.

By default, only properties that are required based on properties that are already set will be walked; that is, if ipv4-addrsrc is set to dhcp, ipv4-addr will not be walked. Including the -a option will result in all available properties being walked.

This subcommand is valid in the profile scope.

This subcommand is only meaningful in interactive mode.

Examples

EXAMPLE 1  Setting an NCU Property

The following command sets an NCU property from the command line (that is, in non-interactive mode).

# netcfg "select ncp User; select ncu phys net1; set mtu=1492"

EXAMPLE 2  Listing Top-Level Profiles

The following command lists all top-level profiles from the command line.

# netcfg list
NCPs:
  Automatic
  User
Locations:
  Automatic
  home
  NoNet
  office
Listing Top-Level Profiles

EXAMPLE 2  Listing Top-Level Profiles  (Continued)

ENMs:
  emntest
  myenm
WLANs:
  sunwifi
  coffeeshop
  linksys

EXAMPLE 3  Destroying a Location Profile
The following command destroys a Location profile from the command line.

# netcfg destroy loc home
Destroyed loc 'home'

EXAMPLE 4  Creating an NCU Profile
The following command sequence interactively creates an NCU profile.

# netcfg
netcfg> select ncp user
netcfg:ncp:User> create ncu ip net1
Created ncu 'net1'. Walking properties ...
ip-version (ipv4,ipv6) [ipv4|ipv6]= ipv4
ipv4-addrsrc (dhcp) [dhcp|static]= static
ipv4-addr= 168.1.2.3
netcfg:ncp:User:ncu:net1> list
ncu:net1
  type: interface
  class: ip
  parent: "User"
  enabled: true
  ip version: ipv4
  ipv4-addrsrc: static
  ipv4-addr: "168.1.2.3"
  ipv6-addrsrc dhcp,autoconf
netcfg:ncp:User:ncu:net1> commit
Committed changes
netcfg:ncp:User:ncu:net1> end
netcfg:ncp:User> exit

EXAMPLE 5  Manipulating an ENM
The following command sequence selects an existing ENM, display its contents, and changes a property value.

# netcfg
netcfg>select enm myenm
netcfg:enm:myenm>list
EXAMPLE 5  Manipulating an ENM  (Continued)

ENM:myenm
  activation-mode manual
  enabled true
  start "/usr/local/bin/myenm start"
  stop  "/usr/local/bin/myenm stop"
netcfg:enm:myenm> set stop="/bin/alt_stop"
netcfg:enm:myenm> list
  ENM:myenm
  activation-mode manual
  enabled true
  start "/usr/local/bin/myenm start"
  stop  "/bin/alt_stop"
netcfg:enm:myenm> exit

Committed changes

EXAMPLE 6  Configuring a Static Address

The following command sequence configures a static address of 192.168.2.12/24 on interface
bge0 using the Home NCP. This interface is enabled by default when the Home NCP is
activated.

  # netcfg
netcfg> create ncp Home

First configure phys NCU:

netcfg:ncp:Home> create ncu phys bge0
Created ncu 'bge0'. Walking properties ...
  activation-mode (manual) [manual|prioritized]>
  mac-address>
  autopush>
  mtu>
netcfg:ncp:Home:ncu:bge0> end
Committed changes
netcfg:ncp:Home>

Then, configure IP NCU:

netcfg:ncp:Home> create ncu ip bge0
Created ncu 'bge0'. Walking properties ...
  ip-version (ipv4,ipv6) [ipv4|ipv6]>
  ipv4-addrsrc (dhcp) [dhcp|static]> static
  ipv4-addr  192.168.2.10/24
  ipv4-default-route>
  ipv6-addrsrc (dhcp,autoconf) [dhcp|autoconf|static]>
  ipv6-default-route>
netcfg:ncp:Home:ncu:bge0> list
  ncu:bge0
EXAMPLE 6  Configuring a Static Address  (Continued)

```
  type               interface
  class              ip
  parent             "Home"
  enabled            true
  ip-version         ipv4,ipv6
  ipv4-addrsrc       static
  ipv4-addr          "192.168.2.10/24"
  ipv6-addrsrc       dhcp,autoconf
```

netcfg:ncp:Home:ncu:bge0> exit
Committed changes
#

Switch to the Home NCP using `netadm(1M)`.

EXAMPLE 7  Configuring Location Based on a Condition

The following command sequences configures a location based on a condition. The location is
activated whenever the IP address is in the 10.0.8.0/24 subnet. Also, NIS is configured in this
location.

```
netcfg> select loc office
netcfg:loc:office> list
loc:office
  activation-mode     conditional-any
  conditions          "ip-address is 10.0.8.0/24"
  enabled             false
  nameservices        dns,nis
  nameservices-config-file  "/etc/nsswitch.nis"
  dns-nameservice-configsrc  dhcp
  nis-nameservice-configsrc manual
  nis-nameservice-servers  "10.2.18.24"
  default-domain       "labs.east.sun.com"
```

EXAMPLE 8  Creating a Known WLAN

The following command sequence establishes a known WLAN named coffeeshop with a
WEP key.

```
netcfg> select wlan coffeeshop
netcfg:wlan:coffeeshop> list
known wlan:coffeeshop
  priority       2
  keyname        "foo"
  security-mode  wep
netcfg:wlan:coffeeshop> set priority=1
netcfg:wlan:coffeeshop> end
Committed changes
```
EXAMPLE 9  Exporting Current Configuration to a File
The following command exports the current configuration to a file.

```
netcfg> export -f /tmp/nwam.config
```

Or, perform the same task from the Unix command line:

```
# netcfg export -f /tmp/nwam.config
```

EXAMPLE 10  Importing Current Configuration from a File
The following command imports the current configuration from a file.

```
# netcfg -f /tmp/nwam.config
```

Name  
netcfgd – network configuration management daemon

Synopsis  
/lib/inet/netcfgd

Description  
netcfgd is a system daemon to manage network configuration. This daemon is started automatically by svc:/network/netcfg:default and should not be invoked directly. It does not constitute a programming interface.

netcfgd manages access to a network configuration repository, insuring that readers and writers have the appropriate authorizations. The required authorizations vary, depending on the portion of the database being accessed.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The solaris.network.interface.config authorization and the sys_dl_config privilege are obtained by means of the Network Management security profile. The solaris.network.autoconf.read authorization is part of the Basic Solaris User profile. The solaris.network.autoconf.wlan and .select authorizations are obtained by means of the Network Autoconf User profile, and the autoconf.write authorization, plus those included in the Network Autoconf User profile, are obtained by means of the Network Autoconf Admin profile.

See also nwam-manager(1M), available in the JDS/GNOME man page collection.
The `netservices` command uses the Solaris service management facility, `smf(5)`, to control services that accept over the network from remote clients.

When `netservices` is invoked with the `limited` command-line argument, all network services except the secure shell daemon, `sshd(1M)`, are either disabled or constrained to respond to local requests only.

Invoking `netservices` with the `open` command-line argument enables a large set of network services, as in previous releases of Solaris.

To customize the configuration set enabled by `netservices`, use `svcadm(1M)` to enable or disable individual services. Use `svccfg(1M)` to set properties that determine whether a service accepts input from remote clients. See the man pages for individual services for the names of service instances and their properties.

Note that the `netservices` command has an interface stability of Obsolete.

**Description**

The `netstat` command displays the contents of certain network-related data structures in various formats, depending on the options you select.

The `netstat` command has the several forms shown in the SYNOPSIS section, above, listed as follows:

- The first form of the command (with no required arguments) displays a list of active sockets for each protocol.
- The second, third, and fourth forms (`-g`, `-p`, and `-s` options) display information from various network data structures.
- The fifth form (`-m` option) displays STREAMS memory statistics.
- The sixth form (`-i` option) shows the state of the interfaces.
- The seventh form (`-r` option) displays the routing table.
- The eighth form (`-M` option) displays the multicast routing table.
- The ninth form (`-D` option) displays the state of DHCP on one or all interfaces.
- The tenth form (`-d` option) displays the table of destination cache entries.

These forms are described in greater detail below.

With no arguments (the first form), `netstat` displays connected sockets for `PF_INET`, `PF_INET6`, and `PF_UNIX`, unless modified otherwise by the `-f` option.
Options

-a
Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, listener sockets used by server processes are not shown. Under most conditions, only interface, host, network, and default routes are shown and only the status of physical interfaces is shown.

-d
Show the destination cache entry table. See DISPLAYS, below.

-f address_family
Limit all displays to those of the specified address_family. The value of address_family can be one of the following:

inet For the AF_INET address family showing IPv4 information.
inet6 For the AF_INET6 address family showing IPv6 information.
unix For the AF_UNIX address family.
sdp For the Socket Description Protocol (SDP) protocol and address family. The address state displayed for an SDP socket are listed below. Flags displayed by netstat are followed by their meanings.

LST Listen
EST Established
PL Path Lookup
HS Hello Request Sent
HR Hello Request Received
HAR Hello Ack Recvd
HAS Hello Ack sent
DR Fin received
DS Fin sent
DSA Fin Ack recv
DRC Simultaneous Disconnect
DSC Disconnect sent (peer already closed)
TW1 Time Wait 1
TW2 Time Wait 2
CLD Closed
ERR Error
INV Invalid
UNK Unknown

For the SDP protocol and address family, netstat displays the following column headings:

Local Address Local IP address
Remote Address | Remote IP address
---|---
State | Current state of the socket
RxBPending | Bytes unread
TxBQueued | Bytes queued for Tx (includes TxBPosted)
TxBPosted | Bytes sent to HW for transmission
LAdvtSz | Local advertised buffer size
RADvtSz | Remote advertised buffer size
LAdvtBuff | Number of local advertised Rx buffers
RADvtBuff | Number of remote advertised Rx buffers
LPostBuff | Number of Rx buffers currently posted

`-f filter`
With `-r` only, limit the display of routes to those matching the specified filter. A filter rule consists of a `keyword:value` pair. The known keywords and the value syntax are:

`af:[inet|inet6|unix|sdp|number]` Selects an address family. This is identical to `-f address_family` and both syntaxes are supported.

`outif:[name|ifIndex|any|none]` Selects an output interface. You can specify the interface by name (such as hme0) or by `ifIndex` number (for example, 2). If `any` is used, the filter matches all routes having a specified interface (anything other than null). If `none` is used, the filter matches all routes having a null interface. Note that you can view the index number (`ifIndex`) for an interface with the `-a` option of `ifconfig(1M)`.

`dst:[ip-address]/[mask]|any|none` Selects a destination IP address. If specified with a mask length, then any routes with matching or longer (more specific) masks are selected. If `any` is used, then all but addresses but 0 are selected. If `none` is used, then address 0 is selected.

`flags:[+ -]?[ABDGHLMSU]+` Selects routes tagged with the specified flags. By default, the flags as specified must be set in order to match. With a leading +, the flags specified must be set but others are ignored. With a leading -, the flags specified must not be set and others are permitted.

You can specify multiple instances of `-f` to specify multiple filters. For example:

```
% netstat -nr -f outif:hme0 -f outif:hme1 -f dst:10.0.0.0/8
```
The preceding command displays routes within network 10.0.0.0/8, with mask length 8 or greater, and an output interface of either hme0 or hme1, and excludes all other routes.

-\( g \)
Show the multicast group memberships for all interfaces. If the -\( v \) option is included, source-specific membership information is also displayed. See DISPLAYS, below.

-\( i \)
Show the state of the interfaces that are used for IP traffic. Normally this shows statistics for the physical interfaces. When combined with the -\( a \) option, this will also report information for the logical interfaces. See ifconfig(1M).

-\( m \)
Show the STREAMS memory statistics.

-\( n \)
Show network addresses as numbers. netstat normally displays addresses as symbols. This option may be used with any of the display formats.

-\( p \)
Show the net to media tables. See DISPLAYS, below.

-\( r \)
Show the routing tables. Normally, only interface, host, network, and default routes are shown, but when this option is combined with the -\( a \) option, all routes will be displayed, including cache. If you have not set up a multicast route, -\( ra \) might not show any multicast routing entries, although the kernel will derive such an entry if needed.

-\( s \)
Show per-protocol statistics. When used with the -\( M \) option, show multicast routing statistics instead. When used with the -\( a \) option, per-interface statistics will be displayed, when available, in addition to statistics global to the system. See DISPLAYS, below.

-\( T \ u | d \)
Display a time stamp.

Specify \( u \) for a printed representation of the internal representation of time. See time(2). Specify \( d \) for standard date format. See date(1).

-\( v \)
Verbose. Show additional information for the sockets, STREAMS memory statistics, routing table, and multicast group memberships.

-\( I \) interface
Show the state of a particular interface. interface can be any valid interface such as hme0 or eri0. Normally, the status and statistics for physical interfaces are displayed. When this option is combined with the -\( a \) option, information for the logical interfaces is also reported.
-M
Show the multicast routing tables. When used with the -s option, show multicast routing
statistics instead.

-P protocol
Limit display of statistics or state of all sockets to those applicable to protocol. The protocol
can be one of ip, ipv6, icmp, icmpv6, icmp, icmpv6, igmp, udp, tcp, rawip. rawip can also
be specified as raw. The command accepts protocol options only as all lowercase.

-D
Show the status of DHCP configured interfaces.

-R
This modifier displays extended security attributes for sockets and routing table entries.
The -R modifier is available only if the system is configured with the Solaris Trusted
Extensions feature.

With -r only, this option displays the routing entries’ gateway security attributes. See
route(1M) for more information on security attributes.

When displaying socket information using the first form of the command, this option
displays additional information for Multi-Level Port(MLP) sockets. This includes:

- The label for the peer if the socket is connected.
- The following flags can be appended to the socket’s “State” output:
  P  The socket is a MLP on zone-private IP addresses.
  S  The socket is a MLP on IP addresses shared between zones.

Operands
interval  Display statistics accumulated since last display every interval seconds, repeating
forever, unless count is specified. When invoked with interval, the first row of
netstat output shows statistics accumulated since last reboot.

The following options support interval: -i, -m, -s and -Ms. Some values are
configuration parameters and are just redisplayed at each interval.

count  Display interface statistics the number of times specified by count, at the interval
specified by interval.

Displays
Active Sockets (First Form)  The display for each active socket shows the local and remote address, the send and receive
queue sizes (in bytes), the send and receive windows (in bytes), and the internal state of the
protocol.

The symbolic format normally used to display socket addresses is either:
hostname:port
when the name of the host is specified, or

```
  network. port
```

if a socket address specifies a network but no specific host.

The numeric host address or network number associated with the socket is used to look up the corresponding symbolic hostname or network name in the `hosts` or `networks` database.

If the network or hostname for an address is not known, or if the `-n` option is specified, the numerical network address is shown. Unspecified, or “wildcard”, addresses and ports appear as an asterisk (`*`). For more information regarding the Internet naming conventions, refer to `inet(7P)` and `inet6(7P)`.

For SCTP sockets, because an endpoint can be represented by multiple addresses, the verbose option (`-v`) displays the list of all the local and remote addresses.

**TCP Sockets**

The possible state values for TCP sockets are as follows:

- **BOUND**: Bound, ready to connect or listen.
- **CLOSED**: Closed. The socket is not being used.
- **CLOSING**: Closed, then remote shutdown; awaiting acknowledgment.
- **CLOSE_WAIT**: Remote shutdown; waiting for the socket to close.
- **ESTABLISHED**: Connection has been established.
- **FIN_WAIT_1**: Socket closed; shutting down connection.
- **FIN_WAIT_2**: Socket closed; waiting for shutdown from remote.
- **IDLE**: Idle, opened but not bound.
- **LAST_ACK**: Remote shutdown, then closed; awaiting acknowledgment.
- **LISTEN**: Listening for incoming connections.
- **SYN_RECEIVED**: Initial synchronization of the connection under way.
- **SYN_SENT**: Actively trying to establish connection.
- **TIME_WAIT**: Wait after close for remote shutdown retransmission.

**SCTP Sockets**

The possible state values for SCTP sockets are as follows:

- **CLOSED**: Closed. The socket is not being used.
- **LISTEN**: Listening for incoming associations.
- **ESTABLISHED**: Association has been established.
- **COOKIE_WAIT**: INIT has been sent to the peer, awaiting acknowledgment.
COOKIE_ECHOED: State cookie from the INIT-ACK has been sent to the peer, awaiting acknowledgement.

SHUTDOWN_PENDING: SHUTDOWN has been received from the upper layer, awaiting acknowledgement of all outstanding DATA from the peer.

SHUTDOWN_SENT: All outstanding data has been acknowledged in the SHUTDOWN_SENT state. SHUTDOWN has been sent to the peer, awaiting acknowledgement.

SHUTDOWN_RECEIVED: SHUTDOWN has been received from the peer, awaiting acknowledgement of all outstanding DATA.

SHUTDOWN_ACK_SENT: All outstanding data has been acknowledged in the SHUTDOWN_RECEIVED state. SHUTDOWN_ACK has been sent to the peer.

SHUTDOWN_ACK_RECEIVED: SHUTDOWN_WRITE has been received from the peer, awaiting acknowledgement.

The form of the display depends upon which of the -g, -m, -p, or -s options you select.

- **g**: Displays the list of multicast group membership.
- **m**: Displays the memory usage, for example, STREAMS mblks.
- **p**: Displays the net to media mapping table. For IPv4, the address resolution table is displayed. See *arp(1M)*. For IPv6, the neighbor cache is displayed.
- **s**: Displays the statistics for the various protocol layers.

The statistics use the MIB specified variables. The defined values for *ipForwarding* are:

- **forwarding(1)**: Acting as a gateway.
- **not-forwarding(2)**: Not acting as a gateway.

The IPv6 and ICMPv6 protocol layers maintain per-interface statistics. If the -a option is specified with the -s option, then the per-interface statistics as well as the total sums are displayed. Otherwise, just the sum of the statistics are shown.

For the second, third, and fourth forms of the command, you must specify at least -g, -p, or -s. You can specify any combination of these options. You can also specify -m (the fifth form) with any set of the -g, -p, and -s options. If you specify more than one of these options, *netstat* displays the information for each one of them.

The interface status display lists information for all current interfaces, one interface per line. If an interface is specified using the -I option, it displays information for only the specified interface.

The list consists of the interface name, *mtu* (maximum transmission unit, or maximum packet size) (see *ifconfig(1M)*), the network to which the interface is attached, addresses for each interface, and counter associated with the interface. The counters show the number of input...
packets, input errors, output packets, output errors, and collisions, respectively. For Point-to-Point interfaces, the Net/Dest field is the name or address on the other side of the link.

If the -a option is specified with either the -i option or the -I option, then the output includes names of the physical interface(s), counts for input packets and output packets for each logical interface, plus additional information.

If the -n option is specified, the list displays the IP address instead of the interface name.

If an optional interval is specified, the output will be continually displayed in interval seconds until interrupted by the user or until count is reached. See OPERANDS.

The physical interface is specified using the -I option. When used with the interval operand, output for the -I option has the following format:

<table>
<thead>
<tr>
<th>input packets</th>
<th>eri0 packets</th>
<th>output packets</th>
<th>colls</th>
<th>input packets</th>
<th>(Total) packets</th>
<th>err</th>
<th>colls</th>
</tr>
</thead>
<tbody>
<tr>
<td>227681</td>
<td>0</td>
<td>659471</td>
<td>1</td>
<td>502</td>
<td>261331</td>
<td>0</td>
<td>502</td>
</tr>
<tr>
<td>10</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>10</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>8</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>8</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>10</td>
<td>0</td>
<td>2</td>
<td>0</td>
<td>0</td>
<td>10</td>
<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>

If the input interface is not specified, the first interface of address family inet or inet6 will be displayed.

The routing table display lists the available routes and the status of each. Each route consists of a destination host or network, and a gateway to use in forwarding packets. The flags column shows the status of the route. These flags are as follows:

- **U** Indicates route is up.
- **G** Route is to a gateway.
- **H** Route is to a host and not a network.
- **M** Redundant route established with the -multirt option.
- **S** Route was established using the -setsrc option.
- **D** Route was created dynamically by a redirect.
- **B** Packets will be silently dropped (RTF_BLACKHOLE set).
- **R** Packets will be dropped with ICMP error sent (RTF_REJECT set).
- **I** Indirect routes (gateway not directly reachable) established with the -indirect option.
- **Z** (non-global exclusive-IP zone only) The route was statically added on boot based on routing information configured using zonecfg(1M) in the global zone.
If the -a option is specified, there will be routing entries with the following flags:

b  Broadcast addresses.
C  Clones interface host route entries for on-link destinations.
L  Local addresses for the host.

Interface routes are created for each interface attached to the local host; the gateway field for such entries shows the address of the outgoing interface.

The use column displays the number of packets sent or forwarded using the route in question.

The interface entry indicates the network interface utilized for the route.

The multicast routing table consists of the virtual interface table and the actual routing table.

The DHCP interface information consists of the interface name, its current state, lease information, packet counts, and a list of flags.

The states correlate with the specifications set forth in RFC 2131.

Lease information includes:

- when the lease began;
- when lease renewal will begin; and
- when the lease will expire.

The flags currently defined include:

BOOTP     The interface has a lease obtained through BOOTP (IPv4 only).
BUSY      The interface is busy with a DHCP transaction.
PRIMARY   The interface is the primary interface. See dhcpi(n) and ifconfig(1M).
FAILED    The interface is in failure state and must be manually restarted.

Packet counts are maintained for the number of packets sent, the number of packets received, and the number of lease offers declined by the DHCP client. All three counters are initialized to zero and then incremented while obtaining a lease. The counters are reset when the period of lease renewal begins for the interface. Thus, the counters represent either the number of packets sent, received, and declined while obtaining the current lease, or the number of packets sent, received, and declined while attempting to obtain a future lease.

The destination cache entry display shows the recorded path MTU, the age (in seconds) of the entry, and flags. The P flag indicates that a path MTU is recorded. The S flag indicates that the path MTU is smaller than the minimum that IP will allow. The U flag indicates that some transport metrics (round-trip time, and so forth) are cached in the destination cache entry.
/etc/default/inet_type DEFAULT_IP setting

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

When displaying interface information, netstat honors the DEFAULT_IP setting in /etc/default/inet_type. If it is set to IP_VERSION4, then netstat will omit information relating to IPv6 interfaces, statistics, connections, routes and the like.

However, you can override the DEFAULT_IP setting in /etc/default/inet_type on the command-line. For example, if you have used the command-line to explicitly request IPv6 information by using the inet6 address family or one of the IPv6 protocols, it will override the DEFAULT_IP setting.

If you need to examine network status information following a kernel crash, use the mdb(1) utility on the savecore(1M) output.

The netstat utility obtains TCP statistics from the system by opening /dev/tcp and issuing queries. Because of this, netstat might display an extra, unused connection in IDLE state when reporting connection status.

Previous versions of netstat had undocumented methods for reporting kernel statistics published using the kstat(7D) facility. This functionality has been removed. Use kstat(1M) instead.

netstat restricts its output to information that is relevant to the zone in which netstat runs. (This is true for both shared-IP and exclusive-IP zones.)
netstrategy (1M)

**Name**
netstrategy – return network configuration information

**Synopsis**
/usr/sbin/netstrategy

**Description**
The `netstrategy` command determines the network configuration strategy in use on a system and returns information in a form that is easily consumable by a script. The command returns three tokens:

\(<\text{root filesystem type}>\) \(<\text{primary interface}>\) \(<\text{network config strategy}>\)

These tokens are described as follows:

\(<\text{root filesystem type}>\)
Type of filesystem that contains the bootable kernel, as would be specified in the `fstype` column of the `mnttab(4)``.

\(<\text{primary interface}>\)
Name of the primary network interface. For a diskless machine, this is the interface used to load the kernel.

\(<\text{network config strategy}>\)
The means by which a system obtains its IP address for booting. This can be one of `rarp`, `dhcp`, or `none`.

The `netstrategy` command is not intended for use on a command line.

**Options**
The `netstrategy` command has no options.

**Exit Status**

<table>
<thead>
<tr>
<th>Exit Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success.</td>
</tr>
<tr>
<td>!=0</td>
<td>An error occurred.</td>
</tr>
</tbody>
</table>

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

**See Also**
`ifconfig(1M), mnttab(4), attributes(5)`
newaliases – rebuild the database for the mail aliases file

newaliases

newaliases rebuilds the random access database for the mail aliases file /etc/mail/aliases.

newaliases accepts all the flags that sendmail(1M) accepts. However, most of these flags have no effect, except for the -C option and three of the Processing Options that can be set from a configuration file with the -o option:

- C /path/to/alt/config/file Use alternate configuration file.
- oAfile Specify possible alias files.
- oLn Set the default log level to n. Defaults to 9.
- on Validate the RHS of aliases when rebuilding the aliases(4) database.

newaliases runs in verbose mode (-v option) automatically.

**Examples**

**EXAMPLE 1** Running the newaliases Command

The following command runs newaliases on an alias file different from the /etc/mail/aliases default in sendmail(1M):

```
example% newaliases -oA/path/to/alternate/alias/file
```

**Exit Status**

newaliases returns an exit status describing what it did. The codes are defined in /usr/include/sysexits.h.

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EX_OK</td>
<td>Successful completion on all addresses.</td>
</tr>
<tr>
<td>EX_NOUSER</td>
<td>User name not recognized.</td>
</tr>
<tr>
<td>EX_UNAVAILABLE</td>
<td>Catchall. Necessary resources were not available.</td>
</tr>
<tr>
<td>EX_SYNTAX</td>
<td>Syntax error in address.</td>
</tr>
<tr>
<td>EX_SOFTWARE</td>
<td>Internal software error, including bad arguments.</td>
</tr>
<tr>
<td>EX_OSERR</td>
<td>Temporary operating system error, such as &quot;cannot fork&quot;.</td>
</tr>
<tr>
<td>EX_NOHOST</td>
<td>Host name not recognized.</td>
</tr>
<tr>
<td>EX_TEMPFAIL</td>
<td>Message could not be sent immediately, but was queued.</td>
</tr>
</tbody>
</table>

</tbody>
</table>

See Also  sendmail(1M), aliases(4), attributes(5)
newfs – construct a UFS file system

**Synopsis**

newfs [-NSBTv] [mkfs-options] raw-device

**Description**

newfs is a friendly front-end to the `mkfs(1M)` program for making UFS file systems on disk partitions. `newfs` calculates the appropriate parameters to use and calls `mkfs`.

If run interactively (that is, standard input is a tty), `newfs` prompts for confirmation before making the file system.

If the `-N` option is not specified and the inodes of the device are not randomized, `newfs` calls `fsirand(1M)`.

You must be super-user or have appropriate write privileges to use this command.

Keep the following limitations in mind when creating a multiterabyte UFS file system:

- `nbpi` is set to 1 Mbyte unless you specifically set it higher. You cannot set `nbpi` lower than 1 Mbyte on a multiterabyte UFS file system.
- `fragsize` is set equal to `bsize`.

**Options**

The following options are supported:

- `-N`
  Print out the file system parameters that would be used to create the file system without actually creating the file system. `fsirand(1M)` is not called here.

- `-S`
  Sends to stdout a human-readable version of the superblock that would be used to create a filesystem with the specified configuration parameters.

- `-B`
  Sends to stdout a binary (machine-readable) version of the superblock that would be used to create a filesystem with the specified configuration parameters.

- `-T`
  Set the parameters of the file system to allow eventual growth to over a terabyte in total file system size. This option sets `fragsize` to be the same as `bsize`, and sets `nbpi` to 1 Mbyte, unless the `-i` option is used to make it even larger. If you use the `-f` or `-i` options to specify a `fragsize` or `nbpi` that is incompatible with this option, the user-supplied value of `fragsize` or `nbpi` is ignored.

- `-v`
  Verbose. `newfs` prints out its actions, including the parameters passed to `mkfs`.

`mkfs-options`

Options that override the default parameters are:

- `-a apc`
  The number of alternate sectors per cylinder to reserve for bad block replacement for SCSI devices only. The default is 0.
This option is not applicable for disks with EFI labels and is ignored.

-\texttt{b bsize}
  The logical block size of the file system in bytes, either 4096 or 8192. The default is 8192. The sun4u architecture does not support the 4096 block size.

-\texttt{c cgsise}
  The number of cylinders per cylinder group, ranging from 16 to 256. The default is calculated by dividing the number of sectors in the file system by the number of sectors in a gigabyte. Then, the result is multiplied by 32. The default value is always between 16 and 256.

\texttt{mkfs} can override this value. See \texttt{mkfs_ufs(1M)} for details.

This option is not applicable for disks with EFI labels and is ignored.

-\texttt{c maxcontig}
  The maximum number of logical blocks, belonging to one file, that are allocated contiguously. The default is calculated as follows:

  \texttt{maxcontig = disk drive maximum transfer size / disk block size}

  If the disk drive's maximum transfer size cannot be determined, the default value for \texttt{maxcontig} is calculated from kernel parameters as follows:

  If \texttt{maxphys} is less than \texttt{ufs_maxmaxphys}, which is typically 1 Mbyte, then \texttt{maxcontig} is set to \texttt{maxphys}. Otherwise, \texttt{maxcontig} is set to \texttt{ufs_maxmaxphys}.

  You can set \texttt{maxcontig} to any positive integer value.

  The actual value will be the lesser of what has been specified and what the hardware supports.

  You can subsequently change this parameter by using \texttt{tunefs(1M)}.

-\texttt{d gap}
  Rotational delay. This option is obsolete in the Solaris 10 release. The value is always set to 0, regardless of the input value.

-\texttt{f fragsize}
  The smallest amount of disk space in bytes that can be allocated to a file. \texttt{fragsize} must be a power of 2 divisor of \texttt{bsize}, where:

  \texttt{bsize} / \texttt{fragsize} is 1, 2, 4, or 8.

  This means that if the logical block size is 4096, legal values for \texttt{fragsize} are 512, 1024, 2048, and 4096. When the logical block size is 8192, legal values are 1024, 2048, 4096, and 8192. The default value is 1024.

  For file systems greater than 1 terabyte or for file systems created with the \texttt{-T} option, \texttt{fragsize} is forced to match block size (\texttt{bsize}).
The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the number of inodes to create.

This value should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used. To create more inodes, a smaller number should be given. The default for *nbpi* is as follows:

<table>
<thead>
<tr>
<th>Disk size</th>
<th>Density</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 1 GB</td>
<td>2048</td>
</tr>
<tr>
<td>Less than 2 GB</td>
<td>4096</td>
</tr>
<tr>
<td>Less than 3 GB</td>
<td>6144</td>
</tr>
<tr>
<td>3 GB to 1 T byte</td>
<td>8192</td>
</tr>
<tr>
<td>Greater than 1 T byte or created with -T</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The number of inodes can increase if the file system is expanded with the *growfs* command.

The minimum percentage of free space to maintain in the file system, between 0% and 99%, inclusively. This space is off-limits to users. Once the file system is filled to this threshold, only the super-user can continue writing to the file system.

The default is ((64 Mbytes/partition size) * 100), rounded down to the nearest integer and limited between 1% and 10%, inclusively.

This parameter can be subsequently changed using the *tunefs(1M)* command.

The number of different rotational positions in which to divide a cylinder group. The default is 8.

This option is not applicable for disks with EFI labels and is ignored.

The file system can either be instructed to try to minimize the time spent allocating blocks, or to try to minimize the space fragmentation on the disk. The default is *time*.

This parameter can subsequently be changed with the *tunefs(1M)* command.

The rotational speed of the disk in revolutions per minute. The default is driver- or device-specific.

Note that you specify *rpm* for *newfs* and *rps* for *mkfs*.

This option is not applicable for disks with EFI labels and is ignored.
newfs(1M)

-th size
The size of the file system in sectors. The default is to use the entire partition.

-t ntrack
The number of tracks per cylinder on the disk. The default is taken from the disk label.

This option is not applicable for disks with EFI labels and is ignored.

Operands
The following operands are supported:

raw-device
The name of a raw special device residing in the /dev directory (for example, /dev/rdsk/c0t0d0s6) on which to create the file system.

Usage
See largefile(5) for the description of the behavior of newfs when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples
EXAMPLE 1  Displaying the Parameters for the Raw Special Device
The following example verbosely displays the parameters for the raw special device, c0t0d0s6. It does not actually create a new file system:

eexample# newfs -Nv /dev/rdsk/c0t0d0s6
mkfs -F ufs -o N /dev/rdsk/c0t0d0s6 1112940 54 15 2044 1024 16 10 60
2048 t 0 1 8 /dev/rdsk/c0t0d0s6: 1112940 sectors in
1374 cylinders of 15 tracks, 54 sectors 569.8MB in 86 cyl
groups (16 c/g, 6.64MB/g, 3072 i/g) super-block backups
(for fsck -b #) at:
32, 13956, 26080, 39104, 52128, 65152, 78176, 91200, 104224, ...

EXAMPLE 2  Creating a UFS File System That Will Eventually Be Grown to a Multiterabyte UFS File System
The following example creates a UFS file system that will eventually be grown to a multiterabyte UFS file system.

This command creates a 800-Gbyte file system on the volume, /dev/md/rdsk/d99.

# newfs -T /dev/md/rdsk/d99
newfs: construct a new file system /dev/md/rdsk/d99: (y/n)? y
/dev/md/rdsk/d99: 1677754368 sectors in 45512 cylinders of
144 tracks, 256 sectors
819216.0MB in 1821 cyl groups (25 c/g, 450.00MB/g, 448 i/g) ...

Then, if you increase the volume size for this file system, you can use the growfs command to expand the file system. The file system is grown to 1.2 terabytes in this example:

# growfs -v /dev/md/rdsk/d99
/usr/lib/fs/ufs/mkfs -G /dev/md/rdsk/d99 2516631552 /dev/md/rdsk/d99:
2516631552 sectors in 68268 cylinders of 144 tracks, 256 sectors
1228824.0MB in 2731 cyl groups (25 c/g, 450.00MB/g, 448 i/g) ...
Exit Status  The following exit values are returned:

0  
The operation was successful.

1, 10  
Usage error or internal error. A message is output to STDERR explaining the error.

Other exit values may be returned by `mkfs(1M)`, which is called by `newfs`.

Attributes  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>

</table>

See Also  `fsck(1M), fsck_ufs(1M), fsirand(1M), mkfs(1M), mkfs_ufs(1M), tunefs(1M), attributes(5), largefile(5), ufs(7FS)`

Diagnostics  `newfs`: No such file or directory
  The device specified does not exist, or a disk partition was not specified.

  `special`: cannot open
  You must write access to the device to use this command.
newkey(1M)

Name
newkey – create a new Diffie-Hellman key pair in the public key database

Synopsis
newkey -h hostname [-s nis | files | ldap]
newkey -u username [-s nis | files | ldap]

Description
newkey establishes new public keys for users and machines on the network. These keys are needed when using secure RPC or secure NFS service. newkey prompts for a password for the given username or hostname and then creates a new public/secret Diffie-Hellman 192 bit key pair for the user or host. The secret key is encrypted with the given password. The key pair can be stored in the /etc/publickey file or the NIS public key map.

newkey consults the publickey entry in the name service switch configuration file (see nsswitch.conf(4)) to determine which naming service is used to store the secure RPC keys. If the publickey entry specifies a unique name service, newkey will add the key in the specified name service. However, if there are multiple name services listed, newkey cannot decide which source to update and will display an error message. The user is required to specify the source explicitly with the -s option.

In the case of NIS, newkey should be run by the superuser on the master NIS server for that domain.

In the case of LDAP, newkey should be run by the superuser on a machine that also recognizes the directory manager’s bind distinguished name (DN) and password to perform an LDAP update for the host.

Options
- h hostname Create a new public/secret key pair for the privileged user at the given hostname. Prompts for a password for the given hostname.
- u username Create a new public/secret key pair for the given username. Prompts for a password for the given username.
- s nis
- s files
- s ldap Update the database in the specified source: nis (for NIS), files, or ldap (LDAP). Other sources may be available in the future.

**Name**  
nfs4cbd – NFS Version 4 callback daemon

**Synopsis**  
/usr/lib/nfs/nfs4cbd

**Description**  
The nfs4cbd daemon manages communication endpoints for the NFS Version 4 protocol callback program. nfs4cbd runs on the NFS Version 4 client and creates a listener port for each transport over which callbacks can be sent.

The nfs4cbd daemon is provided for the exclusive use of the NFS version 4 client.

**Attributes**  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/file-system/nfs</td>
</tr>
</tbody>
</table>

**See Also**  
svcs(1), mount_nfs(1M), svcadm(1M), attributes(5), smf(5)

**Notes**  
The nfs4cbd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/nfs/cbd

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

If it is disabled, it will be enabled by mount_nfs(1M) and automountd(1M) on the first NFSv4 mount, unless its application/auto_enable property is set to false.

This daemon might not exist in a future release of Solaris.
nfsd is the daemon that handles client file system requests. Only users with \{PRIV_SYS_NFS\} and sufficient privileges to write to `/var/run` can run this daemon.

The `nfsd` daemon is automatically invoked using `share(1M)` with the `-a` option.

By default, `nfsd` starts over the TCP and UDP transports for versions 2 and 3. By default, it starts over the TCP for version 4. You can change this with the `-p` option.

A previously invoked `nfsd` daemon started with or without options must be stopped before invoking another `nfsd` command.

To change startup parameters for `nfsd`, use the `sharectl(1M)` command.

The `nfsd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/nfs/server
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service’s status can be queried using the `svcs(1)` command.

If `nfsd` is killed with SIGTERM, it will not be restarted by the service management facility. Instead, `nfsd` can be restarted by other signals, such as SIGINT.

The `sharectl(1M)` command can be used to manage all the parameters related to `nfsd`. The following are the parameters currently supported:

```
server_versmax=num
server_versmin=num
  The NFS server only uses NFS versions in the range specified by these variables. Valid values or versions are: 2, 3, and 4. If one or both of these parameters are left unset, the default minimum version is 2, while the default maximum version is 4.
server_delegation=on | off
  By default, this variable is on and the NFS server provides delegations to clients. The user can turn off delegations for all exported file systems by setting this variable to off (case-sensitive). This variable applies only to NFS Version 4.
max_connections=num
  Sets the maximum number of concurrent, connection-oriented connections. The default is unlimited and is obtained by setting to -1. Equivalent to the `-c` option in `nfsd`.
listen_backlog=num
  Set connection queue length for the NFS over a connection-oriented transport. The default value is 32, meaning 32 entries in the queue. Equivalent to the `-l` option in `nfsd`.
```
protocol=ALL
Start nfsd over the specified protocol only. Equivalent to the -p option in nfsd. ALL is equivalent to -a on the nfsd command line. Mutually exclusive of NFS SMF parameter device. One or the other of NFS SMF parameters device and protocol must not be set. If both are set, the nfs/server service goes into maintenance mode. For the UDP protocol, only version 2 and version 3 service is established. NFS Version 4 is not supported for the UDP protocol. Equivalent to the -p option.

device=devname
Start NFS daemon for the transport specified by the specified device only. Equivalent to the -t option in nfsd. Mutually exclusive of NFS SMF parameter protocol. One or the other of NFS SMF parameters device and protocol must not be set.

servers=num
Maximum number of concurrent NFS requests. The default is 1024. Equivalent to the nservers operand.

See EXAMPLES, below.

Options The following options are supported:

- **a**
  Start an NFS daemon over all available connectionless and connection-oriented transports, including UDP and TCP. Equivalent of setting the protocol parameter to ALL in the SMF for NFS using the sharectl(1M) command.

- **c **_conn
  This sets the maximum number of connections allowed to the NFS server over connection-oriented transports. By default, the number of connections is unlimited. Equivalent of the max_connections parameter in the SMF for NFS using the sharectl(1M) command.

- **l**
  Set connection queue length for the NFS TCP over a connection-oriented transport. The default value is 32 entries. Equivalent of the listen_backlog parameter in the SMF for NFS using the sharectl(1M) command.

- **p protocol**
  Start a NFS daemon over the specified protocol. Equivalent of the protocol parameter in the SMF for NFS using the sharectl(1M) command.

- **t device**
  Start a NFS daemon for the transport specified by the given device. Equivalent of the device parameter in the SMF for NFS using the sharectl(1M) command.

Operands The following operands are supported:

- **nservers**
  This sets the maximum number of concurrent NFS requests that the server can handle. This concurrency is achieved by up to nservers threads created as needed in the kernel. nservers should be based on the load expected on this server. 16 is the usual number of nservers. If nservers is not specified, the maximum number of concurrent NFS requests will default to 1. Equivalent of the servers parameter in
the SMF for NFS using the `sharectl(1M)` command.

**Usage**

If the `nfs_portmon` variable is set in `/etc/system`, then clients are required to use privileged ports (ports < `IPPORT_RESERVED`) to get NFS services. This variable is equal to zero by default. This variable has been moved from the “nfs” module to the “nfssrv” module. To set the variable, edit the `/etc/system` file and add this entry:

```
set nfssrv:nfs_portmon = 1
```

**Examples**

**EXAMPLE 1  Turning Off Delegation**

The `nfsd` properties specified in these examples are described under “SMF Management,” above.

Delegation is an NFSv4 feature in which the server delegates the management of a file to a client. For example, the server could grant (or not grant) either a read delegation or a write delegation to a client. The following command does this, setting the `server_delegation` property to `off`.

```
# sharectl set -p server_delegation=off nfs
```

**EXAMPLE 2  Determining Value of Delegation**

The following command obtains the current value of the `server_delegation` property.

```
# sharectl get -p server_delegation nfs
server_delegation=on
```

**EXAMPLE 3  Setting Maximum Number of Concurrent Requests**

The following command sets the maximum number of concurrent NFS requests.

```
# sharectl set -p servers=32 nfs
```

**EXAMPLE 4  Setting Connection Queue Length**

The following command sets the maximum queue length for the NFS over a connection-oriented transport.

```
# sharectl set -p listen_backlog=48 nfs
```

**Exit Status**

- **0** Daemon started successfully.
- **1** Daemon failed to start.

**Files**

- `.nfsXXX` Client machine pointer to an open-but-unlinked file.
- `/etc/system` System configuration information file.
- `/var/nfs/v4_state` Directories used by the server to manage client state information.
- `/var/nfs/v4_oldstate` These directories should not be removed.

Oracle Solaris Administration: Network Services

Notes  Manually starting and restarting nfsd is not recommended. If it is necessary to do so, use svcadm to enable or disable the nfs service (svc:/network/nfs/server). If it is disabled, it will be enabled by share_nfs(1M), unless its application/auto_enable property is set to false. See the Oracle Solaris Administration: Network Services, and svcadm(1M) for more information.
The `nfslogd` daemon provides operational logging to the Solaris NFS server. It is the `nfslogd` daemon's job to generate the activity log by analyzing the RPC operations processed by the NFS server. The log will only be generated for file systems exported with logging enabled. This is specified at file system export time by means of the `share_nfs(1M)` command.

NFS server logging is not supported on Solaris machines that are using NFS Version 4.

Each record in the log file includes a time stamp, the IP address (or hostname if it can be resolved) of the client system, the file or directory name the operation was performed on, and the type of operation. In the basic format, the operation can either be an input (i) or output (o) operation. The basic format of the NFS server log is compatible with the log format generated by the Washington University FTPd daemon. The log format can be extended to include directory modification operations, such as `mkdir`, `rmdir`, and `remove`. The extended format is not compatible with the Washington University FTPd daemon format. See `nfslog.conf(4)` for details.

The NFS server logging mechanism is divided into two phases. The first phase is performed by the NFS kernel module, which records raw RPC requests and their results in work buffers backed by permanent storage. The location of the work buffers is specified in the `/etc/nfs/nfslog.conf` file. Refer to `nfslog.conf(4)` for more information. The second phase involves the `nfslogd` user-level daemon, which periodically reads the work buffers, interprets the raw RPC information, groups related RPC operations into single transaction records, and generates the output log. The `nfslogd` daemon then sleeps waiting for more information to be logged to the work buffers. The amount of time that the daemon sleeps can be configured by modifying the `IDLE_TIME` parameter in `/etc/default/nfslogd`. The work buffers are intended for internal consumption of the `nfslogd` daemon.

NFS operations use file handles as arguments instead of path names. For this reason the `nfslogd` daemon needs to maintain a database of file handle to path mappings in order to log the path name associated with an operation instead of the corresponding file handle. A file handle entry is added to the database when a client performs a lookup or other NFS operation that returns a file handle to the client.

Once an NFS client obtains a file handle from a server, it can hold on to it for an indefinite time, and later use it as an argument for an NFS operation on the file or directory. The NFS client can use the file handle even after the server reboots. Because the database needs to survive server reboots, it is backed by permanent storage. The location of the database is specified by the `fhtable` parameter in the `/etc/nfs/nfslog.conf` file. This database is intended for the internal use of the `nfslogd` daemon.

In order to keep the size of the file handle mapping database manageable, `nfslogd` prunes the database periodically. It removes file handle entries that have not been accessed in more than a specified amount of time. The `PRUNE_TIMEOUT` configurable parameter in
/etc/default/nfslogd specifies the interval length between successive runs of the pruning process. A file handle record will be removed if it has not been used since the last time the pruning process was executed. Pruning of the database can effectively be disabled by setting the PRUNE_TIMEOUT as high as INT_MAX.

When pruning is enabled, there is always a risk that a client may have held on to a file handle longer than the PRUNE_TIMEOUT and perform an NFS operation on the file handle after the matching record in the mapping database had been removed. In such case, the pathname for the file handle will not be resolved, and the log will include the file handle instead of the pathname.

There are various configurable parameters that affect the behavior of the nfslogd daemon. These parameters are found in /etc/default/nfslogd and are described below:

**UMASK**
Sets the file mode for the log files, work buffer files and file handle mapping database.

**MIN_PROCESSING_SIZE**
Specifies the minimum size, in bytes, that the buffer file must reach before processing the work information and writing to the log file. The value of MIN_PROCESSING_SIZE must be between 1 and ulimit.

**IDLE_TIME**
Specifies the amount of time, in seconds, the daemon should sleep while waiting for more information to be placed in the buffer file. IDLE_TIME also determines how often the configuration file will be reread. The value of IDLE_TIME must be between 1 and INT_MAX.

**MAX_LOGS_PRESERVE**
The nfslogd periodically cycles its logs. MAX_LOGS_PRESERVE specifies the maximum number of log files to save. When MAX_LOGS_PRESERVE is reached, the oldest files will be overwritten as new log files are created. These files will be saved with a numbered extension, beginning with filename.0. The oldest file will have the highest numbered extension up to the value configured for MAX_LOGS_PRESERVE. The value of MAX_LOGS_PRESERVE must be between 1 and INT_MAX.

**CYCLE_FREQUENCY**
Specifies how often, in hours, the log files are cycled. CYCLE_FREQUENCY is used to insure that the log files do not get too large. The value of CYCLE_FREQUENCY must be between 1 and INT_MAX.

**MAPPING_UPDATE_INTERVAL**
Specifies the time interval, in seconds, between updates of the records in the file handle to path mapping tables. Instead of updating the atime of a record each time that record is accessed, it is only updated if it has aged based on this
parameter. The record access time is used by the pruning routine to determine whether the record should be removed from the database. The value of this parameter must be between 1 and INT_MAX.

**PRUNE_TIMEOUT**

Specifies when a database record times out, in hours. If the time that elapsed since the record was last accessed is greater than PRUNE_TIMEOUT then the record can be pruned from the database. The default value for PRUNE_TIMEOUT is 168 hours (7 days). The value of PRUNE_TIMEOUT must be between 1 and INT_MAX.

**Exit Status**
The following exit values are returned:

- 0  Daemon started successfully.
- 1  Daemon failed to start.

**Files**
/etc/nfs/nfslogtab
/etc/nfs/nfslog.conf
/etc/default/nfslogd

nfsmapid – NFS user and group id mapping daemon

/usr/lib/nfs/nfsmapid

The `nfsmapid` daemon maps to and from NFS version 4 owner and owner_group identification attributes and local UID and GID numbers used by both the NFS version 4 client and server.

`nfsmapid` uses the passwd and group entries in the `/etc/nsswitch.conf` file to direct how it performs the mappings.

The `nfsmapid` daemon has no external, customer-accessible interfaces. You can, however, administratively configure `nfsmapid` in one of the following ways:

- Specify the `nfsmapid_domain` parameter in the SMF for NFS using the `sharectl(1M)` command.
- Specify the `_nfsv4idmapdomain` DNS resource record.

The currently selected NFSv4 domain is available in the file `/var/run/nfs4_domain`

Please refer to the Oracle Solaris Administration: Network Services Oracle Solaris Administration: Network Services for further details.

The `nfsmapid` service is managed by the service management facility, `smf(5)`, under the service identifier:

    svc:/network/nfs/mapid

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

If it is disabled, it will be enabled by `mount_nfs(1M), share_nfs(1M), and automountd(1M)`, unless its application/auto_enable property is set to false.

`nfsmapid` caches a user's UID and GID. If a user subsequently changes a UID or GID, using one of the utilities listed below, the `nfsmapid` cache becomes stale. At this point, any NFS operation that gets or set attributes will result in the exchange of this stale information. To resolve this situation, restart `nfsmapid`, as follows:

    # svcadm restart svc:/network/nfs/mapid:default

The startup SMF parameter designating a domain name (`nfsmapid_domain`) can be manipulated with the `sharectl(1M)` command.

    nfsmapid_domain

    The setting for the NFS SMF parameter `nfsmapid_domain` overrides the domain used by `nfsmapid` for building and comparing outbound and inbound attribute strings, respectively. Also, this setting overrides any other mechanism for setting the NFSv4 domain. In the absence of a `nfsmapid_domain` setting, the `nfsmapid` daemon determines the NFSv4 domain as follows:
If a properly configured /etc/resolv.conf (see resolv.conf(4)) exists, nfsmapid queries specified nameserver(s) for the domain.

If a properly configured /etc/resolv.conf (see resolv.conf(4)) exists, but the queried name server does not have a proper record of the domain name, nfsmapid attempts to obtain the domain name through the BIND interface (see resolver(3RESOLV)).

If no /etc/resolv.conf exists, nfsmapid falls back on using the configured domain name (see domainname(1M)), which is returned with the leading domain suffix removed. For example, for widgets.sales.acme.com, sales.acme.com is returned.

If /etc/resolv.conf does not exist, no domain name has been configured (or no /etc/defaultdomain exists), nfsmapid falls back on obtaining the domain name from the host name, if the host name contains a fully qualified domain name (FQDN).

If a domain name is still not obtained following all of the preceding steps, nfsmapid will have no domain configured. This results in the following behavior:

- Outbound owner and owner_group attribute strings are encoded as literal ID's. For example, the UID 12345 is encoded as 12345.
- nfsmapid ignores the domain portion of the inbound attribute string and performs name service lookups only for the user or group. If the user/group exists in the local system name service databases, then the proper UID/GID will be mapped even when no domain has been configured.

This behavior implies that the same administrative user/group domain exists between NFSv4 client and server (that is, the same UID/GIDs for users/groups on both client and server). In the case of overlapping ID spaces, the inbound attribute string could potentially be mapped to the wrong id. However, this is not functionally different from mapping the inbound string to nobody, yet provides greater flexibility. See EXAMPLES, below.

The utilities that allow you to change UID and GID are:

- usermod(1M)
- userdel(1M)
- groupmod(1M)
- groupdel(1M)

Files /var/run/nfs4_domain Contains the domain name currently used by NFSv4.

Examples

**EXAMPLE 1 Setting Domain Name**

The following command uses sharectl to set the domain name.

```
# sharectl set -p nfsmapid_domain=oracle.com nfs
```

The nfsmapid_domain property is described under NOTES, below.
EXAMPLE 2  Obtaining Domain Name
The following command uses sharectl to obtain the current domain name.

```
# sharectl get -p nfsmapid_domain nfs nfsmapid_domain=oracle.com
```

Oracle Solaris Administration: Network Services

Notes  The nfsmapid daemon might not exist in a future release of Solaris.
The `nfsref` command manages NFS Version 4 referrals, which are server-side pointers used to redirect clients to actual locations of file systems. Referrals are based on reparse points (see `reparsed(1M)` and `libreparse(3LIB)`). The path arguments in all forms of the synopsis refer to the path to the reparse point symbolic link. This command currently implements two service types: `nfs-basic`, which is the default, and `nfs-fedfs`. `nfs-basic` referrals embed location information within the reparse point, while `nfs-fedfs` referrals embed information to look up location information in LDAP (see `fedfs(5)`).

The first form of the command, `nfsref add`, creates a referral pointing to the specified locations. If a reparse point does not exist, one is created. If it does exist, NFS service data is added or replaces existing NFS service data. Each location has a `host:/path` format. The path can contain spaces, which must be escaped to ensure proper shell parsing.

The second form of the command, `nfsref delete`, removes an NFS referral. It removes NFS service data from the specified reparse point, and removes the reparse point if there are no other types of service data present.

The third form of the command, `nfsref lookup`, displays the locations to which the specified NFS referral points.

Creating FedFS referrals must always be done with LDAP simple authentication with the root distinguished name and matching password available. The root DN must be stored for the LDAP server in `nsdbparams`; the password may be stored in `nsdbparams`, or the admin may enter it when prompted. The default LDAP host and port will be those set with `nsdbparams` get unless overridden with the `FEDFS_NSDB_HOST` and `FEDFS_NSDB_PORT` environment variables.

### Options

The following options are supported:

- `-t svc_type`
  Specify a service type. Currently, only `nfs-basic` and `nfs-fedfs` are supported.

### Examples

#### Example 1  Adding an NFS Referral

The following command creates an NFS referral at the server path `/pool/home/bob`, pointing to the resource `homeserver:/homepool/bob`.

```
# nfsref add /pool/home/bob homeserver:/homepool/bob
Created reparse point /pool/home/bob
```

```
# nfsref lookup /pool/home/bob
homeserver:/homepool/bob
```
EXAMPLE 2  Removing an NFS Referral

The following command removes an NFS referral at the server path /pool/home/bob.

```
# nfsref remove /pool/home/bob homeserver:/homepool/bob
```

Removed svc_type 'nfs-basic' from /pool/home/bob

**Exit Status**  0

  Successful completion.

>0

  An error occurred.

**Files**  /usr/lib/reparsed/*.so.1

  Per-service plugins for reparsed.

**See Also**  reparsed(1M), libreparse(3LIB), attributes(5), fedfs(5)
nfsstat(1M)

**Name**
nfsstat – NFS statistics

**Synopsis**
nfsstat [-cnrsza] [-Tu | d] [-v version] [interval [count]]

  nfsstat -m [pathname]...

**Description**
nfsstat displays statistical information about the NFS and RPC (Remote Procedure Call), interfaces to the kernel. It can also be used to reinitialize this information. If no options are given the default is as follows:

  nfsstat -csnra

  The default displays everything, but reinitializes nothing.

**Options**

- **-a**
  Display NFS_ACL information.

- **-c**
  Display client information. Only the client side NFS, RPC, and NFS_ACL information is printed. Can be combined with the -n, -r, and -a options to print client side NFS, RPC, and NFS_ACL information only.

- **-m [pathname]...**
  Display statistics for each NFS mounted file system. If pathname is not specified, displays statistics for all NFS mounted file systems. If pathname is specified, displays statistics for the NFS mounted file systems indicated by pathname.

  This includes the server name and address, mount flags, current read and write sizes, the retransmission count, the attribute cache timeout values, failover information, and the timers used for dynamic retransmission. The dynamic retransmission timers are displayed only where dynamic retransmission is in use. By default, NFS mounts over the TCP protocols and NFS Version 3 mounts over either TCP or UDP do not use dynamic retransmission.

  If you specify the -m option, this is the only option that nfsstat uses. If you specify other options with -m, you receive an error message alerting that the -m flag cannot be combined with other options.

- **-n**
  Display NFS information. NFS information for both the client and server side are printed. Can be combined with the -c and -s options to print client or server NFS information only.

- **-r**
  Display RPC information.

- **-s**
  Display server information.

- **-T u | d**
  Display a time stamp.
Specify u for a printed representation of the internal representation of time. See `time(2)`. Specify d for standard date format. See `date(1)`.

-v version
Specify which NFS version for which to print statistics. When followed by the optional version argument, (2|3|4), specifies statistics for that version. By default, prints statistics for all versions.

-z
Zero (reinitialize) statistics. This option is for use by the super user only, and can be combined with any of the above options to zero particular sets of statistics after printing them.

Operands
The following operands are supported:

count
Display only count reports

interval
Report once each interval seconds.

pathname
Specify the pathname of a file in an NFS mounted file system for which statistics are to be displayed.

Displays
The server RPC display includes the following fields:

badcalls
The total number of calls rejected by the RPC layer (the sum of badlen and xdr call as defined below).

badlen
The number of RPC calls with a length shorter than a minimum-sized RPC call.

calls
The total number of RPC calls received.

dupchecks
The number of RPC calls that looked up in the duplicate request cache.

dupreqs
The number of RPC calls that were found to be duplicates.

nullrecv
The number of times an RPC call was not available when it was thought to be received.

xdr call
The number of RPC calls whose header could not be XDR decoded.

The server NFS display shows the number of NFS calls received (calls) and rejected (badcalls), and the counts and percentages for the various calls that were made.
The server NFS_ACL display shows the counts and percentages for the various calls that were made.

The client RPC display includes the following fields:

- **calls**
  The total number of RPC calls made.

- **badcalls**
  The total number of calls rejected by the RPC layer.

- **badverfs**
  The number of times the call failed due to a bad verifier in the response.

- **badxids**
  The number of times a reply from a server was received which did not correspond to any outstanding call.

- **cantconn**
  The number of times the call failed due to a failure to make a connection to the server.

- **cantsend**
  The number of times a client was unable to send an RPC request over a connectionless transport when it tried to do so.

- **interrupts**
  The number of times the call was interrupted by a signal before completing.

- **newcreds**
  The number of times authentication information had to be refreshed.

- **nomem**
  The number of times the call failed due to a failure to allocate memory.

- **retrans**
  The number of times a call had to be retransmitted due to a timeout while waiting for a reply from the server. Applicable only to RPC over connection-less transports.

- **timeout**
  The number of times a call timed out while waiting for a reply from the server.

- **timers**
  The number of times the calculated time-out value was greater than or equal to the minimum specified time-out value for a call.

The client NFS display shows the number of calls sent and rejected, as well as the number of times a CLIENT handle was received (clgets), the number of times the CLIENT handle cache had no unused entries (cltoo many), as well as a count of the various calls and their respective percentages.
The client NFS_ACL display shows the counts and percentages for the various calls that were made.

The -m option includes information about mount flags set by mount options, mount flags internal to the system, and other mount information. See mount_nfs(1M).

The following mount flags are set by mount options:

- **forcedirectio**
  - Data transferred directly between client and server, with no buffering on client.

- **gid**
  - BSD group id inheritance. See description in mount_nfs(1M).

- **hard**
  - Hard mount.

- **intr**
  - Interrupts allowed on hard mount.

- **llock**
  - Local locking being used (no lock manager). Note that this is a private interface.

- **noac**
  - Client is not caching attributes.

- **nointr**
  - No interrupts allowed on hard mount.

- **nocto**
  - No close-to-open consistency.

- **retrans**
  - NFS retransmissions.

- **rpctime**
  - RPC time sync.

- **rsize**
  - Read buffer size in bytes.

- **sec**
  - sec has one of the following values:
    - **dh**
      - des-style authentication (encrypted timestamps).
    - **krb5**
      - kerberos v5-style authentication.
    - **krb5i**
      - kerberos v5-style authentication with integrity.
krb5p
  kerberos v5-style authentication with privacy.

none
  No authentication.

short
  Short hand UNIX-style authentication.

sys
  UNIX-style authentication (UID, GID).

soft
  Soft mount.

timeo
  Initial NFS timeout, in tenths of a second.

wsize
  Write buffer size in bytes.

The following mount flags are internal to the system:

acl
  Server supports NFS_ACL.

down
  Server is down.

dynamic
  Dynamic transfer size adjustment.

link
  Server supports links.

mirrormount
  Mounted automatically by means of the mirrormount mechanism.

printed
  “Not responding” message printed.

readdironly
  Use readdir instead of readdirplus.

referral
  Mounted automatically by means of the referral mechanism.

symlink
  Server supports symbolic links.

The following flags relate to additional mount information:
proto
  Protocol.

vers
  NFS version.

The `-m` option also provides attribute cache timeout values. The following fields in `-m` output provide timeout values for attribute cache:

acdirmax
  Maximum seconds to hold cached directory attributes.

acdirmin
  Minimum seconds to hold cached directory attributes.

acregmax
  Maximum seconds to hold cached file attributes.

acregmin
  Minimum seconds to hold cached file attributes.

The following fields in `-m` output provide failover information:

currserver
  Which server is currently providing NFS service. See the System Administration Guide: IP Services for additional details.

failover
  How many times a new server has been selected.

noresponse
  How many times servers have failed to respond.

remap
  How many times files have been re-evaluated to the new server.

The fields in `-m` output shown below provide information on dynamic retransmissions. These items are displayed only where dynamic retransmission is in use.

cur
  Current backed-off retransmission value, in milliseconds.

dev
  Estimated deviation, in milliseconds.

srtt
  The value for the smoothed round-trip time, in milliseconds.

**Exit Status**  The following exit values are returned:

0
  Successful completion.
An error occurred.

System Administration Guide: IP Services
nscadm – network storage control utility

**Synopsis**

```
nscadm freeze device
nscadm unfreeze device
nscadm isfrozen device
```

**Description**
The `nscadm` command performs several network storage control functions.

The `nscadm freeze` command closes existing references to the specified device, and blocks future accesses. This allows maintenance of virtual volume device drivers (for example, RAID 0, RAID 1, RAID 5) to be performed without shutting down the system.

The `nscadm unfreeze` command reverses the effects of `nscadm freeze` for the specified device.

The `nscadm isfrozen` command returns the current status of the specified device.

**Options**
The `nscadm` command supports the following option.

- `-h`
  Display the usage menu.

**Operands**
The `nscadm` command line supports the following operand.

- `device`
  Specifies the storage device to be acted upon by `nscadm`.

**Exit Status**
For the `freeze` and `unfreeze`, subcommands `nscadm` returns the following exit values:

- `0` Success
- `255` Error

For the `isfrozen` subcommand, `nscadm` returns the following exit values:

- `0` Device is currently frozen.
- `1` Device is not currently frozen.
- `255` Error

<table>
<thead>
<tr>
<th>Name</th>
<th>nscd – name service cache daemon</th>
</tr>
</thead>
<tbody>
<tr>
<td>Synopsis</td>
<td>/usr/sbin/nscd [-f configuration-file] [-g] [-e cachename, yes</td>
</tr>
<tr>
<td>Description</td>
<td>The nscd daemon is a process that provides a cache for most name service requests. The service properties of the svc:/system/name-service/cache SMF service determine the behavior of the cache daemon. See nscd.conf(4).</td>
</tr>
</tbody>
</table>

nscd provides caching for the passwd(4), group(4), hosts(4), ipnodes(4), exec_attr(4), prof_attr(4), user_attr(4), ethers(4), rpc(4), protocols(4), networks(4), bootparams(4), auth_attr(4), services(4), netmasks(4), project(4) databases through standard libc interfaces, such as gethostbyname(3NSL), getipnodebyname(3SOCKET), gethostbyaddr(3NSL), and others. The shadow file is specifically not cached. getspnam(3C) calls remain uncached as a result.

Each cache has a separate time-to-live for its data. By default, modifying the local database (/etc/hosts, /etc/passwd, and so forth) causes that cache to become invalidated upon the next call to nscd.

The updating and refreshing of any of the services that svc:/system/name-service/cache is optionally dependent upon (listed below) causes nscd to restart, which effectively clears all caches.

- svc:/network/dns/client, see resolv.conf(4)
- svc:/network/nis/client, see ypbind(1M) and ypfiles(4)
- svc:/network/ldap/client, see ldapclient(1M)
- svc:/system/name-service/switch, see nsswitch.conf(4)

See nscd.conf(4).

nscd also acts as its own administration tool. If an instance of nscd is already running, commands are passed to the running version transparently.

When running with per-user lookups enabled (see nscd.conf(4)), nscd forks one and only one child process (that is, a per-user nscd) on behalf of the user making the request. The per-user nscd will use the credentials of the user to open a per-user connection to the name repository configured for the per-user style of lookups. The lookup will be performed in the child process. The results are cached in the process and are available only to the same user. The caches are managed exactly the same as the main nscd daemon manages its own caches. Subsequent requests from the user will be handled by that per-user nscd until it terminates. The per-user nscd uses a configurable inactivity time-to-live (TTL) value and terminates itself after the inactivity TTL expires.

The maximum number of per-user nscds that can be created by the main nscd is configurable (see nscd.conf(4)). After the maximum number of them are created, the main nscd will use an LRU algorithm to terminate less active child nscds as needed.
The main nscd daemon creates, monitors, and manages all the child nscds. It creates a user’s own nscd upon receiving the user’s first per-user lookup. When the nscd daemon is started, if per-user lookups are enabled, it checks to ensure all conditions are met before getting ready to create a per-user nscd. When the daemon is stopped, it terminates all the per-user nscds under its control.

Per-user nscds use the same configuration as the main nscd. They read and use the same default configuration file or the one specified with the -f command line option. Once the configuration is read, the per-user nscd will use it for its entire lifetime.

Options

Several of the options described below require a `cachename` specification. Supported values for `cachename` are: passwd, group, hosts, ipnodes, exec_attr, prof_attr, user_attr, ethers, rpc, protocols, networks, bootparams, auth_attr, services, netmasks, printers, and project.

- `-f configuration-file`
  Causes nscd to read its configuration data from the specified file. This option is obsolete and will be removed in a future release.

- `-g`
  Prints current configuration and statistics to standard output. This is the only option executable by non-root users.

- `-e cachename`, yes|no
  Enables or disables the specified cache.

- `-i cachename`
  Invalidate the specified cache.

Examples

**EXAMPLE 1**  Stopping and Restarting the nscd Daemon.

```
example# svcadm disable system/name-service/cache
example# svcadm enable system/name-service/cache
```

Files

/`etc/nscd.conf`  Obsolete. Formerly determined the behavior of the cache daemon

Attributes

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also

`svecs(1), svcadm(1M), ypbind(1M), getspnam(3C), gethostbyname(3NSL), getipnodebyname(3SOCKET), auth_attr(4), bootparams(4), ethers(4), exec_attr(4), group(4), hosts(4), netmasks(4), networks(4), nscd.conf(4), nsswitch.conf(4), passwd(4), prof_attr(4), project(4), protocols(4), resolv.conf(4), rpc(4), services(4), user_attr(4), attributes(5)`
The output from the -g option to nscd is subject to change. Do not rely upon it as a programming interface.

The nscd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/name-service/cache

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

The obsolete service svc:/system/name-service-cache has been retained for backwards compatibility with scripts that might reference it. Its only purpose is to serve as an optional_all dependency on the service svc:/system/name-service/cache. The obsolete service name will be removed in a future release.
**nscfg – import, export name service configurations**

**Synopsis**

```
/usr/sbin/nscfg command [cmd_options] [operands]
/usr/sbin/nscfg import [-fnvq] FMRI
/usr/sbin/nscfg export [-nvq] FMRI
/usr/sbin/nscfg unconfig [-nvq] FMRI
/usr/sbin/nscfg validate [-vq] FMRI
/usr/sbin/nscfg help
```

**Description**

The `nscfg` utility imports or exports legacy name service configuration files into or out of the SMF repository. Given a valid SMF configuration and corresponding FMRI, `nscfg` will regenerate the legacy naming service configuration files, such as `nsswitch.conf`, `resolv.conf`, `nscd.conf`, and so forth, into their legacy locations. Alternatively, `nscfg` can import those same configuration files populating the SMF repository if it is currently unpopulated.

The following are SMF services that can be operands to `nscfg`. In many instances, the legacy configuration file that is replaced by the SMF service is listed.

- `svc:/system/name-service/switch:default`
  
  Legacy file: `/etc/nsswitch.conf`
  
  Name service switch configuration (used by `nscd`).

- `svc:/system/name-service/cache:default`
  
  Legacy file: `/etc/nscd.conf`
  
  Name service cache (nscd).

- `svc:/network/dns/client:default`
  
  Legacy file: `/etc/resolv.conf`
  
  DNS naming service.

- `svc:/network/nis/domain:default`
  
  Legacy file: `/etc/defaultdomain`
  
  Legacy file: `/var/yp/binding/$DOMAIN/*`
  
  Shared NIS domain configuration. Used by all NIS services. Also (historical) shared use with LDAP naming services. Must be enabled when using `nis/client` or `ldap/client`.

- `svc:/network/nis/client:default`
  
  NIS client naming service (ypbind and related)

- `svc:/network/ldap/client:default`
  
  Legacy file: `/var/ldap/*`
  
  LDAP client naming service (`ldap_cachemgr` and related).
NIS server service (ypserv).
NIS server passwd service (rpc.yppasswd).
NIS server xfr service (ypxfrd)
NIS server update service (rpc.ypupdated)
Import legacy configuration files into SMF service.

Configuration for the following services is managed by location profiles:

svc:/system/name-service/switch:default
svc:/network/dns/client:default
svc:/network/nis/domain:default
svc:/network/nis/client:default
svc:/network/ldap/client:default

See netcfg(1M) for more information about location profiles.

These profiles are either fixed, meaning the network configuration is being managed in the traditional way, or reactive, meaning the network configuration is being managed automatically, reacting to changes in the network environment according to policy rules specified in the profiles.

When a fixed location (there can currently be only one, the DefaultFixed location) is active, changes made to the SMF repository, including those made by means of nscfg, will be applied to the location when it is disabled, and thus will be restored if that location is later re-enabled.

When a reactive location is active, changes should not be applied directly to the SMF repository; these changes will not be preserved in the location profile, and will thus be lost if the location is disabled, or if the system's network configuration, as managed by svc:/network/physical:default and svc:/network/location:default, is refreshed or restarted. Changes should instead be applied to the location itself, using the netcfg(1M) command; this will save the change to the location profile repository, and will also apply it to the SMF repository (if the change is made to the currently active location).

Sub-commands

The nscfg utility supports the subcommands described below. Options are described in the context of the subcommands.

import [-fvq] FMRI

If none of the SMF repository properties for the specified FMRI are currently populated, import the legacy configuration files associated with the specified FMRI into the SMF repository.
With `-f`, force the repopulation of the SMF repository with the legacy configuration, even if currently populated.

With `-v`, issue verbose progress messages during the requested operation. With `-q`, issue no error or other messages during the requested operation.

```
export [-vq] FMRI
```

Export the SMF configuration for the specified FMRI to legacy configuration files. This operation removes any existing affected legacy file(s) and generates new one(s) using the SMF configuration.

```
unconfig [-vq] FMRI
```

Unconfigure the SMF configuration for the specified FMRI. This operation resets the specified FMRI and any existing legacy file(s) to their initial unconfigured state.

With `-v`, issue verbose progress messages during the requested operation. With `-q`, issue no error or other messages during the requested operation.

```
validate [-vq] FMRI
```

Validate the SMF configuration for the specified FMRI. This operation checks the current configuration and verifies whether any errors exist.

With `-v`, issue verbose progress messages during the requested operation. With `-q`, issue no error or other messages during the requested operation.

### Examples

**EXAMPLE 1** Importing DNS Client Configuration

The following command imports the DNS client configuration, stored in `resolv.conf`, into the SMF repository.

```
# nscfg import svc:/network/dns/client:default
```

**EXAMPLE 2** Exporting SMF LDAP Client Configuration

The following command exports the SMF LDAP client configuration to the legacy configuration files in `/var/ldap`.

```
# nscfg export svc:/network/ldap/client:default
```

**EXAMPLE 3** Resetting Name Service Switch Configuration

The following command resets the name service switch configuration to its initial unconfigured state. The command generates no output and exits quietly with status only.

```
# nscfg unconfig -q svc:/system/name-service/switch:default
```

**EXAMPLE 4** Validating LDAP Client Configuration

The following command validates the LDAP client configuration for errors or inconsistencies. The command generates no output and exits quietly with status only.

```
# nscfg validate -q svc:/network/ldap/client:default
```
Exit Status
0
Command successfully executed.

1
An error occurred.

2
Configuration unmodified, no change necessary.

3
No configuration to import.

nsdb-list(1M)

**Name**  
nsdb-list, nsdb-nces, nsdb-resolve-fsn – FedFS observability utilities

**Synopsis**  
nsdb-nces [-l nsdb] [-r port]
nsdb-list [-l nsdb] [-r port] [-e nce]
nsdb-resolve-fsn [-l nsdb] [-r port] fsn

**Description**  
The tools described here permit observability into FedFS data stored in FedFS NSDBs (LDAP servers which store FedFS information).

nsdb-nces will list the naming contexts on the LDAP server that contains FedFS data, and the relative distinguished name of the FedFS container.

The nsdb-list command will list all FedFS data stored in the LDAP server, showing FedFS fileset names (FSNs) and all fileset locations (FSLs) for each.

nsdb-resolve-fsn will show the FSLs that correspond to the passed FSN.

**Examples**  
The following options are supported:

- **-l nsdb**  
  Specify the LDAP server implementing the NSDB.

- **-r port**  
  Specify the port on which the LDAP server implementing the NSDB is listening.

- **-e nce**  
  Specify the distinguished name of the container of FedFS information on the LDAP server implementing the NSDB; this will often be a single unambiguous location and need not be specified.

**Examples**  
**EXAMPLE 1 Using the NSDB Tools**

The following sequence of commands illustrates the use of all of the NSDB tools.

```bash
# nsdb-nces
Host: nsdb.cthon.org:389
  namingContext 'dc=cthon,dc=org' is a FedFS NCE, DI starts at ''

# nsdb-list
NSDB: nsdb.cthon.org:389, dc=cthon,dc=org
  FSN UUID: 7cc0bf04-5459-11e1-8083-80093d11d889
  FSL UUID: 7cc33c02-5459-11e1-8084-00093d11d889 = filer-a:/tmp
  FSN UUID: db48f160-5858-11e1-b459-80093d11d889
  FSL UUID: db4998c2-5858-11e1-b45a-00093d11d889 = filer-j:/tmp

# nsdb-resolve-fsn 7cc0bf04-5459-11e1-8083-80093d11d889
For FSN UUID 7cc0bf04-5459-11e1-8083-80093d11d889
  FSL UUID: 7cc33c02-5459-11e1-8084-00093d11d889 = filer-a:/tmp
  Location: filer-a:/tmp
```

System Administration Commands - Part 2 1753
Exit Status  0
    Successful completion.
   >0  An error occurred.

nsdbparams get
nsdbparams set [-r port] nsdb

**Description**
The nsdbparams command manages defaults and connection information for working with FedFS NSDBs (LDAP servers that store FedFS information).

The first form of the command, nsdbparams update, creates or updates a connection entry for the named NSDB. If the port number is not provided, the default LDAP port of 389 is used. If the NCE is not provided, the server will be queried to enumerate NCEs, and if only one is present it will be used. The LDAP bind DN must be provided if the entry is new. The LDAP bind password may be stored or not; if not stored, the password will be prompted for when needed. The `-w` form may be used to force prompting for a password to be stored instead of placing it on the command line.

The second form of the command, nsdbparams delete, removes a connection entry for nsdb:port or nsdb:389 if the port number is not provided.

The fourth form of the command, nsdbparams list, enumerates all connection entries.

The fifth form of the command, nsdbparams get, shows a system-wide default NSDB and port number.

The sixth form of the command, nsdbparams set, sets the system-wide default NSDB and port number, using the default LDAP port of 389 if one is not provided.

**Options**
The following options are supported:

- `-r port`
  Specify the port on which the LDAP server implementing the NSDB is listening.

- `-e nce`
  Specify the distinguished name of the container of FedFS information on the LDAP server implementing the NSDB; this will often be a single unambiguous location and need not be specified.

- `-D bind_DN`
  Specify the distinguished name of a user permitted to change the NSDB information.

- `-w bind_PW` | `-`
  Specify the password for the bind DN user; use of hyphen (-) will force prompting.
-t sectype
Specify the security level used to contact the LDAP server. Value values are
FEDFS_SEC_NONE, for no encryption, and FEDFS_SEC_TLS for a connection secured with
StartTLS (RFC 4513). If a TLS connection is to be used, the -f certfile argument must be
present or a certificate must already be stored.

-f certfile
Specify a TLS certificate to be used to secure a connection with RFC 4513 StartTLS when
FEDFS_SEC_TLS is used.

Examples
Example 1  Using nsdbparams to Set Up Communications
The following example sets up communications with an NSDB called nsdb.cthon.org and
makes it the default NSDB:

    # nsdbparams update -D cn=Manager,dc=cthon,dc=org -w cthon.org \
    nsdb.cthon.org
    # nsdbparams show nikon.us.example.com
    nikon.us.example.com:389
    default bind DN: cn=Manager,dc=cthon,dc=org
    default bind PW: cthon.org
    default NCE: dc=cthon,dc=org
    sectype: FEDFS_SEC_NONE
    # nsdbparams set nsdb.cthon.org
    # nsdbparams get
    default nsdb: nsdb.cthon.org
    default port: 389

Exit Status
0  Successful completion.
>
An error occurred.

The `nsdb-update-nci` command marks a distinguished name on an LDAP server as a container for FedFS data by adding the `fedfsNsdbContainerInfo` object class to the root of the naming context and setting the `fedfsNcePrefixR` attribute to point to the relative DN from the root of the naming context.

The following options are supported:

- `-l nsdb`
  Specify the LDAP server implementing the NSDB.

- `-r port`
  Specify the port on which the LDAP server implementing the NSDB is listening.

- `-D bind_DN`
  Specify the distinguished name of a user permitted to change the NSDB information.

- `-w bind_PW`
  Specify the password for the bind DN user; use of a hyphen (-) will force prompting.

The following operand is supported.

- `nce`
  The distinguished name of the container to be used to store FedFS information on the LDAP server implementing the NSDB.

**Examples**

**EXAMPLE 1  Using the Utility**

The following sequence illustrates the use of `nsdb-update-nci`.

```
# nsdb-update-nci -l localhost -r 389 -D cn=Manager -w cthon.org dc=cthon,dc=org adding new entry "dc=cthon,dc=org"
NCE entry created
```

```
# nsdb-nces Host: localhost:389
namingContext 'dc=cthon,dc=org' is a FedFS NCE, DIT starts at ''
```

**Exit Status**

0
  Successful completion.

1
  An error occurred.

**nslookup**

**Synopsis**

```bash
nslookup [-option] [name | -] [server]
```

**Description**

The `nslookup` utility is a program to query Internet domain name servers. It has two modes: interactive and non-interactive. Interactive mode allows the user to query name servers for information about various hosts and domains or to print a list of hosts in a domain. Non-interactive mode is used to print just the name and requested information for a host or domain.

**Parameters**

Interactive mode is entered in the following cases:

1. No arguments are given (the default name server is used).
2. The first argument is a hyphen (-) and the second argument is the host name or Internet address of a name server.

Non-interactive mode is used when the name or Internet address of the host to be looked up is given as the first argument. The optional second argument specifies the host name or address of a name server.

Options can also be specified on the command line if they precede the arguments and are prefixed with a hyphen. For example, to change the default query type to host information, and the initial timeout to 10 seconds, type:

```bash
nslookup -query=hinfo -timeout=10 host 
```

**Interactive Commands**

- **host** [server]
  Look up information for host using the current default server or using server, if specified. If host is an Internet address and the query type is A or PTR, the name of the host is returned. If host is a name and does not have a trailing period, the search list is used to qualify the name. To look up a host not in the current domain, append a period to the name.

- **server** domain
  Change the default server to domain; \server uses the initial server to look up information about domain, while \server uses the current default server. If an authoritative answer can't be found, the names of servers that might have the answer are returned.

- **root**
  Not implemented.

- **finger**
  Not implemented.

- **ls**
  Not implemented.

- **view**
  Not implemented.
help
  Not implemented.
?
  Not implemented.
exit
  Exits the program.

set keyword=value
  This command is used to change state information that affects the lookups. Valid keywords are:
  all
    Prints the current values of the frequently used options to set. Information about the current default server and host is also printed.
  class=value
    Change the query class to one of:
      IN
        the Internet class
      CH
        the Chaos class
      HS
        the Hesiod class
      ANY
        wildcard

    The class specifies the protocol group of the information.
    (Default = IN; abbreviation = cl)

[no]debug
  Turn on or off the display of the full response packet and any intermediate response packets when searching.
  (Default = nodebug; abbreviation = [no]deb)

[no]d2
  Turn debugging mode on or off. This displays more about what nslookup is doing.
  (Default = nod2)

domain=name
  Sets the search list to name.
[no]search
  If the lookup request contains at least one period but doesn't end with a trailing period, append the domain names in the domain search list to the request until an answer is received.
  (Default = search)

port=value
  Change the default TCP/UDP name server port to value.
  (Default = 53; abbreviation = po)

querytype=value
type=value
  Change the top of the information query.
  (Default = A; abbreviations = q, ty)

[no]recurse
  Tell the nameserver to query other servers if it does not have the information. (Default = recurse; abbreviation = [no]rec)

retry=number
  Set the number of retries to number.

timeout=number
  Change the initial timeout interval for waiting for a reply to number seconds.

[no]vc
  Always use a virtual circuit when sending requests to the server.
  (Default = novc)

[no]fail
  Try the next nameserver if a nameserver responds with SERVFAIL or a referral (nofail) or terminate query (fail) on such a response.
  (Default = novc)

Files
/etc/resolv.conf
  resolver configuration file

See the BIND 9 Administrator's Reference Manual. As of the date of publication of this man page, this document is available at https://www.isc.org/software/bind/documentation.

Notes  
BIND 9 nslookup is deprecated and not as full featured as its BIND 8 version. For more features and functionality refer to dig(1M).

nslookup and dig(1M) now report "Not Implemented" as NOTIMP rather than NOTIMPL. This will have impact on scripts that are looking for NOTIMPL.
nsupdate — Dynamic DNS update utility

Synopsis

nsupdate [-dv] [-y keynamesecret | -k keyfile] [-t timeout]
       [-u udptimeout] [-r udpretries] [filename]

Description

The nsupdate utility submits Dynamic DNS Update requests as defined in RFC 2136 to a
name server. This utility allows resource records to be added or removed from a zone without
manually editing the zone file. A single update request can contain requests to add or remove
more than one resource record.

Zones that are under dynamic control with nsupdate or a DHCP server should not be edited
by hand. Manual edits could conflict with dynamic updates and cause data to be lost.

The resource records that are dynamically added or removed with nsupdate must be in the
same zone. Requests are sent to the zone’s master servers identified by the MNAME field of the
zone’s SOA record.

Transaction signatures can be used to authenticate the Dynamic DNS updates using the TSIG
resource record type described in RFC 2845. The signatures rely on a shared secret that should
only be known to nsupdate and the name server. Currently, the only supported encryption
algorithm for TSIG is HMAC-MD5, which is defined in RFC 2104. Once other algorithms are
defined for TSIG, applications will need to ensure that they select the appropriate algorithm as
well as the key when authenticating each other. For instance, suitable key and server
statements would be added to /etc/named.conf so that the name server can associate the
appropriate secret key and algorithm with the IP address of the client application that will be
using TSIG authentication. The nsupdate utility does not read /etc/named.conf.

The nsupdate utility uses the -y or -k option to provide the shared secret needed to generate a
TSIG record for authenticating Dynamic DNS update requests. These options are mutually
exclusive. See OPTIONS.

Options

The following options are supported:

-d
  Operate in debug mode. This provides tracing information about the
  update requests that are made and the replies received from the name
  server.

-k keyfile
  Read the shared secret from the file keyfile, whose name is of the form
  K{name}.+157.+{random}.private. For historical reasons, the file
  K{name}.+157.+{random}.key must also be present.

-r udpretries
  Set the number of UDP retries. The default is 3 retries. If udpretries is
  set to zero, only one update request is made.

-t timeout
  Set timeout interval in seconds before update is aborted. The default is
  300 seconds. A setting of zero disables the timeout.

-u udptimeout
  Set interval in seconds between UDP retries, the default is 3 seconds. A
  setting of zero causes the interval to be calculated based on the timeout
  (-t) and the number of UDP retries (-r).
Use a TCP connection. Using a TCP connection could be preferable when a batch of update requests is made. By default, nsupdate uses UDP to send update requests to the name server.

`-y keyname:secret` Generate a signature from `keyname:secret`, where `keyname` is the name of the key and `secret` is the base64 encoded shared secret.

Use of the `-y` option is discouraged because the shared secret is supplied as a command line argument in clear text and could be visible in the output from `ps(1)` or in a history file maintained by the user's shell.

**Input Format**

The `nsupdate` utility reads input from `filename` or the standard input. Each command is supplied on exactly one line of input. Some commands are for administrative purposes. The others are either update instructions or prerequisite checks on the contents of the zone. These checks set conditions that some name or set of resource records (RRset) either exists or is absent from the zone. These conditions must be met if the entire update request is to succeed. Updates will be rejected if the tests for the prerequisite conditions fail.

Every update request consists of zero or more prerequisites and zero or more updates. This condition allows a suitably authenticated update request to proceed if some specified resource records are present or missing from the zone. A blank input line (or the `send` command) causes the accumulated commands to be sent as one Dynamic DNS update request to the name server.

The command formats and their meaning are as follows:

```
server servername [ port ]
```

Send all dynamic update requests to the name server `servername`. When no `server` statement is provided, `nsupdate` sends updates to the master server of the correct zone. The `MNAME` field of that zone's SOA record identifies the master server for that zone. The `port` argument is the port number on `servername` where the dynamic update requests get sent. If no port number is specified, the default DNS port number of 53 is used.

```
local address [ port ]
```

Send all dynamic update requests using the local `address`. When no `local` statement is provided, `nsupdate` sends updates using an address and port chosen by the system. The `port` argument can also be used to make requests come from a specific port. If no port number is specified, the system assigns one.

```
zone zonename
```

Specify that all updates are to be made to the zone `zonename`. If no `zone` statement is provided, `nsupdate` attempts to determine the correct zone to update based on the rest of the input.

```
class classname
```

Specify the default class. If no class is specified the default class is IN.
key name secret

Specify that all updates are to be TSIG signed using the name secret pair. The key command
overrides any key specified on the command line with -y or -k.

prereq nxdomain domain-name

Require that no resource record of any type exists with the name domain-name.

prereq yxdomain domain-name

Require that domain-name exists (has at least one resource record, of any type).

prereq nxrrset domain-name [ class ] type

Require that no resource record exists of the specified type, class and domain-name. If class
is omitted, IN (internet) is assumed.

prereq yxrrset domain-name [ class ] type

Require that a resource record of the specified type, class and domain-name must exist. If
class is omitted, IN (internet) is assumed.

prereq yxrrset domain-name [ class ] type data...

The data from each set of prerequisites of this form sharing a common type, class, and
domain-name are combined to form a set of RR. This set of RR must exactly match the set
of RR existing in the zone at the given type, class, and domain-name. The data are written
in the standard text representation of the resource record’s RDATA.

update delete domain-name [ ttl ] [ class ] [ type [ data... ] ]

Delete any resource records named domain-name. If type and data are provided, only
matching resource records are removed. The internet class is assumed if class is not
supplied. The ttl is ignored, and is only provided for compatibility.

update add domain-name ttl [ class ] type data...

Add a new resource record with the specified ttl, class and data.

show

Display the current message, containing all of the prerequisites and updates specified since
the last send.

send

Sends the current message. This is equivalent to entering a blank line.

answer

Displays the answer.

Lines beginning with a semicolon are comments and are ignored.

Examples

EXAMPLE 1 Inserting and Deleting Resource Records from the Zone

The examples below show how nsupdate could be used to insert and delete resource records
from the example.com zone. Notice that the input in each example contains a trailing blank
line so that a group of commands are sent as one dynamic update request to the master name
server for example.com.
EXAMPLE 1  Inserting and Deleting Resource Records from the Zone  (Continued)

# nsupdate
> update delete oldhost.example.com A
> update add newhost.example.com 86400 A 172.16.1.1
> send

Any A records for oldhost.example.com are deleted. An A record for newhost.example.com with IP address 172.16.1.1 is added. The newly-added record has a 1 day TTL (86400 seconds).

EXAMPLE 2  Adding CNAME Only If No Records Exist

The following command adds a CNAME only if no records already exist for it.

# nsupdate
> prereq nxdomain nickname.example.com
> update add nickname.example.com 86400 CNAME somehost.example.com
> send

The prerequisite condition gets the name server to check that there are no resource records of any type for nickname.example.com. If there are, the update request fails. If this name does not exist, a CNAME for it is added. This action ensures that when the CNAME is added, it cannot conflict with the long-standing rule in RFC 1034 that a name must not exist as any other record type if it exists as a CNAME. (The rule has been updated for DNSSEC in RFC 4035 to allow CNAMEs to have RSIG, DNSKEY, and NSEC records.)

Files  /etc/resolv.conf  used to identify default name server

K{name}.+157.+{random}.key  base-64 encoding of HMAC-MD5 key created by dnssec-keygen(1M).

K{name}.+157.+{random}.private  base-64 encoding of HMAC-MD5 key created by dnssec-keygen(1M)

Bugs  The TSIG key is redundantly stored in two separate files. This is a consequence of nsupdate using the DST library for its cryptographic operations and could change in future releases.

ntfscat – display NTFS files and streams on the standard output

Synopsis

ntfscat [options] device [file]

Description

The ntfscat command reads a file or stream from an NTFS volume and display the contents on the standard output.

The case of the filename passed to ntfscat is ignored.

Options

Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

-a, --attribute type

Display the contents of a particular attribute type. By default, the unnamed $DATA attribute will be shown. The attribute can be specified by a number in decimal or hexadecimal, or by name.

<table>
<thead>
<tr>
<th>Hex</th>
<th>Decimal</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x10</td>
<td>16</td>
<td>&quot;$STANDARD_INFORMATION&quot;</td>
</tr>
<tr>

<td>&quot;$PROPERTY_SET&quot;</td>
</tr>
<tr>
<td>0x100</td>
<td>256</td>
<td>&quot;$LOGGED_INFORMATION_STREAM&quot;</td>
</tr>
</tbody>
</table>

The attribute names can be specified without the leading dollar sign ($) symbol. If you use the $ symbol, you must quote the name to prevent the shell from interpreting the name.

-f, --force

Overrides some sensible defaults, such as not using a mounted volume. Use this option with caution.

-h, --help

Show a list of options with a brief description of each.

-i, --inode num

Specify a file by its inode number instead of its name.
-n, --attribute-name name
  Display the attribute identified by name.

-q, --quiet
  Suppress some debug, warning, and error messages.

-V, --version
  Show the version number, copyright, and license information.

-v, --verbose
  Display more debug, warning, and error messages.

Examples  EXAMPLE 1  Displaying Contents of File in Root
The following command displays the contents of a file in the root of an NTFS volume.

  # ntfscat /dev/dsk/c0d0p1 boot.ini

EXAMPLE 2  Displaying Contents of File in Subdirectory
The following command displays the contents of a file in a subdirectory of an NTFS volume.

  # ntfscat /dev/dsk/c0d0p1 /winnt/system32/drivers/etc/hosts

EXAMPLE 3  Display Contents of an Attribute
The following command displays the contents of the $INDEX_ROOT attribute of the root directory (inode 5).

  # ntfscat /dev/dsk/c0d0p1 -a INDEX_ROOT -i 5

ntfsclone --clone, image, restore, or rescue an NTFS filesystem

Synopsis

ntfsclone [options] source
ntfsclone --save-image [options] source
ntfsclone --restore-image [options] source
ntfsclone --metadata [options] source

Description

The ntfsclone utility efficiently clones (which includes copy, save, backup, and restore operations) or rescues an NTFS filesystem to a sparse file, an image, a device (partition), or to standard output. It works at disk sector level and copies only the written data (that is, not empty space). Unused disk space becomes zero (cloning to sparse file), encoded with control codes (saving in special image format), left unchanged (cloning to a disk/partition) or filled with zeros (cloning to standard output).

ntfsclone can be useful in making backups—taking an exact snapshot of an NTFS filesystem—and restoring it later on. It also can be used to test NTFS read/write functionality and allows you to troubleshoot users' issues using the clone, without the risk of destroying the original file system.

If not using the special image format (see section of the same name below), the clone is an exact copy of the original NTFS file system, from sector to sector. Thus, it can also be mounted just like the original NTFS filesystem. For example, if you clone to a file and the kernel has a loopback device and NTFS support, then the file can be mounted using:

```
# mount -t ntfs -o loop ntfsclone.img
```

Windows Cloning

You must exercise great care to copy, move or restore a system or boot partition to another computer, or to a different disk or partition (for example, /dev/dsk/c0d0p1 to /dev/dsk/c0d0p2, /dev/dsk/c0d0p1 to /dev/dsk/c0d1p1 or to a different disk sector offset).

Under most circumstances, to enable Windows to boot you must copy, move, or restore NTFS to the same partition that has the following characteristics as the original partition and disk:

- starts at the same sector
- on the same type of disk
- having the same BIOS legacy cylinder setting

The ntfsclone utility guarantees an exact copy of NTFS but does not deal with booting issues. This is by design: ntfsclone is a file system, not a system, utility. Its goal is only NTFS cloning, not Windows cloning. Because of this, ntfsclone can be used as a very fast and reliable building block for Windows cloning, but is not a complete answer. You can find useful tips on NTFS cloning at the NTFS web site, http://wiki.linux-ntfs.org.

Sparse Files

A file containing unallocated blocks (holes) is referred to as a "sparse file". The reported size of such files is always higher than the disk space consumed by them. The du(1) command reports the real disk space used by a sparse file. The holes are always read as zeros. All major Linux file
systems, such as, ext2, ext3, reiserfs, Reiser4, JFS, and XFS support sparse files. However, the ISO 9600 CD-ROM file system, as one example, does not.

**Special Image Format**

It is recommended that you save an NTFS filesystem to a special image format. Instead of representing unallocated blocks as holes, they are encoded using control codes. Thus, the image saves space without requiring sparse file support. The image format is ideal for streaming file system images over the network. The disadvantage of the special image format is that you cannot mount the image directly; you must first restore it.

To save an image using the special image format, use the `--save-image` option. To restore an image, use the `--restore-image` option. Note that you can restore images from standard input by using a hyphen (`-`) as the source file.

**Metadata-only Cloning**

Using the `--metadata` option, ntfsclone can save only the NTFS metadata and the clone still will be mountable. In this usage, all non-metadata file content is lost; reading back the data results in all zeros.

The metadata-only image can be compressed very well, usually to a size in the range of 1 to 8 MB. It is convenient to transfer such an image for investigation and troubleshooting.

In metadata-only mode, ntfsclone saves none of the user’s data, which includes the resident user’s data embedded into metadata. All is filled with zeros. Moreover, all the file timestamps, and deleted and unused spaces inside the metadata are filled with zeros. Thus, this mode is inappropriate, for example, for forensic analyses.

Note that filenames are not removed. Because a filename might contain sensitive information, consider the possibilities for breaches of security or privacy before sending out a metadata-only image.

**Options**

Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

- `-f`, `--force`
  Forces ntfsclone to proceed, even if the filesystem is marked "dirty" following a consistency check.

- `-h`, `--help`
  Show a list of options with a brief description of each one.

- `-i`, `--ignore-fs-check`
  Ignore the result of the file system consistency check. This option can be used only with the `--metadata` option. Any clusters that cause an inconsistency are saved.

- `-m`, `--metadata`
  Clone only metadata. With this option, you must clone only to a file.

- `-o`, `--output file`
  Clone NTFS to the non-existent file. If file is a hyphen (`-`), clone to the standard output.
-0, --overwrite file
   Clone NTFS to file, overwriting file if it already exists.

--rescue
   Ignore disk read errors so that a disk having bad sectors, for example, a failing disk, can be
   rescued with minimal impact on the disk. ntfsclone works at the lowest, sector level in
   this mode, enabling more data to be rescued. The contents of the unreadable sectors are
   filled with the question mark (?) character; the beginning of such sectors are marked by the
   string: BadSector.

-r, --restore-image source
   Restore from the special image format specified by source. If source is a hyphen (-), the
   image is read from the standard input.

-s, --save-image
   Save to the special image format. In terms of space usage and speed, this is the most efficient
   option if imaging is done to the standard output. This option is useful for image
   compression, encryption, or streaming through a network.

Examples
EXAMPLE 1 Cloning with Overwrite Option
   The following command clones with the --overwrite option.
   
   # ntfsclone --overwrite /dev/dsk/c0d2p1 /dev/dsk/c0d0p1

EXAMPLE 2 Saving to Special Image Format
   The following command clones to the special image format to its original partition.
   
   # ntfsclone --save-image --output backup.img /dev/dsk/c0d0p1

EXAMPLE 3 Restoring from a Special Image File
   The following command restores an NTFS from a special image file.
   
   # ntfsclone --restore-image --overwrite /dev/dsk/c0d0p1 backup.img

EXAMPLE 4 Saving to a Compressed Image
   The following command saves an NTFS to a compressed image file.
   
   # ntfsclone --save-image -o - /dev/dsk/c0d0p1

EXAMPLE 5 Restoring from a Compressed Image
   The following command restores an NTFS volume from a compressed image file.
   
   # gunzip -c backup.img.gz | 
   ntfsclone --restore-image --overwrite /dev/dsk/c0d0p1 -
**EXAMPLE 6**  Backing up to a Remote Host Using ssh

The following command backs up to a remote host, using `sshd`. Note that `sshd` will probably require a password.

```
# ntdsclone --save-image --output - /dev/dsk/c0d0p1 | 
    gzip -c | ssh host 'cat > backup.img.gz'
```

**EXAMPLE 7**  Restoring from a Remote Host Using ssh

The following command restores from a remote host, using `sshd`. Note that `sshd` will probably require a password.

```
# ssh host 'cat backup.img.gz' | gunzip -c | 
    ntdsclone --restore-image --overwrite /dev/dsk/c0d0p1 -
```

**EXAMPLE 8**  Streaming an Image File from a Web Server

The following command streams an image file from a web server and restore it to a partition.

```
# wget -qO - http://server/backup.img | 
    ntdsclone --restore-image --overwrite /dev/dsk/c0d0p1 -
```

**EXAMPLE 9**  Cloning to a New File

The following command clones an NTFS volume to a non-existent file.

```
# ntdsclone --output ntfs-clone.img /dev/dsk/c0d0p1
```

**EXAMPLE 10**  Packing NTFS Metadata

The following command packs NTFS metadata into an image file. Note that `bunzip2` takes a much longer time than `gzip`, but produces an archive that is up to ten times smaller than the latter produces.

```
# ntdsclone --metadata --output ntfsmeta.img /dev/dsk/c0d0p1 
bzip2 ntfsmeta.img
```

**EXAMPLE 11**  Unpacking NTFS Metadata

The following command unpacks NTFS metadata into a sparse file.

```
# bunzip2 -c ntfsmeta.img.bz2 | 
    cp --sparse=always /proc/self/fd/0 ntfsmeta.img
```

**Exit Status**  The return code is zero on success, non-zero otherwise.

ntfscluster(1M)

Name ntfscluster – identify files in a specified region of an NTFS volume

Synopsis ntfscluster [options] device

Description The ntfscluster utility has three modes of operation: info, sector, and cluster, described as follows.

Info
The default mode, info is currently not implemented. It will display general information about the NTFS volume when it is working.

Sector
The sector mode displays a list of files that have data in the specified range of sectors. This mode is put in effect by the --sector option.

Cluster
The cluster mode displays a list of files that have data in the specified range of clusters. When the cluster size is one sector, this is equivalent to the sector mode of operation. This mode is put in effect by the --cluster option.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

-c, --cluster range
Any files whose data is in this range of clusters will be displayed.

-F, --filename filename
Display information about filename.

-f, --force
Overrides some sensible defaults, such as not working with a mounted volume. Use this option with caution.

-h, --help
Show a list of options with a brief description of each.

-I, --inode num
Show information about this inode.

-i, --info
This option is not yet implemented.

-q, --quiet
Suppress some debug, warning, and error messages.

-s, --sector range
Any files whose data is in this range of sectors will be displayed.

-V, --version
Show the version number, copyright, and license information.
-v, --verbose
    Display more debug, warning, and error messages.

**Examples**

**EXAMPLE 1**  Displaying Information About a Volume
The following command displays information about the volume /dev/dsk/c0d0p1.

```
# ntfscluster /dev/dsk/c0d0p1
```

**EXAMPLE 2**  Displaying List of Files in a Cluster Range
The following command looks for files in the first 500 clusters of /dev/dsk/c0d0p1.

```
# ntfscluster -c 0-500 /dev/dsk/c0d0p1
```

ntfscmp(1M)

Name  ntfscmp – compare two NTFS file systems and report the differences

Synopsis  ntfscmp [options] device1 device2

Description  The ntfscmp utility compares all aspects of two NTFS file systems and reports all differences it finds. The file systems can be on block devices or in image files. ntfscmp can be used for volume verification. However, its primary purpose is to be an efficient development tool, used to quickly locate, identify, and check the correctness of the metadata changes made to NTFS.

If one is interested only in the NTFS metadata changes, it can be useful to compare the metadata images created by using the --metadata option of ntfsclo (1M) to eliminate the usually uninteresting timestamp changes.

The terse output of ntfscmp is intentional, because the provided information is sufficient to determine exact differences. More copious output can be obtained by using diff(1) to compare the verbose output of ntfsc (1M) for each reported inode.

Options  Supported options are listed below. Options have both single-letter and full-name forms.

- -h, --help
  Display help and exit.

- -P, --no-progress-bar
  Do not show progress bars.

- -v, --verbose
  Display more debug, warning, and error messages.

Exit Status  The exit code is 0 on success, non-zero otherwise.

ntfscp – copy file to an NTFS volume

Synopsis  

ntfscp  [options]  device  source_file  destination

Description  

The ntfscp utility copies files to an NTFS volume. destination (see Synopsis) can be either a file or a directory. If destination is a directory specified by name, source_file is copied into this directory. If destination is a directory specified by inode number, an unnamed data attribute is created for this inode and source_file is copied into it. Consider possible negative consequence before specifying a directory by inode number: it is unusual to have an unnamed data stream in a directory.

Data Streams  

All data on NTFS is stored in streams, which can have names. A file can have more than one data stream, but exactly one must have no name. The size of a file is the size of its unnamed data stream. Usually, when you do not specify a stream name, you are seeking access to the unnamed data stream. If you want access to a named data stream, you need to add :stream_name to the filename. For example, by opening some.mp3:artist you will open stream artist in some.mp3. In an operating system, such as Windows, that prevents you from accessing named data streams, you need to use some program like FAR or utilities from cygwin to access those streams.

Options  

Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

-a, --attribute num
Write to attribute designated by num.

-f, --force
Overrides some sensible defaults, such as not working with a mounted volume. Use this option with caution.

-h, --help
Show a list of options with a brief description of each one.

-i, --inode
Treat destination (see Synopsis) as inode number.

-N, --attr-name name
Write to attribute with this name.

-n, --no-action
Use this option to make a test run before doing the actual copy operation. Volume will be opened read-only and no write will be done.

-q, --quiet
Supress some debug, warning, and error messages.

-V, --version
Show the version number, copyright, and license information.
-v, --verbose
Display more debug, warning, and error messages.

Examples

Example 1  Copying from Home to Root Directory

The following command copies new_boot.ini from /home/user as boot.ini to the root of an
/dev/dsk/c0d0p1 NTFS volume.

```
# ntfscp /dev/dsk/c0d0p1 /home/user/new_boot.ini boot.ini
```

Example 2  Copying a Stream

The following command copies myfile to C:some\path\myfile:stream (assume that
/dev/dsk/c0d0p1 drive designator is C).

```
# ntfscp -N stream /dev/dsk/c0d0p1 myfile /some/path
```

Name  ntfsfix – fix common errors and force operating system to check NTFS

Synopsis  ntfsfix [options] device

Description  The ntfsfix utility fixes some common NTFS problems. Note that it is not a version of chkdsk. It repairs some fundamental NTFS inconsistencies, resets the NTFS journal file, and schedules an NTFS consistency check for the next reboot of the operating system.

Run ntfsfix on an NTFS volume if you think it was damaged by the operating system or in some other way and it cannot be mounted.

Options  Supported options are listed below.

  -h, --help
  Show a list of options with a brief description of each.

  -V, --version
  Show the version number, copyright, and license information.

Attributes  See attributes(5) for descriptions of the following attributes:

ntfsinfo(1M)

Name
ntfsinfo – dump a file's attributes

Synopsis
ntfsinfo [options] device

Description
The ntfsinfo utility dumps the attributes of inode inode-number or the file path-filename and/or information about the MFT (-m option). Run ntfsinfo without arguments for a full list of options.

Options
Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -f v is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

- F, --file file
  Show information about file.

- f, --force
  Overrides some sensible defaults, such as not overwriting an existing file. Use this option with caution.

- h, --help
  Show a list of options with a brief description of each.

- i, --inode num
  Show information about inode identified by num.

- m, --mft
  Show information about the volume.

- q, --quiet
  Suppress some debug, warning, and error messages.

- t, --notime
  Do not display timestamps in the output.

- V, --version
  Show the version number, copyright, and license information.

- v, --verbose
  Display more debug, warning, and error messages.

ntfslabel – display or change the label on an NTFS file system

Synopsis

ntfslabel [options] device [new_label]

Description

The ntfslabel utility displays or changes the file system label on the NTFS file system located on device (see Synopsis).

If the optional argument new_label is not present, ntfslabel displays the current file system label.

If the optional argument new_label is present, ntfslabel sets the file system label to be new_label. NTFS file system labels can be at most 128 Unicode characters long; if new_label is longer than 128 Unicode characters, ntfslabel truncates it and displays a warning message.

It is also possible to set the file system label using the -L option of mknfts(1M) during creation of the file system.

Options

Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

- f, --force
  Overrides some sensible defaults, such as not working with a mounted volume. Use this option with caution.

- h, --help
  Show a list of options with a brief description of each.

- n, --no-action
  Do not actually write a new label to disk.

- q, --quiet
  Suppress some debug, warning, and error messages.

- V, --version
  Show the version number, copyright, and license information.

- v, --verbose
  Display more debug, warning, and error messages.

### ntfsls(1M)

**Name**  
ntfsls – list directory contents on an NTFS file system

**Synopsis**  
ntfsls [options] device

**Description**  
The ntfsls utility lists information about the files specified by the PATH option (the root directory by default). *device* (see Synopsis) is the special file corresponding to the device (for example, /dev/dsk/c0d0p0num) or an NTFS image file.

**Options**  
Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

- `-a`, `--all`  
  Display all files. If this option is not specified file names in the POSIX namespace are not displayed.

- `-F`, `--classify`  
  Append one of the indicators shown below to entries.
  
  * `/` = @ |

- `-f`, `--force`  
  Force execution. For example, this option is necessary to run on an NTFS partition stored in a normal file.

- `-h`, `--help`  
  Display usage information and exit.

- `-i`, `--inode`  
  Display the inode number of each file. This is the MFT reference number, in NTFS terminology.

- `-l`, `--long`  
  Use a long listing format.

- `-p`, `--path path`  
  The directory whose contents to list or the file (including the path) about which to display information.

- `-q`, `--quiet`  
  Suppress some debug, warning, and error messages.

- `-R`, `--recursive`  
  Show the contents of all directories beneath the specified directory.

- `-s`, `--system`  
  Unless this option is specified, all files beginning with a dollar sign character will not be listed, as these files are usually system files.

- `-v`, `--verbose`  
  Display more debug, warning, and error messages.
-V, --version
  Display the nfts1s version number and exit.

-x, --dos
  Display short file names, that is, files in the DOS namespace, instead of long file names, that is, files in the WIN32 namespace.

Attributes

**ntfsprogs–listofNTFStools**

**ntfsprogs**

is the name of a suite of NTFS utilities based around a shared library. The tools are available for free and come with full source code. The tools are listed below.

- **mkntfs(1M)**
  - Create an NTFS filesystem.

- **ntfscat(1M)**
  - Dump a file's content to the standard output.

- **ntfsclone(1M)**
  - Efficiently clone, backup, restore, or rescue NTFS.

- **ntfscluster(1M)**
  - Locate the files that use the specified sectors or clusters.

- **ntfscmp(1M)**
  - Compare two NTFS filesystems and report the differences.

- **ntfscp(1M)**
  - Copy a file to an NTFS volume.

- **ntfsfix(1M)**
  - Check and fix some common errors, clear the log file, and make the operating system perform a thorough check next time it boots.

- **ntfsinfo(1M)**
  - Show information about NTFS or one of the files or directories within it.

- **ntfslabel(1M)**
  - Show, or set, an NTFS filesystem's volume label.

- **ntfsls(1M)**
  - List information about files in a directory residing on an NTFS.

- **ntfsmount(1M)** (not a SunOS man page)
  - Read-write NTFS user space driver.

- **ntfsresize(1M)**
  - Resize NTFS without losing data.

- **ntfsundelete(1M)**
  - Recover deleted files from NTFS.

ntfsresize – resize an NTFS file system without data loss

Synopsis

```bash
ntfsresize [options] --info device
ntfsresize [options] [--size size[k|M|G]] device
```

Description

The `ntfsresize` program safely resizes Windows XP, Windows Server 2003, Windows 2000, Windows NT4 and Longhorn NTFS file systems without data loss. All NTFS versions used by 32-bit and 64-bit Windows “operating systems” are supported. Defragmentation is not required prior to resizing, because `ntfsresize` can relocate any data if needed, without risking data integrity.

`ntfsresize` can be used to shrink or enlarge any NTFS file system located on an unmounted device (usually a disk partition). The new file system will have a size that you specify. The size parameter can have one of the optional modifiers k, M, G, denoting, respectively, kilobytes, megabytes, or gigabytes. `ntfsresize` conforms to the SI, ATA, an IEEE standards and the disk manufacturers by supporting k=10^3, M=10^6 and G=10^9.

If both `--info` and `--size` options are omitted then the NTFS file system will be enlarged to the underlying device size.

To resize a file system on a partition, you must resize both the file system and the partition, by editing the partition table on the disk. Similarly to other command-line file system resizers, `ntfsresize` does not manipulate the size of the partitions. To do that you must use a disk partitioning tool, such as `fdisk(1M)`. Alternatively, you could use one of the many user friendly partitioners that uses `ntfsresize` internally. Such partitioners include, among others, Mandriva’s DiskDrake, QTParted, SUSE/Novell’s YaST Partitioner, IBM’s EVMS, GParted, or Debian/Ubuntu’s Partman.

Back up your data and your partition table before using any partitioning tool. For an NTFS file system, you can use `ntfsclone(1M)` as a means of backup.

To shrink an NTFS partition, first use `ntfsresize` to shrink the size of the file system. Then use a utility such as `fdisk(1M)` to shrink the size of the partition by deleting the partition and recreating it with the smaller size. Do not make the partition smaller than the new size of NTFS; otherwise, you will not be able to boot from that partition. If you mistakenly made a too-small partition, you would have to recreate the partition to be as large as newly sized NTFS file system.

To enlarge an NTFS file system, you must first enlarge the size of the underlying partition. You can use `fdisk(1M)` to delete the partition and recreate it with a larger size. Make sure the newly sized partition does not overlap with any other partition. Then use `ntfsresize` to enlarge the file system.

When recreating a partition, make sure you create it at the same starting sector and with the same partition type as was used in the partition you are replacing. Otherwise, you will not be able to access your file system. Use the `fdisk u` command to switch from the default cylinder
unit to the reliable sector unit. Also, if the bootable flag was set in the old partition, make sure to set it in the recreated partition. Otherwise, you might not be able to boot from the new partition.

**Extended Description**

There are a handful of very rarely met restrictions in the use of `ntfsresize`. An example of such a restriction occurs with a file system stored on a disk having unknown bad sectors. Relocation of the first MFT extent and resizing into the middle of an $MFTMirr$ extent are not supported. These cases are detected and resizing is restricted to a safe size or the closest safe size is displayed.

Upon completion of a resizing, `ntfsresize` schedules an NTFS consistency check. In Windows, this check is performed by `chkdsk`. Upon the first subsequent reboot into Windows, you will note `chkdsk` running in a blue background. This is normal. Windows might force a quick reboot after the consistency check. Depending on your hardware configuration, Windows might alert you to a systems setting change and recommend or require a reboot. Acknowledge the message and reboot a second time.

**Options**

Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

- `-b`, `--bad-sectors`
  
  By default, `ntfsresize` exits upon encountering bad sectors. This option allows the utility to proceed in spite of such sectors.

  Prior using this option, it is strongly recommended that you use `ntfsclone(1M)` with the `--rescue` option to make a backup, then, in Windows, run `chkdsk /f /r volume` from the command line. If the disk guarantee displays as valid, then replace it, as it is defective. Note that no software can repair bad sector errors. The most that can be done is to work around these defects.

  This option has no effect if a disk has no bad sectors.

- `-f`, `--force`
  
  `ntfsresize` always marks a file system for consistency check before a real (not using `--no-action`) resize operation and it leaves that way for extra safety. Thus, if an NTFS file system was marked by `ntfsresize`, it is safe to use this option. You must use this option, if you need to resize several times without booting into Windows between each resizing step.

- `-h`, `--help`
  
  Display usage information and exit.

- `-i`, `--info`
  
  Used when you want to shrink a file system. Causes `ntfsresize` to determine the smallest shrunk file system size supported. Most of the time the smallest size is the space already used on the file system. `ntfsresize` does not shrink a file system to a smaller size than what is returned by this option. Depending on several factors, it might be unable to shrink to this...
theoretical size. Although the integrity of your data should be never at risk, it is nevertheless strongly recommended to make a test run by using the `-no-action` option before actual resizing.

Based on testing, the smallest attainable size is approximately space used in the file system plus 20–200 MB. Note also that Windows might need an additional 50–100 MB to boot safely.

This option never causes any changes to the file system; the partition is opened read-only.

- `-n, --no-action`
  Use this option to make a test run before doing the resize operation. Volume will be opened read-only and `ntfsresize` displays what it would do if it were to resize the file system. Proceed with the actual resizing only if the test run passed.

- `-P, --no-progress-bar`
  Do not display progress bars during `ntfsresize` operation.

- `-s, --size size[k|M|G]`
  Resize file system to `size` bytes. The new file system will have a size that you specify. The size parameter can have one of the optional modifiers `k`, `M`, `G`, denoting, respectively, kilobytes, megabytes, or gigabytes. `ntfsresize` conforms to the SI, ATA, an IEEE standards and the disk manufacturers by supporting `k=10^3`, `M=10^6` and `G=10^9`. Before performing an actual resizing, run `ntfsresize` with the `-no-action` option, along with this option, first.

- `-v, --verbose`
  Display copious output.

- `-V, --version`
  Display the version number of `ntfsresize`.

**Exit Status**
Display zero on success, non-zero otherwise.

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>

`fdisk(1M), ntfsclone(1M), parted(1M), attributes(5)`

http://wiki.linux-ntfs.org

**Notes**
In Linux version 2.6, with partitions that have been manipulated by `parted(1M)`, use of `ntfsresize` preceded corruption of partition tables, which resulted in unbootable Windows systems. This occurred even if the NTFS file system was consistent. This problem is independent of NTFS and, thus, `ntfsresize`. Moreover, `ntfsresize` never touches the
partition table. Under the conditions just described, you can, in the BIOS, change disk Access Mode to LBA to regain the ability to boot. For further discussion of this condition see the ntfsresize FAQ at: http://mlf.linux.rulez.org/maf/ezag/ntfsresize.html.

Authors ntfsresize was written by Szabolcs Szakacsits, with contributions from Anton Alpatarmakov and Richard Russon.
The `ntfsundelete` utility can, under the right circumstances, recover a deleted file from an NTFS volume. The command has three modes of operation:

**Scan**
The default mode, `scan`, simply reads an NTFS Volume and looks for files that have been deleted. It then displays a list, giving the inode number, name, and size of each deleted file.

**Undelete**
The undelete mode takes the files either matching the regular expression (option `-m`) or specified by the `inode-expressions` and recovers as much of the data as possible. It saves the result to another location.

**Copy**
The “wizard’s” option. Saves a portion of the MFT to a file, which can be useful when debugging `ntfsundelete`.

There are many circumstances under which `ntfsundelete` is unable to recover a file. For example, consider the following scenario. When a file is deleted the MFT Record is marked as not in use and the bitmap representing the disk usage is updated. If the power is not turned off immediately, the free space, where the file used to reside might get overwritten. Worse, the MFT Record might be reused for another file. If this happens, it is impossible to tell where the file was on disk.

Even if all the clusters of a file are not in use, there is no guarantee that they have not been overwritten by some short-lived file.

`ntfsundelete` cannot recover compressed or encrypted files. During a scan, it will display such a file as being 0% recoverable.

**Locale**
In NTFS, all filenames are stored as Unicode. A filename is converted into the current locale for display by `ntfsundelete`. The utility has successfully displayed Chinese pictogram filenames and then correctly recovered them.

**Extended MFT Records**
In rare circumstances, a single MFT Record will not be large enough to hold the metadata describing a file (a file would have to be in hundreds of fragments for this to happen). In these cases, one MFT record might hold the filename, while another will hold the information about the data. `ntfsundelete` will not try and piece together such records. It will simply list unnamed files with data.

**Recovered File's Size and Creation Date**
To recover a file, `ntfsundelete` has to read the file's metadata. Unfortunately, when a file is deleted, the metadata can be left in an inconsistent state. For example, the file size might be recorded as zero; the creation date of a file might be set to the time it was deleted or to a random time. In such situations, `ntfsundelete` picks the largest file size it finds and writes that to disk. It also tries to set the file's creation date to the last-modified date. This date might be the correct last modified date, or something unexpected.
**Options**

Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

- **-b, --byte num**
  Fill in the parts of unrecoverable file clusters with byte represented by `num`. The default is zeros.

- **-c, --case**
  Make filenames search, when attempting a match with the `--match` option, case-sensitive. The default filename search is case-insensitive.

- **-c, --copy range**
  This “wizard” option writes a block of MFT FILE records to a file. The default file is `.mft` which will be created in the current directory. This option can be combined with the `--output` and `--destination` options.

- **-d, --destination dir**
  Specify the location of the output file for the `--copy` and `--undelete` options.

- **-f, --force**
  Overrides some sensible defaults, such as not overwriting an existing file. Use this option with caution.

- **-h, --help**
  Show a list of options with a brief description of each one.

- **-i, --inodes range**
  Recover the files within the specified range of inode numbers. `range` can be a single inode number, several numbers separated by commas, or a range separated by a dash (`-`).

- **-m, --match pattern**
  Filter the output by looking only for filenames that match `pattern`. The pattern can include the wildcards `?`, matching exactly one character, or `*`, matching zero or more characters. By default, the matching is case-insensitive. To make the search case-sensitive, use the `--case` option.

- **-O, --optimistic**
  Recover parts of the file even if they are currently marked as in use.

- **-o, --output file**
  Set the name of the output file created by the `--copy` or `--undelete` options.

- **-P, --parent**
  Display the parent directory of a deleted file.

- **-p, --percentage num**
  Filter the output of the `--scan` option by matching only files with `num` percent of recoverable content.
-q, --quiet
Reduce the amount of output to a minimum. This option is not useful with the --scan option.

-s, --scan
Search through an NTFS volume and display a list of files that could be recovered. This is the default action of ntfsundelete. This list can be filtered by filename, size, percentage recoverable, or last modification time, using the --match, --size, --percent, and --time options, respectively.

In the output from this option, the %age (percentage) field displays how much of a file can potentially be recovered.

-S, --size range
Filter the output of the --scan option by looking for a particular range of file sizes. range can be specified as two numbers separated by a hyphen (-). A unit of size can be abbreviated using the suffixes k, m, g, and t, for kilobytes, megabytes, gigabytes, and terabytes respectively.

-t, --time since
Filter the output of the --scan option. Match only files that have been altered since this time. The time must be given as number and a suffix of d, w, m, or y for, respectively, days, weeks, months, or years.

-T, --truncate
The default behavior of ntfsundelete is to round up a file’s size to the nearest cluster (which will be a multiple of 512 bytes). In cases where the utility has complete data about the size of a file, this option restores the file to exactly that size.

-u, --undelete
Specifies undelete mode. You can specify the files to be recovered using by using --match or --inodes options. This option can be combined with --output, --destination, and --byte.

When the file is recovered it will be given its original name, unless the --output option is used.

-v, --verbose
Increase the amount of output that ntfsundelete displays.

-V, --version
Display the version number, copyright, and license for ntfsundelete.
EXAMPLE 2  Scanning for Files Matching a Wildcard
The following command searches for deleted files that match *.doc.

# ntsundelete /dev/dsk/c0d0p1 -s -m '*.doc'

EXAMPLE 3  Searching for Files of a Certain Size
The following command looks for deleted files between 5000 and 6000000 bytes, with at least 90% of the data recoverable, on /dev/dsk/c0d0p1.

# ntsundelete /dev/dsk/c0d0p1 -S 5k-6m -p 90

EXAMPLE 4  Searching for Recently Changed Files
The following command searches for deleted files altered in the last two days.

# ntsundelete /dev/dsk/c0d0p1 -t 2d

EXAMPLE 5  Specifying an Inode Range
The following command undeletes inodes 2, 5 and 100 to 131 of device /dev/sda1.

# ntsundelete /dev/sda1 -u -i 2,5,100-131

EXAMPLE 6  Specifying an Output File and Directory
The following command undeletes inode number 3689, names the file work.doc, and stores it in the user's home directory.

# ntsundelete /dev/dsk/c0d0p1 -u -i 3689 -o work.doc -d ~

EXAMPLE 7  Saving MFT Records
The following command saves MFT records 3689 to 3690 to a file debug.

# ntsundelete /dev/dsk/c0d0p1 -c 3689-3690 -o debug

nwamd(1M)

Name  nwamd – network auto-magic daemon

Synopsis  /lib/inet/nwamd

Description  nwamd is a system daemon to manage network interfaces.

This daemon is started automatically by the network/physical:default service and should not
be invoked directly. It does not constitute a programming interface.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>

smf(5)

See also nwan-manager(1M), available in the JDS/GNOME man page collection.

Notes  The networking service is managed by the service management facility, smf(5), under the
service identifier:

svc:/network/physical:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can
be performed using svcadm(1M). The service's status can be queried using the svcs(1)
command.
**Name**
obpsym – Kernel Symbolic Debugging for OpenBoot Firmware

**Synopsis**
modload -p misc/obpsym

**Description**
obpsym is a kernel module that installs OpenBoot callback handlers that provide kernel symbol information to OpenBoot. OpenBoot firmware user interface commands use the callbacks to convert numeric *addresses* to kernel symbol names for display purposes, and to convert kernel symbol names to numeric *literals* allowing symbolic names to be used as input arguments to user interface commands.

Once obpsym is installed, kernel symbolic names may be used anywhere at the OpenBoot firmware’s user interface command prompt in place of a literal (numeric) string. For example, if obpsym is installed, the OpenBoot firmware commands `ctrace` and `dis` typically display symbolic names and offsets in the form `modname:symbolname + offset`. User interface Commands such as `dis` can be given a kernel symbolic name such as `ufs:ufs_mount` instead of a numeric address.

Placing the command

```
forceload: misc/obpsym
```

into the `system(4)` file forces the kernel module `misc/obpsym` to be loaded and activates the kernel callbacks during the kernel startup sequence.

obpsym may be useful as a kernel debugger in situations where other kernel debuggers are not useful. For example, on SPARC machines, if obpsym is loaded, you may be able to use the OpenBoot firmware’s `ctrace` command to display symbolic names in the stack backtrace after a watchdog reset.

**Kernel Symbolic Name Syntax**
The syntax for a kernel symbolic name is:

```
[ module-name : ] symbol-name
```

Where *module-name* is the name of the kernel module that the symbol *symbol-name* appears in. A NULL module name is taken as “all modules, in no particular order” by obpsym. The module name `unix` is equivalent to a NULL module name, so that conflicts with words defined in the firmware’s vocabulary can be avoided.

Typically, OpenBoot firmware reads a word from the input stream and looks the word up in its internal *vocabulary* before checking if the word is a *literal*. Thus, kernel symbols, such as `reset` may be given as `unix:reset` to avoid the unexpected side effect of the firmware finding and executing a matching word in its vocabulary.

**Files**

```
/etc/system
/platform/platform-name/kernel/misc/obpsym
```

System configuration information file.
Platform-specific kernel symbol information.

OpenBoot 2.x Command Reference Manual

Warnings

Some OpenBoot firmware user interface commands may use system resources incompatibly with the way they are used by the Unix kernel. These commands and the use of this feature as a kernel debugger may cause interactions that the Unix kernel is not prepared to deal with. If this occurs, the Unix kernel and/or the OpenBoot firmware user interface commands may react unpredictably and may panic the system, or may hang or may cause other unpredictable results. For these reasons, the use of this feature is only minimally supported and recommended to be used only as a kernel debugger of last resort.

If a breakpoint or watchpoint is triggered while the console frame buffer is powered off, the system can crash and be left in a state from which it is difficult to recover. If one of these is triggered while the monitor is powered off, you will not be able to see the debugger output.

Notes

platform-name can be found using the -i option of uname(1)

obpsym is supported only on architectures that support OpenBoot firmware.

On some systems, OpenBoot must be completely RAM resident so the obpsym symbol callback support can be added to the firmware, if the firmware doesn’t include support for the symbol callbacks. On these systems, obpsym may complain that it requires that "you must use ramforth to use this module”.

See the OpenBoot 2.x Command Reference Manual for details on how to use the ramforth command, how to place the command into nvramrc, and how to set use-nvramrc to true. On systems with version 1.x OpenBoot firmware, nvramrc doesn't exist, and the ramforth command must be typed manually after each reset, in order to use this module.

Once installed, the symbol table callbacks can be disabled by using the following OpenBoot firmware command:

0 0 set-symbol-lookup
Name

oplhp - Hot plug daemon for SPARC Enterprise Server line

Synopsis

/usr/platform/SUNW,SPARC-Enterprise/lib/sparcv9/lib/oplhpd

Description

The hot plug daemon for SPARC Enterprise Servers is a daemon process that runs on the SUNW,SPARC-Enterprise family of servers. The daemon is started by the service management facility (see smf(5)) and communicates with the service processor when hot plug PCI cassettes change their dynamic reconfiguration state.

The service FMRI for oplhp is:

tc:/platform/sun4u/oplhpd:default

A domain supports only one running oplhp process at a time.

Errors

OPLHPD uses syslog(3C) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility.

Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_DEBUG priority. The default entries in the /etc/syslog.conf file log all of the OPLHPD error messages to the /var/adm/messages log.

svcs(1), inetadm(1M), svcadm(1M), syslog(3C), syslog.conf(4), attributes(5), smf(5)
parted(1M)

Name parted – partition manipulation program

Synopsis parted [options] [device [command [options ...]]]

Description parted is a disk partitioning and partition resizing program. It allows you to create, destroy, resize, move, and copy ext2, linux-swap, FAT, FAT32, and reiserfs partitions. It can create, resize, and move Macintosh HFS partitions, as well as detect jfs, ntfs, ufs, and xfs partitions. It is useful for creating space for new operating systems, reorganizing disk usage, and copying data to new hard disks.

This manual page documents parted briefly. Complete parted documentation is distributed with the package in “GNU Info” format.

parted is implemented with a set of top-level options and a set of subcommands, most of which have their own options and operands. These subcommands are described below.

parted has an optional operand:

device The block device to be used. When none is given, parted uses the first block device it finds.

If you invoke parted without an argument, the program displays a command prompt.

Options The following options are supported:

-a alignment-type, --align alignment-type
Sets alignment for newly created partitions. Valid alignment types are:

none Use the minimum alignment allowed by the disk type.

cylinder Align partitions to cylinders.

minimal Use minimum alignment as given by the disk topology information. This and the opt value will use layout information provided by the disk to align the logical partition table addresses to actual physical blocks on the disks. The min value is the minimum alignment needed to align the partition properly to physical blocks, which avoids performance degradation.

optimal Use optimum alignment as given by the disk topology information. This aligns to a multiple of the physical block size in a way that guarantees optimal performance.

-h, --help
Displays a help message.

-l, --list
Lists partition layout on all block devices.
-m, --machine
  Displays machine-parseable output.

-s, --script
  Never prompts for user intervention.

-v, --version
  Displays the version number.

**Sub-commands** If you omit a subcommand in a `parted` command line, the utility issues a command prompt.

- `check partition`
  Do a simple check on `partition`.

- `cp [source-device] source dest`
  Copy the source partition's filesystem on `source-device` (or the current device if no other device was specified) to the `dest` partition on the current device.

- `help command`
  Display general help, or help on a command, if specified.

- `mkfs partition fs-type`
  Make a filesystem of `fs-type` on `partition`. `fs-type` can be one of `fat16`, `fat32`, `ext2`, `linux-wap`, or `reiserfs`.

- `mklabel label-type`
  Create a new disk label (partition table) of `label-type`. `label-type` should be one of `bsd`, `dvh`, `gpt`, `loop`, `mac`, `msdos`, `pc98`, or `sun`.

- `mkpart part-type [fs-type] start end`
  Make a `part-type` partition with file system `fs-type` (if specified), beginning at `start` and ending at `end` (by default, in megabytes). `fs-type` can be one of `fat16`, `fat32`, `ext2`, `HFS`, `linux-swap`, `NTFS`, `reiserfs`, or `ufs`. `part-type` should be one of `primary`, `logical`, or `extended`.

- `mkpartfs part-type fs-type start end`
  Make a `part-type` partition with file system `fs-type`, beginning at `start` and ending at `end` (by default, in megabytes).

  Use of this subcommand is discouraged. Instead use `mkpart` to create an empty partition, and then use external tools such as `mk2fs (8)` (part of Linux) to create the filesystem.

- `move partition start end`
  Move partition so that it begins at `start` and ends at `end`. Note that `move` never changes the minor number.

- `name partition name`
  Set the name of partition to `name`. This option works only on Mac, PC98, and GPT disk labels. The name can be placed in quotes, if necessary.
Display the partition table.

Exit from parted.

Rescue a lost partition that was located somewhere between start and end. If a partition is found, parted will ask if you want to create an entry for it in the partition table.

Rescue the filesystem on partition so that it begins at start and ends at end (by default, in megabytes).

Delete partition.

Choose device as the current device to edit. device should usually be a Solaris or Linux hard disk device, but it can be a partition, software raid device, or an SVM or LVM logical volume if necessary.

Change the state of the flag on partition to state. Supported flags are: boot, root, swap, hidden, raid, lvm, lba, and palo. state should be either on or off.

Set unit as the unit to use when displaying locations and sizes, and for interpreting those given by the user when not suffixed with an explicit unit. unit can be one of s (sectors), B (bytes), kB, MB, GB, TB, % (percentage of device size), cyl (cylinders), chs (cylinders, heads, sectors), or compact (megabytes for input, and a human-friendly form for output).

Display version information and a copyright message.

fdisk(1M), mkfs(1M), attributes(5)

The parted program is fully documented in the info(1) format GNU partitioning software manual.
ext3 filesystem functionality does not currently work. To manage ext3 type filesystems use tools like resize2fs(8) or mke2fs(8) (both part of Linux). Note that the currently supported ext2 filesystem will be deprecated once ext3 support is finalized. Further note that ext3 support will have limited functionality that is yet to be defined. Use tools like resize2fs(8) and mke2fs(8) to manage these types of filesystems.

To manually resize an ext3 filesystem or a partition, use resize2fs(8), fdisk(8), or similar tools. For LVM situations, you will need to use the LVM commands to resize the LVM elements.

This manual page was written by Timshel Knoll for the Debian GNU/Linux system. It is here adapted for the Solaris operating system.
Name  
**pbind** – control and query bindings of processes or LWPs

Synopsis  
```bash
pbind -b processor_id pid [/lwpid]...
pbind [-q] [pid [/lwpid]]...
pbind -Q [processor_id]...
pbind -u pid [/lwpid]...
pbind -U [processor_id]...
```

Description  
**pbind** controls and queries bindings of processes and LWPs (lightweight processes) to processors. **pbind** can also remove processor bindings that were previously established.

When an LWP is bound to a processor, it will be executed only by that processor except when the LWP requires a resource that is provided only by another processor. The binding is not exclusive, that is, the processor is free to execute other LWPs as well.

Bindings are inherited, so new LWPs and processes created by a bound LWP will have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.

Superusers may bind or unbind any process or LWP, while other users can bind or unbind any process or LWP for which they have permission to signal, that is, any process that has the same effective user ID as the user.

Options  
The following options are supported:

- **-b processor_id**  
  Binds all or a subset of the LWPs of the specified processes to the processor `processor_id`. Specify `processor_id` as the processor ID of the processor to be controlled or queried. `processor_id` must be present and on-line. Use the `psrinfo` command to determine whether or not `processor_id` is present and on-line. See `psrinfo(1M)`.

- **-q**  
  Displays the bindings of the specified processes or of all processes. If a process is composed of multiple LWPs which have different bindings and the LWPs are not explicitly specified, the bindings of only one of the bound LWPs will be displayed. The bindings of a subset of LWPs can be displayed by appending “/lwpids” to the process IDs. Multiple LWPs may be selected using “,” and “,” delimiters. See EXAMPLES.

- **-Q**  
  Displays the LWPs bound to the specified list of processors, or all LWPs with processor bindings. For processes composed of multiple LWPs, the bindings of individual LWPs will be displayed.

- **-u**  
  Removes the bindings of all or a subset of the LWPs of the specified processes, allowing them to be executed on any on-line processor.
Removes the bindings of all LWPs bound to the specified list of processors, or to any processor if no argument is specified.

**Operands**
The following operands are supported:

- `pid`
  The process ID of the process to be controlled or queried.

- `lwpid`
  The set of LWP IDs of the specified process to be controlled or queried. The syntax for selecting LWP IDs is as follows:
  - `2,3,4-8`
    LWP IDs 2, 3, and 4 through 8
  - `-4`
    LWPs whose IDs are 4 or below
  - `4-`
    LWPs whose IDs are 4 or above

- `processor_id`
  The processor ID of the processor to be controlled or queried.

**Examples**

**EXAMPLE 1  Binding Processes**
The following example binds processes 204 and 223 to processor 2:

```
example% pbind -b 2 204 223
process id 204: was 2, now 2
process id 223: was 3, now 2
```

**EXAMPLE 2  Unbinding a Process**
The following example unbinds process 204:

```
example% pbind -u 204
```

**EXAMPLE 3  Querying Bindings**
The following example queries bindings. It demonstrates that process 1 is bound to processor 0, process 149 has at least one LWP bound to CPU3, and process 101 has no bound LWPs.

```
example% pbind -q 1 149 101
process id 1: 0
process id 149: 3
process id 101: not bound
```

**EXAMPLE 4  Querying LWP Bindings**
The following example queries bindings of LWPs. It demonstrates that LWP 1 of process 149 is bound to CPU3, and LWP 2 of process 149 is not bound.

```
example% pbind -q 149/1-2
lwp id 149/1: 3
lwp id 149/2: not bound
```
EXAMPLE 5  Querying LWP Bindings for Processor 2:
The following example queries all LWPs bound to processor 2:

    example% pbind -Q 2
    lwp id 149/4: 2
    lwp id 149/5: 2

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

See Also  psradm(1M), psrinfo(1M), psrset(1M), processor_bind(2), processor_info(2), sysconf(3C), attributes(5)

Diagnostics  pbind: cannot query pid 31: No such process  
              The process specified did not exist or has exited.

    pbind: cannot bind pid 31: Not owner  
              The user does not have permission to bind the process.

    pbind: cannot bind pid 31: Invalid argument  
              The specified processor is not on-line.
**Name**
pcitool – interrupt routing tool

**Synopsis**
/usr/sbin/pcitool -h

x86:
/usr/sbin/pcitool pci@unit-address -i cpu#,ino# | all [-r [-c] | -w cpu# [-g] | [-v] [-q]

SPARC:
/usr/sbin/pcitool pci@unit-address -i ino# | all [-r [-c] | -w cpu# [-g] | [-v] [-q]

/opt/sbin/pcitool pci@unit-address -m msi# | all [-r [-c] | -w cpu# [-g] | [-v] [-q]

**Description**
PCItool is a low-level tool that provides a facility for getting and setting interrupt routing information.

**Interrupt Routing**
The pcitool -i command displays device and CPU routing information for INOs on a given nexus, and allows rerouting of a given INO or INO group to a specific CPU.

On SPARC platforms, the INO is mapped to an interrupt mondo, where as one or more MSI/Xs are mapped to an INO. So, INO and MSI/Xs are individually retargetable. Use the -i option to retrieve or reroute a given INO; use the -m option for MSI/Xs.

Specifying cpu# is available on the x86 platform. In combination with ino#, this identifies an exclusive vector. The cpu# argument is not supported on the SPARC platform.

**Required Privileges**
A user must have all privileges in order to access interrupt information. A regular user can access interrupt information following an su(1M) to root or if he is granted the “Maintenance and Repair” rights profile in the user_attr file. See user_attr(4) and rbac(5).

**Options**
The following options are supported:

- **-h**
  Display command usage.

- **-q**
  No errors are displayed as messages. However, pcitool still returns Unix error codes.

- **-r [-c]**
  Display device and CPU routing information for INOs on a given nexus. The device path and instance number of each device for each displayed INO is displayed. On some platforms, interrupts dedicated to the root complex are indicated by the string (Internal) appended to their pathnames.

  With -c, dump interrupt controller information.

  If neither -r nor -w are provided on the command line, -r is assumed. See Examples.
```
-v
  Verbose output.
-w cpu# [-g]
  Route the given INO or MSI/X to the given CPU. Display the new and original routing information. The INO or MSI/X must be specified.

  On some platforms (such as x86) multiple MSI interrupts of a single function need to be rerouted together. Use -g to do this. The -g option works only on supported platforms and only for groups of MSI interrupts. (A "group" of 1 is accepted.) When -g is used, the vector provided must be the lowest-numbered vector of the group. The size of the group is determined internally. See Examples.

Examples

**EXAMPLE 1**  Displaying All INOs

The command for showing all INOs on /pci@0,0 is:

```
# pcitool /pci@0,0 -i all
```

**EXAMPLE 2**  Displaying Output for Specific INO

The command for showing INO 0x0,0x21 on the root nexus /pci@0,0 differs slightly between x86 and SPARC platforms.

On an x86 platform:

```
# pcitool /pci@0,0 -i 0,21
0x0,0x21: mpt 0
/pci@7b,0/pci1022,7458@11/pci1000,3060@2
```

On a SPARC platform:

```
# pcitool /pci@0,0 -i 21
0x0,0x21: mpt 0
/pci@7b,0/pci1022,7458@11/pci1000,3060@2
```

Output shown above is an example and might vary from your output.

**EXAMPLE 3**  Displaying Output for Specific MSI

The command for showing MSI 0x1 on the root nexus /pci@0,0, along with sample output, is shown below.

```
# pcitool /pci@0,0 -m 0x1
0x0,0x1: pcieb 0 /pci@7b,0/pci10de,5d@e
```

**EXAMPLE 4**  Rerouting an INO from One CPU to Another

Successful rerouting INO 21 from CPU 0 to CPU 1 produces the output shown below.

On an x86 platform:
```
EXAMPLE 4  Rerouting an INO from One CPU to Another (Continued)

```bash
# pcitool /pci@0,0 -i 0,21 -w 1
0x0,0x21 -> 0x1,0x20
```

On a SPARC platform:

```bash
# pcitool /pci@0,0 -i 21 -w 1
0x0,0x21 -> 0x1,0x20
```

EXAMPLE 5  Rerouting an MSI from One CPU to Another

Successful rerouting MSI 1 from CPU 1 to CPU 0 produces the output shown below.

```bash
# pcitool /pci@0,0 -m 1 -w 0
0x1,0x1 -> 0x0,0x1
```

EXAMPLE 6  Rerouting a Group of INOs

Successful rerouting of a group of INOs starting at 24 from CPU 0 to CPU 1 produces the output shown below.

On an x86 platform:

```bash
# pcitool /pci@0,0 -i 3,24 -w 1 -g
0x3,0x24 => 0x1,0x22
```

On a SPARC platform:

```bash
# pcitool /pci@0,0 -i 24 -w 1 -g
0x3,0x24 => 0x1,0x22
```

Exit Status

- 0
  - No error.
- EINVAL
  - Out-of-range, misaligned, or otherwise invalid argument has been passed in.
- ETIME
  - Timeout waiting for pending interrupt to settle before changing interrupts to a new CPU.
- E10
  - An I/O error occurred.

pfedit(1M)

**Name**  
pfedit – per-file authorized edit of administrative files

**Synopsis**  
pfedit [-r] file

**Description**  
The `pfedit` command allows authorized users to edit system configuration files. The `file` argument is a pathname of the file to be edited. If file is not an absolute pathname, the pathname of the current working directory is prepended, and all further processing proceeds as if that were the argument. The invoking user must have the authorization `solaris.admin.edit/path_to_file` or the blanket authorization `solaris.admin.edit`. The `pfedit` command allows use of symbolic links, by also checking for authorization for the `realpath(3C)` of file.

The `pfedit` command creates a copy of file owned by the invoking user, then invokes an editor on that file using the id and privileges of the invoking user. The default editor is `/usr/bin/vi`, but can be selected through the use of the `EDITOR` or `VISUAL` environment variable; if both are set, `VISUAL` has precedence. When the user exits the editor and if the copied file has been updated, the updated contents are applied atomically to file. All discretionary access attributes (owner, group, permissions and ACLs) of file are retained, together with any system or extended attributes on the original file. In any case, the user-owned file copy is removed before `pfedit` exits.

If file does not exist the file will be created with owner root, group root, and permissions 644 (`-rw-r--r--`), and then the previously described operations are applied that file. If `pfedit` has been used to create and modify file, the `-r` option can be used to remove file.

The `pfedit` command sets a discretionary lock on file, so that simultaneous updates by means of `pfedit` are prohibited.

The `pfedit` command is careful not to break hard links to other files. Since the atomic update requires replacement of the existing file with a new one with the updated contents, `pfedit` will refuse to operate on a file with a link count greater than one.

The `pfedit` command is restricted to editing text files, and will not accept updates which include non-text characters (NULs).

If configured, in the case of a successful update, an attempt to make unauthorized use, or if an error occurs, an audit record is generated to capture the subject, the file name, the authorization used, the file change if any, and the success or failure of the operation. The audit event type and default class is one of:

- `AUE_admin_edit:edit administrative file:as`
- `AUE_admin_file_create:create administrative file:as`
- `AUE_admin_file_remove:remove administrative file:as`

**Options**  
The following option is supported:

- `-r`
  Remove specified file (if file has been created by `pfedit`).
Examples

EXAMPLE 1  Creating a Profile

To create a profile with `solaris.admin.edit` authorization that can be assigned to users to modify `/etc/syslog.conf`, use the `profiles(1)` command.

```
% profiles -p "syslog Configure"
profiles: syslog Configure> set auths=solaris.admin.edit/etc/syslog.conf
profiles: syslog Configure> set desc="Edit syslog configuration"
profiles: syslog Configure> exit
```

EXAMPLE 2  Modifying /etc/syslog.conf

If a user has the "syslog Configure" profile as configured in the previous example then invoking:

```
# pfedit /etc/syslog.conf
```

...creates a copy of `/etc/syslog.conf` owned by that user, and by default invokes `/usr/bin/vi` running as that user on the copy. When the user exits the editor, `/etc/syslog.conf` is atomically updated with the contents saved by the user.

Exit Status  The `pfedit` command has an exit value of 0 if it completes successfully, and a non-zero value if any part of the operation fails.

Attributes  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Uncommitted</td>
</tr>
</tbody>
</table>

See Also  `auths(1), passwd(1), profiles(1), groupadd(1M), groupdel(1M), groupmod(1M), useradd(1M), userdel(1M), usermod(1M), fgetattr(3C), realpath(3C), attributes(5), fsattr(5)`

Notes  Oracle Solaris includes administrative configuration files for which use of `pfedit` and the `solaris.admin.edit/path_to_file` authorization is not recommended. Alternate commands exist which are both domain-specific and safer. For example, for the `/etc/passwd, /etc/shadow, or /etc/user_attr` files, use instead `passwd(1), useradd(1M), userdel(1M)`, or `usermod(1M)`. For the `/etc/group` file, use instead `groupadd(1M), groupdel(1M), or groupmod(1M)`. For updating `/etc/security/auth_attr, /etc/security/exec_attr, or /etc/security/prof_attr`, the preferred command is `profiles(1)`.

The ability to modify the contents of some configuration files can be used to escalate the privileges assigned to the user. Assignment of an authorization to edit such a file, or of a profile containing such an authorization, should be considered equivalent to providing full privileged access.
pginfo(1M)

Name  pginfo – display information about processor groups

           [pg ... | -c processor_id ...]
pginfo -s [-v] [-r string] [-R string] [pg ... | -c processor_id ...]
pginfo -c | -I [-r string] [-R string] [pg ... | -c processor_id ...]
pginfo -h

Description  The pginfo displays information about the Processor Group (PG) hierarchy, its contents, and its characteristics. A PG is a set of CPUs that are grouped together by a common characteristic.

PGs are used by the operating system to represent the CPUs that share performance relevant hardware such as the execution pipelines, caches, and so forth. These PGs are organized into a hierarchy that models the processor topology of the machine. In this hierarchy, each CPU (strand) has a leaf PG that represents the CPUs that share the most hardware with it. Each successive ancestor of the leaf PG shares progressively less hardware with the CPU until the root PG is reached. The root PG contains all of the CPUs in the system and represents the group of CPUs sharing the least hardware with each other. (See EXAMPLES below for an example of PG hierarchy.)

If a machine does not have any performance-relevant hardware sharing relationships, then pginfo displays only a root PG that contains all of the CPUs in the system.

By default, pginfo displays information about each PG in the system, including its PG ID, sharing relationship, and online and offline CPUs. It displays the PGs in depth first order by default and uses indentation to help show how the PGs are related to each other (see EXAMPLES below).

You can specify options to:

- Display the PG hierarchy graphically
- List the PG sharing relationships that exist on the running system
- Give current PG utilization information, specifying PGs of interest by PG ID, CPU ID, or sharing relationship
- Specify that only CPU or PG IDs be displayed

In addition, there is a -p option to show which PGs contain the CPUs that correspond to the CPUs with a common physical relationship such as system, chip, and core. These physical relationships describe the physical characteristics of the CPUs and might or might not encapsulate performance-relevant processor sharing relationships.

If the system configuration repeatedly changes when pginfo is obtaining a snapshot of system data, pginfo displays an error message and terminates with exit status 1.

System Administration Commands - Part 2
Options  The following options are supported:

- `c processor_id ...`
  Interpret arguments as processor IDs and display only information about PGs that contain the specified processors.

  When used with the `-T` option, this option limits the PG hierarchy displayed to include only the lineage of each of the specified CPUs. This option cannot be used when specifying PGs of interest by PG ID.

- `C`
  Display only CPU IDs for all CPUs belonging to the PGs. This option cannot be used at the same time as the `-I` option.

- `h`
  Display short help message and exit with exit status 0.

- `I`
  Display only PG IDs for the PGs. This option cannot be used at the same time as the `-C` option.

- `p`
  Display the physical relationship that corresponds to a PGs. If a PG has the same CPUs as the whole system, a processor core, or a chip, `system`, `core`, or `chip` will be displayed, as appropriate, after the sharing relationship of the PG in square brackets ("[ ]").

- `r string1,string2,...`
  Display only information about PGs with a sharing relationship name that matches any of the specified strings.

  Each specified string can be a whole relationship name or a portion of one or more relationship names and the string matching is case-insensitive. The possible relationship names are in the list of sharing relationships that the `-s` option displays.

  You can specify multiple `-r` options, which results in matching all PGs with a relationship name that contain any of the specified strings. When used with the `-T` option, this option limits the PG hierarchy displayed to include only the lineage of each of the PGs with the specified relationship.

- `R string1,string2,...`
  Display only information about PGs with a sharing relationship name other than the one(s) specified.

  String matching is the same as described above for the `-r` option. Multiple `-R` options can be entered.

- `s`
  Display all sharing relationships supported on the running system for the specified PGs. The `-v` option can be used with this option to get the list of PGs for each sharing relationship.
In the resulting hierarchy, the lineage of each CPU (hardware strand) is arranged from the PGs that share the most hardware in common with the CPU to the PGs that share the least with the CPU. If any CPUs, PGs, or relationships of interest are specified, the resulting PG hierarchy is limited to the lineages of the PGs with the specified CPUs, PGs, or relationships in the PG hierarchy.

**-v**
Verboso mode. Display additional information about PGs. When used without -s, -C, or -I, it is equivalent to giving the -T and -p options together at the same time. When used with the -s option, it gives the list of PGs for each sharing relationship.

**Operands**
The following operands can be given on the command line by specifying one or more of their corresponding IDs or the keyword all. Multiple IDs can be specified as a space-separated list (for example, 1 3), a range of numbers (for example, 5-8), or both (for example, 1 3 5-8 13-16). PGs and CPUs cannot be specified at the same time.

- `pg` PGs of interest can be specified on the command line by PG ID.
- `processor_id` When the -c option is entered, CPUs of interest can be specified on the command line by CPU ID.

If an invalid PG or CPU is specified, the `pginfo` command displays a message on standard error showing the invalid ID and continues processing other PGs or CPUs specified on the command line. When none of the specified PGs or CPUs are valid, `pginfo` exits with an exit status of 2.

**Examples**
In the examples below, the system contains one UltraSPARC T1 processor chip with 8 cores and 32 strands.

**EXAMPLE 1** Displaying Information About Every PG
The following command, using no arguments, displays information about every PG.

```bash
$ pginfo
PG RELATIONSHIP CPUs
0 System 0-31
3 Data_Pipe_to_memory 0-31
2 Floating_Point_Unit 0-31
1 Integer_Pipeline 0-3
4 Integer_Pipeline 4-7
5 Integer_Pipeline 8-11
6 Integer_Pipeline 12-15
7 Integer_Pipeline 16-19
8 Integer_Pipeline 20-23
9 Integer_Pipeline 24-27
10 Integer_Pipeline 28-31
```
EXAMPLE 2  Displaying Information About All Sharing Relationships

The following command displays information about all sharing relationships.

```
$ pginfo -s -v

RELATIONSHIP
----------- -------
System 0
Data_Pipe_to_memory 3
Floating_Point_Unit 2
Integer_Pipeline 1 4-10
```

EXAMPLE 3  Displaying PG Hierarchy

The following command displays general information about all PGs in the system. The output shows which PGs belong to chips and cores.

```
$ pginfo -p -T

0 (System) CPUs: 0-31
  '-- 3 (Data_Pipe_to_memory [system,chip]) CPUs: 0-31
   '-- 2 (Floating_Point_Unit [system,chip]) CPUs: 0-31
      |-- 1 (Integer_Pipeline [core]) CPUs: 0-3
      |-- 4 (Integer_Pipeline [core]) CPUs: 4-7
      |-- 5 (Integer_Pipeline [core]) CPUs: 8-11
      |-- 6 (Integer_Pipeline [core]) CPUs: 12-15
      |-- 7 (Integer_Pipeline [core]) CPUs: 16-19
      |-- 8 (Integer_Pipeline [core]) CPUs: 20-23
      |-- 9 (Integer_Pipeline [core]) CPUs: 24-27
     '-- 10 (Integer_Pipeline [core]) CPUs: 28-31
```

EXAMPLE 4  Displaying List with Specific Criterion

The following command displays a list of CPUs sharing integer pipeline with CPU 0. This example also demonstrates the use of -r option to filter PGs by sharing relationship name.

```
$ pginfo -r integer_pipeline -C -c 0
0 1 2 3
```

EXAMPLE 5  Using Option to Exclude by Specific Criterion

The following command lists all PGs other than the ones that have Integer_Pipeline as their relationship.

```
$ pginfo -R Integer_Pipeline

PG RELATIONSHIP CPUs
0 System 0-31
3 Data_Pipe_to_memory 0-31
2 Floating_Point_Unit 0-31
```
Exit Status  0
   Successful completion.
  1
   An error occurred.
  2
   Invalid syntax.

## Description

The `pgstat` displays utilization statistics about Processor Groups (PGs). A PG is a set of CPUs that are grouped together by a common characteristic.

PGs are used by the operating system to represent CPUs that share performance relevant hardware, such as execution pipelines, caches, and so forth. These PGs are organized into a hierarchy that models the processor topology of the machine. In this hierarchy, each CPU (strand) has a leaf PG that represents the CPUs that share the most hardware with it. Each successive ancestor of the leaf PG shares progressively less hardware with the CPU until the root PG is reached. The root PG contains all of the CPUs in the system and represents the group of CPUs sharing the least hardware with each other. (See “Examples” below for an example of PG hierarchy).

If a machine does not have any performance-relevant hardware sharing relationships, then `pgstat` displays only a root PG that contains all of the CPUs in the system.

By default, `pgstat` does the following:

- Measures the hardware and software utilization of all PGs in the PG hierarchy over a one second interval.
- Displays the utilization of the PGs in depth first order using indentation to help show how the PGs relate to each other.
- Displays the ID, sharing relationship, hardware load, software load, and online CPUs for each PG at the end of each interval.

The interval and count can be given as arguments to specify the number of seconds in the sampling interval and number of times to measure and display the utilization for the specified PGs.

You can specify options to further tailor the output, organize the output a certain way, and specify PGs of interest (see “Options” below for details).

A hyphen ("-"") is displayed when the utilization for a given PG is not supported and a question mark (?) is displayed when the utilization is not available. On systems where the CPU hardware performance counters are needed to measure the hardware utilization, the hardware utilization might be unavailable because the counters are being used by a `cpc(3CPC)` consumer such as `attributes(5)`, `cputrack(1)`, `dtrace(1M)`, or another application that uses `libcpc(3LIB)`.

### Synopsis

```
[-r string] [-R string] [-P pg ...] [-c processor_id ...]
[interval [count]]
```
Options

The following options are supported:

- A
  Display summary of utilization data when pgstat is run over multiple intervals.

- c processor_id...
  Display utilization about PGs that contain the specified CPUs. The CPUs can be specified as a comma separated list of CPU IDs. A hyphen ("-"; ) can be used to specify contiguous ranges of CPU IDs (for example, 0 - 3).

- C
  Display utilization of each CPU in each PG.

- h
  Display short help message and exit with exit status 0.

- p
  Display the physical relationship that corresponds to a PG. If a PG has the same CPUs as the whole system, a processor core, or a chip, system, core, or chip, as appropriate, is displayed after the sharing relationship of the PG in square brackets (" [ ]").

- P pg,...
  Display utilization for specified PGs. Multiple PGs can be specified as a comma-separated list of PG IDs. A hyphen ("-"; ) can be used to specify a contiguous range of PG IDs (for example, 0 - 3).

- r string1,string2,...
  Display utilization only for PGs with a sharing relationship name that matches any of the specified strings. The string can be a whole relationship name or a portion of one or more relationship names. The string matching is case-insensitive.

  Multiple - r options can be entered, which results in matching all PGs with a relationship name that matches any of the specified strings.

- R string1,string2,...
  Display information only about PGs with a sharing relationship name other than the one(s) specified.

  String matching is the same as described above for the - r option. Multiple - R options can be entered.

- s key
  Sort output lines by the specified key in descending order. The specified key can be one of the following:

  - pg
    Sort by PG ID.

  - hwLoad
    Sort by hardware utilization.
swload
   Sort by software utilization.

user
   Sort by user time.

sys
   Sort by system time.

idle
   Sort by idle time.

depth
   Sort by descending PG tree from root to leaves, depth-first (default).

breadth
   Sort by descending PG tree from root to leaves, breadth-first.

-S key
   Sort output lines by the specified key in ascending order. Possible key values are the same as for the -s option.

-t number
   Show the top number of PGs for the specified integer number.

-T u | d
   Display timestamp for each sampling interval in Unix time (see time(2)) or the standard date format used by date(1).

-v
   Display extra information about each PG including hardware utilization and capacity and software user, system, and idle times.

**Output Headings**  
Pgstat displays the column headings, which are listed below, along with the meanings of those headings.

PG
   Processor Group ID.

RELATIONSHIP
   Sharing relationship for PG.

HW
   Hardware load in percent (calculated as UTIL/CAP for interval).

UTIL
   Hardware utilization of PG’s shared hardware component over the interval. This can be a large number, so K, M, B, and T are used for denoting thousand, million, billion, and trillion, respectively.
CAP
Approximate maximum possible utilization for PG's shared hardware component over the interval. This can be a large number, so K, M, B, and T are used for denoting thousand, million, billion, and trillion, respectively.

SW
Software load in percent (calculated as (USR + SYS) / (USR + SYS + IDLE))

USR
Percentage of time that software threads ran in user mode on CPUs in PG during interval.

SYS
Percentage of time that software threads ran in system mode on CPUs in PG during interval.

IDLE
Percentage of time that no software threads ran on CPUs in PG during interval.

CPUS
CPU IDs for CPUs in PG.

Examples
In the following examples, the system contains one UltraSPARC T1 processor chip with 8 cores and 32 strands.

EXAMPLE 1  Displaying Utilization for Specified Period
The following command displays utilization for all PGs over the last two seconds.

$ pgstat 1 2
PG RELATIONSHIP HW SW CPUS
0 System - 0.4% 0-31

The Platform Information and Control Library (PICL) provides a mechanism to publish platform-specific information for clients to access in a platform-independent way. picld maintains and controls access to the PICL information from clients and plug-in modules. The daemon is started in both single-user and multi-user boot mode.

Upon startup, the PICL daemon loads and initializes the plug-in modules. These modules use the libpicltree(3PICLTREE) interface to create nodes and properties in the PICL tree to publish platform configuration information. After the plug-in modules are initialized, the daemon opens the PICL daemon door to service client requests to access information in the PICL tree.

The PICL tree is the repository of all the nodes and properties created by the plug-in modules to represent the platform configuration. Every node in the PICL tree is an instance of a well-defined PICL class. The name of the base PICL class is picl, which defines a basic set of properties that all nodes in the tree must possess. Two of those properties are name and _class, where name contains the name of the node, and the _class contains the PICL class name of the node. Certain nodes in the PICL tree have well-known names. For example, the name of the root node of the PICL tree is / and the name of the root node of the sub-tree containing platform device nodes is platform.

The PICL plug-in modules are shared objects that publish platform-specific data in the PICL tree. They are located in well-known directories so that the daemon can locate and load them. Plug-in modules are located in one of the following plug-in directories depending on the platform-specific nature of the data that they collect and publish:

```
/usr/platform/uname -i/lib/picl/plugins
/usr/platform/uname -m/lib/picl/plugins
```

A plug-in module can specify its dependency on another plug-in module using the -l or -R linker option. The plug-ins are loaded by the daemon using dlopen(3C) according to the specified dependencies. Each plug-in module must define a .init section, which is executed when the plug-in module is loaded, to register themselves with the daemon. See picld_plugin_register(3PICLTREE) for additional information on plug-in registration.

The plug-in modules use the libpicltree(3PICLTREE) interface to publish nodes and properties in the PICL tree so that clients can access them.

When the PICL daemon invokes the initialization routine of the plug-in module, the plug-in collects the platform information and creates nodes and/or properties to represent the configuration in the PICL tree. A plug-in can create additional threads to monitor the platform configuration and update the PICL tree with any changes. This enables a PICL plug-in to operate as a daemon within the PICL framework.
An environmental monitor is an example of a plug-in module that uses a thread to monitor the temperatures and fan speeds of the platform, then publishes the environmental information in the PICL tree so clients can access them.

Clients use the `libpicl(3PICL)` interface to send requests to `picld` for accessing the PICL tree.

**Exit Status**
`picld` does not return an exit status.

**Files**
/var/run/picld_door  PICAL daemon door
/usr/lib/picl/picld  PICAL daemon

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>

**Notes**
The `picld` service is managed by the service management facility, `smf(5)`, under the service identifier:

svc:/system/picl

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
ping – send ICMP (ICMP6) ECHO_REQUEST packets to network hosts

**Synopsis**

```
/usr/sbin/ping host [timeout]
```

```
/usr/sbin/ping -s [-l | -U] [-aL] [-A addr_family]
    [-c traffic_class] [-g gateway [-g gateway...]]
    [-N next_hop_router] [-F flow_label] [-I interval]
    [-i interface] [-P tos] [-p port] [-t ttl] host
    [data_size] [npackets]
```

**Description**

The utility `ping` utilizes the ICMP (ICMP6 in IPv6) protocol's ECHO_REQUEST datagram to elicit an ICMP (ICMP6) ECHO_RESPONSE from the specified `host` or network `gateway`. If `host` responds, `ping` will display:

```
host is alive
```

...on the standard output and exit. Otherwise, after `timeout` seconds, it will write:

```
o answer from host
```

The default value of `timeout` is 20 seconds.

When you specify the `-s` flag, sends one datagram per second (adjust with `-I`) and prints one line of output for every ECHO_RESPONSE that it receives. `ping` produces no output if there is no response. In this second form, `ping` computes round trip times and packet loss statistics; it displays a summary of this information upon termination or timeout. The default data_size is 56 bytes, or you can specify a size with the `data_size` command-line argument. If you specify the optional `npackets`, `ping` sends `ping` requests until it either sends `npackets` requests or receives `npackets` replies.

When using `ping` for fault isolation, first `ping` the local host to verify that the local network interface is running.

**Options**

The following options are supported:

- `-A addr_family`
  Specify the address family of the target host. `addr_family` can be either `inet` or `inet6`. Address family determines which protocol to use. For an argument of `inet`, IPv4 is used. For `inet6`, IPv6 is used.

  By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, `ping` will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.

  Specify the address family `inet` or `inet6` to override the default behavior. If the argument specified is `inet`, `ping` will use the IPv4 address associated with the host name. If none exists, `ping` will state that the host is unknown and exit. It does not try to determine if an IPv6 address exists in the name service database.

  If the specified argument is `inet6`, `ping` uses the IPv6 address that is associated with the host name. If none exists, `ping` states that the host is unknown and exits.
-F flow_label
  Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.

-D
  Turn off fragmentation. For IPv4, this means setting the Don't Fragment bit. For IPv4 and IPv6, this means do not allow fragmentation as the datagrams are sent. If the data_size exceeds the MTU, then ping might report that sending failed due to Message too long.

-I interval
  Turn on the statistics mode and specify the interval between successive transmissions. The default is one second. See the discussion of the -s option.

-L
  Turn off loopback of multicast packets. Normally, members are in the host group on the outgoing interface, a copy of the multicast packets will be delivered to the local machine.

-N next_hop_router
  Specify a next-hop router so that the probe packet goes through the specified router along its path to the target host. This option essentially bypasses the system routing table and leaves the probe packet header unmodified. Only one next-hop router can be specified.

-P tos
  Set the type of service (tos) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways also in the path can route the probe packet differently, depending upon the value of tos that is set in the probe packet. This option is valid only on IPv4.

-R
  Record route. Sets the IPv4 record route option, which stores the route of the packet inside the IPv4 header. The contents of the record route are only printed if the -v and -s options are given. They are only set on return packets if the target host preserves the record route option across echos, or the -l option is given. This option is valid only on IPv4.

-U
  Send UDP packets instead of ICMP (ICMP6) packets. ping sends UDP packets to consecutive ports expecting to receive back ICMP (ICMP6) PORT_UNREACHABLE from the target host.

-a
  ping all addresses, both IPv4 and IPv6, of the multihomed destination. The output appears as if ping has been run once for each IP address of the destination. If this option is used together with -A, ping probes only the addresses that are of the specified address family. When used with the -s option and npackets is not specified, ping continuously probes the destination addresses in a round robin fashion. If npackets is specified, ping sends npackets number of probes to each IP address of the destination and then exits.
- b
  Bypass the global IPsec policy and send and receive packets in the clear for this connection
  only. This option can be used to troubleshoot network connectivity independent of IPsec.
  Because this option bypasses system-wide policy for this connection, it can only be used by
  superuser or a user granted the sys_net_config privilege.

- c traffic_class
  Specify the traffic class of probe packets. The value must be an integer in the range from 0 to
  255. Gateways along the path can route the probe packet differently, depending upon the
  value of traffic_class set in the probe packet. This option is valid only on IPv6.

- d
  Set the SO_DEBUG socket option.

- g gateway
  Specify a loose source route gateway so that the probe packet goes through the specified
  host along the path to the target host. The maximum number of gateways is 8 for IPv4 and
  127 for IPv6. Note that some factors such as the link MTU can further limit the number of
  gateways for IPv6.

- i interface_address
  Specify the outgoing interface address to use for multicast packets for IPv4 and both
  multicast and unicast packets for IPv6. The default interface address for multicast packets
  is determined from the (unicast) routing tables. interface_address can be a literal IP
  address, for example, 10.123.100.99, or an interface name, for example, en10, or an
  interface index, for example 2.

- l
  Use to send the probe packet to the given host and back again using loose source routing.
  Usually specified with the -R option. If any gateways are specified using - g, they are visited
  twice, both to and from the destination. This option is ignored if the -U option is used.

- n
  Show network addresses as numbers. ping normally does a reverse name lookup on the IP
  addresses it extracts from the packets received. The - n option blocks the reverse lookup, so
  ping prints IP addresses instead of host names.

- p port
  Set the base UDP port number used in probes. This option is used with the -U option. The
  default base port number is 33434. The ping utility starts setting the destination port
  number of UDP packets to this base and increments it by one at each probe.

- r
  Bypass the normal routing tables and send directly to a host on an attached network. If the
  host is not on a directly attached network, an error is returned. This option can be used to
  ping a local host through an interface that has been dropped by the router daemon. See
  in.routed(1M).
Send one datagram per second and collect statistics.

Specify the IPv4 time to live, or IPv6 hop limit, for unicast and multicast packets. The default time to live (hop limit) for unicast packets can be set with the `ipadm(1M)` set-prop subcommand, using the `icmp_ipv4_ttl` property for IPv4 and the `icmp_ipv6_hoplimit` property for IPv6. The default time to live (hop limit) for multicast is one hop. See `EXAMPLES`. For further information, see `ipadm(1M)`.

Note – You might observe property names that begin with "_" (underbar). These properties are private to a protocol and are subject to change or removal. See `ipadm(1M)`.

Verbose output. List any ICMP (ICMP6) packets, other than replies from the target host.

Operands

*host*

The network host

Examples

**EXAMPLE 1 Using ping With IPv6**

This example shows `ping` sending probe packets to all the IPv6 addresses of the host `xyz`, one at a time. It sends an ICMP6 ECHO_REQUEST every second until the user interrupts it.

```
istanbul% ping -s -A inet6 -a xyz
PING xyz: 56 data bytes
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=0. time=0.479 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=1. time=0.843 ms
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=2. time=0.516 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=3. time=4.943 ms
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=4. time=0.485 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=5. time=2.201 ms
^C
---xyz PING Statistics---
6 packets transmitted, 6 packets received, 0% packet loss
round-trip (ms) min/avg/stddev = 0.479/1.583/4.943/1.823
```

**EXAMPLE 2 Using ipadm to Set Hop Limits**

The following commands use `ipadm(1M)` to set IPv4 and IPv6 hop limits.

```
# ipadm set-prop -p _ipv6_hoplimit=100 icmp
# ipadm set-prop -p _ipv4_ttl=100 icmp
```

Exit Status

The following exit values are returned:

0

Successful operation; the machine is alive.
An error has occurred. Either a malformed argument has been specified, or the machine was not alive.

pkg2du – convert driver packages to Driver Update format

```
```

The /usr/bin/pkg2du utility takes one or more packages as input and converts them to Driver Update (DU) format. If the -d option is specified, the resulting DU directory tree is placed in the directory dir. If the -o option is specified, a Solaris ISO image of the DU directory tree is written in the file iso. The ISO image can be burned onto CD/DVD using cdrw(1) or cdrecord(1) (not a SunOS man page) and used during Solaris installation.

At least one of the -d and -o options must be specified. If both are specified, then both an ISO image and a directory tree are generated.

Options

The following options are supported:

- **-d dir**
  Directory where the DU directory should be created.

- **-o iso**
  Create a Solaris ISO image of the DU directory.

- **-f**
  If dir/du or iso exists, remove it without asking first.

- **-l label**
  Label/volume name of the ISO image (if -o option is specified).

- **-r release**
  Solaris release number to use. It takes the form of the return from `uname -r` command, for example, `5.10`. If unspecified, the release number of the currently running Solaris is used.

- **-v**
  Verbose. Multiple -v options increase verbosity.

Operands

The following operands are supported:

```
pkg [pkg ...]
```

One or more packages to be converted to DU format.

Examples

**EXAMPLE 1** Creating a DU CD/DVD

The following commands create a DU CD or DVD containing packages SUNWfoo and SUNWbar.

```
# /usr/bin/pkg2du -r 5.10 -o my.iso SUNWfoo SUNWbar
# /usr/bin/cdrw -i my.iso
```

mksíofs(8) (not a SunOS man page)
pkgadd transfers the contents of a software package from the distribution medium or directory to install it onto the system. Used without the -d device source specifier, pkgadd looks in the default spool directory (/var/spool/pkg) for the package. Used with the -s option, it writes the package to a spool directory instead of installing it.

The pkgadd utility requires an amount of temporary space the size of the package that is being installed. pkgadd determines which temporary directory to use by checking for the existence of the $TMPDIR environment variable. If $TMPDIR is not defined, pkgadd uses P_tmpdir from stdio.h. P_tmpdir has a default of /var/tmp/.

Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgadd. These packages require user interaction throughout the installation and not just at the very beginning, or require that their request scripts be run as the root user.

To install these older packages (released prior to Solaris 2.4), set the following environment variable: NONABI_SCRIPTS=TRUE

As long as this environment variable is set, pkgadd permits keyboard interaction throughout the installation and package request scripts are run as root.

If you have package request scripts that require running as user root (instead of noaccess [the default] or user install), use the rscript_alt parameter in the admin(4) file to make an appropriate selection. See admin(4).

Note that, in Solaris 8 and Solaris 9, the default user when running a request script was either root or nobody, depending on the operating system’s patch level. In the current release, the default user is noaccess.

Package commands are largefile(5)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, pkgadd, pkgtrans(1) and other package commands can process a datastream of up to 4 GB.

The -d, -Y, and pkginst arguments shown in the SYNOPSIS are described under OPERANDS, following OPTIONS.
Options  The supported options are described as follows. The -d device source specifier is described under OPERANDS, below.

- a admin
   Define an installation administration file, admin, to be used in place of the default administration file. The token none overrides the use of any admin file, and thus forces interaction with the user. Unless a full path name is given, pkgadd first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgadd looks in the /var/sadm/install/admin directory for the administration file.

- G
   This option is deprecated.

- k keystore
   Use keystore as the location from which to get trusted certificate authority certificates when verifying digital signatures found in packages. If no keystore is specified, then the default keystore locations are searched for valid trusted certificates. See KEYSTORE LOCATIONS for more information.

- M
   Instruct pkgadd not to use the $root_path/etc/vfstab file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

- n
   Installation occurs in non-interactive mode. Suppress output of the list of installed files. The default mode is interactive.

- P passwd
   Password to use to decrypt keystore specified with -k, if required. See PASS PHRASE ARGUMENTS for more information about the format of this option's argument.

- r response
   Identify a file or directory which contains output from a previous pkgask(1M) session. This file supplies the interaction responses that would be requested by the package in interactive mode. response must be a full pathname.

- R root_path
   Define the full path name of a directory to use as the root_path. All files, including package system information files, are relocated to a directory tree starting in the specified root_path. The root_path may be specified when installing to a client from a server (for example, /export/root/client1).

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).
-s spool
Write the package into the directory spool instead of installing it.

-v
Trace all of the scripts that get executed by pkgadd, located in the pkginst/install directory. This option is used for debugging the procedural and non-procedural scripts.

-v fs_file
Specify an alternative fs_file to map the client’s file systems. For example, used in situations where the $root_path/etc/vfstab file is non-existent or unreliable.

-x proxy
Specify a HTTP[S] proxy to use when downloading packages. The format of proxy is host:port, where host is the hostname of the HTTP[S] proxy, and port is the port number associated with the proxy. This switch overrides all other methods of specifying a proxy. See ENVIRONMENT VARIABLES for more information on alternate methods of specifying a default proxy.

When executed without options or operands, pkgadd uses /var/spool/pkg (the default spool directory).

Operands
The following operands are supported:

Sources
By default, pkgadd looks in the /var/spool/pkg directory when searching for instances of a package to install or spool. Optionally, the source for the package instances to be installed or spooled can be specified using:

-d device
-d datastream pkgnames,... | all
Install or copy a package from device. device can be any of the following:
- A full path name to a directory or the identifiers for tape or removable medium (for example, /var/tmp).
- A datastream created by pkgtrans (see pkgtrans(1)).
- A URL pointing to a datastream created by pkgtrans. The supported Universal Resource Identifiers (URIs) are http: and https:.

The second form of the -d specifier, above, indicates the syntax you use when specifying a datastream. In this case you must specify either a comma-separated list of package names or the keyword all.

Instances
By default, pkgadd searches the specified source, and presents an interactive menu allowing the user to select which package instances found on the source are to be installed. As an alternative, the package instances to be installed can be specified using:

pkginst
The package instance or list of instances to be installed. The token all may be used to refer to all packages available on the source medium. The format pkginst.* can be used to indicate all instances of a package.
The asterisk character (\*) is a special character to some shells and may need to be escaped. In the C-Shell, the asterisk must be surrounded by single quotes (\') or preceded by a backslash (\). 

-Y category[,category...]
Install packages based on the value of the CATEGORY parameter stored in the package’s pkginfo(4) file. All packages on the source medium whose CATEGORY matches one of the specified categories will be selected for installation or spooling.

Keystore Locations
Package such as pkgadd use a set of trusted certificates to perform signature validation on any signatures found within the packages. If there are no signatures included in the packages then signature validation is skipped. The certificates can come from a variety of locations. If -k keystore is specified, and keystore is a directory, then keystore is assumed to be the base directory of the certificates to be used. If keystore is a file, then the file itself is assumed to have all required keys and certificates. When -k is not specified, then /var/sadm/security is used as the base directory.

Within the specified base directory, the store locations to be searched are different based on the application doing the searching and the type of store being searched for. The following directories are searched in the specified order:
1. <store_dir>/<app_name>/<store_type>
2. <store_dir>/<store_type>

Where <store_dir> is the directory specified by -k, <app_name> is the name of the application doing the searching, and <store_type> is one of keystore (for private keys), certstore (for untrusted public key certificates), or truststore (for trusted certificate authority certificates).

For example, when pkgadd is run with -k /export/certs, then the following locations are successively searched to find the trust store:
1. /export/certs/pkgadd/truststore
2. /export/certs/truststore

This searching order enables administrators to have a single location for most applications, and special certificate locations for certain applications.

Keystore And Certificate Formats
The packaging utilities, such as pkgtrans, require access to a set of keys and certificates in order to sign, and optionally verify, packages.

The keystore files found by following the search pattern specified in KEYSTORE LOCATIONS must each be a self-contained PKCS#12-format file.

When signing a package with pkgtrans, if a certstore has more than one public key certificate, then each public key must have a friendlyName attribute in order to be identifiable and selectable with the -a option when signing packages. In addition, the public key certificate selected with -a and found in the certstore must have an associated private key in the keystore.
Several browsers and utilities can be used to export and import certificates and keys into a PKCS#12 keystore. For example, a trusted certificate can be exported from Mozilla, and then imported into a PKCS#12 keystore for use with pkgadd with the OpenSSL Toolkit.

### Pass Phrase Arguments

pkgtrans and pkgadd accept password arguments, typically using `--p` to specify the password. These allow the password to be obtained from a variety of sources. Both of these options take a single argument whose format is described below. If no password argument is given and a password is required then the user is prompted to enter one: this will typically be read from the current terminal with echoing turned off.

- **pass:** `password`
  - The actual password is `password`. Because the password is visible to utilities such as `ps` this form should only be used where security is not important.

- **env:** `var`
  - Obtain the password from the environment variable `var`. Because the environment of other processes is visible on certain platforms this option should be used with caution.

- **file:** `pathname`
  - The first line contained within `pathname` is the password. `pathname` need not refer to a regular file: it could, for example, refer to a device or named pipe. For example, to read the password from standard input, use `file:/dev/stdin`.

- **console**
  - Read the password from `/dev/tty`.

### Examples

**EXAMPLE 1**  Installing a Package from a Solaris DVD

The following example installs a package from a Solaris DVD. You are prompted for the name of the package you want to install.

```
example# pkgadd -d /cdrom/cdrom0/s0/Solaris_10/Product
```

**EXAMPLE 2**  Installing a Set of Packages from a Datastream

The example command shown below installs all of the packages in the datastream specified by the `-d` source specifier. Prior to this command, this datastream must have been created with the `pkgtrans(1)` command.

```
example# pkgadd -d /var/tmp/datastream all
```

The keyword `all` specifies that all of the packages found in the designated datastream will be installed.

### Exit Status

- **0**
  - Successful completion

- **1**
  - Fatal error.
Warning.

Interruption.

Administration.

Administration. Interaction is required. Do not use pkgadd -n.

Reboot after installation of all packages.

Reboot after installation of this package.

**Environment Variables**

**HTTPPROXY**
Specifies an HTTP proxy host. Overrides administration file setting, and http_proxy environment variable.

**HTTPPROXYPORT**
Specifies the port to use when contacting the host specified by HTTPPROXY. Ignored if HTTPPROXY is not set.

http_proxy
URL format for specifying proxy host and port. Overrides administration file setting.

**Files**
/var/sadm/install/logs/
Location where pkgadd logs an instance of software installation.

Application Packaging Developer's Guide

http://www.openssl.org
When transferring a package to a spool directory, the -r, -n, and -a options cannot be used. The -r option can be used to indicate a directory name as well as a filename. The directory can contain numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when adding multiple interactive packages with one invocation of pkgadd. In this situation, each package would need a response file. If you create response files with the same name as the package (for example, pkinst1 and pkinst2), then name the directory in which these files reside after the -r.

The -n option causes the installation to halt if any interaction is needed to complete it.

If the default admin file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See admin(4) for details.

If a package stream is specified with -d, and a digital signature is found in that stream, the default behavior is to attempt to validate the certificate and signature found. This behavior can be overridden with admin file settings. See admin(4) for more information.
pkgadm – manage packaging and patching system

### Synopsis

```
pkgadm addcert [-ty] [-a app] [-k keystore] [-e keyfile]
   [-f format] [-n name] [-P passarg]
   [-p import_passarg] [-R rootpath] certfile
pkgadm removecert [-a app] [-k keystore] [-n name]
    [-P passarg] [-R rootpath]
pkgadm listcert [-a app] [-f format] [-k keystore] [-n name]
   [-P passarg] [-o outfile] [-R rootpath]
pkgadm dbstatus [-R rootpath]
pkgadm sync [-R rootpath] [-q]
pkgadm -V
pkgadm -?
```

### Description

The `pkgadm` utility is used for managing the packaging and patching system. It has several subcommands that perform various operations relating to packaging. The `pkgadm` command includes subcommands for managing certificates and keys used.

#### Managing Keys and Certificates

`pkgadm` maintains the packaging-system-wide keystore in `/var/sadm/security`, and individual user's certificates in `~/.pkg/security`. The following subcommands operate on the package keystore database:

- **addcert**
  
  Add (import) a certificate into the database, with optional trust. Once added, trusted certificates can be used to verify signed packages and patches. Non-trusted user certificates and their associated keys can be used to sign packages and patches. Added user certificates are *not* used to build certificate chains during certificate verification.

- **removecert**
  
  Removes a user certificate/private key pair, or a trusted certificate authority certificate from the keystore. Once removed, the certificate and keys cannot be used.

- **listcert**
  
  Print details of one or more certificates in the keystore.

- **sync**
  
  Writes the contents file and rolls the contents log file. With use of the `-q` option, forces the contents file server to quit.

#### Internal Install Database

The Solaris operating system relies upon enhanced System V revision 4 (SVr4) packages as the basis for its software installation and revision management. The package maintenance software stores information about installed packages in an internal database. The `pkgadm` subcommand `dbstatus` is used to determine how the package internal database is implemented. The `dbstatus` command returns a string that indicates the type of internal database in use. In
the current implementation, the \texttt{dbstatus} command always returns the string \texttt{text}, which indicates that the \texttt{contents(4)} package database is in use. Future releases of Solaris might supply alternative database implementations.

\begin{section}{Options}

The following options are supported:

\begin{description}
\item[-a \texttt{app}]
If this option is used, then the command only affects the keystore associated with a particular application. Otherwise, the global keystore is affected.
\item[-e \texttt{keyfile}]
When adding a non-trusted certificate/key combination, this option can be used to specify the file that contains the private key. If this option is not used, the private key must be in the same file as the certificate being added.
\item[-f \texttt{format}]
When adding certificates, this specifies the format to expect certificates and private keys in. Possible values when adding are:
\begin{description}
\item[\texttt{pem}]
Certificate and any private key uses PEM encoding.
\item[\texttt{der}]
Certificate and any private key uses DER encoding.
\end{description}
When printing certificates, this specifies the output format used when printing. Acceptable values for \texttt{format} are:
\begin{description}
\item[\texttt{pem}]
Output each certificate using PEM encoding.
\item[\texttt{der}]
Output each certificate using DER encoding.
\item[\texttt{text}]
Output each certificate in human-readable format.
\end{description}
\item[-k \texttt{keystore}]
Overrides the default location used when accessing the keystore.
\item[-n \texttt{name}]
Identifies the entity in the store on which you want to operate. When adding a user certificate, or removing certificates, this name is required. The name is associated with the certificate/key combination, and when adding, can be used later to reference the entity. When printing certificates, if no alias is supplied, then all keystore entities are printed.
\item[-o \texttt{outfile}]
Output the result of the command to \texttt{outfile}. Only used when examining (printing) certificates from the key store. Standard out is the default.
\end{description}
\end{section}
-P passarg
  Password retrieval method to use to decrypt keystore specified with -k, if required. See PASS PHRASE ARGUMENTS in pkgadd(1M) for more information about the format of this option's argument. console is the default.

-p import_passarg
  This option's argument is identical to -P, but is used for supplying the password used to decrypt the certificate and/or private key being added. console is the default.

-q
  (Applies to sync subcommand.) Shuts down the contents file cache daemon.

-R rootpath
  Defines the full name of a directory to use as the root (/) path. The default user location of the certificate operations is ${HOME}/.pkg. If the -R option is supplied, the certificates and keys will be stored under <altroot>/var/sadm/security. Note that this operation fails if the user does not have sufficient permissions to access this directory. The listcert command requires read permission, while addcert and removecert require both read and write permission.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-t
  Indicates the certificate being added is a trusted CA certificate. The details of the certificate (including the Subject Name, Validity Dates, and Fingerprints) are printed and the user is asked to verify the data. This verification step can be skipped with -y. When importing a trusted certificate, a private key should not be supplied, and will be rejected if supplied. Once a certificate is trusted, it can be used as a trust anchor when verifying future untrusted certificates.

-V
  Print version associated with packaging tools.

-y
  When adding a trusted certificate, the details of the certificate (Subject name, Issuer name, Validity dates, Fingerprints) are shown to the user and the user is asked to verify the correctness before proceeding. With -y, this additional verification step is skipped.

-?
  Print help message.

Operands
  The following operand is supported:

  certfile
    File containing the certificate and optional private key, used when adding a trust anchor or certificate/key combination. Certificates must be encoded using PEM or binary DER.
Keystore Aliases

All keystore entries (user cert/key and trusted certificate entries) are accessed via unique aliases. Aliases are case-sensitive.

An alias is specified when you add an entity to a keystore using the addcert or trustcert subcommand. If an alias is not supplied for a trust anchor, the trust anchor’s Common Name is used as the alias. An alias is required when adding a signing certificate or chain certificate. Subsequent pkgcert or other package tool commands must use this same alias to refer to the entity.

Keystore Passwords

See the pkgadd(1M) man page for a description of the passwords supplied to the pkgadm utility.

Examples

EXAMPLE 1  Adding a Trust Anchor

The following example adds a well-known and trusted certificate to be used when verifying signatures on packages.

example% pkgadm addcert -t /tmp/certfile.pem

EXAMPLE 2  Adding a Signing Certificate

The following example adds a signing certificate and associated private key, each of which is in a separate file, which can then be used to sign packages.

example% pkgadm addcert -a pkgtrans -e /tmp/keyfile.pem \ /tmp/certfile.pem

EXAMPLE 3  Printing Certificates

The following example prints all certificates in the root keystore.

example% pkgadm listcert

Exit Status

0

successful completion

non-zero

fatal error

Attributes

The service for `pkgadm` is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/pkgserv
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
pkgask(1M)

Name  pkgask – stores answers to a request script

Synopsis  pkgask [-d device] [-R root_path] -r response pkginst...

Description  pkgask allows the administrator to store answers to an interactive package (one with a request script, that is, a user-created file that must be named request). Invoking this command generates a response file that is then used as input at installation time. The use of this response file prevents any interaction from occurring during installation since the file already contains all of the information the package needs.

Options  The following options are supported

- d device  Run the request script for a package on device. device can be a directory pathname or the identifiers for tape or removable medium (for example, /var/tmp and /dev/dsk/c1d0s0). The default device is the installation spool directory.

- R root_path  Define the full path name of a directory to use as the root_path. All files, including package system information files, are relocated to a directory tree starting in the specified root_path.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).

- r response  Identify a file or directory which should be created to contain the responses to interaction with the package. The name must be a full pathname. The file, or directory of files, can later be used as input to the pkgadd(1M) command.

Operands  The following operands are supported:

pkginst  Specify the package instance, or list of instances for which request scripts will be created. The token all may be used to refer to all packages available on the source medium.

Exit Status  0       Successful completion.
              >0       An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  pkginfo(1), pkgmk(1), pkgparam(1), pkgproto(1), pkgtrans(1), installf(1M), pkgadd(1M), pkgchk(1M), pkgrm(1M), removef(1M), admin(4), attributes(5)
Notes The -r option can be used to indicate a directory name as well as a filename. The directory name is used to create numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when you will be adding multiple interactive packages with one invocation of `pkgadd(1M)`. Each package would need a response file. To create multiple response files with the same name as the package instance, name the directory in which the files should be created and supply multiple instance names with the `pkgask` command. When installing the packages, you will be able to identify this directory to the `pkgadd(1M)` command.

If the default `admin` file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See `admin(4)` for details.
Name  pkgchk – check package installation accuracy

Synopsis  pkgchk [-l | -acfnqxv] [-i file |-]
[-p path... | -P partial-path...] [-R root_path]
[-m pkgmap [-e envfile]] | pkginst... | -Y category, category...

pkgchk -d device [-l | -fv] [-i file |-] [-M] [-p path...]
[-V fs_file]
[pkginst... | -Y category[.category...]]

Description  pkgchk checks the accuracy of installed files or, by using the -l option, displays information about package files. pkgchk checks the integrity of directory structures and files. Discrepancies are written to standard error along with a detailed explanation of the problem.

The first synopsis defined above is used to list or check the contents and/or attributes of objects that are currently installed on the system, or in the indicated pkgmap. Package names may be listed on the command line, or by default, the entire contents of a machine will be checked.

The second synopsis is used to list or check the contents of a package which has been spooled on the specified device, but not installed. Note that attributes cannot be checked for spooled packages.

Options  The following options are supported:

-a
Audit the file attributes only and do not check file contents. Default is to check both.

-c
Audit the file contents only and do not check file attributes. Default is to check both.

-d device
Specify the device on which a spooled package resides. device can be a directory path name or the identifiers for tape or removable medium (for example, /var/tmp).

-e envfile
Request that the package information file named as envfile be used to resolve parameters noted in the specified pkgmap file.

-f
Correct file attributes if possible. If used with the -x option, this option removes hidden files. When pkgchk is invoked with this option, it creates directories, named pipes, links, and special devices if they do not already exist. If the -d option calls out an uninstalled package, the -f option will only take effect if the package is in directory (not stream) format. All file attributes will be set to agree with the entries in the pkgmap file except that setuid, setgid, and sticky bits will not be set in the mode.
-l file
   Read a list of path names from file or from stdin (−) and compare this list against the
   installation software database or the indicated pkgmap file. Path names that are not
   contained in file or stdin are not checked.

- l
   List information on the selected files that make up a package. This option is not compatible
   with the -a, -c, -f, -g, and -v options.

- m pkgmap
   Check the package against the package map file, pkgmap.

- M
   Instruct pkgchk not to use the $root_path/etc/vfstab file for determining the client’s
   mount points. This option assumes the mount points are correct on the server and it
   behaves consistently with Solaris 2.5 and earlier releases.

- n
   Do not check volatile or editable files’ contents. This should be used for most
   post-installation checking.

- p path
   Check the accuracy only of the path name or path names listed. path can be one or more
   path names separated by commas (or by whitespace, if the list is quoted).

   To specify a path that includes a comma, you must use the -i option, described above. See
   EXAMPLES.

- P partial-path
   Check the accuracy of only the partial path name or path names listed. partial-path can be
   one or more partial path names separated by commas (or by whitespace, if the list is
   quoted). This option can be used instead of -p and is not compatible with the other option.
   This option matches any path name that contains the string contained in the partial path.
   See the note about paths that contain commas in the description of -p.

- q
   Quiet mode. Do not give messages about missing files.

- R root_path
   Define the full name of a directory to use as the root_path. All files, including package
   system information files, are relocated to a directory tree starting in the specified root_path.
   The root_path may be specified when installing to a client from a server (for example,
   /export/root/client1).

Note – The root file system of any non-global zones must not be referenced with the - R
option. Doing so might damage the global zone’s file system, might compromise the
security of the global zone, and might damage the non-global zone’s file system. See
zones(5).
-v
  Verbose mode. Files are listed as processed.

-\ Vfs_file
  Specify an alternative fs_file to map the client’s file systems. For example, used in situations
  where the $root_path/etc/vfstab file is non-existent or unreliable.

-x
  Search exclusive directories, looking for files which exist that are not in the installation
  software database or the indicated pkgmap file.

-Y category
  Check packages based on the value of the CATEGORY parameter stored in the installed or
  spooled package’s pkginfo(4) file.

Operands

pkginst
  The package instance or instances to be checked. The format pkginst.* can be used to
  check all instances of a package. The default is to display all information about all installed
  packages.

  The asterisk character (*) is a special character to some shells and may need to be escaped.
  In the C-Shell, an asterisk must be surrounded by single quotes (’) or preceded by a
  backslash (\);

partial-path
  A portion of a path, such as a file or directory name.

Examples

EXAMPLE 1  Using pkgchk for Displaying Package Installation Information

The following example displays package installation information for /usr/bin/ls:

  example% pkgchk -l -p /usr/bin/ls

EXAMPLE 2  Checking on Java Font Properties

The following example displays package installation information for all Java font properties
installed on the system.

  example% pkgchk -l -P font.properties

EXAMPLE 3  Specifying a Path That Contains a Comma

Assume you want to specify the path:

/platform/SUNW,Netra-T12/lib

List this path in a file. Here is one way in which you can do that:

  example% echo "/platform/SUNW,Netra-T12/lib" > /tmp/p

You can then enter:
EXAMPLE 3 Specifying a Path That Contains a Comma (Continued)

example% pkgchk -i /tmp/p -l
Pathname: /platform/SUNW,Netra-T12/lib
Type: directory
Expected mode: 0755
Expected owner: root
Expected group: bin
Referenced by the following packages:
   system/core-osar
Current status: installed

Exit Status  0
   Successful completion.

>0
   An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  pkginfo(1), pkgtrans(1), pkgadd(1M), pkgask(1M), pkgrm(1M), pkginfo(4), attributes(5), largefile(5)

Application Packaging Developer’s Guide

Notes  Package commands are largefile(5)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, pkgadd(1M), pkgtrans(1) and other package commands can process a data stream of up to 4 GB.
pkgcond — determine type and capability of target

 pkgcond(1M)

Name
pkgcond — determine type and capability of target

Synopsis
/usr/bin/pkgcond [-nv] condition

Description
The pkgcond command allows you to determine the type of target being operated on (global zone, non-global zone, diskless client, and so forth) and the capabilities available for that type of client (can add a driver, path is writable, and so forth). The pkgcond command is intended to be invoked from package and patch scripts, but can also be used in situations that mimic the context of these scripts. See NOTES for further guidance.

pkgcond has one mandatory argument, a condition. The command tests whether the condition is true for the specified path. The condition can be one of the following:

- can_add_driver [path]
- can_remove_driver [path]
- can_update_driver [path]
- is_alternative_root [path]
- is_boot_environment [path]
- is_diskless_client [path]
- is_global_zone [path]
- is_mounted_miniroot [path]
- is_netinstall_image [path]
- is_nonglobal_zone [path]
- is_path_writable path
- is_running_system [path]
- is_sparse_root_nonglobal_zone [path]
- is_what [path]
- is_whole_root_nonglobal_zone [path]

The path argument usually denotes the root of the global zone or non-global zone, or alternate root. If path is optional and not specified, the default is /.

The behavior of the is_what condition is somewhat special, because it displays results of all other conditions to standard output.

Options
The following options are supported:

- -n
  Negate return status (0 becomes 1 and 1 becomes 0). It negates results in the case of is_what condition.
- -v
  Verbose mode. Displays detailed data about intermediate checks performed.

Examples
EXAMPLE 1  Listing All Available Information

The following command lists all available information about the current running system, in a user-friendly way.

example# pkgcond -n is_what
Determining if Target is an Alternate Root

The following command determines whether an alternate boot environment exists under /altroot_mount.

docker mount

doctor mount

Exit Status

0
Condition is true unless -n was specified.
1
Condition is false unless -n was specified.
2
Command line usage error.
3
Command failed to perform the test due to a fatal error.

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTETYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Uncommitted</td>
</tr>
</tbody>
</table>

See Also
pkgtrans(1), pkgadd(1M), pkgask(1M), pkgchk(1M), pkgrm(1M), pkginfo(4), attributes(5)

Notes
Supported usage of pkgcond is subject to the following constraints:

1. Do not use pkgcond outside of the Solaris marketing release in which it is provided (for example, do not use Solaris 10 pkgcond against a Solaris 9 target).

2. Restrict use of the optional path argument according to the following rules:
   - The command pkgcond condition $ROOTDIR can be used in patch level scripts.
   - The command pkgcond condition $PKG_INSTALL_ROOT can be used in package level scripts.
   - A command of the form pkgcond condition without the optional path argument can be used in any context.

Use of pkgcond with an arbitrary path argument is not recommended or supported, as the results returned might not be accurate.
pkg.depotd – Image Packaging System depot server

**Synopsis**
/usr/lib/pkg.depotd [-c source] [-a address]
  [-N content-root root_dir] [-d inst_root]
  [-D debug feature_list] [-o disable-ops=op/1][,...]
  [-i image-root path] [-l log-access dest]
  [-S log-errors dest] [-m mirror mode] [-p port]
  [-b proxy-base url] [-r readonly mode] [-t threads]
  [-f sort-file-max-size bytes] [-S ssl-cert-file source]
  [-s ssl-dialog type] [-S ssl-key-file source]
  [-s socket_timeout] [-w writable-root path]

**Description**

pkg.depotd is the depot server for the Image Packaging System. It provides network access to the data contained within a package repository. Clients that do not support direct access to a repository through the file system, or for which network access is the only available or preferred method of transport, typically use the package depot.

Clients such as pkg, the retrieval client, can retrieve a list of packages and package metadata from a repository directly or through the depot server. pkgsend, the publication client, can send new versions of packages to a repository directly or through the depot server. pkgrepo can be used to create repositories for use with the depot server, or to manage them both directly and through the depot server.

pkg.depotd is typically run as a service on the system. Package and software developers might want to run private copies for testing.

The depot does not provide any access control methods of its own. By default, all of the clients that are able to connect are able to read all package data and publish new package versions. The exception is that when running under Service Management Facility (SMF), the default is to run in read-only mode. The “Notes” section below describes some best practices for maintaining a public depot server with evolving content.

**Smf Properties**
The pkg.depot server is generally configured via the SMF properties associated with its service. See the smf(5) man page for information about SMF properties. The following properties are recognized:

pkg/address
  (net_address) The IP address on which to listen for connections. The default value is 0.0.0.0 (INADDR_ANY), which listens on all active interfaces. To listen on all active IPv6 interfaces, use ::. Only the first value is used.

pkg/content_root
  (astring) The file system path at which the instance should find its static and other web content. The default value is /usr/share/lib/pkg.

pkg/debug
  (astring) A comma-separated list of debug features to enable. Possible values are:
    headers   Logs the headers of every request to the error log.
pkg/disable_ops
   (string) A comma-separated list of operations that should be disabled for the depot server. Operations are given as operation[/version] (catalog or search_1, for example).

pkg/image_root
   (string) The path to the image whose file information will be used as a cache for file data.

pkg/inst_root
   (string) The file system path at which the instance should find its repository data. Required unless file_root or PKG_REPO has been provided. The default value is /var/pkgrepo.

pkg/log_access
   (string) The destination for any access related information logged by the depot process. Possible values are: stderr, stdout, none, or an absolute path name. The default value is stdout if stdout is a tty. If stdout is not a tty, the default value is none. If you run pkg as a service, the default value for log_access is none and output is written to /var/svc/log/application-pkg-server:*. See the logadm(1M) man page for examples of managing large log files.

pkg/log_errors
   (string) The destination for any errors or other information logged by the depot process. Possible values are: stderr, stdout, none, or an absolute path name. The default value is stderr. See the logadm(1M) man page for examples of managing large log files.

pkg/mirror
   (boolean) Sets whether package mirror mode is used. When true, publishing and metadata operations are disabled and only a limited browser user interface is provided. This property cannot be true when the pkg/readonly property is true. The default value is false.

pkg/port
   (count) The port number on which the instance should listen for incoming package requests. If SSL certificate and key information has not been provided, the default value is 80; otherwise, the default value is 443.

pkg/proxy_base
   (uri) This changes the base URL for the depot server and is most useful when running behind Apache or some other web server in a reverse proxy configuration.

pkg/readonly
   (boolean) Sets whether modifying operations, such as those initiated by pkgsend, are disabled. Retrieval operations are still available. This property cannot be true when the pkg/mirror property is true. The default value is true.

pkg/socket_timeout
   (count) The maximum number of seconds the server should wait for a response from a client before closing a connection. The default value is 60.
pkg/sort_file_max_size
(count) The maximum size of the indexer sort file. Used to limit the amount of RAM the depot uses for indexing, or increase it for speed.

pkg/ssl_cert_file
(astring) The absolute path name to a PEM-encoded Certificate file. The default value is none. This property must be used with ssl_key_file. The depot only responds to SSL requests if both ssl_cert_file and ssl_key_file are provided.

pkg/ssl_dialog
(astring) Specifies what method should be used to obtain the passphrase used to decrypt the ssl_key_file. Possible values are:

  builtin
  Prompt for the passphrase. This is the default value.

  exec:/path/to/program
  Execute the specified external program to obtain the passphrase. The first argument to the program is ''), and is reserved. The second argument to the program is the port number of the server. The passphrase is printed to stdout.

  smf:fmri
  Attempt to retrieve the value of the property pkg_secure/ssl_key_passphrase from the service instance related to the FMRI.

pkg/ssl_key_file
(astring) The absolute path name to a PEM-encoded Private Key file. This property must be used with the property ssl_cert_file. The depot only responds to SSL requests if both /ssl_key_file and ssl_cert_file are provided.

pkg/threads
(count) The number of threads started to serve requests. The default value is 60. Suitable only for small deployments. This value should be approximately 20 times the number of concurrent clients. The maximum value of threads is 5000.

pkg/writable_root
(astring) The file system path to a directory to which the program has write access. This is used with the -readonly option to enable the depot server to create files, such as search indexes, without needing write access to the package information.

pkg_secure/ssl_key_passphrase
(astring) The password to use to decrypt the pkg/ssl_key_file. This value is read-authorization protected using the attribute solaris.smf.read.pkg-server.

The presentation and behavior of the Browser User Interface (BUI) of the depot server is controlled using the following properties:

pkg_bui/feed_description
(astring) A descriptive paragraph for the RSS/Atom feed.
pkg_bui/feed_icon
(astring) The path name of a small image used to visually represent the RSS/Atom feed. The path name should be relative to the content_root. The default value is web/_themes/pkg-block-icon.png.

pkg_bui/feed_logo
(astring) The path name of a large image that will be used to visually brand or identify the RSS/Atom feed. This value should be relative to the content_root. The default value is web/_themes/pkg-block-icon.png.

pkg_bui/feed_name
(astring) A short, descriptive name for RSS/Atom feeds generated by the depot serving the repository. The default value is “package repository feed”.

pkg_bui/feed_window
(count) The number of hours before the feed for the repository was last generated, to include when generating the feed.

The package depot is also able to act as a mirror server for local client images from pkg(5). This enables clients that share a subnet on a LAN to mirror their file caches. Clients can download files from one another, thereby reducing load on the package depot server. This functionality is available as an alternate depot service configured by SMF. It uses mDNS and dns-sd for service discovery.

The mDNS mirror is generally configured via the SMF properties associated with its service. The following properties are recognized:

pkg/image_root
(astring) The path to the image whose file information will be used as a cache for file data. The default value is /.

pkg/port
(count) The port number on which the instance should listen for incoming package requests. The default value is 80.

Options  pkg.depotd can read its base configuration information from a file or from the property data of an existing SMF service instance.

- -cfg source
Specify the path name of a file to use when reading and writing configuration data, or a string of the form smf:fmri where fmri is the service fault management resource identifier (FMRI) of the instance to read configuration data from. See “Depot Configuration” below for details on the format of the file specified.

If no preexisting configuration source is available, or to override values read from a configuration file provided using - -cfg, the following options can be used to alter the default behavior of the depot server:
-a address
  See pkg/address above.

--content-root root_dir
  See pkg/content_root above.

-d inst_root
  See pkg/inst_root above.

--debug feature_list
  See pkg/debug above.

--disable-ops=op[/1][...]
  See pkg/disable_ops above.

--image-root path
  See pkg/image_root above.

--log-access dest
  See pkg/log_access above.

--log-errors dest
  See pkg/log_errors above.

--mirror mode
  See pkg/mirror above.

-p port
  See pkg/port above.

--proxy-base url
  See pkg/proxy_base above. This option is ignored if an empty value is provided.

--readonly mode
  See pkg/readonly above.

-s threads
  See pkg/threads above.

--sort-file-max-size bytes
  See pkg/sort_file_max_size above.

--ssl-cert-file source
  See pkg/ssl_cert_file above.

--ssl-dialog type
  See pkg/ssl_dialog above.

--ssl-key-file source
  See pkg/ssl_key_file above.

-t socket_timeout
  See pkg/socket_timeout above.
--writable-root path
   See pkg/writable_root above.

-?
--help
   Display a usage message.

Additional administrative and management functionality for package repositories is provided by pkgrepo.

Depot Configuration

When a configuration file is provided (instead of an SMF FMRI) by using the --cfg option, the depot server reads and writes all configuration data in a simple text format. The configuration data is described in "SMF Properties" above. The configuration data consists of sections, lead by a [section] header, and followed by name = value entries. Continuations are in the style of RFC 822. Values can be split over multiple lines by beginning continuation lines with whitespace.

Any required values not provided in the configuration file must be provided using the option listed in "Options" above. A sample configuration file might look like this:

```
[pkg]
port = 80
inst_root = /export/repo

[pub.example.com]
feed_description = example.com's software
   update log
```

Examples

EXAMPLE 1  Enabling the Depot Server

```bash
# svcadm enable application/pkg/server
```

EXAMPLE 2  Changing the Listening Port of the Server.

```bash
# svccfg -s application/pkg/server setprop pkg/port = 10000
# svcadm refresh application/pkg/server
# svcadm restart application/pkg/server
```

EXAMPLE 3  Enabling the Mirror

```bash
# svcadm enable application/pkg/dynamic-mirror
```

Environment Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PKG_REPO</td>
<td>Specifies the directory that contains the repository to serve. This value is ignored if -d is specified.</td>
</tr>
<tr>
<td>PKG_DEPOT_CONTENT</td>
<td>Specifies the directory that contains static content served by the depot. The files listed below under &quot;Files&quot; should be present in this directory, although their content can differ from the supplied default content.</td>
</tr>
</tbody>
</table>
Exit Status  The following exit values are returned:

0  Successful operation.
1  An error occurred.
2  Invalid command line options were specified.
99  An unanticipated exception occurred.

Files  /usr/share/lib/pkg
  Default presentation content location. Modify pkg/content_root to select an alternate location.

See Also  dns-sd(1M), mdnsd(1M), pkg(1), pkgrepo(1), pkgsend(1), syslogd(1M), smf(5)

http://hub.opensolaris.org/bin/view/Project+pkg/

Notes  The pkg.depotd service is managed by SMF under the service identifier svc:/application/pkg/server.

The mDNS mirror service is managed by SMF under the service identifier svc:/application/pkg/dynamic-mirror.

To control read access to the depot, you can use an HTTP reverse proxy in combination with authentication methods such as client based SSL certificate access, which pkg natively supports.

Changes to configuration, or changes to package data using file system based operations, require a restart of the depot server process so that the changes can be reflected in operations and output. Use one of the following methods to restart the depot server process:

- Use svcadm to restart the application/pkg/server instance.
- Send a SIGUSR1 signal to the depot server process using kill. This executes a "graceful restart" that leaves the process intact but reloads all configuration, package, and search data:
  
  # kill -USR1 pid
pkgrm(1M)

Name  pkgrm – remove a package from the system

Synopsis  pkgrm [-nv] [-a admin] [ [-A | -M] -R root_path]
            [ -Y fs_file]
            [pkginst... | -Y category[,category...]]

          pkgrm -s spool
            [pkginst... | -Y category[,category...]]

Description  pkgrm will remove a previously installed or partially installed package from the system. A check is made to determine if any other packages depend on the one being removed. If a dependency exists, the action taken is defined in the admin file.

The default state for the command is in interactive mode, meaning that prompt messages are given during processing to allow the administrator to confirm the actions being taken. Non-interactive mode can be requested with the -n option.

The -s option can be used to specify the directory from which spooled packages should be removed.

Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgrm. These packages require user interaction throughout the removal and not just at the very beginning.

To remove these older packages (released prior to Solaris 2.4), set the following environment variable: NONABI_SCRIPTS=True pkgrm permits keyboard interaction throughout the removal as long as this environment variable is set.

Options  The following options are supported:

    -a admin
          Use the installation administration file, admin, in place of the default admin file. pkgrm first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgrm looks in the /var/sadm/install/admin directory for the administration file.

    -A
          Remove the package files from the client’s file system, absolutely. If a file is shared with other packages, the default behavior is to not remove the file from the client’s file system.

    -M
          Instruct pkgrm not to use the $root_path/etc/vfstab file for determining the client’s mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

    -n
          Non-interactive mode. If there is a need for interaction, the command will exit.
Use of this option requires that at least one package instance be named upon invocation of the command. Certain conditions must exist for a package to be removed non-interactively or a non-restrictive admin file needs to be used.

-R root_path
Defines the full path name of a directory to use as the root_path. All files, including package system information files, are relocated to a directory tree starting in the specified root_path.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).

-s spool
Remove the specified package(s) from the directory spool. The default directory for spooled packages is /var/sadm/pkg.

-v
Trace all of the scripts that get executed by pkgrm, located in the pkginst/install directory. This option is used for debugging the procedural and non-procedural scripts.

-Y fs_file
Specify an alternative fs_file to map the client’s file systems. Used in situations where the $root_path/etc/vfstab file is non-existent or unreliable.

-Y category
Remove packages based on the value of the CATEGORY parameter stored in the installed or spooled package’s pkginfo(4) file. No package with the CATEGORY value of system can be removed from the file system with this option.

Operands
The following operand is supported:

pkginst
Specifies the package to be removed. The format pkginst.* can be used to remove all instances of a package.

The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, “*” must be surrounded by single quotes (‘) or preceded by a backslash (\).

Examples

EXAMPLE 1 Removing All Instances of SUNWjunk from client1
The following example removes all instances of SUNWjunk from client1:

example% pkgrm -R /export/root/client1 SUNWjunk*

Note the caveat on the use of the -R option in the description of that option, above.
Exit Status  The following exit values are returned:

0  Successful completion.
1  Fatal error.
2  Warning.
3  Interruption.
4  Administration.
10  Reboot after removal of all packages.
20  Reboot after removal of this package.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  pkginfo(1), pkgmk(1), pkgparam(1), pkgproto(1), pkgtrans(1), install(1M), pkgadd(1M), pkgask(1M), pkgchk(1M), removef(1M), admin(4), pkginfo(4), attributes(5), largefile(5)

Application Packaging Developer's Guide

Notes  Package commands are largefile(5)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, pkgadd(1M), pkgtrans(1) and other package commands can process a datastream of up to 4 GB.
pkg.sysrepo is used to generate the configuration files for the Image Packaging System (IPS) system repository. pkg.sysrepo is called by the svc:/application/pkg/system-repository Service Management Facility (SMF) service. Changes in configuration should be made to the properties in the SMF service.

The system repository is responsible for providing access to the package repositories configured in a reference image through a centralized proxy. Publisher configuration changes made to that reference image are seen immediately by any clients configured to use the system repository.

The system repository is primarily used in the global zone to allow non-global zones to access the repositories configured in the global zone. The SMF services svc:/application/pkg/zones-proxyd and svc:/application/pkg/zones-proxy-client are responsible for providing the transport between non-global zones and the global zone. This transport is only used by pkg(5).

Note that only http, https, and v4 file repositories and p5p archives are supported. Older file repository formats are not supported. See pkgrepo(1) for more information about repository versions.

Options

The following options are supported:

- **c cache_dir**
  Specify the absolute path to a directory that should be used by the system repository for caching responses from the publishers configured.

  By default, a file-cache is used. However, the special value memory can be used to indicate the an in-memory cache should be used. The special value None can be used to indicate that the system repository should not perform any caching. This setting should be configured using the config/cache_dir SMF property.

- **p port**
  Specify the port that the system repository should use to listen for requests. This setting should be configured using the config/port SMF property.

- **s cache_size**
  An integer value in megabytes that defines the maximum cache size of the system repository. This setting should be configured using the config/cache_max SMF property.

- **w http_proxy**
  A string of the form scheme://hostname[:port] that defines a web proxy that the system repository can use to access http-based package repositories. This setting can be configured using the config/http_proxy SMF property.
-w https_proxy
   A string of the form scheme://hostname[:port] that defines a web proxy that the system repository can use to access https-based package repositories. This setting can be configured using the config/https_proxy SMF property.

Examples

   EXAMPLE 1  Enabling the System Repository
   $ svcadm enable svc:/application/pkg/system-repository

Exit Status

The following exit values are returned:

   0  Command succeeded.
   1  Command failed to write a valid configuration.
   2  Invalid command line options were specified.
   99 An unanticipated exception occurred.

pkg(1), pkg.depotd(1M), pkg(5)

http://hub.opensolaris.org/bin/view/Project+pkg/
The plockstat utility gathers and displays user-level locking statistics. By default, plockstat monitors all lock contention events, gathers frequency and timing data about those events, and displays the data in decreasing frequency order, so that the most common events appear first.

plockstat gathers data until the specified command completes or the process specified with the -p option completes.

plockstat relies on DTrace to instrument a running process or a command it invokes to trace events of interest. This imposes a small but measurable performance overhead on the processes being observed. Users must have the dtrace_proc privilege and have permission to observe a particular process with plockstat. Refer to the Solaris Dynamic Tracing Guide for more information about DTrace security features.

The following options are supported:

- **-A** Watch all lock events. This option is equivalent to -CH.
- **-C** Watch contention events.
- **-H** Watch hold events.
- **-e secs** Exit after the number of seconds specified have elapsed.
- **-n count** Display only the specified number of entries for each output category.
- **-s depth** Record a stack trace rather than just the calling function.
- **-p pid** Specify a process ID from which plockstat is to gather data.
- **-v** Print out a message to indicate that tracing has started.
- **-x arg[=val]** Enable or modify a DTrace runtime option or D compiler option. The list of options is found in the Solaris Dynamic Tracing Guide. Boolean options are enabled by specifying their name. Options with values are set by separating the option name and value with an equals sign (=).
- **-V** Print the DTrace commands used to gather the data. The output can then be used directly with the dtrace(1M) command.

The following operands are supported:

- **arg** A string to be passed as an argument to command.
- **command** The name of a utility to be invoked.
**count**  A positive integer value.

**pid**  A process identifier for a process to be monitored.

**secs**  Duration specified as a positive integer number of seconds.

**Display Headers**  The following headers appear over columns of data in `plockstat` output.

- **Count**
  Number of times an event occurred.

- **nsec**
  Average duration of an event, in nanoseconds.

- **Lock**
  Address of a lock, displayed symbolically if possible.

- **Caller**
  Address of a caller, displayed symbolically if possible.

**Exit Status**  The following exit values are returned:

- **0**  Successful completion.
- **>0**  An error occurred.

**Attributes**  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

*Solaris Dynamic Tracing Guide*
**Name**  
pntadm – DHCP network table management utility

**Synopsis**  
pntadm -C [-r resource] [-p path] [-u uninterpreted] network

- **pntadm -A** name_IP_address [-c comment] [-e mm/dd/yyyy]
  -f num | keywords [-h client_hostname]
  -i [-a] client_ID [-m [-y] macro] [-s server]
  [-r resource] [-p path] [-u uninterpreted] network

- **pntadm -M** name_IP_address [-c comment] [-e mm/dd/yyyy]
  -f num | keywords [-h client_hostname]
  -i [-a] client_ID [-m [-y] macro]
  [-n new_client_IP_address] [-s server] [-r resource]
  [-p path] [-u uninterpreted] network

- **pntadm -D** name_IP_address [-y] [-r resource] [-p path]
  [-u uninterpreted] network

- **pntadm -P** [-v] [-x] [-r resource] [-p path]
  [-u uninterpreted] network

- **pntadm -R** [-r resource] [-p path] [-u uninterpreted] network

- **pntadm -L** [-r resource] [-p path] [-u uninterpreted]

- **pntadm -B** [-v] [batchfile]

**Description**  
The `pntadm` command is used to manage the Dynamic Host Configuration Protocol (DHCP) network tables. It is used to add and remove networks under DHCP management, and add, delete, or modify IP address records within network tables, or to view tables. For a description of the format of DHCP network tables, see `dhcp_network(4)`.

`pntadm` can be run as root or by other users assigned to the DHCP Management profile. See `rbac(5)` and `user_attr(4)`.

If the networks you want to add are subnetted, you need to update the `netmasks(4)` table.

One of the following options (function flags) must be specified with the `pntadm` command: -A, -B, -C, -D, -L, -M, -P, or -R.

The `pntadm` utility is obsolete and is subject to removal in a future release of Oracle Solaris.

**Options**  
The following options are supported:

- **-A name_IP_address**
  Add a client entry with hostname or client IP address, `name_IP_address`, to the named DHCP network table.

  The following sub-options are optional:

  - **-c comment**
    Comment text. The default is NULL.
-e mm/dd/yyyy
   Absolute lease. The default is 0.

- f num | keywords
   Flag value. The default is 00.

The flag (-f) option can be specified either as a single number denoting the intended flag value, or as a series of the following keywords, combined using the plus (+) symbol:

DYNAMIC or 00
   Server manager’s assignment.

PERMANENT or 01
   Lease on entry is permanent.

MANUAL or 02
   Administrator managed assignment.

UNUSABLE or 04
   Entry is not valid.

BOOTP or 08
   Entry reserved for BOOTP clients.

For a more detailed description of the flag values, see dhcp_network(4).

-h client_hostname
   Client hostname. The default is NULL.

   When the -h option is used in this mode, the client_hostname is added to the hosts table within the resource used for storing host names (files or DNS). The command will fail if this client_hostname is already present in the hosts table.

-i client_ID [-a]
   Client identifier [-a]. The default is 00.

   The -i option modified with -a specifies that the client identifier is in ASCII format, and thus needs to be converted to hexadecimal format before insertion into the table.

-m macro [-y]
   Macro name. Default is UNKNOWN.

   The -m option modified with -y verifies the existence of the named macro in the dhcp.tab table before adding the entry.

-s server
   Server IP or name. Default is system name (uname -n).

-B
   Activate batch mode. pntadm will read from the specified file or from standard input a series of pntadm commands and execute them within the same process. Processing many
pntadm commands using this method is much faster than running an executable batchfile itself. Batch mode is recommended for using pntadm in scripts.

The following sub-option is optional:

-\v
Display commands to standard output as they are processed.

-\C
Create the DHCP network table for the network specified by \textit{network}. See \texttt{Operands}. For details, see \texttt{dhcp_network(4)} and \texttt{networks(4)}.

-\D \textit{name/IP_address}
Delete the specified client entry with hostname or client IP address, \textit{name/IP_address}, in the named DHCP network table. (See \texttt{dhcp_network(4)}.)

The following sub-option is optional:

-\y
Remove associated host table entry. The -\y option requests that all hostnames associated with the IP address in the hosts table in the resource be removed.

-\L
List the DHCP network tables presently configured, one per line, on standard output. If none are found, no output is printed and an exit status of 0 is returned.

-\M \textit{name/IP_address}
Modify the specified client entry with hostname or client IP address, \textit{name/IP_address}, in the named DHCP network table. See \texttt{dhcp_network(4)}. The default for the sub-options is what they currently are set to.

The following sub-options are optional.

-\c \textit{comment}
New comment text.

-\e \textit{mm/dd/yy}
New absolute lease expiration date. Time defaults to 12:00 AM of the day specified.

-\f \textit{num | keyboard}
New flag value, see explanation following the description of the \texttt{-A} option.

-\h \textit{host_name}
New client hostname.

-\h\ a
The -h option allows you to change the current hostname associated with the IP address or to add a new hostname to the hosts table if an entry associated with this IP address does not exist.

-\i \textit{client_ID}
New client identifier [ -\a].
-m <macro> [-y]
Macro name defined in dhcptab.

-n <new_client_IP_address>
New IP address.

-s <server>
New server IP or name.

For more detailed description of the sub-options and flag values, see dhcp_network(4).

-<P>
Display the named DHCP network table.

The following sub-options are optional:

-<v>
Display lease time in full verbose format and resolve IP addresses for the clients and server to hostnames.

-<x>
Display lease time in raw format.

These flag codes are used with the -<P> sub-options:

<table>
<thead>
<tr>
<th>-&lt;v&gt;</th>
<th>-&lt;x&gt;</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>00</td>
<td>DYNAMIC</td>
</tr>
<tr>
<td>P</td>
<td>01</td>
<td>PERMANENT</td>
</tr>
<tr>
<td>M</td>
<td>02</td>
<td>MANUAL</td>
</tr>
<tr>
<td>U</td>
<td>04</td>
<td>UNUSABLE</td>
</tr>
<tr>
<td>B</td>
<td>08</td>
<td>BOOTP</td>
</tr>
</tbody>
</table>

See dhcp_network(4) for information on these sub-options and associated flag codes.

-<p> <path>
Override the dhcpsvc.conf(4) configuration value for data store resource path, <path> See dhcpsvc.conf(4)

-R
Remove the named DHCP network table. See dhcp_network(4).

-r <data_store_resource>
Override the /etc/inet/dhcpsvc.conf configuration value for RESOURCE= with the data_store_resource specified. See the dhcpsvc.conf(4) man page for more details on resource type, and the Oracle Solaris DHCP Service Developer’s Guide for more information about adding support for other data stores.
-u uninterpreted
  Data which will be ignored by pntadm, but passed to the currently configured public
  module to be interpreted by the data store. This might be used for a database account name
  or other authentication or authorization parameters required by a particular data store.

Operands

The following operand is supported:

  network
  The network address or network name which corresponds to the dhcp network table. See
  dhcp_network(4).

Examples

EXAMPLE 1  Creating a Table for the 10.0.0.0 DHCP Network

The following command creates a table for the 10.0.0.0 (subnetted to class C) DHCP
network table. Note that if you have an alias for this network in your networks(4) table, you
can use that value rather than the dotted Internet Address notation.

  example# pntadm -C 10.0.0.0

EXAMPLE 2  Adding an Entry to the 10.0.0.0 Table

The following command adds an entry to the 10.0.0.0 table in the files resource in the
/var/mydhcp directory:

  example# pntadm -r SUNWfiles -p /var/mydhcp -A 10.0.0.1 10.0.0.0

EXAMPLE 3  Modifying the 10.0.0.1 Entry of the 10.0.0.0 Table

The following command modifies the 10.0.0.1 entry of the 10.0.0.0 table, changing the
macro name to Green, setting the flags field to MANUAL and PERMANENT:

  example# pntadm -M 10.0.0.1 -m Green -f 'PERMANENT+MANUAL' 10.0.0.0

EXAMPLE 4  Changing the 10.0.0.1 Entry to 10.0.0.2

The following command changes the 10.0.0.1 entry to 10.0.0.2, making an entry in the
hosts(4) table called myclient:

  example# pntadm -M 10.0.0.1 -n 10.0.0.2 -h myclient 10.0.0.0

EXAMPLE 5  Setting the Client ID as ASCII

The following command sets the client ID as ASCII aruba.foo.com for the myclient entry:

  example# pntadm -M myclient -i 'aruba.foo.com' -a 10.0.0.0

EXAMPLE 6  Deleting the myclient Entry from the 10.0.0.0 Table

The following command deletes the myclient (10.0.0.2) entry from the 10.0.0.0 table:

  example# pntadm -D myclient 10.0.0.0
The following command lists the configured DHCP network tables:

```
example# pntadm -L
192.168.0.0
10.0.0.0
```

The following command runs a series of `pntadm` commands contained in a batch file:

```
example# pntadm -B addclients
```

**Exit Status**

0

Successful completion.

1

Object already exists.

2

Object does not exist.

3

Non-critical error.

4

Critical error.

**Files**

- `/etc/inet/dhcpsvc.conf`
- `/etc/inet/hosts`

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>

polkit-is-privileged(1M)

Name  polkit-is-privileged – check PolicyKit privileges

Synopsis  polkit-is-privileged [-hvV] -u user -p privilege [-r resource]

Description  The polkit-is-privileged command queries system policy to determine whether a user is allowed for a given privilege and resource. The resource name can be omitted. On the Solaris operating system, RBAC authorizations names should be used as privilege names.

Currently, the only consumer of PolicyKit is hald(1M).

Options  The following options are supported:

- h, --help  Display list of options and exit.
- p privilege, --privilege privilege  Name of privilege associated with user. Command tests for this privilege.
- r resource, --resource resource  Name of resource associated with user and privilege. Command tests for this resource.
- u user, --user user  User name or user id that is tested for.
- v, --verbose  Verbose mode.
- V, --version  Displays version number.

pooladm(1M)

Name
pooladm – activate and deactivate the resource pools facility

Synopsis
/usr/sbin/pooladm [-n] [-s] [-c] [filename] | -x
/usr/sbin/pooladm [-d | -e]

Description
The pooladm command provides administrative operations on pools and sets. pooladm reads the specified filename and attempts to activate the pool configuration contained in it.

Before updating the current pool run-time configuration, pooladm validates the configuration for correctness.

Without options, pooladm prints out the current running pools configuration.

Options
The following options are supported:

- c Instantiate the configuration at the given location. If a filename is not specified, it defaults to /etc/pooladm.conf.
- d Disable the pools facility so that pools can no longer be manipulated.
- e Enable the pools facility so that pools can be manipulated.
- n Validate the configuration without actually updating the current active configuration. Checks that there are no syntactic errors and that the configuration can be instantiated on the current system. No validation of application specific properties is performed.
- s Update the specified location with the details of the current dynamic configuration.

This option requires update permission for the configuration that you are going to update. If you use this option with the -c option, the dynamic configuration is updated before the static location.
- x Remove the currently active pool configuration. Destroy all defined resources, and return all formerly partitioned components to their default resources.

Operands
The following operands are supported:

filename Use the configuration contained within this file.

Examples
EXAMPLE 1 Instantiating a Configuration

The following command instantiates the configuration contained at /home/admin/newconfig:

eexample# /usr/sbin/pooladm -c /home/admin/newconfig

EXAMPLE 2 Validating the Configuration Without Instantiating It

The following command attempts to instantiate the configuration contained at /home/admin/newconfig. It displays any error conditions that it encounters, but does not actually modify the active configuration.
EXAMPLE 2 Validating the Configuration Without Instantiating It (Continued)

```
example# /usr/sbin/pooladm -n -c /home/admin/newconfig
```

EXAMPLE 3 Removing the Current Configuration

The following command removes the current pool configuration:

```
example# /usr/sbin/pooladm -x
```

EXAMPLE 4 Enabling the Pools Facility

The following command enables the pool facility:

```
example# /usr/sbin/pooladm -e
```

EXAMPLE 5 Enabling the Pools Facility Using SMF

The following command enables the pool facility through use of the Service Management Facility. See smf(5).

```
example# /usr/sbin/svcadm enable svc:/system/pools:default
```

EXAMPLE 6 Saving the Active Configuration to a Specified Location

The following command saves the active configuration to /tmp/state.backup:

```
example# /usr/sbin/pooladm -s /tmp/state.backup
```

Files /etc/pooladm.conf Configuration file for pooladm.

Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management

Notes Resource bindings that are not presented in the form of a binding to a partitionable resource, such as the scheduling class, are not necessarily modified in a pooladm -x operation.
The pools facility is not active by default when Solaris starts. pooladm -e explicitly activates the pools facility. The behavior of certain APIs related to processor partitioning and process binding are modified when pools is active. See libpool(3LIB).

You cannot enable the pools facility on a system where processor sets have been created. Use the psrset(1M) command or pset_destroy(2) to destroy processor sets manually before you enable the pools facility.

Because the Resource Pools facility is an smf(5) service, it can also be enabled and disabled using the standard SMF interfaces.
poolbind - bind processes, tasks, or projects or query binding of processes to resource pools

**Synopsis**
/usr/sbin/poolbind -p poolname -e command [arguments]...
/usr/sbin/poolbind -p poolname [-i idtype] id...
/usr/sbin/poolbind -q pid...
/usr/sbin/poolbind -Q pid...

**Description**
The `poolbind` command allows an authorized user to bind zones, projects, tasks, and processes to pools. With the `-e` option (see below), it can execute a command you specify, placing the executed command in a specified pool. It can also enable you to query a process to determine which pool a process is bound to.

**Options**
The following options are supported:

- `-e command [arguments...]`  Executes `command`, bound to the pool you specify with `-p`.

- `-i idtype`  This option, together with the `idlist` arguments, specifies one or more processes to which the poolbind command is to apply. The interpretation of `idlist` depends on the value of `idtype`. The valid `idtype` arguments and corresponding interpretations of `idlist` are as follows:
  - `pid`  `idlist` is a list of process IDs. Binds the specified processes to the specified pool. This is the default behavior if no `idtype` is specified.
  - `taskid`  `idlist` is a list of task IDs. Bind all processes within the list of task IDs to the specified pool.
  - `projid`  `idlist` is a list of project IDs. Bind all processes within the list of projects to the specified pool. Each project ID can be specified as either a project name or a numerical project ID. See `project(4)`.
  - `zoneid`  `idlist` is a list of zone IDs. Bind all processes within the list of zones to the specified pool. Each zone ID can be specified as either a zone name or a numerical zone ID. See `zones(5)`.

- `-p poolname`  Specifies the name of a pool to which the specified zone, project, tasks, or processes are to be bound.

- `-q pid ...`  Queries the pool bindings for a given list of process IDs. If the collection of resources associated with the process does not correspond to any currently existing pool, or if there are multiple pools with the set of resources that the process is bound to, the query fails for that particular process ID.
The following command binds all processes in projects 5 and 7 to the pool `web_app`:

```
example# /usr/sbin/poolbind -p web_app -i projid 5 7
```

**EXAMPLE 2**  Binding the Running Shell

The following command binds the running shell to the pool `web_app`:

```
example# /usr/sbin/poolbind -p web_app $$
```

**EXAMPLE 3**  Querying the Pool Bindings

The following command queries the bindings to verify that the shell is bound to the given pool:

```
example# /usr/sbin/poolbind -q $$
```

**EXAMPLE 4**  Querying the Resource Bindings

The following command queries the bindings to verify that the shell is bound to the given resources:

```
example# /usr/sbin/poolbind -Q $$
```

**Exit Status**  The following exit values are returned:

- **0**  Successful completion.
- **1**  Requested operation could not be completed.
- **2**  Invalid command line options were specified.

**Attributes**  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>

*Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management*
poolcfg - create and modify resource pool configuration files

/usr/sbin/poolcfg -c command
[ -d | [filename]]

/usr/sbin/poolcfg -f command_file [ -d | [filename]]

/usr/sbin/poolcfg -h

The poolcfg utility provides configuration operations on pools and sets. These operations are performed upon an existing configuration and take the form of modifications to the specified configuration file. If you use the -d option, the modifications occur to the kernel state. Actual activation of the resulting configuration is achieved by way of the pooladm(1M) utility.

Pools configuration files are structured files that must have been constructed using poolcfg itself or libpool(3LIB) directly.

An invocation of poolcfg with the pool dynamic location and write permission will hang if the dynamic location has already been opened for writing.

The configurations which are created by this utility can be used by pooladm to instantiate the configuration upon a target host.

The following options are supported:

- **-c command** Specify command as an editing command. See USAGE.

- **-d** Operate directly on the kernel state. No filename is allowed.

- **-f command_file** Take the commands from command_file. command_file consists of editing commands, one per line.

- **-h** Display extended information about the syntax of editing commands.

### Usage

A script consists of editing commands, one per line, of the following:

- **info entity-name**
  Display configuration (or specified portion) in human readable form to standard output. If no entity is specified, system information is displayed. Therefore, poolcfg -c 'info'
  afi le is an equivalent invocation to poolcfg -c 'info system name' afi le.

- **create entity-name [property-list]**
  Make an entity of the specified type and name.

- **destroy entity-name**
  Remove the specified entity.

- **modify entity-name [property-list]**
  Change the listed properties on the named entity.

- **associate pool-name [resource-list]**
  Connect one or more resources to a pool, or replace one or more existing connections.
transferto [resource type] name[component-list]
   Transfer one or more discrete components to a resource.

transfer [quantity] from [resource type] [src] to [tgt]
   Transfer a resource quantity from src to tgt.

transfer [quantity] to [resource type] [tgt] from [src]
   Transfer a resource quantity to tgt from src.

discover
   Create a system entity, with one pool entity and resources to match current system
   configuration. All discovered resources of each resource type are recorded in the file, with
   the single pool referring to the default resource for each resource type.

   This command is a NO-OP when poolcfg operates directly on the kernel. See the -d
   option.

   You should avoid use of this command. The preferred method for creating a configuration
   is to export the dynamic configuration using pooladm(1M) with the -s option.

rename entity-name to new-name
   Change the name of an entity on the system to its new name.

Property Lists
   The property list is specified by:
   ( proptype name = value [ ; proptype name = value ]* )
   where the last definition in the sequence for a given proptype, name pair is the one that holds.
   For property deletion, use ~ proptype name.

Resource Lists
   A resource list is specified by:
   ( resource type name [ ; resource type name ]* )
   where the last specification in the sequence for a resource is the one that holds. There is no
   deletion syntax for resource lists.

Component Lists
   A component list is specified by:
   ( component type name [ ; component type name ]* )
   where the last specification in the sequence for a component is the one that holds. There is no
   deletion syntax for component lists.

Recognized Entities
   system     Machine level entity
   pool        Named collection of resource associations

Resource Types
   pset        Processor set resource
### Property Types

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>Takes one of two values true or false.</td>
</tr>
<tr>
<td>int</td>
<td>A 64–bit signed integer value.</td>
</tr>
<tr>
<td>uint</td>
<td>A 64–bit unsigned integer value.</td>
</tr>
<tr>
<td>string</td>
<td>Strings are delimited by quotes (&quot;), and support the character escape sequences defined in formats(5).</td>
</tr>
<tr>
<td>float</td>
<td>Scientific notation is not supported.</td>
</tr>
</tbody>
</table>

### Examples

#### EXAMPLE 1 Writing a poolcfg Script

The following poolcfg script creates a pool named Accounting, and a processor set, small-1. The processor set is created first, then the pool is created and associated with the set.

```bash
create pset small-1 ( uint pset.min = 1 ; uint pset.max = 4)  
create pool Accounting  
associate pool Accounting ( pset small-1 )
```

#### EXAMPLE 2 Reporting on pool_0

The following command reports on pool_0 to standard output in human readable form:

```bash
# poolcfg -c 'info pool pool_0' /etc/pooladm.conf
```

#### EXAMPLE 3 Destroying pool_0 and Its Associations

The following command destroys pool_0 and associations, but not the formerly associated resources:

```bash
# poolcfg -c 'destroy pool pool_0' /etc/pooladm.conf
```

#### EXAMPLE 4 Displaying the Current Configuration

The following command displays the current configuration:

```bash
$ poolcfg -c 'info' /etc/pooladm.conf
```

```bash
system example_system  
  int system.version 1  
  boolean system.bind-default true  
  string system.comment Discovered by libpool

  pool pool_default  
    boolean pool.default true  
    boolean pool.active true  
    int pool.importance 5  
    string pool.comment  
    string.pool.scheduler FSS  
    pset pset_default

  pset pset_default
```
EXAMPLE 4  Displaying the Current Configuration  (Continued)

    int pset.sys_id -1
    string pset.units population
    boolean pset.default true
    uint pset.max 4294967295
    uint pset.min 1
    string pset.comment
    boolean pset.escapable false
    uint pset.load 0
    uint pset.size 2

    cpu
      int cpu.sys_id 0
      string cpu.comment

    cpu
      int cpu.sys_id 2
      string cpu.comment

EXAMPLE 5  Moving cpu with ID 2 to Processor Set pset1 in the Kernel

The following command moves cpu with ID 2 to processor set pset1 in the kernel:

    # poolcfg -dc 'transfer to pset pset1 ( cpu 2 )'

EXAMPLE 6  Moving 2 cpus from Processor Set pset1 to Processor Set pset2 in the Kernel

The following command moves 2 cpus from processor set pset1 to processor set pset2 in the kernel:

    # poolcfg -dc 'transfer 2 from pset pset1 to pset2'

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/resource-mgmt/resource-pools</td>

Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management
**poold (1M)**

**Name**  
poold – automated resource pools partitioning daemon

**Synopsis**  
```bash
poold [-l level]
```

**Description**  
poold provides automated resource partitioning facilities. poold can be enabled or disabled using the Solaris Service Management Facility, `smf(5)`. poold requires the Resource Pools facility to be active in order to operate.

The dynamic resource pools service's fault management resource identifier (FMRI) is:

```
svc:/system/pools/dynamic
```

The resource pools service's FMRI is:

```
svc:/system/pools
```

poold's configuration details are held in a `libpool(3LIB)` configuration and you can access all customizable behavior from this configuration.

poold periodically examines the load on the system and decides whether intervention is required to maintain optimal system performance with respect to resource consumption. poold also responds to externally initiated (with respect to poold) changes of either resource configuration or objectives.

If intervention is required, poold attempts to reallocate the available resources to ensure that performance objectives are satisfied. If it is not possible for poold to meet performance objectives with the available resources, then a message is written to the log. poold allocates scarce resources according to the objectives configured by the administrator. The system administrator must determine which resource pools are most deserving of scarce resource and indicate this through the importance of resource pools and objectives.

**Options**  
The following options are supported:

- `-l level`  
  Specify the verbosity level for logging information.

  Specify `level` as `ALERT`, `CRIT`, `ERR`, `WARNING`, `NOTICE`, `INFO`, and `DEBUG`. If `level` is not supplied, then the default logging level is `INFO`.

  - **ALERT**  
    A condition that should be corrected immediately, such as a corrupted system database.

  - **CRIT**  
    Critical conditions, such as hard device errors.

  - **ERR**  
    Errors.

  - **WARNING**  
    Warning messages.

  - **NOTICE**  
    Conditions that are not error conditions, but that may require special handling.

  - **INFO**  
    Informational messages.
DEBUG Messages that contain information normally of use only when debugging a program.

When invoked manually, with the -l option, all log output is directed to standard error.

**Examples**

**EXAMPLE 1**  Modifying the Default Logging Level
The following command modifies the default logging level to ERR:

```
# /usr/lib/pool/poold -l ERR
```

**EXAMPLE 2**  Enabling Dynamic Resource Pools
The following command enables dynamic resource pools:

```
# /usr/sbin/svcadm enable svc:/system/pools/dynamic
```

**Attributes** See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/resource-mgmt/resource-pools</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The invocation is Committed. The output is Uncommitted.

*Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management*
poolstat(1M)

**Name**
poolstat – report active pool statistics

**Synopsis**

```bash
poolstat [-p pool-list] [-r rset-list] [-Tu | d] [interval [count]]
```

```bash
poolstat [-p pool-list] [-o format -r rset-list]
[-Tu | d] [interval [count]]
```

**Description**
The `poolstat` utility iteratively examines all active pools on the system. It reports statistics based on the selected output mode. `poolstat` provides options to examine only specified pools and report resource set-specific statistics.

Without options, `poolstat` examines all pools, reports basic statistics for their resource sets, and exits.

**DISPLAY FORMATS**
In default output format, `poolstat` outputs a header line and a line for each pool. The line begins with the pool ID and its name, followed by a column of statistical data for the processor set attached to the pool.

The columns are defined as follows:

- **id**: Pool ID.
- **pool**: Pool name.
- **rid**: Resource set id.
- **rset**: Resource set name.
- **type**: Resource set type.
- **min**: Minimum resource set size.
- **max**: Maximum resource set size.
- **size**: Current resource set size.
- **used**: The measure of how much of the resource set is currently in use. This is calculated as the percentage utilization of the resource set multiplied by its size. If resource set has been reconfigured during last sampling interval, this value might not be reported (-).
- **load**: The absolute representation of the load that is put on the resource set. For the definition of this property see `libpool(3LIB)`.

**Options**
The following options are supported:

- **-o format**: Report statistics according to the format specification given in format. See DISPLAY FORMATS.

The `-o` option accepts lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

You can specify multiple `-o` options. The format specification is interpreted as the whitespace separated concatenation of all the format option arguments.
The -o option must be used in conjunction with the -r option.

-p pool-list  Report only pools whose names are in the given list. If the -r option is also used, this option selects only resource sets which belong to pools in the given list. Statistics for pools or resource sets are reported in the same order in which pool names are listed on the pool-list. Pool can be specified by name or by ID.

The -p option accepts lists as arguments. Items in a pool-list can only be separated by spaces.

-r rset-list  Report resource set statistics. If the rset-list argument is "all", then all possible resource set types are selected.

The -r option accepts lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

The following resource set types are supported:
- all        All resource set types
- pset       Processor set

-T u | d     Display a time stamp.

Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See date(1).

Operands  The following operands are supported:

- count      The number of times that the statistics are repeated. By default, poolstat reports statistics only once.

If neither interval nor count are specified, statistics are reported once. If interval is specified and count is not, statistics are reported indefinitely.

- interval   The sampling interval in seconds.

If neither interval nor count are specified, statistics are reported once. If interval is specified and count is not, statistics are reported indefinitely.

Examples  EXAMPLE1  Using poolstat

The following example shows the default output from the poolstat utility:

% poolstat

<table>
<thead>
<tr>
<th>id</th>
<th>pool</th>
<th>size</th>
<th>used</th>
<th>load</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>pool_default</td>
<td>4</td>
<td>3.6</td>
<td>6.2</td>
</tr>
<tr>
<td>1</td>
<td>pool_admin</td>
<td>4</td>
<td>3.3</td>
<td>8.4</td>
</tr>
</tbody>
</table>
EXAMPLE 2  Reporting Resource Set Statistics

The following example reports resource set statistics.

`% poolstat -r pset`

<table>
<thead>
<tr>
<th>id</th>
<th>pool</th>
<th>type</th>
<th>rid</th>
<th>rset</th>
<th>min</th>
<th>max</th>
<th>size</th>
<th>used</th>
<th>load</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>pool_default</td>
<td>pset</td>
<td>-1</td>
<td>pset_default</td>
<td>1</td>
<td>65K</td>
<td>2</td>
<td>1.2</td>
<td>8.3</td>
</tr>
<tr>
<td>1</td>
<td>pool_admin</td>
<td>pset</td>
<td>1</td>
<td>pset_admin</td>
<td>1</td>
<td>1</td>
<td>0.4</td>
<td>5.2</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>pool_other</td>
<td>pset</td>
<td>-1</td>
<td>pset_default</td>
<td>1</td>
<td>65K</td>
<td>2</td>
<td>1.2</td>
<td>8.3</td>
</tr>
</tbody>
</table>

Resource sets attached to multiple pools, as `pset_default` in the example above, are listed multiple times, once for each pool.

EXAMPLE 3  Restricting the Output to the List of Pools

The following example restricts the output to the list of pools

`% poolstat -p pool_default`

<table>
<thead>
<tr>
<th>id</th>
<th>pool</th>
<th>size</th>
<th>used</th>
<th>load</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>pool_default</td>
<td>8</td>
<td>5.3</td>
<td>10.3</td>
</tr>
</tbody>
</table>

`% poolstat -p 'pool_admin pool_default'`

<table>
<thead>
<tr>
<th>id</th>
<th>pool</th>
<th>size</th>
<th>used</th>
<th>load</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>pool_admin</td>
<td>6</td>
<td>4.3</td>
<td>5.3</td>
</tr>
<tr>
<td>0</td>
<td>pool_default</td>
<td>2</td>
<td>1.9</td>
<td>2.0</td>
</tr>
</tbody>
</table>

`% poolstat -r all -p 'pool_admin pool_default'`

<table>
<thead>
<tr>
<th>id</th>
<th>pool</th>
<th>type</th>
<th>rid</th>
<th>rset</th>
<th>min</th>
<th>max</th>
<th>size</th>
<th>used</th>
<th>load</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>pool_admin</td>
<td>pset</td>
<td>1</td>
<td>pset_admin</td>
<td>1</td>
<td>1</td>
<td>0.9</td>
<td>2.3</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>pool_default</td>
<td>pset</td>
<td>-1</td>
<td>pset_default</td>
<td>1</td>
<td>65K</td>
<td>2</td>
<td>2.0</td>
<td>2.0</td>
</tr>
</tbody>
</table>

EXAMPLE 4  Customizing Output

The following example customizes output:

`% poolstat -r -o pool,rset,size,load`

<table>
<thead>
<tr>
<th>pool</th>
<th>rset</th>
<th>size</th>
<th>load</th>
</tr>
</thead>
<tbody>
<tr>
<td>pool_default</td>
<td>pset_default</td>
<td>4</td>
<td>4.5</td>
</tr>
<tr>
<td>pool_admin</td>
<td>pset_admin</td>
<td>4</td>
<td>2.1</td>
</tr>
</tbody>
</table>

Exit Status  The following exit values are returned:

0  Successful completion.
1  An error occurred.
2  Invalid command line options were specified.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/resource-mgmt/resource-pools</td>

Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management

Notes  The system ids associated with resources can change after the system reboots or the resource configuration is altered.
ports(1M)

Name
 ports – creates /dev entries and inittab entries for serial lines

Synopsis
 /usr/sbin/ports [ {-r rootdir]}

Description
 devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of ports.

The ports command creates symbolic links in the /dev/term and /dev/cua directories to the serial-port character device files in /devices and adds new entries in /etc/inittab for non-system ports found. System-board ports are given single lower-case letters for names (such as a and b) while other ports are named numerically.

ports searches the kernel device tree to find the serial devices attached to the system. It also checks /dev/term and /dev/cua to see what symbolic links to serial devices already exist. ports then performs the following:

1. Assigns new numbers (or letters for system-board ports) to ports that are attached to the system but do not have /dev/term and /dev/cua entries. The numbers or letters assigned are the lowest-unused numbers or letters.
2. Removes dangling links: links from /dev/term and /dev/cua pointing to no-longer-existing ports.

If the configuration has not changed, ports exits without doing anything.

Notice to Driver Writers
 ports considers devices with a node type of DDI_NT_SERIAL, DDI_NT_SERIAL_MB, DDI_NT_SERIAL_DO, or DDI_NT_SERIAL_MB_DO to be serial port devices. Devices with one of these node types must create minor device names that obey the following conventions when calling ddi_create_minor_node(9F).

- The minor name for non-system port devices (DDI_NT_SERIAL) consists of an ASCII numeric string, where the first port on the device is named 0, the second named 1, the third named 2, up to the number of ports provided by the device.
- The minor name for non-system dialout devices (DDI_NT_SERIAL_DO) is the ASCII numeric port name, concatenated with ,cu. For example, the minor name for the first dialout port on the serial board is 0, cu.
- The minor name for system-board port devices (DDI_NT_SERIAL_MB) consists of a string containing a single ASCII lowercase character, where the first port on the device is named a, the second is named b, the third is named c, for all ports on the device (or up through port z).
- The minor name for system-board dialout devices (DDI_NT_SERIAL_MB_DO) consists of the lowercase character port name, concatenated with ,cu. For example, the minor name for the first dialout port on the on-board serial device is a, cu.

To prevent disks from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using one of the above node types when calling ddi_create_minor_node(9F).
Options

The following options are supported:

- \texttt{r rootdir} Causes ports to presume that the /dev/term, /dev/cua, and /devices directories are found under rootdir, not directly under /.

Examples

**EXAMPLE 1** Creating the Serial and Dialout Minor Device Nodes

The following example creates the serial and dialout minor device nodes from the xkserial driver's \texttt{attach(9E)} function:

```c
/*
 * Create the minor number by combining the instance number
 * with the port number.
 */
#define XKNUMPORTS 8
#define XKMINORNUM(i, p) ((i) << 4 | (p))
#define XKMINORNUM_DO(i, p) ((i) << 4 | (p) | 0x80)

int xkserialattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance, portnum;
    char name[8];
    /* other stuff in attach... */
    instance = ddi_get_instance(dip);
    for (portnum = 0; portnum < XKNUMPORTS; portnum++) {
        /*
         * create the serial port device
         */
        sprintf(name, "%d", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR, 
            XKMINORNUM(instance, portnum), DDI_NT_SERIAL, 0);

        /*
         * create the dialout device
         */
        sprintf(name,"%d,cu", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR, 
            XKMINORNUM_DO(instance, portnum), DDI_NT_SERIAL_DO, 0);
    }
}
```

**EXAMPLE 2** Installing the xkserial Port Driver on a Sun Fire 4800

The following example installs the xkserial port driver on a Sun Fire 4800 (with the driver controlling the fictional XKSerial 8 port serial board), with these special files in /devices:

```
# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/xkserial@f,800000/
crw-r---- 1 root sys 32, 16 Aug 29 00:02 xkserial@2000:0
```
Installing the xkserial Port Driver on a Sun Fire 4800 (Continued)

```
crw-r----- 1 root sys 32, 145 Aug 29 00:02 xk serial@2000:1, cu  
crw-r----- 1 root sys 32, 18 Aug 29 00:02 xk serial@2000:2   
crw-r----- 1 root sys 32, 146 Aug 29 00:02 xk serial@2000:2, cu 
crw-r----- 1 root sys 32, 19 Aug 29 00:02 xk serial@2000:3  
crw-r----- 1 root sys 32, 147 Aug 29 00:02 xk serial@2000:3, cu 
crw-r----- 1 root sys 32, 20 Aug 29 00:02 xk serial@2000:4  
crw-r----- 1 root sys 32, 148 Aug 29 00:02 xk serial@2000:4, cu 
crw-r----- 1 root sys 32, 21 Aug 29 00:02 xk serial@2000:5  
crw-r----- 1 root sys 32, 149 Aug 29 00:02 xk serial@2000:5, cu 
crw-r----- 1 root sys 32, 22 Aug 29 00:02 xk serial@2000:6  
crw-r----- 1 root sys 32, 150 Aug 29 00:02 xk serial@2000:6, cu 
crw-r----- 1 root sys 32, 23 Aug 29 00:02 xk serial@2000:7  
crw-r----- 1 root sys 32, 151 Aug 29 00:02 xk serial@2000:7, cu
```

/dev/term contain symbolic links to the serial port device nodes in /devices

```
# ls -l /dev/term
/dev/term/0 -> ../../../devices/[...]/xkserial@2000:0
/dev/term/1 -> ../../../devices/[...]/xkserial@2000:1
/dev/term/2 -> ../../../devices/[...]/xkserial@2000:2
/dev/term/3 -> ../../../devices/[...]/xkserial@2000:3
/dev/term/4 -> ../../../devices/[...]/xkserial@2000:4
/dev/term/5 -> ../../../devices/[...]/xkserial@2000:5
/dev/term/6 -> ../../../devices/[...]/xkserial@2000:6
/dev/term/7 -> ../../../devices/[...]/xkserial@2000:7
```

and /dev/cua contain symbolic links to the dialout port device nodes in /devices

```
# ls -l /dev/cua
/dev/cua/0 -> ../../../devices/[...]/xkserial@2000:0,cu
/dev/cua/1 -> ../../../devices/[...]/xkserial@2000:1,cu
/dev/cua/2 -> ../../../devices/[...]/xkserial@2000:2,cu
/dev/cua/3 -> ../../../devices/[...]/xkserial@2000:3,cu
/dev/cua/4 -> ../../../devices/[...]/xkserial@2000:4,cu
/dev/cua/5 -> ../../../devices/[...]/xkserial@2000:5,cu
/dev/cua/6 -> ../../../devices/[...]/xkserial@2000:6,cu
/dev/cua/7 -> ../../../devices/[...]/xkserial@2000:7,cu
```

Files

- /dev/term/n Logical serial port devices
- /dev/cua/n Logical dialout port devices
- /etc/inittab Controls dispatching by init.

Writing Device Drivers
poweradm(1M)

Name: poweradm – manage power management properties

Synopsis:

```
poweradm [-v] get [-a all|smf|platform|current] property ...
poweradm [-v] set property=value ...
poweradm [-v] list
poweradm show
poweradm -?
```

Description: The `poweradm` program is used to display and manage the Power Management settings within a Solaris instance.

The Power Management properties and their values are stored in the service management facility (see `smf(5)`).

All users can run the `list`, `get`, and `show` forms given in the SYNOPSIS. These commands allow all users to view the current Power Management settings within a Solaris instance.

Only users and roles that belong to the Maintenance and Repair RBAC profile can execute the `set` form of `poweradm` given in the SYNOPSIS. See also the NOTES section below.

`poweradm` supports the following service property:

```administrative-authority```

The value for this property is specified as a string and can have the values:

```
- smf
- platform
- none
```

...with `platform` as the default value. The significance of this property is the source of administrative control for power management within the Solaris kernel. That is, this property indicates the origin of `time-to-full-capacity` and `time-to-minimum-responsiveness` settings within the Solaris kernel. Only a Solaris user with appropriate privileges can set this property.

When the `administrative-authority` is set to `platform` the values of `time-to-full-capacity` and `time-to-minimum-responsiveness` will be taken from the platform code. Setting these values in SMF, using the `poweradm` command will have no effect upon the values in the kernel. The `poweradm list` command will indicate that the kernel is currently using the platform values. As these values are changed by the platform administrator, so they will be modified in the kernel. Also, commands to enable or disable the power management within the Solaris kernel will come from the platform code. On systems that run virtual machines, the hypervisor or virtual machine manager can be the source of this property.
When the administrative-authority is set to smf, the values of time-to-full-capacity and time-to-minimum-responsiveness will be taken from SMF. As these values in SMF are changed by the Solaris administrator, so they will be applied to the kernel. Setting these values in the platform will have no effect upon the values in the kernel while administrative-authority is set to smf. Under this condition, the poweradm command will indicate that the kernel is currently using the values from SMF. As these values are changed by the Solaris administrator, so they will be modified in kernel.

When the administrative-authority is set to none, power management within the Solaris kernel will be turned off, although the power service will continue to run. Any power management instructions from the platform will be ignored, as will the settings in SMF. Only when administrative-authority is set to one of the other values will power management within the Solaris kernel restart, using the settings from the specified source.

time-to-full-capacity
Specified in microseconds.

This parameter constrains the dynamic capacity adjustment allowed while the system is in an active state.

This parameter defines the maximum time the system is allowed to reach (re-provision and make available) its full capacity, returning from any lower-capacity/less-responsive state, while it has been using any or all of the PM features falling within this bound.

By default, this value is taken from the platform (for example, i86pc), because the default setting for administrative-authority is set to platform.

Alternatively, if administrative-authority is set to smf, this value is taken from the definition provided by the power service (that is, SMF). At install time this value is set to be undefined. If the Solaris administrator chooses to modify this property, a value appropriate to the needs of the workload or applications must be picked.

time-to-minimum-responsiveness
Specified in milliseconds.

This parameter constrains the dynamic capacity adjustment allowed while the system is in an inactive state.

This parameter defines how long the system is allowed to return to its active state—that is, to provide the minimum capacity required to meet the above time-to-full-capacity constraint.

Moderate values (seconds) allow hardware components or subsystems on the platform to be placed in slower-response inactive states; larger values still (for example, 30 seconds to minutes) allow for such as whole system suspension, using techniques such as suspend-to-RAM.

By default, this value is taken from the platform (for example, i86pc), because the default setting for administrative-authority is set to platform.
Alternatively, if administrative-authority is set to smf, this value is taken from the definition provided by the power service (that is, SMF). At install time this value is set to be undefined. If the Solaris administrator chooses to modify this property, a value appropriate to the needs of the workload or applications must be picked.

**suspend-enable**

By default no machine running Solaris is permitted to attempt a suspend operation. Setting this property to true will permit a suspend operation to be attempted. The value of administrative-authority has no effect upon this property.

**platform-disabled**

This property cannot be changed by the poweradm command. The value of platform-disabled can be viewed by running the list subcommand. If set to true and administrative-authority is set to platform, power management has been disabled by the platform. If set to false, control of power management will be through the values of the other properties, described above. The output of the show subcommand will display the values of these properties. On systems that run virtual machines, the hypervisor or virtual machine manager can be the source of platform-disabled. The default value for platform-disabled is false.

### Options

The following options are supported.

- `?`
  Display a synopsis of available subcommands and options.

- `v`
  Provide verbose output. Can be used with any of the subcommands listed below.

### Sub-commands

The following subcommands are supported:

- `get [-a all|smf|platform|current]`
  Retrieves the current value of the named property. The -a option can be used to indicate the origin of the value either: SMF (smf), the platform (platform), the current value used by the kernel (current) or all of the preceding (all). By default, if no origin is specified then current is assumed.

  The administrative-authority and suspend-enable properties do not have a platform value.

- `set property=value...`
  Changes the named property to the given value. The properties administrative-authority and suspend-enable are automatically synchronized to the new value in the kernel. The properties time-to-full-capacity and time-to-minimum-responsiveness are synchronized to the kernel if and only if administrative-authority is set to smf. If the -v option is used and the kernel cannot be updated immediately because administrative-authority is not set to smf, a warning message will be issued.
Only users and roles that belong to the Maintenance and Repair RBAC profile can execute the `set` subcommand.

list
Lists all the available Power Management properties values and indicate whether power management is active.

show
Output human readable text that indicates whether the platform or the Solaris instance is controlling power management, whether power management is enabled, and, if it is enabled, the values of `time-to-full-capacity` and `time-to-minimum-responsiveness`.

**Examples**

**EXAMPLE 1** Setting Platform to Control Power Management

The following command sets the platform to control power management.

```
# poweradm set administrative-authority=platform
```

**EXAMPLE 2** Disabling Power Management

The following command disables power management.

```
# poweradm set administrative-authority=none
```

**EXAMPLE 3** Setting Useful Parameters

The following sequence of commands sets `time-to-full-capacity` to 300 microseconds, `settime-to-minimum-responsiveness` to 500 milliseconds, and informs the Solaris instance of the new values.

```
# poweradm set time-to-full-capacity=300
# poweradm set time-to-minimum-responsiveness=500
# poweradm set administrative-authority=smf
```

**EXAMPLE 4** Disabling Suspend and Resume

The following command disables suspend and resume.

```
# poweradm set suspend-enable=false
```

**EXAMPLE 5** Listing Power Management Properties

The following command lists all available power management properties.

```
# poweradm list
```

**EXAMPLE 6** Obtaining Value of a Property

The following command shows the current value of `time-to-full-capacity`.

```
# poweradm get time-to-full-capacity
```
EXAMPLE 7  Showing Value of a Property as Set by Platform
The following command retrieves the value of time-to-full-capacity set by the platform.

# poweradm get -a platform time-to-full-capacity

Note that this will only be the same as current value if administrative-authority has been set to platform. See the explanation of the administrative-authority property, above.

EXAMPLE 8  Showing Value of a Property as Set by Solaris Instance
The following command retrieves the value of time-to-full-capacity set by the Solaris instance.

# poweradm get -a smf time-to-full-capacity

Note that this will only be the same as current value if administrative-authority has been set to smf. See the explanation of the administrative-authority property, above.

EXAMPLE 9  Invoking show Subcommand
The following example commands illustrate the four possible contexts in which poweradm show can be invoked.

The following command is invoked when power management has been disabled by the platform.

# poweradm show
Power management is disabled with the hardware platform as the authority

The following command is invoked when power management has been disabled by the Solaris administrator.

# poweradm show
Power management is disabled with the Solaris instance as the authority

The following command is invoked when power management has been enabled by the platform.

# poweradm show
Power management is enabled with the hardware platform as the authority
time-to-full-capacity 300 microseconds
time-to-minimum-responsiveness 500 milliseconds

The following command is invoked when power management has been enabled by the Solaris instance.

# poweradm show
Power management is enabled with the Solaris instance as the authority
time-to-full-capacity 300 microseconds
time-to-minimum-responsiveness 500 milliseconds
Exit Status

0  
Successful completion.

1  
An error occurred.

2  
Invalid command line options were specified.

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

</tbody>
</table>

See Also  attributes(5), smf(5), smf_security(5)

Notes

The power service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/power:default

The properties that can be set by poweradm are defined in that service as:

- active_control/administrative-authority, which is described under administrative-authority above
- active_config/time-to-full-capacity, which is described under time-to-full-capacity above
- active_config/time-to-minimum-responsiveness, which is described under time-to-minimum-responsiveness above
- suspend/suspend-enable, which is described under suspend-enable above

If the service is disabled, no power management settings will be uploaded to the kernel in the future. Existing settings will not be undone until the next reboot. Disabling all power management is best accomplished by setting administrative-authority to none.

If administrative-authority is set to the value smf before both time-to-full-capacity and time-to-minimum-responsiveness have been set, the service will go into maintenance mode. In such a situation, set administrative-authority to the value none then set both time-to-full-capacity and time-to-minimum-responsiveness to the values you want, clear the service and then set administrative-authority to smf.

To set properties in the active_config and suspend property groups, the solaris.smf.value.power_config authorization is required. To set properties in the
active_control property group requires the `solaris.smf.value.power_control` authorization is required. Both of these authorizations are part of the Maintenance and Repair profile.
**Description**

`PowerTOP` is an observability tool that shows how effectively the system is taking advantage of the CPU’s power management features. By running the tool on an otherwise idle system, the user can see for how long the CPU is running at different power states. Ideally, an unutilized (idle) system spends 100% of its time running at the lowest power state, but because of background user and kernel activity (random software periodically waking to poll status), idle systems can consume more power than they should.

The tool analyzes system activity periodically and displays a summary of how long the processor is executing at each supported power state. It also displays the top activities responsible for causing the CPU to wake up and use more energy. This report allows the user to identify and diagnose problematic areas of the system and optimize its power efficiency.

`PowerTOP` averages the amount of activity that is preventing the CPU from entering a lower power state and presents it on the “Wakes from idle per second” field. This value represents the total number of wake-ups divided by the current interval. Notice that not all events are displayed on the screen at all times.

During execution, a user can force a refresh of the analysis by pressing the R key. The interval time is restored to the default or to a specified value. To quit the application, the user must press the Q key.

`PowerTOP` runs on some virtual domains. However, the report for idle state transitions might or might not be accurate as the physical CPU can be shared by different virtual CPUs. Both wakeup count and event report displays information regarding the current virtualized environment.

**Options**

The following options are supported:

- `-c [processor_id]`
  Specifies which CPU the tool should observe.

- `-d [count]`
  Dumps the results of `count` analysis of system activity to the screen.

- `-h`
  Displays the command’s usage.

- `-t [interval]`
  Specifies the interval, in seconds, at which the tool analyzes the system. The possible values are in the range of 1 through 30; the default is 5 seconds.

- `-v`
  Switches to verbose mode, including noting firings of the kernel cyclic subsystem in the event report.
Examples

EXAMPLE 1  Setting the Interval

The following command sets the interval to two seconds.

% powertop -t 2

EXAMPLE 2  Analyzing and Dumping System Activity

The following command analyzes and dumps system activity to the standard output four times.

% powertop -d 4

EXAMPLE 3  Reporting Cyclic Subsystem Activity

The following command reports cyclic subsystem activity.

% powertop -v

EXAMPLE 4  Analyzing Activity on a Specific Processor

The following command runs PowerTOP and only displays data for CPU 3:

% powertop -c 3

Exit Status

0  Successful operation.
1  An error occurred.
2  Incorrect usage.

Usage

You must have DTrace privileges to run PowerTOP.
**Name**  pppd – point to point protocol daemon

**Synopsis**  pppd [tty_name] [speed] [options]

**Description**  The point-to-point protocol (PPP) provides a method for transmitting datagrams over serial point-to-point links. PPP is composed of three components: a facility for encapsulating datagrams over serial links, an extensible link control protocol (LCP), and a family of network control protocols (NCP) for establishing and configuring different network-layer protocols.

The encapsulation scheme is provided by driver code in the kernel. pppd provides the basic LCP authentication support and several NCPs for establishing and configuring the Internet Protocol (referred to as the IP Control Protocol or "IPCP") and IPv6 (IPV6CP).

**Options**  The following sections discuss the pppd options:

**Options Files**  Options are taken from files and the command line. pppd reads options from the files /etc/ppp/options, $HOME/.ppprc and /etc/ppp/options.ttyname (in that order) before processing the options on the command line. (Command-line options are scanned for the terminal name before the options.ttyname file is read.) To form the name of the options.ttyname file, the initial /dev/ is removed from the terminal name, and any remaining forward slash characters (/) are replaced with dots. For example, with serial device /dev/cua/a, option file /etc/ppp/options.cua.a is read.

An options file is parsed into a series of words that are delimited by whitespace. Whitespace can be included in a word by enclosing the word in double-quotes ("'). A backslash (\) quotes the succeeding character. A hash (#) starts a comment, which continues until the end of the line. There is no restriction on using the file or call options within an options file.

**Frequently Used Options**  Communicate over the named device. The string /dev/ is prepended if necessary. If no device name is given, or if the name of the terminal connected to the standard input is given, pppd uses that terminal and does not fork to put itself in the background. A value for this option from a privileged source cannot be overridden by a non-privileged user.

**<speed>**  Set the baud rate to <speed> (a decimal number). The default is to leave the baud rate unchanged. This option is normally needed for dial-out only.

**asyncmap <map>**  Set the async character map to <map>. The map describes which control characters cannot be successfully received over the serial line. pppd asks the peer to send these characters as a 2-byte escape sequence. The argument is a 32 bit hex number, with each bit representing a character to escape. Bit 0 (00000001) represents the character 0x00; bit 31 (80000000) represents the character 0x1f or ^_. If multiple asyncmap options are given, the values are ORed together. If no asyncmap option is given, pppd attempts to negotiate a value of 0. If the
peer agrees, this disables escaping of the standard control characters. Use the `default-asyncmap` option to disable negotiation and escape all control characters.

auth

Required the peer to authenticate itself before allowing network packets to be sent or received. This option is the default if the system has a default route. If the `auth` or the `noauth` option is not specified, `pppd` allows the peer to use only those IP addresses to which the system does not already have a route.

call name

Read options from the file `/etc/ppp/peers/name`. This file may contain privileged options, including `noauth`, even if `pppd` is not being run by root. The `name` string may not begin with a slash (`"/"`) or include consecutive periods (`".."`) as a pathname component.

callback number

Request a callback to the given telephone number using Microsoft CBCP.

connect script

Use the executable or shell command specified by `script` to set up the serial line. This script would typically use the `chat(1M)` program to dial the modem and start the remote PPP session. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.

crtscts

Use hardware flow control, that is, RTS/CTS, to control the flow of data on the serial port. If the `crtscts`, `nocrtscts`, `cdircts` or `nocdircts` option is not provided, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output and use this mode to implement unidirectional flow control. The serial port suspends transmission when requested by the modem by means of CTS but cannot request the modem to stop sending to the computer. This mode allows the use of DTR as a modem control line.

defaultroute

Add a default route to the system routing tables when IPCP negotiation successfully completes, using the peer as the gateway. This entry is removed when the PPP connection is broken. This option is privileged if the `nodefaultroute` option is specified.

disconnect script

Run the executable or shell command specified by `script` after `pppd` terminates the link. Typically, this script is used to command the modem to hang up if hardware modem control signals are not available. `disconnect` is not run if the modem has already hung up. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.

escape xx,yy,...

Specifies that certain characters be escaped on transmission regardless of whether the peer requests them to be escaped with its async control
character map. The characters to be escaped are specified as a list of hex numbers separated by commas. Note that almost any character can be specified for the escape option, unlike the asyncmap option which allows only control characters to be specified. Characters that cannot be escaped are those containing hex values 0x20 through 0x3f and 0x5e.

**file name**
Read options from file *name*. If this option is used on the command line or in $HOME/.ppprc, the file must be readable by the user invoking pppd. See "Options Files," above, for a list of files that pppd always reads, regardless of the use of this option.

**init script**
Run the executable or shell command specified by *script* to initialize the serial line. This script would typically use the *chat*(1M) program to configure the modem to enable auto-answer. A value for this option from a privileged source cannot be overridden by a non-privileged user.

**lock**
Directs pppd to create a UUCP-style lock file for the serial device to ensure exclusive access to the device.

**mr u n**
Set the Maximum Receive Unit (MRU) value to *n*. pppd asks the peer to send packets of no more than *n* bytes. Minimum MRU value is 128. Default MRU value is 1500. A value of 296 is recommended for slow links (40 bytes for TCP/IP header + 256 bytes of data). For IPv6, MRU must be at least 1280.

**mt u n**
Set the Maximum Transmit Unit (MTU) value to *n*. Unless the peer requests a smaller value via MRU negotiation, pppd requests the kernel networking code to send data packets of no more than *n* bytes through the PPP network interface. For IPv6, MTU must be at least 1280.

**passive**
Enables the "passive" option in the LCP. With this option, pppd attempts to initiate a connection; if no reply is received from the peer, pppd waits passively for a valid LCP packet instead of exiting, as it would without this option.

**Options**
  <local_IP_address>::<remote_IP_address>
Set the local and/or remote interface IP addresses. Either one may be omitted, but the colon is required. The IP addresses are specified with a host name or in decimal dot notation, for example: :10.1.2.3. The default local address is the first IP address of the system unless the noipdefault option is provided. The remote address is obtained from the peer if not specified in any option. Thus, in simple cases, this option is not required. If a local and/or remote IP address is specified with this option, pppd will not accept a different value from the peer in the IPCP negotiation unless the ipcp-accept-local and/or ipcp-accept-remote options are given, respectively.
allow-fcs fcs-type
Set allowable FCS type(s) for data sent to the peer. The fcs-type is a comma-separated list of "crc16", "crc32", "null", or integers. By default, all known types are allowed. If this option is specified and the peer requests a type not listed, a LCP Configure-Nak is sent to request only the listed types.

allow-ip address(es)
Allow peers to use the given IP address or subnet without authenticating themselves. The parameter is parsed in the same manner as each element of the list of allowed IP addresses is parsed in the secrets files. See the "Authentication" section more more details.

bsdcomp nr,nt
Request that the peer compress packets that it sends using the BSD-Compress scheme, with a maximum code size of nr bits, and agree to compress packets sent to the peer with a maximum code size of nt bits. If nt is not specified, it defaults to the value given for nr. Values in the range 9 to 15 may be used for nr and nt; larger values provide better compression but consume more kernel memory for compression dictionaries. Alternatively, a value of 0 for nr or nt disables compression in the corresponding direction. Use nobsdcomp or bsdcomp 0 to disable BSD-Compress compression entirely. If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

cdtrcts
Use a non-standard hardware flow control such as DTR/CTS to control the flow of data on the serial port. If the ctscts, nocrtscts, cdtrcts or nocdtrcts option is not specified, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output. Such serial ports use this mode to implement true bi-directional flow control. Note that this flow control mode does not permit using DTR as a modem control line.

chap-interval n
If this option is given, pppd will rechallenge the peer every n seconds.

chap-max-challenge n
Set the maximum number of CHAP challenge transmissions to n (default 10).

chap-restart n
Set the CHAP restart interval (retransmission timeout for challenges) to n seconds. The default is 3.

connect-delay n
Wait for up to n milliseconds after the connect script finishes for a valid PPP packet from the peer. When the wait period elapses or when a valid PPP packet is received from the peer, pppd begins negotiation by sending its first LCP packet. The default value is 1000 (1 second). A wait period applies only if the connect or pty option is used.

data-rate n
Set maximum data rate to n (in bytes per second) when using the pty, notty, record, or socket options.
debug
Enables connection debugging facilities. If this option is given, pppd logs the contents of all control packets sent or received in a readable form. The packets are logged through syslog with facility daemon and level debug. This information can be directed to a file by configuring /etc/syslog.conf appropriately.

default-asyncmap
Disable asyncmap negotiation, forcing all control characters to be escaped for both the transmit and the receive direction.

default-fcs
Disable FCS Alternatives negotiation entirely. By default, no FCS Alternatives option is sent to the peer, but the option is accepted. If this option is specified by the peer, then LCP Configure-Reject is sent.

default-mru
Disable MRU [Maximum Receive Unit] negotiation. With this option, pppd uses the default MRU value of 1500 bytes for the transmit and receive directions.

deflate nr,nt,e
Request that the peer compress packets that it sends, using the deflate scheme, with a maximum window size of $2^{nr}$ bytes, and agree to compress packets sent to the peer with a maximum window size of $2^{nt}$ bytes and effort level of $e$ (1 to 9). If $nt$ is not specified, it defaults to the value given for $nr$. If $e$ is not specified, it defaults to 6. Values in the range 9 to 15 may be used for $nr$ and $nt$; larger values provide better compression but consume more kernel memory for compression dictionaries. (Value 8 is not permitted due to a zlib bug.) Alternatively, a value of 0 for $nr$ or $nt$ disables compression in the corresponding direction. Use nodiflate or deflate 0 to disable deflate compression entirely. (Note: pppd requests deflate compression in preference to BSD-Compress if the peer can do either.) If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

demand
Initiate the link only on demand, that is, when data traffic is present. With this option, the remote IP address must be specified by the user on the command line or in an options file. pppd initially configures and enables the interface for IP traffic without connecting to the peer. When traffic is available, pppd connects to the peer and performs negotiation, authentication and other actions. When completed, pppd passes data packets across the link. The demand option implies the persist option. If this behavior is not desired, use the npersist option after the demand option. The idle and holdoff options can be used in conjunction with the demand option.

domain d
Append the domain name $d$ to the local host name for authentication purposes. For example, if gethostname() returns the name porsche, but the fully qualified domain name is porsche.Quotron.COM, you could specify domain Quotron.COM. With this configuration, pppd uses the name porsche.Quotron.COM for accessing secrets in the secrets file and as the default name when authenticating to the peer. This option is privileged.
endpoint endpoint-value
Set the endpoint discriminator (normally used for RFC 1990 Multilink PPP operation).
The endpoint-value consists of a class identifier and a class-dependent value. The class
derentifier is one of "null," "local," "IP," "MAC," "magic," "phone," or a decimal integer. If
present, the class-dependent value is separated from the identifier by a colon ("".) or period
("."). This value may be a standard dotted-decimal IP address for class "IP," an optionally
colon-or-dot separated hex Ethernet address for class "MAC" (must have 6 numbers), or an
arbitrary string of bytes specified in hex with optional colon or dot separators between
bytes. Although this option is available, this implementation does not support multilink.

fcs fcs-type
Set FCS type(s) desired for data sent by the peer. The fcs-type is a comma-separated list of
crc16, crc32, null, or integers. By default, an FCS Alternatives option is not specified, and
the medium-dependent FCS type is used. If this option is specified and the peer sends an
LCP Configure-Nak, only the listed types are used. If none are in common, the FCS
Alternatives option is omitted from the next LCP Configure-Request to drop back to the
default.

hide-password
When logging the contents of PAP packets, this option causes pppd to exclude the password
string from the log. This is the default.

holdoff n
Specifies how many seconds to wait before re-initiating the link after it terminates. This
option is effective only if the persist or demand option is used. The holdoff period is not
applied if the link is terminated because it was idle.

ident string
Set the LCP Identification string. The default value is a version string similar to that
displayed by the --version option.

idle n
Specifies that pppd must disconnect if the link is idle for n seconds. The link is idle when no
data packets (i.e. IP packets) are being sent or received. Do not use this option with the
persist option but without the demand option.

ipcp-accept-local
With this option, pppd accepts the peer's idea of the local IP address, even if the local IP
address is specified in an option.

ipcp-accept-remote
With this option, pppd accepts the peer's idea of its remote IP address, even if the remote IP
address is specified in an option.

ipcp-max-configure n
Set the maximum number of IPCP Configure-Request transmissions to n (default 10).
ipcp-max-failure $n$
Set the maximum number of IPCP Configure-NAKs sent before sending Configure-Rejects instead to $n$ (default 10).

ipcp-max-terminate $n$
Set the maximum number of IPCP terminate-request transmissions to $n$ (default 3).

ipcp-restart $n$
Set the IPCP restart interval (retransmission timeout) to $n$ seconds (default 3).

ipparam string
Provides an extra parameter to the ip-up and ip-down scripts. When this option is given, the string supplied is given as the sixth parameter to those scripts. See the "Scripts" section.

ipv6 <local_interface_identifier>,<remote_interface_identifier>
Set the local and/or remote 64-bit interface identifier. Either one may be omitted. The identifier must be specified in standard ASCII notation of IPv6 addresses (for example: ::dead:beef). If the ipv6cp-use-ipaddr option is given, the local and remote identifiers are derived from the respective IPv4 addresses (see above). The ipv6cp-use-persistent option can be used instead of the ipv6 <local>,<remote> option.

ipv6cp-accept-local
Accept peer's interface identifier for the local link identifier.

ipv6cp-max-configure $n$
Set the maximum number of IPv6CP Configure-Request transmissions to $n$ (default 10).

ipv6cp-max-failure $n$
Set the maximum number of IPv6CP Configure-NAKs sent before sending Configure-Rejects instead to $n$ (default 10).

ipv6cp-max-terminate $n$
Set the maximum number of IPv6CP terminate-request transmissions to $n$ (default 3).

ipv6cp-restart $n$
Set the IPv6CP restart interval (retransmission timeout) to $n$ seconds (default 3).

ipv6cp-use-ipaddr
If either the local or remote IPv6 address is unspecified, use the corresponding configured IPv4 address as a default interface identifier. (This option uses the configured addresses, not the negotiated addresses. Do not use it with ipcp-accept-local if the local IPv6 identifier is unspecified or with ipcp-accept-remote if the remote IPv6 identifier is unspecified.)

ipv6cp-use-persistent
Use uniquely-available persistent value for link local address.

kdebug $n$
Enable debugging code in the kernel-level PPP driver. Argument $n$ is the sum of the following values: 1 to enable general debug messages, 2 to request that contents of received
packets be printed, and 4 to request contents of transmitted packets be printed. Messages printed by the kernel are logged by `syslogd(1M)` to a file directed in the
/etc/syslog.conf configuration file. Do not use the kdebug option to debug failed links. Use the debug option instead.

`lcp-echo-failure n`
If this option is given, `pppd` presumes the peer to be dead if `n` LCP Echo-Requests are sent without receiving a valid LCP Echo-Reply. If this happens, `pppd` terminates the connection. This option requires a non-zero value for the `lcp-echo-interval` parameter. This option enables `pppd` to terminate after the physical connection is broken (for example, if the modem has hung up) in situations where no hardware modem control lines are available.

`lcp-echo-interval n`
If this option is given, `pppd` sends an LCP Echo-Request frame to the peer every `n` seconds. Normally the peer responds to the Echo-Request by sending an Echo-Reply. This option can be used with the `lcp-echo-failure` option to detect that the peer is no longer connected.

`lcp-max-configure n`
Set the maximum number of LCP Configure-Request transmissions to `n` (default 10).

`lcp-max-failure n`
Set the maximum number of LCP Configure-NAKs sent before starting to send Configure-Rejects instead to `n` (default 10).

`lcp-max-terminate n`
Set the maximum number of LCP Terminate-Request transmissions to `n` (default 3).

`lcp-restart n`
Set the LCP restart interval (retransmission timeout) to `n` seconds (default 3).

`linkname name`
Sets the logical name of the link to `name`. `pppd` creates a file named `ppp-name.pid` in /var/run containing its process ID. This is useful in determining which instance of `pppd` is responsible for the link to a given peer system. This is a privileged option.

`local`
Do not use modem control lines. With this option, `pppd` ignores the state of the CD (Carrier Detect) signal from the modem and does not change the state of the DTR (Data Terminal Ready) signal.

`logfd n`
Send log messages to file descriptor `n`. `pppd` sends log messages to (at most) one file or file descriptor (as well as sending the log messages to syslog), so this option and the `logfile` option are mutually exclusive. By default `pppd` sends log messages to stdout (file descriptor 1) unless the serial port is open on stdout.

`logfile filename`
Append log messages to the file `filename` (and send the log messages to syslog). The file is opened in append mode with the privileges of the user who invoked `pppd`. 
login
Use the system password database for authenticating the peer using PAP, and record the
user in the system wtmp file. Note that the peer must have an entry in the
/etc/ppp/pap-secrets file and the system password database to be allowed access.

maxconnect n
Terminate the connection after it has been available for network traffic for n seconds (that
is, n seconds after the first network control protocol starts). An LCP Time-Remaining
message is sent when the first NCP starts, and again when 5, 2, and 0.5 minutes are
remaining.

maxfail n
Terminate after n consecutive failed connection attempts. A value of 0 means no limit. The
default value is 10.

modem
Use the modem control lines. This option is the default. With this option, pppd waits for
the CD (Carrier Detect) signal from the modem to be asserted when opening the serial
device (unless a connect script is specified), and drops the DTR (Data Terminal Ready)
signal briefly when the connection is terminated and before executing the connect script.

ms-dns <addr>
If pppd is acting as a server for Microsoft Windows clients, this option allows pppd to
supply one or two DNS (Domain Name Server) addresses to the clients. The first instance
of this option specifies the primary DNS address; the second instance (if given) specifies the
secondary DNS address. If the first instance specifies a name that resolves to multiple IP
addresses, then the first two addresses are used. (This option is present in some older
versions of pppd under the name dns-addr.)

ms-lanman
If pppd connects as a client to a Microsoft server and uses MS-CHAPv1 for authentication,
this option selects the LAN Manager password style instead of Microsoft NT.

ms-wins <addr>
If pppd acts as a server for Microsoft Windows or Samba clients, this option allows pppd to
supply one or two WINS (Windows Internet Name Services) server addresses to the clients.
The first instance of this option specifies the primary WINS address; the second instance (if
given) specifies the secondary WINS address. As with ms-dns, if the name specified resolves
to multiple IP addresses, then the first two will be taken as primary and secondary.

name name
Set the name of the local system for authentication purposes to name. This is a privileged
option. With this option, pppd uses lines in the secrets files that have name as the second
field to look for a secret to use in authenticating the peer. In addition, unless overridden
with the user option, name is used as the name to send to the peer when authenticating the
local system. (Note that pppd does not append the domain name to name.)
no-acm-test
Disable use of asyncmap (ACCM) checking using LCP Echo-Request messages. If the lcp-echo-failure is used on an asynchronous line, pppd includes all control characters in the first n LCP Echo-Request messages. If the asyncmap is set incorrectly, the link drops rather than continue operation with random failures. This option disables that feature.

noaccomp
Disable HDLC Address/Control compression in both directions (send and receive).

noauth
Do not require the peer to authenticate itself. This option is privileged.

nobsdcomp
Disables BSD-Compress compression; pppd will not request or agree to compress packets using the BSD-Compress scheme. This option is not necessary if noccp is specified.

noccp
Disable CCP (Compression Control Protocol) negotiation. This option should only be required if the peer has bugs or becomes confused by requests from pppd for CCP negotiation. If CCP is disabled, then BSD and deflate compression do not need to be separately disabled.

nocrtscts
Disable hardware flow control (i.e. RTS/CTS) on the serial port. If the crtscts, nocrtscts, cdtrcts or nocdtrcts options are not given, the hardware flow control setting for the serial port is left unchanged.

nocdtrcts
This option is a synonym for nocrtscts. Either option will disable both forms of hardware flow control.

nodefaultroute
Disable the default route option. You can prevent non-root users from creating default routes with pppd by placing this option in the /etc/ppp/options file.

nodeflate
Disables deflate compression; pppd will not request or agree to compress packets using the deflate scheme. This option is not necessary if noccp is specified.

nodeflatedraft
Do not use Internet Draft (incorrectly assigned) algorithm number for deflate compression. This option is not necessary if noccp is specified.

nodetach
Do not detach from the controlling terminal. Without this option, pppd forks to become a background process if a serial device other than the terminal on the standard input is specified.

noendpoint
Do not send or accept the Multilink Endpoint Discriminator option.
noident
   Disable use of LCP Identification. LCP Identification messages will not be sent to the peer, but received messages will be logged. (Specify this option twice to completely disable LCP Identification. In this case, pppd sends LCP Code-Reject in response to received LCP Identification messages.)

noip
   Disable IPCP negotiation and IP communication. Use this option only if the peer has bugs or becomes confused by requests from pppd for IPCP negotiation.

noipv6
   Disable IPv6CP negotiation and IPv6 communication. IPv6 is not enabled by default.

noipv6default
   Disables the default behavior when no local IP address is specified, which is to determine (if possible) the local IP address from the hostname. With this option, the peer must supply the local IP address during IPCP negotiation (unless it specified explicitly on the command line or in an options file).

nolog
   Do not send log messages to a file or file descriptor. This option cancels the \logfd and \logfile options. nologfd acts as an alias for this option.

nomagic
   Disable magic number negotiation. With this option, pppd cannot detect a looped-back line. Use this option only if the peer has bugs. Do not use this option to work around the “Serial line is looped back” error message.

nopam
   This privileged option disables use of pluggable authentication modules. If this option is specified, pppd reverts to standard authentication mechanisms. The default is not to use PAM.

comp
   Disable protocol field compression negotiation in the receive and the transmit direction.

nopersist
   Exit once a connection has been made and terminated. This is the default unless the persist or demand option is specified.

noplink
   Cause pppd to use I_LINK instead of I_PLINK. This is the default. When I_LINK is used, the system cleans up terminated interfaces (even when SIGKILL is used) but does not allow ifconfig(1M) to unplug PPP streams or insert or remove modules dynamically. Use the plink option if ifconfig(1M) modinsert, modremove or unplumb support is needed.

nopredictor1
   Do not accept or agree to Predictor-1 compression. (This option is accepted for compatibility. The implementation does not support Predictor-1 compression.)
noproxyarp
   Disable the proxyarp option. If you want to prevent users from creating proxy ARP entries
   with pppd, place this option in the /etc/ppp/options file.

notty
   Normally, pppd requires a terminal device. With this option, pppd allocates itself a
   pseudo-tty master/slave pair and uses the slave as its terminal device. pppd creates a child
   process to act as a character shunt to transfer characters between the pseudo-tty master and
   its standard input and output. Thus, pppd transmits characters on its standard output and
   receives characters on its standard input even if they are not terminal devices. This option
   increases the latency and CPU overhead of transferring data over the ppp interface as all of
   the characters sent and received must flow through the character shunt process. An explicit
   device name may not be given if this option is used.

novj
   Disable Van Jacobson style TCP/IP header compression in both the transmit and the
   receive direction.

novjccomp
   Disable the connection-ID compression option in Van Jacobson style TCP/IP header
   compression. With this option, pppd does not omit the connection-ID byte from Van
   Jacobson compressed TCP/IP headers, nor does it ask the peer to do so. This option is
   unnecessary if novj is specified.

pam
   This privileged option enables use of PAM. If this is specified, pppd uses the pam(3PAM)
   framework for user authentication with a service name of "ppp" if the login option and
   PAP authentication are used. The default is not to use PAM.

papcrypt
   Indicates that pppd should not accept a password which, before encryption, is identical to
   the secret from the /etc/ppp/pap-secrets file. Use this option if the secrets in the
   pap-secrets file are in crypt(3C) format.

pap-max-authreq n
   Set the maximum number of PAP authenticate-request transmissions to n (default 10).

pap-restart n
   Set the PAP restart interval (retransmission timeout) to n seconds (default 3).

pap-timeout n
   Set the maximum time that pppd waits for the peer to authenticate itself with PAP to n
   seconds (0= no limit). The default is 30 seconds.

password string
   Password string for authentication to the peer.

persist
   Do not exit after a connection is terminated; instead try to reopen the connection.
plink
Cause pppd to use _PLINK instead of _LINK. The default is to use _LINK, which cleans up terminated interface (even if SIGKILL is used), but does not allow ifconfig(1M) to unplumb PPP streams or insert or remove modules dynamically. Use this option if ifconfig(1M) modinsert/modremove/unplumb support is needed. See also the plumbed option.

plugin filename
Load the shared library object file filename as a plugin. This is a privileged option. Unless the filename specifies an explicit path, /etc/ppp/plugins and /usr/lib/inet/ppp will be searched for the object to load in that order.

plumbed
This option indicates that pppd should find a plumbed interface and use that for the session. If IPv4 addresses or IPv6 interface IDs or link MTU are otherwise unspecified, they are copied from the interface selected. This mode mimics some of the functionality of the older aspppd implementation and may be helpful when pppd is used with external applications that use ifconfig(1M).

pppmux timer
Enable PPP Multiplexing option negotiation and set transmit multiplexing timeout to timer microseconds.

privgroup group-name
Allows members of group group-name to use privileged options. This is a privileged option. Because there is no guarantee that members of group-name cannot use pppd to become root themselves, you should be careful using this option. Consider it equivalent to putting the members of group-name in the root or sys group.

proxyarp
Add an entry to the system’s Address Resolution Protocol (ARP) table with the IP address of the peer and the Ethernet address of this system. When you use this option, the peer appears to other systems to be on the local Ethernet. The remote address on the PPP link must be in the same subnet as assigned to an Ethernet interface.

pty script
Specifies that the command script, and not a specific terminal device is used for serial communication. pppd allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. script runs in a child process with the pseudo-tty master as its standard input and output. An explicit device name may not be given if this option is used. (Note: if the record option is used in conjunction with the pty option, the child process will have pipes on its standard input and output.)

receive-all
With this option, pppd accepts all control characters from the peer, including those marked in the receive asyncmap. Without this option, pppd discards those characters as specified in RFC 1662. This option should be used only if the peer has bugs, as is often found with dial-back implementations.
record filename
Directs pppd to record all characters sent and received to a file named \textit{filename}. \textit{filename} is opened in append mode, using the user's user-ID and permissions. Because this option uses a pseudo-tty and a process to transfer characters between the pseudo-tty and the real serial device, it increases the latency and CPU overhead of transferring data over the PPP interface. Characters are stored in a tagged format with timestamps that can be displayed in readable form using the \texttt{pppdump(1M)} program. This option is generally used when debugging the kernel portion of pppd (especially CCP compression algorithms) and not for debugging link configuration problems. See the \texttt{debug} option.

remotename \textit{name}
Set the assumed name of the remote system for authentication purposes to \textit{name}. Microsoft Windows NT does not provide a system name in its CHAP Challenge messages, and this option is often used to work around this problem.

refuse-chap
With this option, pppd will not agree to authenticate itself to the peer using standard Challenge Handshake Authentication Protocol (CHAP). (MS-CHAP is not affected.)

refuse-mschap
Do not agree to authenticate to peer with MS-CHAPv1. If this option is specified, requests for MS-CHAPv1 authentication from the peer are declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

refuse-mschapv2
Do not agree to authenticate to peer with MS-CHAPv2. If specified, this option requests that MS-CHAPv2 authentication from the peer be declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

refuse-pap
With this option, pppd will not agree to authenticate itself to the peer using Password Authentication Protocol (PAP).

require-chap
Require the peer to authenticate itself using standard CHAP authentication. MS-CHAP is not affected.

require-mschap
Require the peer to authenticate itself using MS-CHAPv1 authentication.

require-mschapv2
Require the peer to authenticate itself using MS-CHAPv2 authentication.

require-pap
Require the peer to authenticate itself using PAP authentication.

show-password
When logging contents of PAP packets, this option causes pppd to show the password string in the log message.
silent
With this option, pppd will not transmit LCP packets to initiate a connection until a valid LCP packet is received from the peer. This is like the "passive" option with older versions of pppd and is retained for compatibility, but the current passive option is preferred.

small-accm-test
When checking the asyncmap (ACCM) setting, pppd uses all 256 possible values by default. See no-accm-test. This option restricts the test so that only the 32 values affected by standard ACCM negotiation are tested. This option is useful on very slow links.

socket host:port
Connect to given host and port using TCP and run PPP over this connection.

sync
Use synchronous HDLC serial encoding instead of asynchronous. The device used by pppd with this option must have sync support. Currently supports zs, se, and hsi drivers.

unit n
Set PPP interface unit number to n, if possible.

updetach
With this option, pppd detaches from its controlling terminal after establishing the PPP connection. When this is specified, messages sent to stderr by the connect script, usually chat(1M), and debugging messages from the debug option are directed to pppd's standard output.

usehostname
Enforce the use of the hostname with domain name appended, if given, as the name of the local system for authentication purposes. This overrides the name option. Because the name option is privileged, this option is normally not needed.

usepeerdnss
Ask the peer for up to two DNS server addresses. Addresses supplied by the peer, if any, are passed to the /etc/ppp/ip-up script in the environment variables DNS1 and DNS2. In addition, pppd creates an /etc/ppp/resolv.conf file containing one or two nameserver lines with the address(es) supplied by the peer.

user name
Sets the name used for authenticating the local system to the peer to name.

vj-max-slots n
Sets the number of connection slots to be used by the Van Jacobson TCP/IP header compression and decompression code to n, which must be between 2 and 16 (inclusive).

welcome script
Run the executable or shell command specified by script before initiating PPP negotiation, after the connect script, if any, has completed. A value for this option from a privileged source cannot be overridden by a non-privileged user.
xonxoff
Use software flow control, that is, XON/XOFF, to control the flow of data on the serial port.

Obsolete Options
The following options are obsolete:
- +ua name
  Read a PAP user name and password from the file name. This file must have two lines for name and password. Name and password are sent to the peer when the peer requests PAP authentication.
- +ipv6
  Enable IPv6 and IPv6CP without specifying interface identifiers.
- --version
  Show version number and exit.
- -help
  Show brief help message and exit.

Extended Description
Security
pppd allows system administrators to provide legitimate users with PPP access to a server machine without fear of compromising the security of the server or the network it runs on. Access control is provided by restricting IP addresses the peer may use based on its authenticated identity (if any), and through restrictions on options a non-privileged user may use. Options that permit potentially insecure configurations are privileged. Privileged options are accepted only in files that are under the control of the system administrator or when pppd is being run by root.

By default, pppd allows an unauthenticated peer to use a given IP address only if the system does not already have a route to that IP address. For example, a system with a permanent connection to the wider Internet will normally have a default route, meaning all peers must authenticate themselves to set up a connection. On such a system, the auth option is the default. Conversely, a system with a PPP link that comprises the only connection to the Internet probably does not possess a default route, so the peer can use virtually any IP address without authenticating itself.

Security-sensitive options are privileged and cannot be accessed by a non-privileged user running pppd, either on the command line, in the user’s $HOME/.ppprc file, or in an options file read using the file option. Privileged options may be used in /etc/ppp/options file or in an options file read using the call option. If pppd is run by the root user, privileged options can be used without restriction. If the /etc/ppp/options file does not exist, then only root may invoke pppd. The /etc/ppp/options file must be created (but may be empty) to allow ordinary non-root users to access pppd.

When opening the device, pppd uses the invoking user’s user ID or the root UID (that is, 0), depending if the device name was specified by the user or the system administrator. If the device name comes from a privileged source, that is, /etc/ppp/options or an options file read using the call option, pppd uses full root privileges when opening the device. Thus, by creating an appropriate file under /etc/ppp/peers, the system administrator can allow users
to establish a PPP connection via a device that they would not normally have access to. Otherwise pppd uses the invoking user’s real UID when opening the device.

Authentication

During the authentication process, one peer convinces the other of its identity by sending its name and some secret information to the other. During authentication, the first peer becomes the “client” and the second becomes the “server.” Authentication names can (but are not required to) correspond to the peer’s Internet hostnames.

pppd supports four authentication protocols: the Password Authentication Protocol (PAP) and three forms of the Challenge Handshake Authentication Protocol (CHAP). With the PAP protocol, the client sends its name and a cleartext password to the server to authenticate itself. With CHAP, the server initiates the authentication exchange by sending a challenge to the client who must respond with its name and a hash value derived from the shared secret and the challenge.

The PPP protocol is symmetrical, meaning that each peer may be required to authenticate itself to the other. Different authentication protocols and names can be used for each exchange.

By default, pppd authenticates if requested and does not require authentication from the peer. However, pppd does not authenticate itself with a specific protocol if it has no secrets that can do so.

pppd stores authentication secrets in the `/etc/ppp/pap-secrets` (for PAP), and `/etc/ppp/chap-secrets` (for CHAP) files. Both files use the same format. pppd uses secrets files to authenticate itself to other systems and to authenticate other systems to itself.

Secrets files contain one secret per line. Secrets are specific to a particular combination of client and server and can only be used by that client to authenticate itself to that server. Each line in a secrets file has a minimum of three fields that contain the client and server names followed by the secret. Often, these three fields are followed by IP addresses that are used by clients to connect to a server.

A secrets file is parsed into words, with client name, server name and secrets fields allocated one word each. Embedded spaces or other special characters within a word must be quoted or escaped. Case is significant in all three fields.

A secret beginning with an at sign (“@”) is followed by the name of a file containing the secret. An asterisk (*) as the client or server name matches any name. When choosing a match, pppd selects the one with the fewest wildcards. Succeeding words on a line are interpreted by pppd as acceptable IP addresses for that client. IP Addresses are disallowed if they appear in lines that contain only three words or lines whose first word begins with a hyphen (“-“). To allow any address, use “*”. An address starting with an exclamation point (“!”) indicates that the specified address is not acceptable. An address may be followed by “/” and a number n to indicate a whole subnet (all addresses that have the same value in the most significant n bits).
In this form, the address may be followed by a plus sign ("+") to indicate that one address from the subnet is authorized, based on the ppp network interface unit number in use. In this case, the host part of the address is set to the unit number, plus one.

When authenticating the peer, pppd chooses a secret with the peer’s name in the first field of the secrets file and the name of the local system in the second field. The local system name defaults to the hostname, with the domain name appended if the domain option is used. The default can be overridden with the name option unless the usehostname option is used.

When authenticating to the peer, pppd first determines the name it will use to identify itself to the peer. This name is specified with the user option. If the user option is not used, the name defaults to the host name of the local system. pppd then selects a secret from the secrets file by searching for an entry with a local name in the first field and the peer’s name in the second field. pppd will know the name of the peer if standard CHAP authentication is used because the peer will have sent it in the Challenge packet. However, if MS-CHAP or PAP is being used, pppd must determine the peer’s name from the options specified by the user. The user can specify the peer’s name directly with the remotename option. Otherwise, if the remote IP address was specified by a name, rather than in numeric form, that name will be used as the peer’s name. If that fails, pppd uses the null string as the peer’s name.

When authenticating the peer with PAP, the supplied password is compared with data in the secrets file. If the password and secret do not match, the password is encrypted using crypt() and checked against the secret again. If the papcrypt option is given, the first unencrypted comparison is omitted for better security, and entries must thus be in encrypted crypt(3C) form.

If the login option is specified, the username and password are also checked against the system password database. This allows you to set up the pap-secrets file to enable PPP access only to certain users, and to restrict the set of IP addresses available to users. Typically, when using the login option, the secret in /etc/ppp/pap-secrets would be “”, which matches any password supplied by the peer. This makes having the same secret in two places unnecessary. When login is used, the pam option enables access control through pam(3PAM).

Authentication must be completed before IPCP (or other network protocol) can be started. If the peer is required to authenticate itself and fails, pppd closes LCP and terminates the link. If IPCP negotiates an unacceptable IP address for the remote host, IPCP is closed. IP packets are sent or received only when IPCP is open.

To allow hosts that cannot authenticate themselves to connect and use one of a restricted set of IP addresses, add a line to the pap-secrets file specifying the empty string for the client name and secret.

Additional pppd options for a given peer may be specified by placing them at the end of the secrets entry, separated by two dashes (---). For example

```
peername servername secret ip-address -- novj
```
Routing

When IPCP negotiation is complete, pppd informs the kernel of the local and remote IP addresses for the PPP interface and creates a host route to the remote end of the link that enables peers to exchange IP packets. Communication with other machines generally requires further modification to routing tables and/or Address Resolution Protocol (ARP) tables. In most cases the default route and/or proxyarp options are sufficient for this, but further intervention may be necessary. If further intervention is required, use the /etc/ppp/ip-up script or a routing protocol daemon.

To add a default route through the remote host, use the default route option. This option is typically used for “client” systems; that is, end-nodes that use the PPP link for access to the general Internet.

In some cases it is desirable to use proxy ARP, for example on a server machine connected to a LAN, to allow other hosts to communicate with the remote host. proxyarp instructs pppd to look for a network interface on the same subnet as the remote host. That is, an interface supporting broadcast and ARP that is not a point-to-point or loopback interface and that is currently up. If found, pppd creates a permanent, published ARP entry with the IP address of the remote host and the hardware address of the network interface.

When the demand option is used, the interface IP addresses are already set at the time when IPCP comes up. If pppd cannot negotiate the same addresses it used to configure the interface, it changes the interface IP addresses to the negotiated addresses. This may disrupt existing connections. Using demand dialing with peers that perform dynamic IP address assignment is not recommended.

Scripts

pppd invokes scripts at various stages during processing that are used to perform site-specific ancillary processing. These scripts may be shell scripts or executable programs. pppd does not wait for the scripts to finish. The scripts are executed as root (with the real and effective user-id set to 0), enabling them to update routing tables, run privileged daemons, or perform other tasks. Be sure that the contents of these scripts do not compromise your system’s security. pppd runs the scripts with standard input, output and error redirected to /dev/null, and with an environment that is empty except for some environment variables that give information about the link. The pppd environment variables are:

- DEVICE: Name of the serial tty device.
- IFNAME: Name of the network interface.
- IPOLOCAL: IP address for the link’s local end. This is set only when IPCP has started.
- IPREMOTE: IP address for the link’s remote end. This is set only when IPCP has started.
- PEERNAME: Authenticated name of the peer. This is set only if the peer authenticates itself.
- SPEED: Baud rate of the tty device.
- ORIG_UID: Real user-id of user who invoked pppd.
PPPLOGNAME  Username of the real user-id who invoked pppd. This is always set.

pppd also sets the following variables for the ip-down and auth-down scripts:

CONNECT_TIME  Number of seconds between the start of PPP negotiation and connection termination.

BYTES_SENT  Number of bytes sent at the level of the serial port during the connection.

BYTES_RCVD  Number of bytes received at the level of the serial port during the connection.

LINKNAME  Logical name of the link, set with the \texttt{linkname} option.

If they exist, pppd invokes the following scripts. It is not an error if they do not exist.

/etc/ppp/auth-up  Program or script executed after the remote system successfully authenticates itself. It is executed with five command-line arguments: \texttt{interface-name peer-name user-name tty-device speed}. Note that this script is not executed if the peer does not authenticate itself, for example, when the noauth option is used.

/etc/ppp/auth-down  Program or script executed when the link goes down if /etc/ppp/auth-up was previously executed. It is executed in the same manner with the same parameters as /etc/ppp/auth-up.

/etc/ppp/ip-up  A program or script that is executed when the link is available for sending and receiving IP packets (that is, IPCP has come up). It is executed with six command-line arguments: \texttt{interface-name tty-device speed local-IP-address remote-IP-address ipparam}.

/etc/ppp/ip-down  A program or script which is executed when the link is no longer available for sending and receiving IP packets. This script can be used for undoing the effects of the /etc/ppp/ip-up script. It is invoked in the same manner and with the same parameters as the ip-up script.

/etc/ppp/ipv6-up  Similar to /etc/ppp/ip-up, except that it is executed when the link is available for sending and receiving IPv6 packets. Executed with six command-line arguments: \texttt{interface-name tty-device speed local-link-local-address remote-link-local-address ipparam}.

/etc/ppp/ipv6-down  Similar to /etc/ppp/ip-down, but executed when IPv6 packets can no longer be transmitted on the link. Executed with the same parameters as the ipv6-up script.

**Examples**

**EXAMPLE 1**  Using the auth Option

The following examples assume that the /etc/ppp/options file contains the auth option.
pppd is commonly used to dial out to an ISP. You can do this using the "pppd call isp" command where the /etc/ppp/peers/isp file is set up to contain a line similar to the following:

cua/a 19200 ctscts connect '/usr/bin/chat -f /etc/ppp/chat-isp' noauth

For this example, chat(1M) is used to dial the ISP's modem and process any login sequence required. The /etc/ppp/chat-isp file is used by chat and could contain the following:

```bash
ABORT "NO CARRIER"
ABORT "NO DIALTONE"
ABORT "ERROR"
ABORT "NO ANSWER"
ABORT "BUSY"
ABORT "Username/Password Incorrect"
** "at"
OK "at$fd26c1"
OK "atdt2468135"
"name: "Ummyuserid"
"word: "qmpassword"
"ispts" "q"Uppp"
".--.Uppt--"
```

See the chat(1M) man page for details of chat scripts.

**Example 2 Using pppd with proxyarp**

pppd can also provide a dial-in ppp service for users. If the users already have login accounts, the simplest way to set up the ppp service is to let the users log in to their accounts and run pppd as shown in the following example:

```
example% pppd proxyarp
```

**Example 3 Providing a User with Access to PPP Facilities**

To provide a user with access to the PPP facilities, allocate an IP address for the user's machine, create an entry in /etc/ppp/pap-secrets or /etc/ppp/chap-secrets. This enables the user's machine to authenticate itself. For example, to enable user "Joe" using machine "joespc" to dial in to machine "server" and use the IP address "joespc.my.net," add the following entry to the /etc/ppp/pap-secrets or /etc/ppp/chap-secrets files:

```
joespc server "joe's secret" joespc.my.net
```

Alternatively, you can create another username, for example "ppp," whose login shell is /usr/bin/pppd and whose home directory is /etc/ppp. If you run pppd this way, add the options to the /etc/ppp/.ppprc file.
Providing a User with Access to PPP Facilities  (Continued)

If your serial connection is complex, it may be useful to escape such control characters as XON (^Q) and XOFF (^S), using asyncmap a0000. If the path includes a telnet, escape ^] (asyncmap 200a0000). If the path includes a rlogin command, add escape ff option to the options, because rlogin removes the window-size-change sequence [0xff, 0xff, 0x73, 0x73, followed by any 8 bytes] from the stream.

Exit Status  The pppd exit status indicates errors or specifies why a link was terminated. Exit status values are:

0  pppd has detached or the connection was successfully established and terminated at the peer’s request.
1  An immediately fatal error occurred. For example, an essential system call failed.
2  An error was detected in the options given. For example, two mutually exclusive options were used, or /etc/ppp/options is missing and the user is not root.
3  pppd is not setuid - root and the invoking user is not root.
4  The kernel does not support PPP. For example, the PPP kernel driver is not included or cannot be loaded.
5  pppd terminated because it was sent a SIGINT, SIGTERM or SIGHUP signal.
6  The serial port could not be locked.
7  The serial port could not be opened.
8  The connect script failed and returned a non-zero exit status.
9  The command specified as the argument to the pty option could not be run.
10  The PPP negotiation failed because no network protocols were able to run.
11  The peer system failed or refused to authenticate itself.
12  The link was established successfully, but terminated because it was idle.
13  The link was established successfully, but terminated because the connect time limit was reached.
14  Callback was negotiated and an incoming call should arrive shortly.
15  The link was terminated because the peer is not responding to echo requests.
16  The link was terminated by the modem hanging up.
17  The PPP negotiation failed because serial loopback was detected.
18  The init script failed because a non-zero exit status was returned.
19  Authentication to the peer failed.
Files

/var/run/ppp.pid Process-ID for pppd process on PPP interface unit n.
/var/run/ppp-name.pid Process-ID for pppd process for logical link name (see the
   linkname option).
/etc/ppp/pap-secrets Usernames, passwords and IP addresses for PAP
   authentication. This file should be owned by root and not
   readable or writable by any other user, otherwise pppd will
   log a warning.
/etc/ppp/chap-secrets Names, secrets and IP addresses for all forms of CHAP
   authentication. The /etc/ppp/pap-secrets file should be
   owned by root should not readable or writable by any other
   user, otherwise, pppd will log a warning.
/etc/ppp/options System default options for pppd, read before user default
   options or command-line options.
$HOME/.ppprc User default options, read before
/etc/ppp/options.ttyname.
/etc/ppp/options.ttyname System default options for the serial port in use; read after
$HOME/.ppprc. The ttyname component of this filename is
formed when the initial /dev/ is stripped from the port
name (if present), and slashes (if any) are converted to dots.
/etc/ppp/peers Directory with options files that may contain privileged
   options, even if pppd was invoked by a user other than root.
   The system administrator can create options files in this
directory to permit non-privileged users to dial out without
requiring the peer to authenticate, but only to certain
trusted peers.

Jacobson, V. RFC 1144, Compressing TCP/IP Headers for Low-Speed Serial Links. Network
   Working Group. February, 1990

Notes These signals affect pppd behavior:

SIGINT, SIGTERM Terminate the link, restore the serial device settings and exit.

SIGHUP Terminate the link, restore the serial device settings and close the serial device. If the persist or demand option is specified, pppd attempts to reopen the serial device and start another connection after the holdoff period. Otherwise pppd exits. If received during the holdoff period, SIGHUP causes pppd to end the holdoff period immediately.

SIGUSR1 Toggles the state of the debug option and prints link status information to the log.

SIGUSR2 Causes pppd to renegotiate compression. This is useful to re-enable compression after it has been disabled as a result of a fatal decompression error. (Fatal decompression errors generally indicate a bug in an implementation.)

Diagnostics Messages are sent to the syslog daemon using facility LOG_DAEMON. To see error and debug messages, edit the /etc/syslog.conf file to direct the messages to the desired output device or file, or use the updatelog or logfile options.

The debug option causes the contents of all LCP, PAP, CHAP or IPCP control packets sent or received to be logged. This is useful if PPP negotiation does not succeed or if authentication fails.

Debugging can also be enabled or disabled by sending a SIGUSR1 signal, which acts as a toggle to the pppd process.
The pppoec utility implements the client-side negotiation of PPPoE. It is intended to be used with the pppd(1M) connect option, in the same manner as the chat(1M) utility is used for asynchronous dial-up PPP.

When given with the -i flag, pppoec sends out a broadcast query on the given interface named by the device parameter. You can specify no other arguments in this mode. All responding PPPoE servers and the offered services are displayed on standard output.

Otherwise, when given without the -i flag, pppoec does the full PPPoE client-side negotiation. The device parameter is the intended Ethernet interface, and must already be plumbed with sptptun(1M). The optional service parameter specifies a particular service desired; other offered services will be ignored. The optional server parameter specifies a specific server desired. You can specify server as an Ethernet address in the usual x:x:x:x:x format (with "*" in any of the six byte positions interpreted to mean "any"), or as a symbolic name resolved through /etc/ethers (or NIS), or as a PPPoE access concentrator name. The sense of the match (true or false) can be inverted by specifying the keyword except before this string. This parameter can be specified more than once, and the first match is taken.

If you specify the server parameter, then the selected servers become "preferred." If no preferred server responds, then the first responding server is used instead. To exclude non-matching servers entirely, append the keyword only.

The following options are supported:

- **-i** Sends out broadcast query over interface specified by device.
- **-o** Sets the initial wait time in milliseconds for PADO from the server before PADI is retried. The default is 500 milliseconds for normal operation, or 3000 milliseconds (3 seconds) for inquiry (-i) mode.
- **-s** Sets the initial wait time in milliseconds for PADS from the server before PADR is retried. The default is 2000 milliseconds (2 seconds).
- **-v** Displays verbose progress messages, including all PPPoE messages sent, and all state machine transitions.

You normally do not need to adjust the parameters set with -o and -s. They are provided for coping with unusually slow servers.

The following operands are supported:

- **device** plumbed Ethernet interface
server  preferred server or, if you specify only, the specified server
service  desired service; other available services are ignored

Examples

EXAMPLE 1  Connecting to Any Service on hme0
The following command enables you to connect to any PPPoE service on hme0:

```
# /usr/bin/pppd sppptun plugin pppoe.so \
  connect "/usr/lib/inet/pppoec hme0" debug
```

Often, a command such as the preceding is specified in an /etc/ppp/peers file instead. For example, enter the following in /etc/ppp/peers/myisp:

```
sppptun
  plugin pppoe.so
  connect "/usr/lib/inet/pppoec hme0"
  debug
```

To invoke the PPP connection described in the file, enter:

```
% /usr/bin/pppd call myisp
```

Note that, because the /etc/ppp/peers files are considered privileged by pppd, you need not be root to invoke the preceding command.

EXAMPLE 2  Connecting to a Particular Service
A more complex example: on hme0, connect to only the internet service offered by PPPoE servers with access concentrator name isp, but not to any Ethernet addresses starting with 40:0:1a.

```
# /usr/lib/inet/pppoec hme0 internet except 40:0:1a:*:*::* isp only
```

Note that the except 40:0:1a:*:*::* filter must come before isp, because the filters are first-match.

Exit Status
The following exit values are returned:

0  Successful completion.
>0  An error occurred.

Files
/usr/lib/inet/pppoec  executable command
/dev/sppptun  Solaris PPP tunneling device driver.
/etc/ppp/connect-errors  usual location of error output (see DIAGNOSTICS, below)

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

Diagnostics

Error messages are written to standard error, which is normally redirected by pppd to /etc/ppp/connect-errors. The errors can also be redirected to pppd's standard output by using the updetach option.

If you specify the -v, verbose progress messages are displayed, including all PPPoE messages sent, and all state machine transitions. Specifying the updetach or nodetach pppd option is helpful when using verbose mode.
The `pppoed` daemon implements the server-side negotiation of PPPoE. When a client requests service from this daemon, a copy of `pppd(1M)` is invoked to handle the actual PPP communication.

At startup, options are read from the command line and the `/etc/ppp/pppoe` file. After these options have been read, options in the per-device `/etc/ppp/pppoe.device` files are read, using the device names specified on the command line or in `/etc/ppp/pppoe`. Device names are not permitted in the per-device files. It is not an error if any of these files are absent; missing files are ignored.

Options are reread in the same order on SIGHUP. Except for the possibility of short delays due to the processing time, SIGHUP does not interfere with any client operations. Current status, including options read, is dumped to `/tmp/pppoed.pid` on SIGINT.

The options are used to set up a list of services to be offered to PPPoE clients on the broadcast domains (Ethernet subnets) specified by the named devices. Option parsing is always in one of two modes, either global mode or service mode. The initial mode at the beginning of each file (and the command line) is global mode. Options specified in global mode serve as default values for subsequently defined services. Service mode is entered by the `service name` option. In this mode, the named option is defined. Options that appear in this mode override any global mode definitions for the current service.

The option parsing follows standard shell tokenizing rules, using whitespace to delimit tokens, quotes to enclose strings that can contain whitespace, and escape sequences for special characters. Environment variables are substituted using familiar `$VAR` and `${VAR}` syntax and set using `NEWVAR=string`. Variables are both usable in subsequent options and provided to the `pppd(1M)` processes spawned for each client, but they are interpreted as they are encountered during option processing. Thus, all set variables are seen by all processes spawned; position in the configuration files has no effect on this.

The `pppoed` daemon supports the following options:

```
client [except] client-list
```

This option restricts the clients that may receive the service. If the `except` keyword is given, then the clients on the list cannot access the service, but others can. If this keyword is not given, then only the listed clients can access the service.

This option can be specified more than once for a given service. For a given client, first match among all listed options encountered specifies the handling. If it matches an option with `except` specified, then access is denied. Otherwise, it is granted. The `client list` within a service is prepended to any list specified in the global context.
If no client options are given or if all options are specified with except, then all clients are permitted by default. If any client options without except are specified, then no clients are permitted by default.

The client-list is a comma-separated list of client identifiers. The match is made if any client on the list matches; thus, these are logically "ORed" together. Each client identifier can be either a symbolic name (resolved through /etc/ethers or NIS, as defined by /etc/nsswitch.conf) or a hexadecimal Ethernet address in the format x:x:x:x:x:x. In the latter case, any byte of the address can be "*", which matches any value in that position. For example, 40:0:1a:*:*:* matches Ethernet adapters from the manufacturer assigned block 40:0:1a.

debug

Increase debug logging detail level by one. The detail levels are 0 (no logging), 1 (errors only; the default), 2 (warnings), 3 (informational messages), and 4 (debug messages). Log messages are written by default to syslog(3C) using facility daemon (see the log option below). When specified on the command line or in the global context of the /etc/ppp/pppoe file, this option also sets the daemon’s default (non-service-related) detail level.

device device-list

Specify the devices on which the service is available. The device-list is a comma-separated list of logical device names (without the leading /dev/), such as hme0. This option is ignored if encountered in the per-device /etc/ppp/pppoe .device files.

extra string

Specifies extra options to pppd(1M). It defaults to "plugin pppoe.so directtty" and usually does not need to be overridden.

file path

Suspends parsing of the current file, returns to global mode, and reads options from path. This file must be present and readable; if it is not, an error is logged. When the end of that file is reached, processing returns to the current file and the mode is reset to global again.

The global mode options specified in files read by this command use the options set in the current file’s global mode; this condition extends to any file included by those files. All files read are parsed as though the command line had specified this option, and thus inherit the command line’s global modes.
This option can be used to revert to global mode at any point in an option file by specifying file /dev/null.

**group name**
Specifies the group ID (symbolic or numeric) under which pppd is executed. If pppoe is not run as root, this option is ignored.

**log path**
Specifies an alternate debug logging file. Debug messages are sent to this file instead of syslog. The special name syslog is recognized to switch logging back to syslog. When specified on the command line or in the global context of the /etc/ppp/pppoe file, this option also sets the daemon’s default (non-service-related) log file.

**nodebug**
Set debug logging detail level to 0 (no logging). When specified on the command line or in the global context of the /etc/ppp/pppoe file, this option also sets the daemon’s default (non-service-related) detail level.

**nowildcard**
Specifies that the current service should not be included in response to clients requesting "any" service. The client must ask for this service by name. When specified on the command line or in the global context of the /etc/ppp/pppoe file, this option causes pppoe to ignore all wildcard service requests.

**path path**
Specifies the path to the pppd executable. Defaults to /usr/bin/pppd.

**pppd string**
Passes command-line arguments to pppd. It can be used to set the IP addresses or configure security for the session. The default value is the empty string.

**server string**
Specifies the PPoE Access Concentrator name to be sent to the client. It defaults to "Solaris PPoE".

**service name**
Closes any service being defined and begins definition of a new service. The same service name can be used without conflict on multiple devices. If the same service name is used on a single device, then the last definition encountered during parsing overrides all previous definitions.

**user name**
Specifies the user ID, symbolic or numeric, under which pppd is executed. If pppoe is not run as root, this option is ignored.

**wildcard**
Specifies that the service should be included in responses to client queries that request "any" service, which is done by requesting a service name of length zero. When specified on the command line or in the global context of the
/etc/ppp/pppoe file, this option causes pppoed to ignore all wildcard service requests. This is the default.

**Examples**

**EXAMPLE 1**  Configuring for Particular Services

In the /etc/ppp/pppoe file:

```plaintext
service internet
device $DEV
    pppd "proxyarp 192.168.1.1:"
service debugging
device hme0,$DEV
    pppd "debug proxyarp 192.168.1.1:"
```

You then invoke the daemon with:

```plaintext
example% /usr/lib/inet/pppoed DEV=eri0
```

The lines in /etc/ppp/pppoe and the preceding command result in offering services "internet" and "debugging" (and responding to wildcard queries) on interface eri0, and offering only service "debugging" on interface hme0.

**Signals**
The pppoed daemon responds to the following signals:

- **SIGHUP**  Causes pppoed to reparse the original command line and all configuration files, and close and reopen any log files.
- **SIGINT**  Causes a snapshot of the state of the pppoed daemon to be written to `/tmp/pppoed.pid` (where `pid` is the decimal process ID of the daemon).

**Files**

- `/usr/lib/inet/pppoed`  executable command
- `/dev/sppptun`  Solaris PPP tunneling device driver
- `/etc/ppp/pppoe`  main configuration option file
- `/etc/ppp/pppoe.device`  per–device configuration option file
- `/etc/ppp/pppoe-errors`  location of output from pppd’s stderr
- `/etc/ppp/pppoe.if`  list of Ethernet interfaces to be plumbed at boot time
- `/tmp/pppoed.pid`  ASCII text file containing dumped pppoed state information

pppoed(1M)

See Also  pppd(1M), pppoe(1M), sppptun(1M), sppptun(7M)

Notes  Because pppd is installed setuid root, this daemon need not be run as root. However, if it is not run as root, the user and group options are ignored.

The Ethernet interfaces to be used must be plumbed for PPPoE using the sppptun(1M) utility before services can be offered.

The daemon operate runs even if there are no services to offer. If you want to modify a configuration, it is not necessary to terminate the daemon. Simply use pkill -HUP pppoed after updating the configuration files.

The PPPoE protocol is far from perfect. Because it runs directly over Ethernet, there is no possibility of security and the MTU is limited to 1492 (violating RFC 1661’s default value of 1500). It is also not possible to run the client and the server of a given session on a single machine with a single Ethernet interface for testing purposes. The client and server portions of a single session must be run on separate Ethernet interfaces with different MAC addresses.
**Name**  
pppstats – print PPP statistics

**Synopsis**  

**Description**  
The pppstats utility reports PPP-related statistics at regular intervals for the specified PPP interface. If the interface is unspecified, pppstats defaults to sppp0. The display is split horizontally into input and output sections containing columns of statistics describing the properties and volume of packets received and transmitted by the interface.

**Options**  
The pppstats options are:

- **-a**  
  Display absolute values rather than deltas. With this option, all reports show statistics for the time elapsed since the link was initiated. Without this option, the second and subsequent reports show statistics for the time since the last report.

- **-c count**  
  Repeat the display count times. If this option is not specified, the default repeat count is 1 if the -w option is not specified, otherwise infinity.

- **-r**  
  Display additional statistics summarizing the compression ratio achieved by the packet compression algorithm in use.

- **-v**  
  Display additional statistics relating to the performance of the Van Jacobson TCP header compression algorithm.

- **-w wait**  
  Pause wait seconds between each display. If this option is not specified, the default interval is five seconds.

- **-z**  
  Instead of the standard display, show statistics indicating the performance of the packet compression algorithm in use.

**Extended Description**  
The following fields are printed on the input side when the -z option is not used:

- **IN**  
  Total number of bytes received by this interface.

- **PACK**  
  Total number of packets received by this interface.

- **VJCOMP**  
  Number of header-compressed TCP packets received by this interface.

- **VJUNC**  
  Number of header-uncompressed TCP packets received by this interface. Not reported when the -r option is specified.

- **VJERR**  
  Number of corrupted or bogus header-compressed TCP packets received by this interface. Not reported when the -r option is specified.

- **VJTOSS**  
  Number of VJ header-compressed TCP packets dropped on reception by this interface because of preceding errors. Only reported when the -v option is specified.

- **NON-VJ**  
  Total number of non-TCP packets received by this interface. Only reported when the -v option is specified.
RATIO  Compression ratio achieved for received packets by the packet compression scheme in use, defined as the uncompressed size divided by the compressed size. Only reported when the -r option is specified.

UBYTE  Total number of bytes received, after decompression of compressed packets. Only reported when the -r option is specified.

The following fields are printed on the output side:

OUT  Total number of bytes transmitted from this interface.

PACK  Total number of packets transmitted from this interface.

VJCOMP  Number of TCP packets transmitted from this interface with VJ-compressed TCP headers.

VJUNC  Number of TCP packets transmitted from this interface with VJ-uncompressed TCP headers. Not reported when the -r option is specified.

NON-VJ  Total number of non-TCP packets transmitted from this interface. Not reported when the -r option is specified.

VJSRCH  Number of searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the -v option is specified.

VJMISS  Number of failed searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the -v option is specified.

RATIO  Compression ratio achieved for transmitted packets by the packet compression scheme in use, defined as the size before compression divided by the compressed size. Only reported when the -r option is specified.

UBYTE  Total number of bytes to be transmitted before packet compression is applied. Only reported when the -r option is specified.

When the -z option is specified, pppstats displays the following fields relating to the packet compression algorithm currently in use. If packet compression is not in use, these fields display zeroes. The fields displayed on the input side are:

COMPRESSED BYTE  Number of bytes of compressed packets received.

COMPRESSED PACK  Number of compressed packets received.

INCOMPRESSIBLE BYTE  Number of bytes of incompressible packets (that is, those which were transmitted in uncompressed form) received.

INCOMPRESSIBLE PACK  Number of incompressible packets received.

COMP RATIO  Recent compression ratio for incoming packets, defined as the uncompressed size divided by the compressed size (including both compressible and incompressible packets).
The fields displayed on the output side are:

COMPRESSED BYTE  Number of bytes of compressed packets transmitted.
COMPRESSED PACK  Number of compressed packets transmitted.
INCOMPRESSIBLE BYTE  Number of bytes of incompressible packets received; that is, those that were transmitted by the peer in uncompressed form.
INCOMPRESSIBLE PACK  Number of incompressible packets transmitted.
COMP RATIO  Recent compression ratio for outgoing packets.

Attributes

See Also  
pppd(1M), attributes(5)
praudit reads the listed filenames (or standard input, if no filename is specified) and interprets the data as audit trail records as defined in audit.log(4). By default, times, user and group IDs (UIDs and GIDs, respectively) are converted to their ASCII representation. Record type and event fields are converted to their ASCII representation. A maximum of 100 audit files can be specified on the command line.

The following options are supported:

- `-d del`
  Use del as the field delimiter instead of the default delimiter, which is the comma. If del has special meaning for the shell, it must be quoted. The maximum size of a delimiter is three characters. The delimiter is not meaningful and is not used when the `-x` option is specified.

- `-l`
  Print one line per record.

- `-r`
  Print records in their raw form. Times, UIDs, GIDs, record types, and events are displayed as integers. This option is useful when naming services are offline. The `-r` option and the `-s` option are exclusive. If both are used, a format usage error message is output.

- `-s`
  Display records in their short form. Numeric fields' ASCII equivalents are looked up by means of the sources specified in the `/etc/nsswitch.conf` file (see nsswitch.conf(4)). All numeric fields are converted to ASCII and then displayed. The short ASCII representations for the record type and event fields are used. This option and the `-r` option are exclusive. If both are used, a format usage error message is output.

- `-x`
  Print records in XML form. Tags are included in the output to identify tokens and fields within tokens. Output begins with a valid XML prolog, which includes identification of the DTD which can be used to parse the XML.

Files

/etc/security/audit_event
  Audit event definition and class mappings.

/etc/security/audit_class
  Audit class definitions.

/usr/share/lib/xml/dtd
  Directory containing the versioned DTD file referenced in XML output, for example, adt_record.dtd.1.

/usr/share/lib/xml/style
  Directory containing the versioned XSL file referenced in XML output, for example, adt_record.xsl.1.

projadd(1M)

**Name**
projadd – administer a new project on the system

**Synopsis**
projadd [-n] [-f filename] [-p projid [-o]] [-c comment]
   [-u user [,user]...] [-G group [,group]...]  
   [-K name [=value [,value]...]]] project

**Description**
projadd adds a new project entry to the /etc/project file. If the files backend is being used for the project database, the new project is available for use immediately upon the completion of the projadd command.

**Options**
The following options are supported:

- `-c comment`  
  Add a project comment. Comments are stored in the project's entry in the /etc/project file. Generally, comments contain a short description of the project and are used as the field for the project's full name.

  Specify `comment` as a text string. `comment` cannot contain a colon (:) or NEWLINE.

- `-f filename`  
  Specify the project file to modify. If no `filename` is specified, the system project file, /etc/project, is modified.

- `-G group[,group...]`  
  Specify a group list for the project.

- `-K name [=value [,value]...]`  
  Specify an attribute list for the project. Multiple `-K` options can be specified to set values on multiple keys, such as:

  `-K key1=value1`  
  `-K "key2=(value2a),(value2b)"`

  Resource control attributes use parentheses to specify values for a key. Because many user shells interpret parentheses as special characters, it is best to enclose an argument to `-K` that contains parentheses with double quotes, as shown above and in EXAMPLES, below. See `resource_controls(5)` for a description of the resource controls you can specify for a project.

- `-n`  
  Syntax check. Check the format of the existing system project file and modifications only. The contents of the existing project file, such as user names, group names, and resources that are specified in the project attributes are not checked.

- `-o`  
  This option allows the project ID specified by the `-p` option to be non-unique within the project file.

- `-p projid`  
  Set the project ID of the new project.

  Specify `projid` as a non-negative decimal integer below `UID_MAX` as defined in `limits.h`. `projid` defaults to the next available
unique number above the highest number currently assigned. For example, if projids 100, 105, and 200 are assigned, the next default projid is 201. projids between 0-99 are reserved by SunOS.

- U user[,user...] Specify a user list for the project.

Operands

The following operands are supported:

project The name of the project to create. The project operand is a string consisting of characters from the set of alphabetic characters, numeric characters, underline (_), and hyphen (-). The period (’.’) is reserved for projects with special meaning to the operating system. The first character of the project name must be a letter. An error message is displayed if these restrictions are not met.

Examples

EXAMPLE 1 Adding a Project

The following command creates the project salesaudit and sets the resource controls specified as arguments to the - K option.

projadd - p 111 - G sales,finance - c "Auditing Project" \  
-K "rcap.max-rss=10GB" \  
-K "process.max-file-size=(priv,50MB,deny)" \  
-K "task.max-lwps=(priv,100,deny)" salesaudit

This command would produce the following entry in /etc/project:

salesaudit:111:Auditing Project::sales,finance: \  
process.max-file-size=(priv,52428800,deny); \  
rcap.max-rss=10737418240;task.max-lwps=(priv,100,deny)

Note that the preceding would appear as one line in /etc/project.

Comparing the projadd command and resulting output in /etc/project, note the effect of the scaling factor in the resource cap (rcap.max-rss=10GB) and the resource control (process.max-file-size=(priv,50MB,deny)). Modifiers, such as B, KB, and MB, and scaling factors are specified in resource_controls(5).

Exit Status

The following exit values are returned:

0 Successful completion.
2 The command syntax was invalid. A usage message for projadd is displayed.
3 An invalid argument was provided to an option.
4 The projid given with the - p option is already in use.
5 The project files contain an error. See project(4).
6 The project to be added, group, user, or resource does not exist.
The project is already in use.

Cannot update the /etc/project file.

Files
/etc/project    System project file

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

Invocation is evolving. Human readable output is unstable.

Notes
In case of an error, projadd prints an error message and exits with a non-zero status.

projadd adds a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local /etc/project file with additional entries, projadd cannot change information supplied by the network name service.
projdel(1M)

Name projdel – delete a project from the system

Synopsis projdel [-f filename] project

Description The projdel utility deletes a project from the system and makes the appropriate changes to the system file.

Options The following options are supported:

- f filename Specify the project file to modify. If no filename is specified, the system project file, /etc/project, is modified.

Operands The following operands are supported:

project The name of the project to be deleted.

Exit Status The following exit values are returned:

0 Successful completion.
2 The command syntax was invalid. A usage message for projdel is displayed.
3 An invalid argument was provided to an option.
4 The projid given with the - p option is already in use.
5 The project files contain an error. See project(4).
6 The project to be modified, group, user, or resource does not exist.
9 The project is already in use.
10 Cannot update the /etc/project file.

Files /etc/project System project file

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

Invocation is evolving. Human readable output is unstable.

See Also projects(1), groupadd(1M), groupdel(1M), groupmod(1M), grpck(1M), logins(1M), projadd(1M), projmod(1M), useradd(1M), userdel(1M), usermod(1M), project(4), attributes(5)
In case of an error, `projdel` prints an error message and exits with a non-zero status.

**Notes**  `projdel` deletes a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local `/etc/project` file with additional entries, `projdel` cannot change information supplied by the network name service.
projmod: modify a project's information on the system

Synopsis
projmod [-n] [-A] [-f filename | -]

projmod [-n] [-A] [-f filename | -] [-p projid [-o]]
   [-c comment] [-a|-s|-r] [-U user [,user]... ]
   [-G group [,group]... ]
   [-K name [=value [,value]... ]... ]
   [-l new_projectname] project

Description
The projmod utility modifies a project's definition on the system. projmod changes the
definition of the specified project and makes the appropriate project-related system file and
file system changes.

Options
The following options are supported:

-A
Apply the project's resource controls, as defined in the system's
project database, to the project if it is active.

-a
Specify that the users, groups, attributes, or attribute values
specified by the -U, -G or -K options should be added to the
project, rather than replacing the existing member or attribute
list.

-c comment
Specify comment as a text string. Generally, comment contains a
short description of the project. This information is stored in
the project's /etc/project entry.

-f filename | -
Specify the project file to modify or validate or specify input
from stdin for validation. As noted under OPERANDS, if you
do not specify a project in a projmod command line, projmod
validates the argument to -f. If you do not use this option, the
system project file, /etc/project, is modified.

-G group [,group... ]
Specify a replacement list of member groups of the project.
When used in conjunction with the -a or -r options, this option
specifies a list of groups to be added or removed from the
project.

-K name [=value [,value]... ]
Specify a replacement list of project attributes for the project.
When used in conjunction with the -a, -r, or -s options, this option
specifies a list of attribute values to be added, removed,
or replaced in the project. Attributes must be delimited by
semicolons (;). Multiple -K options can be specified to set, add,
remove, or substitute values on multiple keys, such as:

-K key1=value1 -K "key2=(value2a), (value2b)"

Resource control attributes use parentheses to specify values for
a key. Because many user shells interpret parentheses as special
characters, it is best to enclose an argument to -K that contains parentheses with double quotes, as shown above and in EXAMPLES, below. See resource controls(5) for a description of the resource controls you can specify for a project.

```
new_projectname
```

Specify the new project name for the project. The new_projectname argument is a string consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hyphen (-). The first character should be alphabetic. An error message is written if these restrictions are not met. The project name must also be unique within the project file.

```
-n
```

Syntax check. Check the format of the existing system project file and modifications only. The contents of the existing project file, such as user names, group names, and resources that are specified in the project attributes are not checked.

```
-o
```

This option allows the project ID specified by the -p option to be non-unique within the project file.

```
projid
```

Specify a new project ID for the project. It must be a non-negative decimal integer less than MAXUID as defined in param.h. This value must be unique within the project file if the -o option is not specified.

```
-r
```

Specify that the users, groups, attributes, or attribute values specified by the -U, -G or -K options should be removed from the project, rather than replacing the existing member or attribute list.

```
-s
```

Specify that the list of attributes specified by the -K option should have their values replaced. If the attributes do not exist, they are added as if the a option was used. This option has no effect the -U or -G options.

```
user [,user...]
```

Specify a replacement list of member users of the project. When used in conjunction with the -a or -r options, this option specifies a list of users to be added or removed from the project.

Operands The following operands are supported:

```
project
```

An existing project name to be modified or displayed.

```
(none)
```

If no operand is given, the project file is validated without modifying any project.
**Examples**

**EXAMPLE 1** Using the -K Option for Addition of an Attribute Value

Consider the following `project(4)` entry:

```
salesaudit:111:Auditing Project::sales,finance: \
    process.max-file-size=(priv,52428800,deny); \
    task.max-lwps=(priv,100,deny)
```

The preceding would appear as one line in `/etc/project`. For this and the following examples, the focus is on the attributes field in the `project` entry. That is, the last field, the field following the last semicolon.

The attributes field for the project `salesaudit` lists the following resource control:

```
task.max-lwps=(priv,1000,signal=KILL)
```

The following `projmod` command adds an action clause to the preceding entry:

```
# projmod -a -K "task.max-lwps=(priv,100,deny)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:

```
task.max-lwps=(priv,1000,deny),(priv,100,deny),(priv,1000,signal=KILL)
```

**EXAMPLE 2** Using the -K Option for the Substitution of an Attribute Value

Assume an attributes field in a `project(4)` entry for the project `salesaudit` that lists the following resource control:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

The following `projmod` command substitutes the action clause specified in the command for the action clauses in the preceding entry:

```
# projmod -s -K "task.max-lwps=(priv,500,signal=SIGSTOP)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:

```
task.max-lwps=(priv,500,signal=SIGSTOP)
```

**EXAMPLE 3** Using the -K Option for Removal of an Attribute Value

Assume an attributes field in a `project(4)` entry for a project `salesaudit` that lists the following resource control:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

The following `projmod` command removes the first action clause from the preceding entry:

```
# projmod -r -K "task.max-lwps=(priv,100,deny)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:
EXAMPLE 3  Using the -K Option for Removal of an Attribute Value  (Continued)

task.max-lwps=(priv,1000,signal=KILL)

EXAMPLE 4  Specifying Multiple Attribute Values

Suppose you want to achieve the following resource controls for the project salesaudit:

- task.max-lwps=(priv,100,deny)
- process.max-file-size=(priv,50MB,deny)

The following projmod command adds these resource controls for salesaudit:

```
# projmod -a -K "task.max-lwps=(priv,100,deny)" \
-K "process.max-file-size=(priv,50MB,deny)" salesaudit
```

...with the resulting attributes field in the entry for salesaudit:

```
task.max-lwps=(priv,100,deny);process.max-file-size=(priv,52428800,deny)
```

In this example, note the effect of the use of the modifier and scaling factor for the resource control process.max-file-size. The specification in projmod:

```
"process.max-file-size=(priv,50MB,deny)"
```

...becomes, in /etc/project:

```
process.max-file-size=(priv,52428800,deny)
```

That is, 50MB is expanded to 52428800. The modifiers, such as MB, and scaling factors you can use for resource controls are specified in resource_controls(5).

EXAMPLE 5  Binding a Pool to a Project

The following command sets the project.pool attribute for the project sales.

```
# projmod -a -K project.pool=salespool sales
```

EXAMPLE 6  Evaluating Input from stdin

The following command uses the -f option without a project name operand to evaluate the contents of an NIS projects map.

```
# ypcat project | projmod -f -
```

Exit Status  In case of an error, projmod prints an error message and exits with one of the following values:

The following exit values are returned:

- 0  Successful completion.
- 2  The command syntax was invalid. A usage message for projmod is displayed.
3 An invalid argument was provided to an option.
4 The projid given with the -p option is already in use.
5 The project files contain an error. See project(4).
6 The project to be modified, group, user, or resource does not exist.
9 The project is already in use.
10 Cannot update the /etc/project file.

Files
/etc/group  System file containing group definitions
/etc/project  System project file
/etc/passwd  System password file
/etc/shadow  System file containing users' encrypted passwords and related information

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

Invocation is evolving. Human readable output is unstable.

See Also  groupadd(1M), groupdel(1M), groupmod(1M), projadd(1M), projdel(1M), useradd(1M),
           userdel(1M), usermod(1M), passwd(4), project(4), attributes(5), resource_controls(5)

Notes  The projmod utility modifies project definitions only in the local /etc/project file. If a
        network name service such as NIS or LDAP is being used to supplement the local files with
        additional entries, projmod cannot change information supplied by the network name service.
        However projmod verifies the uniqueness of project name and project ID against the external
        name service.
Name  prstat – report active process statistics

Synopsis  prstat [-aCHJmRrtTw] [-d u | d] [-C psrsetlist] [-h lgplist]  
          [-j projlist] [-k tasklist] [-n ntop[, nbottom]]  
          [-p pidlist] [-P cpulist] [-s key | -S key ]  
          [-u euidlist] [-U uidlist] [-z zoneidlist] [-Z]  
          [interval [count]]

Description  The prstat utility iteratively examines all active processes on the system and reports statistics based on the selected output mode and sort order. prstat provides options to examine only processes matching specified PIDs, UIDs, zone IDs, CPU IDs, and processor set IDs.

The -j, -k, -C, -p, -P, -u, -U, and -z options accept lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

If you do not specify an option, prstat examines all processes and reports statistics sorted by CPU usage.

Options  The following options are supported:

- a  
      Report information about processes and users. In this mode prstat displays separate reports about processes and users at the same time.

- c  
      Print new reports below previous reports instead of overprinting them.

- C psrsetlist  
      Report only processes or lwps that are bound to processor sets in the given list. Each processor set is identified by an integer as reported by psrset(1M). The load averages displayed are the sum of the load averages of the specified processor sets (see pset_getloadavg(3C)). Processes with one or more LWPs bound to processor sets in the given list are reported even when the -L option is not used.

- d u | d  
      Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See date(1).

- h lgplist  
      Report only processes or lwps whose home lgroup is in the given list of lgroups. No processes or lwps will be listed for invalid lgroups.

- H  
      Report information about home lgroup. In this mode, prstat adds an extra column showing process or lwps home lgroup with the header LGRP.

- j projlist  
      Report only processes or lwps whose project ID is in the given list. Each project ID can be specified as either a project name or a numerical project ID. See project(4).
-J
Report information about processes and projects. In this mode prstat displays separate reports about processes and projects at the same time.

-k tasklist
Report only processes or lwps whose task ID is in tasklist.

-L
Report statistics for each light-weight process (LWP). By default, prstat reports only the number of LWPs for each process.

-m
Report microstate process accounting information. In addition to all fields listed in -v mode, this mode also includes the percentage of time the process has spent processing system traps, text page faults, data page faults, waiting for user locks and waiting for CPU (latency time).

-n ntop, nbottom
Restrict number of output lines. The ntop argument determines how many lines of process or lwp statistics are reported, and the nbottom argument determines how many lines of user, task, or projects statistics are reported if the -a, -t, -T, -J or -Z options are specified. By default, prstat displays as many lines of output that fit in a window or terminal. When you specify the -c option or direct the output to a file, the default values for ntop and nbottom are 15 and 5.

-p pidlist
Report only processes whose process ID is in the given list.

-P cpuplist
Report only processes or lwps which have most recently executed on a CPU in the given list. Each CPU is identified by an integer as reported by psr info(1M).

-R
Put prstat in the real time scheduling class. When this option is used, prstat is given priority over time-sharing and interactive processes. This option is available only for superuser.

-r
Disable lookups for user names and project names. (Note that this does not apply to lookups for the -j, -u, or -U options.)

-s key
Sort output lines (that is, processes, lwps, or users) by key in descending order. Only one key can be used as an argument.

There are five possible key values:

cpu
Sort by process CPU usage. This is the default.
pri
   Sort by process priority.

rss
   Sort by resident set size.

size
   Sort by size of process image.

time
   Sort by process execution time.

-S key
   Sort output lines by key in ascending order. Possible key values are the same as for the -s option. See -s.

-t
   Report total usage summary for each user. The summary includes the total number of processes or LWPs owned by the user, total size of process images, total resident set size, total cpu time, and percentages of recent cpu time and system memory.

-T
   Report information about processes and tasks. In this mode prstat displays separate reports about processes and tasks at the same time.

-u euidlist
   Report only processes whose effective user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.

-U uidlist
   Report only processes whose real user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.

-v
   Report verbose process usage. This output format includes the percentage of time the process has spent in user mode, in system mode, and sleeping. It also includes the number of voluntary and involuntary context switches, system calls and the number of signals received. Statistics that are not reported are marked with the - sign.

-z zoneidlist
   Report only processes or LWPs whose zone ID is in the given list. Each zone ID can be specified as either a zone name or a numerical zone ID. See zones(5).

-Z
   Report information about processes and zones. In this mode, prstat displays separate reports about processes and zones at the same time.

**Output**
The following list defines the column headings and the meanings of a prstat report:

PID
   The process ID of the process.
USERNAME
The real user (login) name or real user ID.

SWAP
The sum of swap reservations of the associated processes for each user, project, task, or zone. This counts shared memory only once for each user, project, task, or zone. Swap is reserved when anonymous memory is allocated or files are mapped private. The value of swap is expressed in kilobytes (K), megabytes (M), or gigabytes (G).

RSS
The resident set size of the process (RSS), in kilobytes (K), megabytes (M), or gigabytes (G). The RSS value is an estimate provided by proc(4) that might underestimate the actual resident set size. Users who want to get more accurate usage information for capacity planning should use the -x option to pmap(1) instead.

STATE
The state of the process:

 cpuN
  Process is running on CPU N.

 sleep
  Sleeping: process is waiting for an event to complete.

 wait
  Waiting: process is waiting for CPU usage to drop to the CPU-caps enforced limits. See the description of CPU-caps in resource_controls(5).

 run
  Runnable: process in on run queue.

 zombie
  Zombie state: process terminated and parent not waiting.

 stop
  Process is stopped.

PRI
The priority of the process. Larger numbers mean higher priority.

NICE
Nice value used in priority computation. Only processes in certain scheduling classes have a nice value.

TIME
The cumulative execution time for the process.

CPU
The percentage of recent CPU time used by the process. If executing in a non-global zone and the pools facility is active, the percentage will be that of the processors in the processor set in use by the pool to which the zone is bound.
PROCESS
   The name of the process (name of executed file).

LWPID
   The lwp ID of the lwp being reported.

NLWP
   The number of lwp's in the process.

With the some options, in addition to a number of the column headings shown above, there are:

NPROC
   Number of processes in a specified collection.

MEMORY
   Percentage of memory used by a specified collection of processes.

The following columns are displayed when the -v or -m option is specified

USR
   The percentage of time the process has spent in user mode.

SYS
   The percentage of time the process has spent in system mode.

TRP
   The percentage of time the process has spent in processing system traps.

TFL
   The percentage of time the process has spent processing text page faults.

DFL
   The percentage of time the process has spent processing data page faults.

LCK
   The percentage of time the process has spent waiting for user locks.

SLP
   The percentage of time the process has spent sleeping.

LAT
   The percentage of time the process has spent waiting for CPU.

VCX
   The number of voluntary context switches.

ICX
   The number of involuntary context switches.

SCL
   The number of system calls.
SIG
The number of signals received.

Under the -L option, one line is printed for each lwp in the process and some reporting fields show the values for the lwp, not the process.

The following column is displayed when the -H option is specified:

LGRP
The home lgroup of the process or lwp.

Operands
The following operands are supported:

  count
  Specifies the number of times that the statistics are repeated. By default, prstat reports statistics until a termination signal is received.

  interval
  Specifies the sampling interval in seconds; the default interval is 5 seconds.

Examples

EXAMPLE 1Reporting the Five Most Active Super-User Processes
The following command reports the five most active super-user processes running on CPU1 and CPU2:

eample% prstat -u root -n 5 -P 1,2 1 1

<table>

</tbody>
</table>

TOTAL: 71, load averages: 0.02, 0.04, 0.08
Exit Status  The following exit values are returned:

0  Successful completion.

1  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  date(1), lgrpinfo(1), plgrp(1), proc(1), ps(1), time(2), psrinfo(1M), psrcset(1M), sar(1M), pset_getloadavg(3C), proc(4), project(4), attributes(5), resource_controls(5), zones(5)

Notes  The snapshot of system usage displayed by prstat is true only for a split-second, and it may not be accurate by the time it is displayed. When the -m option is specified, prstat tries to turn on microstate accounting for each process; the original state is restored when prstat exits. See proc(4) for additional information about the microstate accounting facility.

The total memory size reported in the SWAP and RSS columns for groups of processes can sometimes overestimate the actual amount of memory used by processes with shared memory segments.
The `prtconf` command prints the system configuration information. The output includes the total amount of memory, and the configuration of system peripherals formatted as a device tree.

If a device path is specified on the command line for those command options that can take a device path, `prtconf` will only display information for that device node.

The following options are supported:

- `-a` Display all the ancestors device nodes, up to the root node of the device tree, for the device specified on the command line.

- `-b` Display the firmware device tree root properties for the purpose of platform identification. These properties are “name”, “compatible”, “banner-name” and “model”.

- `-c` Display the device subtree rooted at the device node specified on the command line, that is, display all the children of the device node specified on the command line.

- `-d` Display vendor ID and device ID for PCI and PCI Express devices, in addition to the nodename.

- `-D` For each system peripheral in the device tree, displays the name of the device driver used to manage the peripheral.

- `-l` Show the `/dev/chassis` location associated with the device node. If `-v` is used, `-l` is implied.

- `-F` Returns the device path name of the console frame buffer, if one exists. If there is no frame buffer, `prtconf` returns a non-zero exit code. This flag must be used by itself. It returns only the name of the console, frame buffer device or a non-zero exit code. For example, if the console frame buffer on a SUNW, Ultra-30 is `fb`, the command returns: `/SUNW,fb@1e,0:fb0`. This option could be used to create a symlink for `/dev/fb` to the actual console device.

- `-p` Displays information derived from the device tree provided by the firmware (PROM) on SPARC platforms or the booting system on x86 platforms. The device tree information displayed using this option is a snapshot of the initial configuration and may not accurately reflect reconfiguration events that occur later.

- `-P` Includes information about pseudo devices. By default, information regarding pseudo devices is omitted.

- `-u` Together with `-v`, displays information for each device listing properties from the vendor and admin lists, if any.
Specifies verbose mode.

Displays platform-dependent PROM (on SPARC platforms) or booting system (on x86 platforms) version information. This flag must be used by itself. The output is a string. The format of the string is arbitrary and platform-dependent.

Reports if the firmware on this system is 64-bit ready. Some existing platforms may need a firmware upgrade in order to run the 64-bit kernel. If the operation is not applicable to this platform or the firmware is already 64-bit ready, it exits silently with a return code of zero. If the operation is applicable to this platform and the firmware is not 64-bit ready, it displays a descriptive message on the standard output and exits with a non-zero return code. The hardware platform documentation contains more information about the platforms that may need a firmware upgrade in order to run the 64-bit kernel.

This flag overrides all other flags and must be used by itself.

Operands

The following operands are supported:

`dev_path` The path to a target device minor node, device nexus node, or device link for which device node configuration information is displayed

Exit Status

The following exit values are returned:

0 No error occurred.

non-zero With the -F option (SPARC only), a non-zero return value means that the output device is not a frame buffer. With the -x option, a non-zero return value means that the firmware is not 64-bit ready. In all other cases, a non-zero return value means that an error occurred.

Sun Hardware Platform Guide

SPARC Only

openprom(7D)

Notes

The output of the `prtconf` command is highly dependent on the version of the PROM installed in the system. The output will be affected in potentially all circumstances.
The **driver not attached** message means that no driver is currently attached to that instance of the device. In general, drivers are loaded and installed (and attached to hardware instances) on demand, and when needed, and may be uninstalled and unloaded when the device is not in use.

On x86 platforms, the use of `prtconf -vp` provides a subset of information from `prtconf -v`. The value of integer properties from `prtconf -vp` might require byte swapping for correct interpretation.
Name  prtdiag – display system diagnostic information

Synopsis  /usr/sbin/prtdiag [-v] [-l]

Description  prtdiag displays system configuration and diagnostic information on sun4u, sun4v, and x86 systems.

The diagnostic information lists any failed field replaceable units (FRUs) in the system.

The interface, output, and location in the directory hierarchy for prtdiag are uncommitted and subject to change in future releases.

prtdiag does not display diagnostic information and environmental status when executed on the Sun Enterprise 10000 server. See the /var/opt/SUNWssp/adm/${SUNW_HOSTNAME}/messages file on the system service processor (SSP) to obtain such information for this server.

Options  The following options are supported:

-Log output. If failures or errors exist in the system, output this information to syslogd(1M) only.

-Verbose mode. Displays the time of the most recent AC Power failure, and the most recent hardware fatal error information, and (if applicable) environmental status. The hardware fatal error information is useful to repair and manufacturing for detailed diagnostics of FRUs.

Exit Status  The following exit values are returned:

0  No failures or errors are detected in the system.

1  Failures or errors are detected in the system.

2  An internal prtdiag error occurred, for example, out of memory.

Attributes  See attributes(5) for descriptions of the following attributes:

Not all diagnostic and system information is available on every Solaris platform, and therefore cannot be displayed by `prtdiag`. On those platforms, further information can be obtained from the System Controller.
**prtdscp(1M)**

**Name**  
prtdscp – display DSCP IP addresses

**Synopsis**  
`prtdscp [-v ]`  
`prtdscp [-v ] -h`  
`prtdscp [-v ] -d`  
`prtdscp [-v ] -s`

**Description**  
prtdscp displays the IP addresses associated with a Domain to Service Processor Communications Protocol (DSCP) link. If no arguments are specified, prtdscp displays the IP addresses on both ends of the DSCP link. The IP address of either the Service Processor or domain side can be displayed separately by the use of the `-s` or `-d` options, respectively.

**Options**  
The following options are supported:

- `-v`  
  Verbose mode. Print additional details about the program’s internal progress to stderr.

- `-h`  
  Help. Print a brief synopsis of the program’s usage and exit. All other command line arguments are ignored.

- `-d`  
  Display only the local domain’s IP address.

- `-s`  
  Display only the remote Service Processor’s IP address.

**Examples**  
**EXAMPLE 1**  
Displaying both addresses

The following example displays both the local domain’s IP address and the remote SP’s IP address:

```
# prtdscp
Domain Address: 192.168.103.2
SP Address: 192.168.103.1
```

**EXAMPLE 2**  
Displaying the local IP address

The following example displays the local domain’s IP address:

```
# prtdscp -d
192.168.103.2
```

**EXAMPLE 3**  
Displaying the remote IP address

The following example display the remote SP’s IP address:

```
# prtdscp -s
192.168.103.1
```

The `prtfru` utility is used to obtain FRUID data from the system or domain. Its output is that of a tree structure echoing the path in the FRU (Field-Replaceable Unit) tree to each container. When a container is found, the data from that container is printed in a tree-like structure as well.

`prtfru` without any arguments will print the FRU hierarchy and all of the FRUID container data. `prtfru` prints to stdout which may be redirected to a file.

The following options are supported:

- `-c` Prints only the containers and their data. This option does not print the FRU tree hierarchy.
- `-d` Prints a DTD for the current registry to stdout.
- `-l` Prints only the FRU tree hierarchy. This option does not print the container data.
- `-x` Prints in XML format with a system identifier (SYSTEM) of `prtfrureg.dtd`.

Options `-c` and `-l` can be used together to obtain a list of the containers.

The following operand is supported:

`container` The name of a particular container in the FRU hierarchy, that is, either the name or path/name of a container as displayed in the `-l` option.

The following exit values are returned:

- `0` All information was found and printed successfully.
- `>0` An error has occurred.

See `attributes(5)` for descriptions of the following attributes:

prtpicl – print PICL tree

Synopsis
/usr/sbin/prtpicl [-c picl_class] [-v]

Description
The prtpicl command prints the PICL tree maintained by the PICL daemon. The output of prtpicl includes the name and PICL class of the nodes.

Options
The following options are supported:
- `-c picl_class`  Print only the nodes of the named PICL class.
- `-v`  Print in verbose mode. In verbose mode, prtpicl prints a list of properties and values for each node. Verbose mode is disabled by default.

Exit Status
The following exit values are returned:
- `0`  Successful completion.
- non-zero  An error occurred.

Attributes

Name  prtvtoc – report information about a disk geometry and partitioning

Synopsis  

prtvtoc [-fhs] [-t vfstab] [-m mnttab] device

Description  The `prtvtoc` command allows the contents of the label to be viewed. The command can be used only by the super-user.

The `device` name can be the file name of a raw device in the form of `/dev/rdsk/c?t?d?s2` or can be the file name of a block device in the form of `/dev/dsk/c?t?d?s2`.

Options  The following options are supported:

- `-f` Report on the disk free space, including the starting block address of the free space, number of blocks, and unused partitions.
- `-h` Omit the headers from the normal output.
- `-m mnttab` Use `mnttab` as the list of mounted filesystems, in place of `/etc/mnttab`.
- `-s` Omit all headers but the column header from the normal output.
- `-t vfstab` Use `vfstab` as the list of filesystem defaults, in place of `/etc/vfstab`.

Examples  

**EXAMPLE 1** Using the `prtvtoc` Command

The following example uses the `prtvtoc` command on a 424-megabyte hard disk:

```bash
example# prtvtoc /dev/rdsk/c0t3d0s2
* /dev/rdsk/c0t3d0s2 partition map
*
* Dimension:
* 512 bytes/sector
* 80 sectors/track
* 9 tracks/cylinder
* 720 sectors/cylinder
* 2500 cylinders
* 1151 accessible cylinders
*
* Flags:

Warnings The mount command does not check the “not mountable” bit.
psradm(1M)

Name psradm – change processor operational status

Synopsis psradm -f | -i | -n | -s [-v] [-F] processor_id
              psradm -a -f | -i | -n | -s [-v] [-F]

Description The psradm utility changes the operational status of processors. The legal states for the processor are on-line, off-line, spare, faulted, and no-intr.

An on-line processor processes LWPs (lightweight processes) and can be interrupted by I/O devices in the system.

An off-line processor does not process any LWPs. Usually, an off-line processor is not interruptible by I/O devices in the system. On some processors or under certain conditions, it might not be possible to disable interrupts for an off-line processor. Thus, the actual effect of being off-line might vary from machine to machine.

A spare processor does not process any LWPs. A spare processor can be brought on-line, off-line or to no-intr by a privileged user of the system or by the kernel in response to changes in the system state.

A faulted processor is identified by the kernel, which monitors the behavior of processors over time. A privileged user can set the state of a faulted processor to be on-line, off-line, spare or no-intr, but must use the force option to do so.

A no-intr processor processes LWPs but is not interruptible by I/O devices.

A processor can not be taken off-line or made spare if there are LWPs that are bound to the processor unless the additional -F option is used. The -F option removes processor bindings of such LWPs before changing the processor’s operational status. On some architectures, it might not be possible to take certain processors off-line or spare if, for example, the system depends on some resource provided by the processor.

At least one processor in the system must be able to process LWPs. At least one processor must also be able to be interrupted. Since an off-line or spare processor can be interruptible, it is possible to have an operational system with one processor no-intr and all other processors off-line or spare but with one or more accepting interrupts.

If any of the specified processors are powered off, psradm might power on one or more processors.

Only users with the PRIV_SYS_RES_CONFIG privilege can use the psradm utility.

Options The following options are supported:

- a Perform the action on all processors, or as many as possible.
- f Take the specified processors off-line.
Forcethetransitiontotheadditionalspecifiedstate.Requiredifoneormoreofthe
specifiedprocessorswasinthefaultedstate.Setthespecifiedprocessors to faulted, if
no other transition option was specified. Forced transitions can only be made to faulted,
spare, or off-line states. Administrators are encouraged to use the -Q option for
psbind(1M) to find out which threads will be affected by forced a processor state
transition.

-i Setthespecifiedprocessors no-intr.

-n Bringthespecifiedprocessors on-line.

-s Makethespecifiedprocessors spare.

-v Outputamessagegivingtheresultsofeachattemptedoperation.

Operands Thefollowingoperandsaresupported:

processor_id The processor ID of the processor to be set on-line or off-line, spare, or
no-intr.

Specify processor_id as an individual processor number (for example, 3),
multiple processor numbers separated by spaces (for example, 1 2 3), or a
range of processor numbers (for example, 1-4). It is also possible to combine
ranges and (individual or multiple) processor_ids (for example, 1-3 5 7-8
9).

Examples EXAMPLE 1 Setting Processors to off-line

The following example sets processors 2 and 3 off-line:

% psradm -f 2 3

EXAMPLE 2 Setting Processors to no-intr

The following example sets processors 1 and 2 no-intr:

% psradm -i 1 2

EXAMPLE 3 Setting Processors to spare

The following example sets processors 1 and 2 spare, even if either of the processors was in the
faulted state:

% psradm -F -s 1 2

EXAMPLE 4 Setting All Processors on-line

% psradm -a -n
EXAMPLE 5  Forcing Processors to off-line
The following example sets processors 1 and 2 offline, and revokes the processor bindings from the processes bound to them:

% psradm -F -f 1 2

Exit Status  The following exit values are returned:

0      Successful completion.
>0     An error occurred.

Files  /etc/wtmpx  Records logging processor status changes

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  pbind(1M), psrinfo(1M), psrset(1M), p_online(2), processor_bind(2), attributes(5)

Diagnostics  psradm: processor 4: Invalid argument
The specified processor does not exist in the configuration.

psradm: processor 3: Device busy
The specified processor could not be taken off-line because it either has LWPs bound to it, is the last on-line processor in the system, or is needed by the system because it provides some essential service.

psradm: processor 3: Device busy
The specified processor could not be set no-interrupts because it is the last interruptible processor in the system, or it is the only processor in the system that can service interrupts needed by the system.

psradm: processor 3: Device busy
The specified processor is powered off, and it cannot be powered on because some platform-specific resource is unavailable.

psradm: processor 0: Not owner
The user does not have permission to change processor status.

psradm: processor 2: Operation not supported
The specified processor is powered off, and the platform does not support power on of individual processors.
### Name
psrinfo – displays information about processors

### Synopsis
psrinfo [-p] [-v] [processor_id]...

    psrinfo [-p] -s processor_id

### Description
psrinfo displays information about processors. Each physical processor may support multiple virtual processors. Each virtual processor is an entity with its own interrupt ID, capable of executing independent threads.

Without the `processor_id` operand, `psrinfo` displays one line for each configured processor, displaying whether it is on-line, non-interruptible (designated by no-intr), spare, off-line, faulted or powered off, and when that status last changed. Use the `processor_id` operand to display information about a specific processor. See `OPERANDS`.

### Options
The following options are supported:

- **-s processor_id**
  - Silent mode. Displays 1 if the specified processor is fully on-line. Displays 0 if the specified processor is non-interruptible, spare, off-line, faulted or powered off.

  Use silent mode when using `psrinfo` in shell scripts.

- **-p**
  - Display the number of physical processors in a system.

  When combined with the `-v` option, reports additional information about each physical processor.

- **-v**
  - Verbose mode. Displays additional information about the specified processors, including: processor type, floating point unit type and clock speed. If any of this information cannot be determined, `psrinfo` displays `unknown`.

  When combined with the `-p` option, reports additional information about each physical processor.

### Operands
The following operands are supported:

- **processor_id**
  - The processor ID of the processor about which information is to be displayed.

  Specify `processor_id` as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) `processor_ids` (for example, 1-3 5 7-8 9).
Examples

**EXAMPLE 1**  Displaying Information About All Configured Processors in Verbose Mode

The following example displays information about all configured processors in verbose mode.

```
psrinfo -v
```

**EXAMPLE 2**  Determining If a Processor is On-line

The following example uses `psrinfo` in a shell script to determine if a processor is on-line.

```
if [ "psrinfo -s 3 2> /dev/null" -eq 1 ]
then
  echo "processor 3 is up"
fi
```

**EXAMPLE 3**  Displaying Information About the Physical Processors in the System

With no additional arguments, the `-p` option displays a single integer: the number of physical processors in the system:

```
> psrinfo -p
8
```

`psrinfo` also accepts command line arguments (processor IDs):

```
> psrinfo -p 0 512  # IDs 0 and 512 exist on the
1  # same physical processor

> psrinfo -p 0 1  # IDs 0 and 1 exist on different
2  # physical processors
```

In this example, virtual processors 0 and 512 exist on the same physical processor. Virtual processors 0 and 1 do not. This is specific to this example and is not a general rule.

**Exit Status**  The following exit values are returned:

- 0  Successful completion.
- >0  An error occurred.

**Attributes**  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

**See Also**  `psradm(1M), p_online(2), processor_info(2), attributes(5)`

**Diagnostics**  `psrinfo: processor 9: Invalid argument`  The specified processor does not exist.
psrset(1M)

Name
psrset – creation and management of processor sets

Synopsis
psrset -a [-F] processor_set_id processor_id...
psrset -b processor_set_id pid [/lwpid]...
psrset -c [-F] [processor_id]...
psrset -d processor_set_id...
psrset -e processor_set_id command [argument(s)]
psrset -f processor_set_id
psrset [-i] [processor_set_id]...
psrset -n processor_set_id
psrset -p [processor_id]...
psrset [-q] [pid [/lwpid]]...
psrset -r [-F] processor_id...
psrset -u pid [/lwpid]...
psrset -U [processor_set_id]...

Description
The psrset utility controls the management of processor sets. Processor sets allow the binding of processes or LWPs to groups of processors, rather than just a single processor. Processes assigned to processor sets can run only LWPs that have been bound to that processor set.

This command cannot be used to modify processor disposition when pools are enabled. Use pooladm(1M) and poolcfg(1M) to modify processor set configuration through the resource pools facility.

Options
The following options are supported:

- **a**
  Assign the specified processors to the specified processor set. With the additional -F option, all LWPs bound to the specified processors will be unbound prior to changing processor sets.

  This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

- **b**
  Bind all or a subset of the LWPs of the specified processes to the specified processor set. LWPs bound to a processor set are restricted to run only on the processors in that set. Processes can only be bound to non-empty processor sets, that is, processor sets that have had processors assigned to them.
Bindings are inherited, so new LWPs and processes created by a bound LWP have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

- c  Create a new processor set and displays the new processor set ID. With the additional - F option, all LWPs bound to the specified processors will be unbound prior to assigning them to the processor set being created.

If a list of processors is given, it also attempts to assign those processors to the processor set. If this succeeds, the processors are idle until LWPs are bound to the processor set. This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

Only a limited number of processor sets can be active (created and not destroyed) at a given time. This limit is always greater than the number of processors in the system. If the - c option is used when the maximum number of processor sets is already active, the command fails.

The following format is used for the first line of output of the - c option when the LC_MESSAGES locale category specifies the "C" locale. In other locales, the strings created, processor, and set can be replaced with more appropriate strings corresponding to the locale.

"created processor set %d\n" processor set ID

- d  Remove the specified processor set, releasing all processors and processes associated with it.

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

- e  Execute a command (with optional arguments) in the specified processor set.

The command process and any child processes are executed only by processors in the processor set.

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

- f  Disables interrupts for all processors within the specified processor set. See ps radm(1M).

If some processors in the set cannot have their interrupts disabled, the other processors still have their interrupts disabled, and the command reports an error and return non-zero exit status.

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.
Forced the specified processor set operation by unbinding all threads bound to the specified processor. Only the -a or the -r option can be used in combination with this option. Administrators are encouraged to use the -0 option for pbind(1M) to find out which threads will be affected by such operation.

Display a list of processors assigned to each named processor set. If no argument is given, a list of all processor sets and the processors assigned to them is displayed. This is also the default operation if the psrset command is not given an option.

Enable interrupts for all processors within the specified processor set. See psradm(1M).

Display the processor set assignments for the specified list of processors. If no argument is given, the processor set assignments for all processors in the system is given.

Display the processor set bindings of the specified processes or of all processes. If a process is composed of multiple LWPs which have different bindings and the LWPs are not explicitly specified, the bindings of only one of the bound LWPs is displayed. The bindings of a subset of LWPs can be displayed by appending "/lwpids" to the process IDs. Multiple LWPs may be selected using "-" and "," delimiters. See EXAMPLES.

Display the LWPs bound to the specified list of processor sets, or all LWPs with processor set bindings.

Remove a list of processors from their current processor sets. Processors that are removed return to the general pool of processors.

Processors with LWPs bound to them using pbind(1M) can be assigned to or removed from processor sets using the -F option.

Remove the processor set bindings of a subset or all the LWPs of the specified processes, allowing them to be executed on any on-line processor if they are not bound to individual processors through pbind.

Users with the PRIV_SYS_RES_CONFIG privilege can unbind any process or LWP from any active processor set. Other users can unbind processes and LWPs from processor sets that do not have the PSET_NORESCAPE attribute set. In addition, the user must have permission to control the affected processes; the real or effective user ID of the user must match the real or saved user ID of the target processes.

Removes the bindings of all LWPs bound to the specified list of processor sets, or to any processor set if no argument is specified.
The following operands are supported:

`pid` Specify `pid` as a process ID.

`lwpid` The set of LWPs of the specified process to be controlled or queried. The syntax for selecting LWPs is as follows:

- `2,3,4-8` LWP IDs 2, 3, and 4 through 8
- `-4` LWPs whose IDs are 4 or below
- `4-` LWPs whose IDs are 4 or above

`processor_id` Specify `processor_id` as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, `1 2 3`), or a range of processor numbers (for example, `1-4`). It is also possible to combine ranges and (individual or multiple) `processor_ids` (for example, `1-3 5 7-8 9`).

`processor_set_id` Specify `processor_set_id` as a processor set ID.

**Exit Status** The following exit values are returned:

- `0` Successful completion.
- non-0 An error occurred.

**Attributes** See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

**See Also** `pbind(1M), pooladm(1M), poolcfg(1M), psradm(1M), psrinfo(1M), processor_bind(2), processor_info(2), pset_bind(2), pset_create(2), pset_info(2), sysconf(3C), libpool(3LIB), attributes(5), privileges(5)`

**Diagnostics** The following output indicates that the specified process did not exist or has exited:

`psrset: cannot query pid 31: No such process`

The following output indicates that the user does not have permission to bind the process:

`psrset: cannot bind pid 31: Not owner`

The following output indicates that the user does not have permission to assign the processor:

`psrset: cannot assign processor 4: Not owner`

The following output indicates that the specified processor is not on-line, or the specified processor does not exist:

`psrset: cannot assign processor 8: Invalid argument`
The following output indicates that an LWP in the specified process is bound to a processor and cannot be bound to a processor set that does not include that processor:

```
psrset: cannot bind pid 67: Device busy
```

The following output indicates that the specified processor could not be added to the processor set. This can be due to bound LWPs on that processor, or because that processor cannot be combined in the same processor set with other processors in that set, or because the processor is the last one in its current processor set:

```
psrset: cannot assign processor 7: Device busy
```

The following output indicates that the specified processor set does not exist:

```
psrset: cannot execute in processor set 8: Invalid argument
```

The following output indicates that the maximum number of processor sets allowed in the system is already active:

```
psrset: cannot create processor set: Not enough space
```

The following output indicates that the pools facility is active.

```
psrset: cannot assign processor 7: Operation not supported
psrset: cannot bind pid 31: Operation not supported
psrset: cannot bind pid 31: Operation not supported
psrset: could not create processor set: Operation not supported
psrset: could not remove processor set 1: Operation not supported
psrset: cannot exec in processor set 1: Operation not supported
psrset: cannot remove processor 7: Operation not supported
psrset: cannot unbind pid 31: Operation not supported
```
pwck(1M)

Name  pwck, grpck – password/group file checkers

Synopsis  
/usr/sbin/pwck [filename]
/usr/sbin/grpck [filename]

Description  pwck scans the password file and notes any inconsistencies. The checks include validation of
the number of fields, login name, user ID, group ID, and whether the login directory and the
program-to-use-as-shell exist. The default password file is /etc/passwd.

grpck verifies all entries in the group file. This verification includes a check of the number of
fields, group name, group ID, whether any login names belong to more than NGROUPS_MAX
groups, and that all login names appear in the password file. grpck also issues a warning if it
finds an entry (a single line) in the group file longer than 2047 characters. Such an entry causes
group maintenance commands, such as groupdel(1M) and groupmod(1M), to fail.

The default group file is /etc/group.

All messages regarding inconsistent entries are placed on the stderr stream.

Files  
- /etc/group
- /etc/passwd

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also  groupdel(1M), groupmod(1M), getpwent(3C), group(4), passwd(4), attributes(5)

Diagnostics  Group entries in /etc/group with no login names are flagged.

Group file 'filename' is empty
  The /etc/passwd or /etc/group file is an empty file.

cannot open file filename: No such file or directory
  The /etc/passwd or /etc/group file does not exist.

Notes  If no filename argument is given, grpck checks the local group file, /etc/group, and also
makes sure that all login names encountered in the checked group file are known to the system
getpwent(3C) routine. This means that the login names may be supplied by a network name
service.
pwconv — installs and updates /etc/shadow with information from /etc/passwd

**Description**

The `pwconv` command creates and updates /etc/shadow with information from /etc/passwd.

`pwconv` relies on a special value of ‘x’ in the password field of /etc/passwd. This value of ‘x’ indicates that the password for the user is already in /etc/shadow and should not be modified.

If the /etc/shadow file does not exist, this command will create /etc/shadow with information from /etc/passwd. The command populates /etc/shadow with the user’s login name, password, and password aging information. If password aging information does not exist in /etc/passwd for a given user, none will be added to /etc/shadow. However, the last changed information will always be updated.

If the /etc/shadow file does exist, the following tasks will be performed:

- Entries that are in the /etc/passwd file and not in the /etc/shadow file will be added to the /etc/shadow file.
- Entries that are in the /etc/shadow file and not in the /etc/passwd file will be removed from /etc/shadow.
- Password attributes (for example, password and aging information) that exist in an /etc/passwd entry will be moved to the corresponding entry in /etc/shadow.

The `pwconv` command can only be used by the super-user.

**Files**

- /etc/opasswd
- /etc/oshadow
- /etc/passwd
- /etc/shadow

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

**See Also**

passwd(1), usermod(1M), passwd(4), attributes(5)

**Diagnostics**

`pwconv` exits with one of the following values:

- 0 SUCCESS.
- 1 Permission denied.
- 2 Invalid command syntax.
- 3 Unexpected failure. Conversion not done.
4  Unexpected failure. Password file(s) missing.
5  Password file(s) busy. Try again later.
6  Bad entry in /etc/shadow file.
Name  quot – summarize file system ownership

Synopsis  quot [ -acfhnv ] filesystem ...
           quot -a [ -cfhnv ]

Description  quot displays the number of blocks (1024 bytes) in the named filesystem (one or more) currently owned by each user. There is a limit of 2048 blocks. Files larger than this will be counted as a 2048 block file, but the total block count will be correct.

Options  The following options are supported:

   -a    Generate a report for all mounted file systems.

   -c    Display three columns giving a file size in blocks, the number of files of that size, and a cumulative total of blocks containing files of that size or a smaller size.

   -f    Display three columns giving, for each user, the number of blocks owned, the count of number of files, and the user name. This option is incompatible with the -c and -v options.

   -h    Estimate the number of blocks in the file. This does not account for files with holes in them.

   -n    Attach names to the list of files read from standard input. quot -n cannot be used alone, because it expects data from standard input. For example, the pipeline

           ncheck myfilesystem | sort +0n | quot -n myfilesystem

       will produce a list of all files and their owners. This option is incompatible with all other options.

   -v    In addition to the default output, display three columns containing the number of blocks not accessed in the last 30, 60, and 90 days.

Operands  filesystem      mount-point of the filesystem(s) being checked

Usage  See largefile(5) for the description of the behavior of quot when encountering files greater than or equal to 2 Gbyte ( 2^{31} bytes).

Exit Status  0    Successful operation.

       32    Error condition (bad or missing argument, bad path, or other error).

Files  /etc/mnttab  Lists mounted file systems.

   /etc/passwd    Used to obtain user names

Attributes  See attributes(5) for descriptions of the following attributes:
### See Also
- du(1), mnttab(4), passwd(4), attributes(5), largefile(5)

### Notes
This command can only be used by the super-user.
quota(1M)

Name
quota – display a user’s UFS or ZFS file system disk quota and usage

Synopsis
quota [-v] [username]

Description
quota displays users’ UFS or ZFS disk usage and limits. Only the super-user may use the
optional username argument to view the limits of other users.

quota without options only display warnings about mounted file systems where usage is over
quota. Remotely mounted file systems which do not have quotas turned on are ignored.

username can be the numeric UID of a user.

Options
- v   Display user’s quota on all mounted file systems where quotas exist.

Usage
See largefile(5) for the description of the behavior of quota when encountering files greater
than or equal to 2 Gbyte (2^{31} bytes).

Files
/etc/mnttab   list of currently mounted filesystems

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

See Also
edquota(1M), quotaon(1M), quotacheck(1M), repquota(1M), rquotad(1M),
attributes(5), largefile(5), zones(5)

Notes
quota displays quotas for NFS mounted UFS- or ZFS-based file systems if the rquotad
d daemon is running. See rquotad(1M). In a zones(5) environment, quota displays quotas only
for the zone in which it is invoked.

quota can display entries for the same file system multiple times for multiple mount points.
For example,

# quota -v user1

might display identical quota information for user1 at the mount points /home/user1,
/home/user2, and /home/user, if all three mount points are mounted from the same file
system with quotas turned on.
**Name**
quotalcheck – ufs file system quota consistency checker

**Synopsis**
quotalcheck [-fp] [-v] filesystem...
quotalcheck -a [-fpv]

**Description**
quotalcheck examines each mounted ufs file system, builds a table of current disk usage, and compares this table against the information stored in the file system’s disk quota file. If any inconsistencies are detected, both the quota file and the current system copy of the incorrect quotas are updated.

*filesystem* is either a file system mount point or the block device on which the file system resides.

quotalcheck expects each file system to be checked to have a quota file named *quotas* in the root directory. If none is present, quotalcheck will not check the file system.

quotalcheck accesses the character special device in calculating the actual disk usage for each user. Thus, the file systems that are checked should be quiescent while quotalcheck is running.

**Options**
The following options are supported:

- **-a** Check the file systems which `/etc/mnttab` indicates are ufs file systems. These file systems must be read-write mounted with disk quotas enabled, and have an *rq* entry in the *mntpts* field in `/etc/vfstab`.
- **-f** Force check on file systems with logging enabled. Use in combination with the -p option.
- **-p** Check quotas of file systems in parallel. For file systems with logging enabled, no check is performed unless the -f option is also specified.
- **-v** Indicate the calculated disk quotas for each user on a particular file system. quotalcheck normally reports only those quotas modified.

**Usage**
See `largefile(5)` for the description of the behavior of quotalcheck when encountering files greater than or equal to 2 Gbyte (2**31** bytes).

**Files**
`/etc/mnttab` Mounted file systems
`/etc/vfstab` List of default parameters for each file system

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>
See Also  edquota(1M), quota(1M), quotaon(1M), repquota(1M), attributes(5), largefile(5),
quotactl(7I), mount_ufs(1M)
Name
quotaon, quotaoff – turn ufs file system quotas on and off

Synopsis

quotaon [ -v ] filesystem...
quotaon -a [ -v ]
quotaoff [ -v ] filesystem...
quotaoff -a [ -v ]

Description

quotaon turns on disk quotas for one or more ufs file systems.

Before a file system may have quotas enabled, a file named quotas, owned by root, must exist in the root directory of the file system. See edquota(1M) for details on how to modify the contents of this file.

quotaoff turns off disk quotas for one or more ufs file systems.

The file systems specified must already be mounted.

These commands update the mntopts field of the appropriate entries in /etc/mnttab to indicate when quotas are on or off for each file system. If quotas are on, the string quota will be added to mntopts; if quotas are off, the quota string is not present.

filesystem must be either the mount point of a file system, or the block device on which the file system resides.

Options

- quotaon - a
  This option is normally used at boot time to enable quotas. It applies only to those file systems in /etc/vfstab which have “rq” in the mntopts field, are currently mounted “rw”, and have a quotas file in the root directory.

- v
  Display a message for each file system after quotas are turned on.

- quotaoff - a
  Force all file systems in /etc/mnttab to have their quotas disabled.

- v
  Display a message for each file system affected.

Usage

See largefile(5) for the description of the behavior of quotaon and quotaoff when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files

/etc/mnttab  mounted file systems
/etc/vfstab  list of default parameters for each file system

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

**rad(1M)**

**Name**  
rad – remote administration daemon

**Synopsis**  
/usr/lib/rad [-d] [-s] [-S fmri]  
[-M module [-M module]...]  
[-m moduledir [-m moduledir]...]  
[-t transpec [-t transpec]...]  
[-e timeout]

**Description**  
rad is a facility that securely exposes programmatic system administrative and monitoring interfaces to consumers in a variety of high-level languages.

rad can be used in the following ways:

- **As a service:**
  
  When run as a service, rad authenticates connections using `getpeerucred(3C)` or `pam(3PAM)`. When used in this way, consumed APIs are run as the authenticated user. This mode of operation is provided with both local consumers looking to isolate execution of their privileged operations and remote consumers in mind.

- **As an unprivileged program:**
  
  When run as an unprivileged program, rad serves solely as a bridge between its clients and the administrative APIs it publishes. When used in this way, any interfaces consumed will be run with the rights held by the rad process.

rad is modular. The APIs published by rad are delivered as shared objects, as are the protocols it understands and the transports it can communicate over. Multiple instances of rad can run simultaneously, each functioning independently of the others, providing different services to different consumers, and listening for different types of connections on different ports or interfaces. rad obtains its configuration from its command-line options, from `smf(5)`, or from a combination of the two.

**Options**  
The following options are available for use on the command line:

- `-d`
  
  Emit verbose debugging output.

- `-e timeout`
  
  Specify a connection timeout in seconds. The default value is 180 seconds.

- `-m moduledir`
  
  Add `moduledir` to the list of directories to scan and load modules from. The `-m` option can be used multiple times to add multiple module directories.

- `-M module`
  
  Add `module` to the list of modules to load. `module` should be an absolute pathname or a pathname relative to the current working directory. Modules loaded with `-M` take precedence over modules found using `-m`. The `-M` option can be used multiple times to add multiple modules.
-t transpec
Instantiate a transport specified by transport specification transpec. A transport specification has the following format:

transport[::option=value1,option2=value2]...

-s
Behave as an svc.startd(1M) start method. This option has the following effects:
- If the -s option is not specified, rad will read its configuration from the service identified by scf_myname() (see scf_handle_create(3SCF)).
- rad will use smf_method(5)-compatible exit statuses.
- rad will daemonize, returning success only once it is ready to handle requests.

-S fmri
Read configuration from the SMF service instance specified by fmri. When the -s option is not specified, configured transports are not read from the service to avoid endpoint conflicts with a running service.

Module directories specified on the command line are searched before module directories configured in SMF, permitting command line configuration to override SMF configuration.

Smf Configuration
When rad reads its configuration from smf(5), it reads general configuration from a property group called config of type application, and reads configuration for each of an arbitrary number of transports from a series of properties groups of type xport_XYZ where XYZ is replaced with the name of the transport type. Multiple instances of a particular transport type can be configured by creating multiple property groups of the corresponding type. The names of the property groups used to configure transports are not important.

The config property group contains the following properties:

moduledir
A list of a strings. The directories to scan and load modules from.

modules
A list of astrings. The file names of specific modules to load.

debug
A boolean. If true, rad will emit verbose debugging output. Defaults to false.

timeout
An integer. The maximum time in seconds to wait for an individual response from the client while authenticating. Defaults to 180.

Service Instances
Two instances of the svc:/system/rad SMF service are configured to run /usr/lib/rad/rad:

svc:/system/rad:local
Configures rad to use the unix transport, with AF_UNIX sockets at:
/system/volatile/rad/radsocket, for getpeerucred(3C)-authenticated connections, and...
/system/volatile/rad/radsocket-unauth, for pam(3PAM)-authenticated connections.

svc:/system/rad:remote
  Configures rad to use the tls transport.

Each service is configured with the following directories in its moduledir setting:

/usr/lib/rad/module
  content-specific modules
/usr/lib/rad/transport
  transport modules
/usr/lib/rad/protocol
  protocol modules
/usr/lib/rad/site-modules
  site-specific modules

Transports
Support for different transport types is delivered in module form. Modules for the following transports are supplied with the system: pipes (pipe), TCP sockets (tcp), TLS sockets (tls), and Unix-domain sockets (unix). Each transport type has a unique set of configuration properties. The options for an instance of a transport type are configured either by defining properties in an SMF property group or by supplying sub-options to a -t command-line option.

The pipe transport reads from and writes to a specific file descriptor, as is needed when a process wishes to communicate with a child rad process using a pipe. The pipe transport has the following options:

proto
  An string. The protocol to use with this transport instance. Defaults to rad.

fd
  An integer. The file descriptor to read from/write to.

exit
  A boolean. If true, rad will exit when communication over the pipe ends. Defaults to false.

The tcp transport listens for clear-text connections on a TCP socket. The tcp transport has the following options:

proto
  An string. The protocol to use with this transport instance. Defaults to rad.

port
  An integer. The port to listen on for connections.
localonly
A boolean. If true, rad will only listen for connections from the local machine. Defaults to true.

pam_service
An astrig. The pam(3PAM) service name to use when authenticating. Defaults to rad-tcp.
See the "Authenticating with PAM" section below.

The tls transport listens for TLS connections on a TCP socket. The tls transport has the following options:

proto
An astrig. The protocol to use with this transport instance. Defaults to rad.

port
An integer. The port to listen on for connections.

localonly
A boolean. If true, rad will only listen for connections from the local machine. Defaults to true.

certificate
An astrig. The location of the PEM-formatted x509 certificate to use.

privatekey
An astrig. The location of the PEM-formatted private key to use.

generate
A boolean. If true, and if the specified certificate and privatekey do not exist, rad will generate a new certificate and private key using openssl(5). Defaults to false.

pam_service
An astrig. The pam(3PAM) service name to use when authenticating. Defaults to rad-tls.
See the "Authenticating with PAM" section below.

The unix transport listens for connections on an AF_UNIX socket. The unix transport has the following options:

proto
An astrig. The protocol to use with this transport instance. Defaults to rad.

path
An astrig. The path to listen on.

peercred
A boolean. If true, rad will attempt to automatically authenticate connections using getpeercred(3C). Defaults to true.

pam_service
An astrig. The pam(3PAM) service name to use when authenticating. Defaults to rad-unix.
See the "Authenticating with PAM" section below.
When `rad` is run as a service, and `getpeerucred(3C)` is not applicable to the transport being used, `pam(3PAM)` is used to authenticate connections. The PAM service name used is dependent on the transport:

- `rad-tls` when connecting by means of the `tls` transport
- `rad-tcp` when connecting by means of the `tcp` transport
- `rad-unix` when connecting by means of the `unix` transport (and `peercred` is `false`)
- `rad` when connecting by means of any other transport

In rare cases, administrators may need to override the PAM service name used on a per-transport basis. For example, two `rad` TLS transports serving a single `rad` instance, with one listening on a local (more trusted) network and the other on a remote (less trusted) network, could require different PAM configurations.

In such cases, administrators can specify the name of the PAM service to use as a transport configuration property (see the “Transports” section above).

As with all PAM services, PAM will for look for entries corresponding to the PAM service for `rad` in `/etc/pam.conf` first and then `/etc/pam.d/service`. If no entries are found PAM will look in `/etc/pam.conf` for entries corresponding to the “other” service. If no “other” entries are found PAM will finally look for entries in `/etc/pam.d/other`.

**Files**

- `/etc/rad/cert.pem`:
  The location where the remote `rad` instance (`svc:/system/rad:remote`) stores its certificate. This file is readable by all users.

- `/etc/rad/key.pem`:
  The location where the remote `rad` instance (`svc:/system/rad:remote`) stores its private key.

- `/system/volatile/rad/radsocket`:
  The `AF_UNIX` socket where the local `rad` instance (`svc:/system/rad:local`) accepts connections that are implicitly authenticated with `getpeerucred(3C)`.

- `/system/volatile/rad/radsocket-unauth`:
  The `AF_UNIX` socket where the local `rad` instance (`svc:/system/rad:local`) accepts connections that must explicitly authenticate using `pam(3PAM)`.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:
<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

radadrgen(1), svc.startd(1M), pipe(2), getpeerucred(3C), pam(3PAM), scf_handle_create(3SCF), attributes(5), openssl(5), smf(5), smf_method(5)

Notes  
Two instances of rad are delivered by the system. svc:/system/rad:local listens to AF_UNIX connections at the paths /system/volatile/rad/radsocket and /system/volatile/rad/radsocket-unauth, and is enabled by default. The former AF_UNIX socket will automatically authenticate the connecting process using getpeerucred(3C), while the latter requires the connecting process to explicitly authenticate. svc:/system/rad:remote listens to TLS connections on the port 12302, requires all clients to explicitly authenticate, and is disabled by default.

Other system components, including some desktop administrative user interfaces, rely on the local instance of rad (svc:/system/rad:local).
Name

raidctl – RAID hardware utility

Synopsis

raidctl -C "disks" [-r raid_level] [-z capacity] [-s stripe_size] [-f] controller

raidctl -d [-f] volume

raidctl -F filename [-f] controller...

raidctl -a {set | unset} -g disk {volume | controller}

raidctl -p "param=value" [-f] volume

raidctl -c [-f] [-r raid_level] disk1 disk2 [disk3...]

raidctl -l -g disk controller

raidctl -l volume

raidctl -l controller...

raidctl [-l]

raidctl -S [volume | controller]

raidctl -S -g disk controller

raidctl -h

Description

The raidctl utility is a hardware RAID configuration tool that supports different RAID controllers by providing a CLI (command-line interface) to end-users to create, delete or display RAID volume(s). The utility can also be used to set properties of a volume, assign hot-spare (HSP) disks to volumes or controllers, and to update firmware/fcode/BIOS for RAID controllers.

The raidctl utility requires privileges that are controlled by the underlying file system permissions. Only privileged users can manipulate the RAID system configuration. If a non-privileged user attempts to run raidctl, the command fails with an exit status of 1.

The raidctl utility, as described in this man page, defines a broad set of command line options to provide management for full-featured RAID controllers. However, support for a given option depends on two elements:

- the presence of a software driver
- the firmware level of the RAID device

The dependency on a software driver is due to the design of raidctl. The utility is built on a common library that enables the insertion of plug-in modules for different drivers. Currently, the Solaris operating system is shipped with a plug-in for the mpt driver. This plug-in does not support all of the raidctl options. On a given storage device, options might be further limited by the device’s firmware level.

The level of support for the various raidctl options cannot be determined by raidctl. The user must rely on the documentation for his RAID controller or hardware platform.
Currently, `raidctl` provides some level of support for the following RAID controllers:

- LSI1020 SCSI HBA
- LSI1030 SCSI HBA
- LSI1064 SAS HBA
- LSI1068 SAS HBA

All of the above HBAs are maintained by the `mpt` driver, on X86-32/64 and SPARC platforms.

**Options**

The following options are supported:

```
-C "disks" [-r raid_level] [-z capacity] [-s stripe_size] [-f] controller
```

Create a RAID volume using specified disks.

When creating a RAID volume using this option, the identity of the newly created volume is automatically generated and `raidctl` reports it to the user.

The argument specified by this option contains the elements used to form the volume that is created. Elements can be either disks or sub-volumes, where disks are separated by space(s) and a sub-volume is a set of disks grouped by parenthesis. All disks should be in C.I.D.L expression (for example, 0.1.2 represents a physical disk of channel 0, target id 1, and logical unit number 2). The argument must match the RAID level specified by the `-r` option, even if it's omitted. This means the argument can only be:

- for RAID 0  
  At least 2 disks
- for RAID 1  
  Only 2 disks
- for RAID 1E  
  At least 3 disks
- for RAID 5  
  At least 3 disks
- for RAID 10  
  At least 2 sub-volumes, each sub-volume must be formed by 2 disks
- for RAID 50  
  At least 2 sub-volumes, each sub-volume must be formed by at least 3 disks, and the disk amount in each sub-volume should be the same

For example, the expression “0.0.0.1.0” means that the 2 specified disks form a RAID volume, which can either be a RAID 0 or a RAID 1 volume. “(0.0.0.1.0)(0.2.0.3.0)” means that the first 2 disks and the last 2 disks form 2 sub-volumes, and that these 2 sub-volumes form a RAID 10 volume. See the EXAMPLES section for more samples.

The `-r` option specifies the RAID level of the volume that is created. Possible levels are 0, 1, 1E, 5, 10, 50. If this option is omitted, `raidctl` creates a RAID 1 volume by default.
The \texttt{-z} option specifies the capacity of the volume that is created. The unit can be tera-bytes, giga-bytes, or mega-bytes (for example, 2t, 10g, 20m, and so on). If this option is omitted, \texttt{raidctl} calculates the maximum capacity of the volume that can be created by the specified disks and uses this value to create the volume.

The \texttt{-s} option specifies the stripe size of the volume that is created. The possible values are 512, 1k, 2k, 4k, 8k, 16k, 32k, 64k, or 128k. If this option is omitted, \texttt{raidctl} chooses an appropriate value for the volume (for example, 64k).

In some cases, the creation of a RAID volume can cause data on specified disks to be lost (for instance, on LSI1020, LSI1030, SAS1064, or SAS1068 HBAs), and \texttt{raidctl} prompts the user for confirmation about the creation. Use the \texttt{-f} option to force the volume creation without prompting the user for confirmation.

The controller argument is used to identify which RAID controller the specified disks belongs. The \texttt{-l} option can be used to list the controller's ID number.

\begin{itemize}
  \item \texttt{-d [-f] volume}
    
    Delete the RAID volume specified as volume. The volume is specified in canonical form (for example, \texttt{c0t0d0}).

    When a volume is deleted, all data is lost. Therefore, unless the \texttt{-f} option is specified, \texttt{raidctl} prompts the user for confirmation before deleting the volume.

  \item \texttt{-F filename [-f] controller…}
    
    Update the firmware running on the specified controller(s). The \texttt{raidctl} utility prompts the user for confirmation of this action, unless the \texttt{-f} option is provided.

  \item \texttt{-a \{set | unset\} -g disk \{volume | controller\}}
    
    If the volume is specified, \texttt{raidctl} sets or unsets the disk as a local hot-spare disk dedicated to the volume, depending on the value specified by the \texttt{-a} option. If the controller is specified, \texttt{raidctl} sets or unsets the disk as a global hot-spare disk.

  \item \texttt{-p "param=value" [-f] volume}
    
    Change the property value for a given RAID volume. This option can be used to change cache write policy or to activate a volume. When changing the cache write policy, \texttt{param} should be the string \texttt{wp} (\texttt{SET_WR_POLICY}), and \texttt{value} can be either \texttt{on} or \texttt{off}. When used to activate a volume, \texttt{param} should be \texttt{state} and \texttt{value} should be \texttt{activate}.

    Changing a RAID volume's property can affect the internal behavior of the RAID controller, so \texttt{raidctl} prompts the user for a confirmation before applying the change, unless the \texttt{-f} option is specified.

  \item \texttt{-c [-f] [-r raid_level] disk1 disk2 [disk3…]}
    
    Create a volume using the specified disks. This is an alternative to the \texttt{-C} option with similar functionality. This option is preserved for compatibility reasons, but only works with LSI1020, LSI1030, SAS1064, and SAS1068 HBAs to create RAID 0, RAID 1, or RAID 1E volumes. For other HBAs, the user can only use the \texttt{-C} option.
\end{itemize}
The `-r` option can be used to specify the RAID level of the target volume. If the `-r` option is omitted, `raidctl` creates a RAID 1 volume.

Disks must be specified in Solaris canonical format (for example, `c0t0d0`).

Creating a RAID 1 volume with this option replaces the contents of disk2 with the contents of disk1.

When the user creates a RAID volume with this option, the RAID volume assumes the identity of disk1. Other disks become invisible and the RAID volume appears as one disk.

Creating a volume with this option is by default interactive. The user must answer a prompt affirmatively to create the volume. Use the `-f` option to force the volume creation without prompting the user for confirmation.

`-l -g disk controller`
Display information about the specified disk of the given controller. The output includes the following information:

Disk
Displays the disk in `C, ID, L` expression disk.

Vendor
Displays the vendor ID string.

Product
Displays the product ID string.

Capacity
Displays the total capacity of the disk.

Status
Displays the current status of disk. The status can be either "GOOD" (operating normally), "FAILED" (non-functional), or "MISSING" (disk not present).

HSP
Indicates if the disk has been set as a global hot-spare disk, local hot-spare disk, or a normal one. If it is a local hot-spare disk, all volumes which this disk is assigned to are displayed.

GUID
GUID string for the specified disk. This is an additional datum and might be unavailable in some cases.

`-l volume`
Display information about the specified volume. The output includes the following information:

Volume
Displays volume in canonical format.
Sub
  Displays sub-volumes, if the specified volume is of RAID 10 or RAID 50 volume.

Disk
  Displays all disks that form the specified volume.

Stripe Size
  Displays the stripe size of the volume.

Status
  Displays the status of the specified volume, or the sub-volumes or disks that form the specified volume. For an inactive volume, the status should be INACTIVE; otherwise it can be OPTIMAL (operating optimally), DEGRADED (operating with reduced functionality), FAILED (non-functional), or SYNC (disks are syncing). For a disk, the status can be GOOD, FAILED, or MISSING.

Cache
  Indicates whether the cache is applied to I/O write activities. The cache can be either "ON" or "OFF".

RAID level
  Displays the RAID level. The RAID level can be either 0, 1, 1E, 5, 10, or 50.

\[-l\]
  controller ...
  Display information about the specified controller(s). The output includes the following information:

  Controller
    Displays the RAID controller's ID number.

  Type
    Displays the RAID controller's product type.

  fw_version
    Displays the controller's firmware version.

\[-l\]
  List all RAID related objects that the raidctl utility can manipulate, including all available RAID controllers, RAID volumes, and physical disks. The -l option can be omitted.

The output includes the following information:

  Controller
    Displays the RAID controller's ID number.

  Volume
    Displays the logical RAID volume name.

  Disk
    Displays the RAID disk in C.ID.L expression.

raidctl(1M)
-S [volume | controller]
Takes a snapshot of the RAID configuration information including all available RAID
devices, RAID controllers, volumes, and disks.

Each line of the output specifies a RAID device and its related information, separated by
space(s). All volumes and disks belong to the last specified controller.

The output lists the following information:

**Controller**
Displays the controller ID number, and the controller type string in double-quotation
marks.

**Volume**
Displays the RAID volume name, number of component disks, the C.ID. L expression of
the component disks, the RAID level, and the status. The status can be either OPTIMAL,
DEGRADED, FAILED, or SYNCING.

**Disk**
Displays the C.ID. L expression of the disk, and the status. The status can be either GOOD,
FAILED, or HSP (disk has been set as a stand-by disk).

If a volume or a controller is specified, a snapshot is only taken of the information for the
specified volume or controller.

-S -g disk controller
Takes a snapshot of the information for the specified disk.

-h
Print out the usage string.

**Examples**

**EXAMPLE 1** Creating the RAID Configuration

The following command creates a RAID 0 volume of 10G on controller 0, and the stripe size is
set to 64k:

```
# raidctl -C "0.0.0 0.2.0" -r 0 -z 10g -s 64k 0
```

The following command creates a RAID 1 volume on controller 2:

```
# raidctl -C "0.0.0 1.1.0" -r 1 2
```

The following command creates a RAID 5 volume on controller 2:

```
# raidctl -C "0.0.0 0.1.0 0.2.0" -r 5 2
```

The following command creates a RAID 10 volume on controller 0:

```
# raidctl -C "(0.0.0 0.1.0)(0.2.0 0.3.0)" -r 10 0
```

The following command creates a RAID 50 volume on controller 0:

```
# raidctl -C "(0.0.0 0.1.0 0.2.0)(0.3.0 0.4.0 0.5.0)" -r 50 0
```
EXAMPLE 2  Displaying the RAID Configuration

The following command displays all available controllers, volumes, and disks:

```
# raidctl -l
```

Controller: 0
Controller: 2

Volume: c2t0d0
Disk: 0.0.0
Disk: 0.1.0
Disk: 0.2.0
Disk: 0.3.0 (HSP)

The following command displays information about controller 2:

```
# raidctl -l 2
```

<table>
<thead>
<tr>
<th>Controller</th>
<th>Type</th>
<th>Fw_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>c2</td>
<td>LSI 1030</td>
<td>1.03.39.00</td>
</tr>
</tbody>
</table>

The following command displays information about the specified volume:

```
# raidctl -l c2t0d0
```

<table>
<thead>
<tr>
<th>Volume</th>
<th>Size</th>
<th>Stripe</th>
<th>Status</th>
<th>Cache</th>
<th>RAID</th>
<th>Level</th>

GUID:20000000000000000000000000000000

EXAMPLE 3  Deleting the RAID Configuration

The following command deletes a volume:

```
# raidctl -d c0t0d0
```
EXAMPLE 4  Updating Flash Images on the Controller
The following command updates flash images on the controller 0:

`# raidctl -F lsi_image.fw 0`

EXAMPLE 5  Setting or Unsetting a Hot-Spare Disk
The following command sets disk 0.3.0 on controller 2 as a global hot-spare disk:

`# raidctl -a set -g 0.3.0 2`

The following command sets disk 0.3.0 on controller 2 as a local hot-spare disk to volume c2t0d0:

`# raidctl -a set -g 0.3.0 c2t0d0`

The following command converts disk 0.3.0 on controller 2 from a global hot-spare disk to a normal one:

`# raidctl -a unset -g 0.3.0 2`

The following command removes disk 0.3.0 from being a local hot-spare disk from volume c2t0d0:

`# raidctl -a unset -g 0.3.0 c2t0d0`

EXAMPLE 6  Setting the Volume’s Property
The following command sets the write policy of the volume to “off”:

`# raidctl -a set -p "wp=off" c0t0d0`

EXAMPLE 7  Creating Volumes with the -c Option
The following command creates a RAID 1 volume:

`# raidctl -c c0t0d0 c0t1d0`

The following command creates a RAID 0 volume:

`# raidctl -c -r 0 c0t1d0 c0t2d0 c0t3d0`

EXAMPLE 8  Taking a Snapshot of the RAID Configuration
The following command takes a snapshot of all RAID devices:

`# # raidctl -S`

`1 "LSI 1030"`
`c1t1d0 2 0.2.0 0.3.0 1 DEGRADED`
`0.2.0 GOOD`
`0.3.0 FAILED`

The following command takes a snapshot about volume c1t0d0:
EXAMPLE 8  Taking a Snapshot of the RAID Configuration  (Continued)

# raidctl -S c1t0d0

c1t0d0 2 0.0.0 0.1.0 1 OPTIMAL

The following command takes a snapshot about disk 0.1.0 on controller 1:

# raidctl -S -g 0.1.0 1

0.1.0 GOOD

Exit Status  The following exit values are returned:

  0    Successful completion.

  1    Invalid command line input or permission denied.

  2    Request operation failed.

Oracle Solaris Administration: Common Tasks

Warnings  Do not create raid volumes on internal SAS disks if you are going to use the Solaris Multipathing I/O feature (also known as MPxIO). Creating a new raid volume under Solaris Multipathing gives your root device a new GUID which does not match the GUID for the existing devices. This causes a boot failure since your root device entry in /etc/vfstab does not match.

Notes  The -z option is not supported on systems that use the mpt driver and LSI RAID controllers.
The `ramdiskadm` command administers `ramdisk(7D)`, the ramdisk driver. Use `ramdiskadm` to create a new named ramdisk device, delete an existing named ramdisk, or list information about existing ramdisks.

Ramdisks created using `ramdiskadm` are not persistent across reboots.

**Options**

The following options are supported:

- `-a name size`
  Create a ramdisk named `name` of size `size` and its corresponding block and character device nodes.

  `name` must be composed only of the characters a-z, A-Z, 0-9, _ (underscore), and - (hyphen), but it must not begin with a hyphen. It must be no more than 32 characters long. Ramdisk names must be unique.

  The size can be a decimal number, or, when prefixed with `0x`, a hexadecimal number, and can specify the size in bytes (no suffix), 512-byte blocks (suffix `b`), kilobytes (suffix `k`), megabytes (suffix `m`) or gigabytes (suffix `g`). The size of the ramdisk actually created might be larger than that specified, depending on the hardware implementation.

  If the named ramdisk is successfully created, its block device path is printed on standard out.

- `-d name`
  Delete an existing ramdisk of the name `name`. This command succeeds only when the named ramdisk is not open. The associated memory is freed and the device nodes are removed.

  You can delete only ramdisks created using `ramdiskadm`. It is not possible to delete a ramdisk that was created during the boot process.

Without options, `ramdiskadm` lists any existing ramdisks, their sizes (in decimal), and whether they can be removed by `ramdiskadm` (see the description of the `-d` option, above).

**Examples**

```bash
# Creating a 2MB Ramdisk Named mydisk
# ramdiskadm -a mydisk 2m /dev/ramdisk/mydisk
```
EXAMPLE 2  Listing All Ramdisks

# ramdiskadm

<table>

See Also  attributes(5), ramdisk(7D)

Notes  The abilities of ramdiskadm and the privilege level of the person who uses the utility are controlled by the permissions of /dev/ramdiskctl. Read access allows query operations, for example, listing device information. Write access is required to do any state-changing operations, for example, creating or deleting ramdisks.

As shipped, /dev/ramdiskctl is owned by root, in group sys, and mode 0644, so all users can do query operations but only root can perform state-changing operations. An administrator can give write access to non-privileged users, allowing them to add or delete ramdisks. However, granting such ability entails considerable risk; such privileges should be given only to a trusted group.
rcapadm(1M)

Name  rcapadm -- configure resource capping daemon

Synopsis  rcapadm

rcapadm [ [-n] -E | -D]
[-i interval=value,...,interval=value] [-c percent]
[-z zonename -m maxvalue]

Description  The rcapadm command allows a user with the privileges described below to configure various attributes of the resource capping daemon. If used without arguments, rcapadm displays the current status of the resource capping daemon if it has been configured. See rcpd(1M) for more information.

In the current release of the Solaris operating environment, rcapadm is available to users with all privileges and to users who have the Process Management profile in their list of profiles. The System Administrator role includes the Process Management profile.

Options  -c percent
Set the minimum physical memory utilization for memory cap enforcement. Caps will not be enforced until the physical memory available to processes is low. The percent value should be in the range 0 to 100. The minimum (and default) value is 0, which means that memory caps are always enforced.

-D
Disable the resource capping daemon so that it will not be started when the system is booted. Also stop the resource capping daemon now, if the -n option is not specified and it is currently running.

-E
Enable the resource capping daemon so that it will be started each time the system is booted. Also start the resource capping daemon now, if the -n option is not specified and it is not currently running.

-i interval=value,...,interval=value
Set intervals for various periodic operations performed by rcpd. All intervals are specified in seconds. You can set the following intervals:

   scan  The interval at which rcpd scans for new processes. The default scan interval is every 15 seconds. The minimum value is 1 second.

   sample  The interval of process resident set size sampling. The default sample interval is every 5 seconds. The minimum value is 1 second.
The interval at which various paging statistics are updated by rcapd, in seconds. These statistics can be viewed by using rcapstat(1SRM). The default reporting interval is every 5 seconds. When the interval is set to 0, statistics will not be updated.

**Note** – Paging refers to the act of relocating portions of memory, called pages, to or from physical memory. rcapd pages out the most infrequently used pages.

The reconfiguration interval, in seconds. At each reconfiguration event, rcapd checks its configuration file for updates, and scans the project databases for new project caps. The default reconfiguration interval is every 60 seconds. The minimum interval is 0. When the interval is set to 0, no periodic reconfiguration occurs, although the running daemon can still be reconfigured by sending it SIGHUP.

**-m maxvalue**

Used in conjunction with the -z option. Specifies a value for rcap.max-rss, a dynamically-set cap on the usage of physical memory for the zone specified by -z. You can apply a scale (K, M, G, T) to the value you specify. K means kilobyte; M, megabyte; G, gigabyte; and T, terabyte. For example, 100M is 100 megabytes.

To remove an existing cap, specify 0M.

**-n**

Do not affect the running state of the resource capping daemon when enabling or disabling it.

**-z zonename**

Used in conjunction with the -m option. Specifies the zone for which you are dynamically specifying a cap on physical memory usage (using -m).

**Note** – To set a persistent cap on memory usage within a zone, use zonecfg(1M).

**Examples**

**EXAMPLE 1** Configuring the Resource Capping Daemon with Immediate Enforcement

```shell
# rcapadm -E -i scan=15, sample=5, report=5, config=60 -c 0
```
EXAMPLE 2  Specifying a Resource Cap for a Zone

The command shown below specifies the maximum amount of memory that can be consumed by a specified zone. Note that this value lasts only until the next reboot. To set a persistent cap, use `zonecfg(1M)`.

```
# rcapadm -z testzone -m 512M
```

**Exit Status** The following exit values are returned:

0  Successful completion. The modifications to the current configuration were valid and made successfully.

1  An error occurred. A fatal error occurred either in obtaining or modifying the resource capping configuration.

2  Invalid command-line options were specified.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

“Physical Memory Control Using the Resource Capping Daemon” in *Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management*
rcapd(-d)

The rcapd daemon enforces resource caps on collections of processes. Per-project and per-zone physical memory caps are supported. For information about projects, see project(4). For zones information, see zones(5)

When the resident set size (RSS) of a collection of processes exceeds its cap, rcapd takes action and reduces the RSS of the collection.

The virtual memory system divides physical memory into segments known as pages. To read data from a file into memory, the virtual memory system reads in individual pages. To reduce resource consumption, the daemon can page out, or relocate, infrequently used pages to an area outside of physical memory.

In the project file, caps are defined for projects that have positive values for the following project attribute:

rcap.max-rss The total amount of physical memory, in bytes, that is available to the project’s member processes

See project(4) for a description of project attributes.

For a system with one or more zones, you can dynamically set the rcap.max-rss value for a zone with rcapadm(1M). To set a persistent cap on memory usage within a zone, you use zonecfg(1M).

You configure rcapd through the use of rcapadm(1M). The daemon can be monitored with rcapstat(1). Configuration changes are incorporated into rcapd by sending it SIGHUP (see kill(1)), or according to the configuration interval (see rcapadm(1M)).

Options

The following option is supported:

-d Enable debug mode. Messages are displayed on the invoking user's terminal.

Examples

EXAMPLE 1 Setting Resident Set Size Cap Attribute

The following line in the /etc/project database sets an RSS cap of 1073741824 bytes for a project named foo.

foo:100::foo,root::rcap.max-rss=10737418240

Exit Status

The following exit values are returned:

0 Successful completion.
1 An error occurred.
2 Invalid command-line options were specified.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/resource-mgmt/resource-caps</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

See Also  rcapstat(1), svcs(1), rcapadm(1M), zonecfg(1M), svcadm(1M), project(4), attributes(5), smf(5), zones(5)

Notes  If killed with SIGKILL, rcapd can leave processes in a stopped state. Use SIGTERM to cause rcapd to terminate properly.

A collection’s RSS can exceed its cap for some time before the cap is enforced, even if sufficient pageable memory is available. This period of time can be reduced by shortening the RSS sampling interval with rcapadm.

The rcapd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/rcap:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service’s status can be queried using the svcs(1) command.
The `rctladm` command allows the examination and modification of active resource controls on the running system. An instance of a resource control is referred to as an `rctl`. See `setrctl(2)` for a description of an `rctl`; see `resource_controls(5)` for a list of the `rctls` supported in the current release of the Solaris operating system. Logging of `rctl` violations can be activated or deactivated system-wide and active `rctls` (and their state) can be listed.

An `rctladm` command without options is the equivalent of an `rctladm` with the `-l` option. See the description of `-l` below.

**Options**

The following options are supported:

- `-d action`
- `-e action`

Disable (`-d`) or enable (`-e`) the global action on the specified `rctls`. If no `rctl` is specified, no action is taken and an error status is returned. You can use the special token `all` with the disable option to deactivate all global actions on a resource control.

You can set the `syslog` action to a specific degree by assigning a severity level. To do this, specify `syslog=level`, where `level` is one of the string tokens given as valid severity levels in `syslog(3C)`. You can omit the common `LOG_` prefix on the severity level. Note that not all `rctls` support the `syslog` action. See `resource_controls(5)`.

If the enabling of the `syslog` action for an `rctl` results in a continuous stream of logged messages, log output will be restricted to one message every five seconds. In such a circumstance, some messages will be dropped. No corrective action need to be taken.

- `-l`

List information about `rctls`. The name, global event actions and statuses, and global flags are displayed. If one or more name operands are specified, only those `rctls` matching the names are displayed.

- `-u`

Configure resource controls based on the contents of `/etc/rctladm.conf`. Any name operands are ignored.

**Operands**

The following operands are supported:

- `name`

The name of the `rctl` to operate on. Multiple `rctl` names can be specified. If no names are specified, and the list action has been specified, then all `rctls` are listed. If the enable or disable action is specified, one or more `rctl` names must be specified.
**Examples**

**EXAMPLE 1**  Activating System Logging for Specific Violations

The following command activates system logging of all violations of `task.max-lwp`.

```
# rctladm -e syslog task.max-lwp
```

**EXAMPLE 2**  Examining the Current Status of a Specific Resource

The following command examines the current status of the `task.max-lwp` resource.

```
$ rctladm -l task.max-lwp
```

**Exit Status**

The following exit values are returned:

0  
Successful completion.

1  
A fatal error occurred. A message is written to standard error to indicate each resource control for which the operation failed. The operation was successful for any other resource controls specified as operands.

2  
Invalid command line options were specified.

**Files**

`/etc/rctladm.conf`

Each time `rctladm` is executed, it updates the contents of `rctladm.conf` with the current configuration.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

**Notes**

By default, there is no global logging of `rctl` violations.
Name  
rende – set system date from a remote host

Synopsis  
rende hostname

Description  
rende sets the local date and time from the hostname given as an argument. You must have the authorization `solaris.system.date` on the local system. Typically, `rende` is used in a startup script.

rende requests are responded to by the “time” service on the specified host. To enable the “time” service, use the following commands:

     svcadm enable time:stream
     svcadm enable time:dgram

Usage  
The `rende` command is IPv6–enabled. See `ip6(7P)`.

Attributes  
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

Name  reboot – restart the operating system

Synopsis  /usr/sbin/reboot [-dlnq] [-f | -p] [boot_arguments]
           /usr/sbin/reboot [-f [-e environment] | -p] [-dlnq] [boot_arguments]

Description  The reboot utility restarts the kernel. The kernel is loaded into memory by the PROM
              monitor, which transfers control to the loaded kernel.

On x86 systems, when the -f flag is specified, the running kernel will load the next kernel into
memory, then transfer control to the newly loaded kernel. This form of reboot is shown in the
second synopsis, above.

Although reboot can be run by the super-user at any time, shutdown(1M) is normally used
first to warn all users logged in of the impending loss of service. See shutdown(1M) for details.

The reboot utility performs a sync(1M) operation on the disks, and then a multi-user reboot
is initiated. See init(1M) for details. On x86 systems, reboot may also update the boot archive
as needed to ensure a successful reboot.

The reboot utility normally logs the reboot to the system log daemon, syslogd(1M), and
places a shutdown record in the login accounting file /var/adm/wtmpx. These actions are
inhibited if the -n or -q options are present.

Normally, the system reboots itself at power-up or after crashes.

Options  The following options are supported:

- d  Force a system crash dump before rebooting. See dumpadm(1M) for information on
      configuring system crash dumps.

- e  If -f is present, reboot to the specified boot environment.

      This option is currently available only on x86 systems.

- f  For x86 systems:

      Fast reboot, bypassing firmware and boot loader. The new kernel will be loaded into
memory by the running kernel, and control will be transferred to the newly loaded kernel.
If disk or kernel arguments are specified, they must be specified before other boot
arguments.

      For SPARC systems:

      Speeds up rebooting by skipping some POST tests.
The service svc:/system/boot-config:default is enabled by default. It requires solaris.system.shutdown as action_authorization and value_authorization. When the config/fastreboot_default property is set to true, reboot will behave as reboot -f. The value of this property can be changed using svccfg(1M) and svcadm(1M), to control the default reboot behavior.

See EXAMPLES for details.

- l
  Suppress sending a message to the system log daemon, syslogd(1M) about who executed reboot.

- n
  Avoid calling sync(2) and do not log the reboot to syslogd(1M) or to /var/adm/wtmpx. The kernel still attempts to sync filesystems prior to reboot, except if the -d option is also present. If -d is used with -n, the kernel does not attempt to sync file systems.

- p
  Reboot to prom. This flag can be used to reboot the system through firmware without changing the default reboot behavior as denoted by the config/fastreboot_default property setting in system/boot-config service.

  The -p and -f options are mutually exclusive.

- q
  Quick. Reboot quickly and ungracefully, without shutting down running processes first.

Operands

The following operands are supported:

boot_arguments

An optional boot_arguments specifies arguments to the uadmin(2) function that are passed to the boot program and kernel upon restart. The form and list of arguments is described in the boot(1M) and kernel(1M) man pages. If the arguments are specified, whitespace between them is replaced by single spaces unless the whitespace is quoted for the shell. If the boot_arguments begin with a hyphen, they must be preceded by the -- delimiter (two hyphens) to denote the end of the reboot argument list.

Examples

EXAMPLE 1  Passing the -r and -v Arguments to boot

In the following example, the delimiter -- (two hyphens) must be used to separate the options of reboot from the arguments of boot(1M).

example# reboot -dl -- -rv

EXAMPLE 2  Rebooting Using a Specific Disk and Kernel

The following example reboots using a specific disk and kernel.

example# reboot disk1 kernel.test/unix
EXAMPLE 3  Fast Rebooting

The following examples use the `-f` option to perform fast reboots.

If the service `svc:/system/boot-config:default` is enabled and property `config/fastreboot_default` is set to `true`, the `-f` option can be omitted.

On an x86 system, the following command reboots to the default entry in the GRUB (see `grub(5)`) menu file `menu.lst`.

```sh
example# reboot -f
```

The following command reboots to another UFS root disk.

```sh
example# reboot -f -- '/dev/dsk/c1d0s0'
```

The following command reboots to another ZFS root pool.

```sh
example# reboot -f -- 'rpool/ROOT/root2'
```

The following command reboots to `mykernel` on the same disk with `-k` option.

```sh
example# reboot -f -- '/platform/i86pc/mykernel/amd64/unix -k'
```

The following command reboots to `mykernel` off another root disk mounted on `/mnt`.

```sh
example# reboot -f -- '/mnt/platform/i86pc/mykernel/amd64/unix -k'
```

The following command reboots to `/platform/i86pc/kernel/$ISADIR/unix` on another boot environment named `second_root`.

```sh
example# reboot -f -e second_root
```

The following command reboots to the same kernel with `-kv` options.

```sh
example# reboot -f -- '-kv'
```

The following commands disable the fast-reboot-by-default behavior.

```sh
example# svccfg -s "system/boot-config:default" \\
  setprop config/fastreboot_default=false
example# svcadm refresh svc:/system/boot-config:default
```

The following commands re-enable the fast-reboot-by-default behavior.

```sh
example# svccfg -s "system/boot-config:default" \\
  setprop config/fastreboot_default=true
example# svcadm refresh svc:/system/boot-config:default
```

EXAMPLE 4  Rebooting to a Particular GRUB Menu

The following commands will reboot to entry 2 in the GRUB menu.

```sh
example# bootadm list-menu
    the location for the active GRUB menu is: /rpool/boot/grub/menu.lst
default 0
```
Rebooting to a Particular GRUB Menu  

```sh
timeout 10
0 zfsbe1
 1 zfsbe1 failsafe
 2 zfsbe2
 3 zfsbe2 Solaris xVM
 4 zfsbe2 failsafe
example# reboot 2
```

**Files**  
/var/adm/wtmpx  

- login accounting file

**Attributes**  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

mdb(1), boot(1M), dumpadm(1M), fsck(1M), halt(1M), init(1M), kernel(1M), shutdown(1M), svcadm(1M), svccfg(1M), sync(1M), syslogd(1M), sync(2), uadmin(2), reboot(3C), attributes(5), grub(5)

**Notes**  
The reboot utility does not execute the scripts in /etc/rcnum.d or execute shutdown actions in inittab(4). To ensure a complete shutdown of system services, use shutdown(1M) or init(1M) to reboot a Solaris system.
rem_drv – remove a device driver from the system

**Synopsis**

rem_drv [-b basedir] [-C] [-n] device_driver

**Description**

The `rem_drv` command informs the system that the device driver `device_driver` is no longer valid. If possible, `rem_drv` unloads `device_driver` from memory. `rem_drv` also updates the system driver configuration files.

If `rem_drv` has been executed, the next time the system is rebooted it automatically performs a reconfiguration boot (see `kernel(1M)`).

**Options**

The following options are supported:

- **-b basedir**
  
  Sets the path to the root directory of the diskless client. Used on the server to execute `rem_drv` for a client. The client machine must be rebooted to unload the driver.

  **Note** – The root file system of any non-global zones must not be referenced with the `-b` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

- **-C**
  
  Remove dangling device attribute nodes bound to the driver being removed. This causes any device ownership or permissions customizations made to any node not to be preserved if the driver is added back. Recommended for use when reprovisioning a machine from one configuration or use to another where past administrative customizations might not be desired.

- **-n**
  
  Do not try to detach and unload `device_driver`, just modify the system configuration files for that driver.

**Examples**

**EXAMPLE 1**  Removing the sd Driver

The following example removes the `sd` driver from use:

```bash
example% rem_drv sd
```

**EXAMPLE 2**  Removing a Diskless Client

The following example removes the driver from the `sun1` diskless client. The driver is not uninstalled or unloaded until the client machine is rebooted.

```bash
example% rem_drv -b /export/root/sun1 sd
```

Note the caveat on the use of the `-b` option in the description of that option, above.

Name  remove_allocatable – remove entries from allocation databases

Synopsis  /usr/sbin/remove_allocatable [-f] -n name
          /usr/sbin/remove_allocatable [-f] [-d] -t dev-type

Description  remove_allocatable removes entries of user allocatable devices from the device allocation mechanism. remove_allocatable also removes entries of some non-allocatable devices, such as printers, whose label range is managed by the mechanism.

Options   The following options are supported:
          -d  Removes system-supplied default attributes of the device type that is specified with -t.
          -f  Force the removal of an entry. remove_allocatable exits with an error if this option is not specified when an entry with the specified device name no longer exists.
          -n name  Removes the entry for the device name.
          -t dev-type  Removes devices of type dev-type.

Exit Status  When successful, remove_allocatable returns an exit status of 0 (true).
remove_allocatable returns a nonzero exit status in the event of an error. The exit codes are as follows:
1  Invocation syntax error
2  Unknown system error
3  Device name or dev-type not found. This error occurs only when the -f option is not specified.
4  Permission denied. User does not have DAC or MAC access to database.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/trusted</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The invocation is Uncommitted. The options are Uncommitted. The output is Not-an-Interface.

See Also  allocate(1), deallocate(1), add_allocatable(1M), attributes(5), device_clean(5)
The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Notes
removef(1M)

Synopsis

removef [ [-M] -R root_path] [-V fs_file] pkginst path...

Description

removef informs the system that the user, or software, intends to remove a pathname. Output from removef is the list of input pathnames that may be safely removed (no other packages have a dependency on them).

Options

The following options are supported:

-f

After all files have been processed, removef should be invoked with the -f option to indicate that the removal phase is complete.

-M

Instruct removef not to use the $root_path/etc/vfstab file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

-R root_path

Define the full path name of a directory to use as the root_path. All files, including package system information files, are relocated to a directory tree starting in the specified root_path. The root_path may be specified when installing to a client from a server (for example, /export/root/client1).

removef inherits the value of the PKG_INSTALL_ROOT environment variable. (See ENVIRONMENT VARIABLES, below.) If PKG_INSTALL_ROOT is set, such as when the -R option is used with pkgadd(1M) or pkgrm(1M)

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-V fs_file

Specify an alternative fs_file to map the client's file systems. For example, used in situations where the $root_path/etc/vfstab file is non-existent or unreliable.

Operands

The following operands are supported:

path

The pathname to be removed.

pkginst

The package instance from which the pathname is being removed.
Using removef

The following example uses the removef command in an optional pre-install script:

```bash
echo "The following files are no longer part of this package and are being removed."
removef $PKGINST /myapp/file1 /myapp/file2 |
while read pathname
do
    echo "$pathname"
    rm -f $pathname
done
removef -f $PKGINST || exit 2
```

Environment Variables

`removef` inherits the value of the following environment variable. This variable is set when `pkgadd(1M)` or `pkgrm(1M)`

PKG_INSTALL_ROOT
If present, defines the full path name of a directory to use as the system's `PKG_INSTALL_ROOT` path. All product and package information files are then looked for in the directory tree, starting with the specified `PKG_INSTALL_ROOT` path. If not present, the default system path of `/` is used.

Exit Status

0  Successful completion.

>0  An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

Application Packaging Developer's Guide

Notes

Package commands are `largefile(5)`-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, `pkgadd(1M), pkgsask(1M)` and other package commands can process a datastream of up to 4 GB.
The reparsed daemon processes kernel upcalls to interpret “reparse points”, which are the basis of Microsoft DFS referrals and NFS referrals support on Solaris SMB and NFS file servers. Only the root user or a user with equivalent privileges can run this daemon. The daemon is under SMF control.

**Exit Status**

- 0
  - Daemon started successfully.
- >0
  - Daemon failed to start.

Error information is reported to syslog at level LOG_ERR.

**Files**

```
/usr/lib/reparsed/*.so.1
```

Per-service plugins for reparsed.

**Attributes**

**Notes**

Do not manually stop, start or restart the reparsed daemon. If you need to change the state of the daemon, use these commands:

```
# svcadm disable svc:/system/filesystem/reparse
# svcadm enable svc:/system/filesystem/reparse
# svcadm restart svc:/system/filesystem/reparse
```

See svcadm(1M) for additional information.
repquota – summarize quotas for a ufs file system

Synopsis
repquota [-v] filesystem...
repquota -a [-v]

Description
repquota prints a summary of the disk usage and quotas for the specified ufs file systems. The current number of files and amount of space (in kilobytes) is printed for each user along with any quotas created with edquota(1M).

The filesystem must have the file quotas in its root directory.

Only the super-user may view quotas which are not their own.

Options
The following options are supported:
- a Report on all mounted ufs file systems that have rq in the mntopts field of the /etc/vfstab file.
- v Report quotas for all users, even those who do not consume resources.

Usage
See largefile(5) for the description of the behavior of repquota when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>

Name  
rmount – removable media mounter for CD-ROM, Jaz drive, and others

Synopsis  
/usr/sbin/rmmount [-D]

Description  
The rmmount utility is a removable media mounter that is executed by volume management whenever a removable medium, such as a CD-ROM is inserted. Removable media is managed by an application or a volume manager. rmmount can also be called by using volrmmount(1).

Upon insertion of a medium and following invocation of the volcheck(1) command, rmmount determines what type of file system (if any) is on that medium. If a file system is present, rmmount mounts the file system in one of the locations listed below.

For a CD-ROM or a DVD-ROM:

/cdrom/cdrom0 symbolic link to mounted CD-ROM in local CD-ROM drive
/cdrom/CD-ROM_name mounted named CD-ROM
/cdrom/CD-ROM_name/partition mounted named CD-ROM with partitioned file system
/cdrom/unnamed_cdrom mounted unnamed CD-ROM

For a Zip drive:

/rmdisk/zip0 symbolic link to mounted Zip medium in local Zip drive
/rmdisk/Zip_name mounted named Zip medium
/rmdisk/Zip_name/partition mounted named Zip medium with partitioned file system
/rmdisk/unnamed_zip mounted unnamed Zip medium

For a Jaz drive:

/rmdisk/jaz0 symbolic link to mounted Jaz medium in local Jaz drive
/rmdisk/Jaz_name mounted named Jaz medium
/rmdisk/Jaz_name/partition mounted named Jaz medium with partitioned file system
/rmdisk/unnamed_Jaz mounted unnamed Jaz medium

For a generic "rmdisk" drive:

/rmdisk/rmdisk0 symbolic link to mounted removable medium in local removable medium drive
/rmdisk/rmdisk_name mounted named removable medium
/rmdisk/rmdisk_name/partition mounted named removable medium with partitioned file system
If the media is read-only (for example, a CD-ROM), the file system is mounted read-only.

If a file system is not identified, `rmmount` does not mount a file system. See the *Oracle Solaris Administration: Common Tasks* for more information on the location of CD-ROM and other media without file systems.

If a file system type has been determined, it is then checked to see that it is “clean.” If the file system is “dirty,” `fsck -p` (see `fsck(1M)`) is run in an attempt to clean it. If `fsck` fails, the file system is mounted read-only.

After the mount is complete, “actions” associated with the media type are executed. These actions allow for the notification to other programs that new media are available.

Actions are executed in the order in which they appear in the configuration file. The action function can return either 1 or 0. If it returns 0, no further actions will be executed. This allows the function to control which applications are executed.

In order to execute an action, `rmmount` performs a `dlopen(3C)` on the shared object and calls the action function defined within it. The definition of the interface to actions can be found in `/usr/include/rmmount.h`.

File systems mounted by `rmmount` are always mounted with the `nosuid` flag set, thereby disabling setuid programs and access to block or character devices in that file system. Upon ejection, `rmmount` unmounts mounted file systems and executes actions associated with the media type. If a file system is “busy” (that is, it contains the current working directory of a live process), the ejection will fail.

**Options**

- `-D` Turn on the debugging output from the `rmmount dprintf` calls.

**Files**

`/usr/lib/rmmount/*.so.1` shared objects used by `rmmount`.

**Attributes**

*Oracle Solaris Administration: Common Tasks*
**Name**
rmt – remote magtape protocol module

**Synopsis**
/usr/sbin/rmt

**Description**
rmt is a program used by the remote dump and restore programs in manipulating a magnetic tape drive through an interprocess communication connection. rmt is normally started up with an reexec(3SOCKET) or rcmd(3SOCKET) call.

The rmt program accepts requests that are specific to the manipulation of magnetic tapes, performs the commands, then responds with a status indication. All responses are in ASCII and in one of two forms. Successful commands have responses of:

```
A number
```

where `number` is an ASCII representation of a decimal number.

Unsuccessful commands are responded to with:

```
E error-number
```

where `error-number` is one of the possible error numbers described in Intro(3), and `error-message` is the corresponding error string as printed from a call to perror(3C).

The protocol consists of the following commands:

- **S**
  Return the status of the open device, as obtained with a MTIOCGET ioctl call. If the operation was successful, an “ack” is sent with the size of the status buffer, then the status buffer is sent (in binary).

- **C** `device`
  Close the currently open device. The `device` specified is ignored.

- **I** `operation` `ncount`
  Perform a MTIOCOP ioctl(2) command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the `mt_op` and `mt_count` fields of the structure used in the ioctl call. When the operation is successful the return value is the `count` parameter.

- **L** `offset` `whence`
  Perform an lseek(2) operation using the specified parameters. The response value is returned from the lseek call.

- **O** `device` `mode`
  Open the specified `device` using the indicated `mode`. `device` is a full pathname, and `mode` is an ASCII representation of a decimal number suitable for passing to open(9E). If a device is already open, it is closed before a new open is performed.

- **R** `count`
  Read `count` bytes of data from the open device. rmt performs the requested read(9E) and responds with hcount-read if the read was successful; otherwise an error in standard format is returned. If the read was successful, the data read is sent.

- **W** `count`
  Write data onto the open device. rmt reads `count` bytes from the connection, aborting if a premature EOF is encountered. The
response value is returned from the `write(9E)` call.

Any other command causes `rmt` to exit.

**Attributes**  See *attributes(5)* for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/network/network-clients</td>
</tr>
</tbody>
</table>

**See Also**  `ufsdump(1M)`, `ufsrestore(1M)`, `Intro(3)`, `ioctl(2)`, `lseek(2)`, `perror(3C)`, `rcmd(3SOCKET)`, `rexec(3SOCKET)`, `attributes(5)`, `mtio(7I)`, `open(9E)`, `read(9E)`, `write(9E)`

**Diagnostics**  All responses are of the form described above.

**Bugs**  Do not use this for a remote file access protocol.
The `rmvolmgr` command is a volume manager that can automatically mount and unmount removable media and hot-pluggable storage. The default mount point is `/media`.

`rmvolmgr` is one of a number of Hardware Abstraction Layer (HAL)-aware tools that are shipped with the Solaris operating system. See `hald(1M)`.

Multiple instances of `rmvolmgr` can be run simultaneously. A system instance of `rmvolmgr` runs by default as a service management facility (SMF) service (see `smf(5)`). Its fault management resource identifier (FMRI) is:

```
svc:/system/filesystem/rmvolmgr
```

You can run your own instance of `rmvolmgr` by adding it to the `.xinitrc` file or a similar session startup script. In such a case, the system `rmvolmgr` instance will not manage volumes that belong to you, the owner of the startup script. For example, a user logged on to the workstation console (/dev/console) who invokes his own instance of `rmvolmgr` will own locally connected devices, such as CD-ROM drives and devices connected to the local USB or FireWire ports.

In addition to mounting volumes under `/media`, `rmvolmgr` also creates legacy symbolic links under `/cdrom` and `/rmdisk`.

`rmvolmgr` also provides backwards compatibility with CDE removable media interfaces by maintaining notification files under `/tmp/.removable`. This functionality can be disabled by using the `-c` option.

The `-c` and `-n` options can also be specified as SMF properties. See “Examples.”

### Options

The following options are supported:

- `-c` Disable CDE compatibility.
- `-h` Display help information and exit.
- `-n` Do not create legacy mountpoint symbolic links.
- `-s` Invoke in system instance mode.

### Examples

**EXAMPLE 1**  Using SMF Properties to Set Options

The following `svccfg(1M)` command and subcommands use SMF properties to set the `-c` and `-n` options.

```bash
example# svccfg
svccfg> select rmvolmgr
svc:/system/filesystem/rmvolmgr> listprop rmvolmgr/
rmvolmgr/legacy_mountpoints boolean true
```
Example 1  Using SMF Properties to Set Options  (Continued)

rmvolmgr/cde_compatible boolean true
svc:/system/filesystem/rmvolmgr> setprop \nrmvolmgr/legacy_mountpoints=false
svc:/system/filesystem/rmvolmgr> setprop rmvolmgr/cde_compatible=false
svc:/system/filesystem/rmvolmgr> exit
example#

The **rndc** utility controls the operation of a name server. It supersedes the **ndc** utility that was provided in previous BIND releases. If **rndc** is invoked with no command line options or arguments, it prints a short summary of the supported commands and the available options and their arguments.

The **rndc** utility communicates with the name server over a TCP connection, sending commands authenticated with digital signatures. The only supported authentication algorithm in the current versions of **rndc** and named(1M) is HMAC-MD5, which uses a shared secret on each end of the connection. This algorithm provides TSIG-style authentication for the command request and the name server's response. All commands sent over the channel must be signed by a **key_id** known to the server.

The **rndc** utility reads a configuration file to determine how to contact the name server and decide what algorithm and key it should use.

### Options

The following options are supported:

- **-b source-address**
  Use **source-address** as the source address for the connection to the server. Multiple instances are permitted to allow setting of both the IPv4 and IPv6 source addresses.

- **-c config-file**
  Use **config-file** as the configuration file instead of the default **/etc/rndc.conf**.

- **-k key-file**
  Use **key-file** as the key file instead of the default, **/etc/rndc.key**. The key in **/etc/rndc.key** is used to authenticate commands sent to the server if the **config-file** does not exist.

- **-s server**
  The **server** argument is the name or address of the server that matches a server statement in the configuration file for **rndc**. If no server is supplied on the command line, the host named by the default-server clause in the options statement of the **rndc** configuration file is used.

- **-p port**
  Send commands to TCP port **port** instead of BIND 9's default control channel port, 953.

- **-V**
  Enable verbose logging.

- **-y key_id**
  Use the key **key_id** from the configuration file. The **key_id** argument must be known by named with the same algorithm and secret string for control message validation to succeed. If no **key_id** is specified, **rndc** will first look for a key clause in the server statement of the
server being used, or if no server statement is present for that host, then the default-key clause of the options statement. The configuration file contains shared secrets that are used to send authenticated control commands to name servers. It should therefore not have general read or write access.

For the complete set of commands supported by \texttt{rndc}, see the \textit{BIND 9 Administrator Reference Manual} or run \texttt{rndc} without arguments to see its help message.

**Limitations**  
The \texttt{rndc} utility does not support all the commands of the BIND 8 \texttt{ndc} utility.

There is no way to provide the shared secret for a \texttt{key\_id} without using the configuration file.

Several error messages tend toward the cryptic.

**Attributes**  
See \texttt{attributes(5)} for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>network/dns/bind</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Volatile</td>
</tr>
</tbody>
</table>

**See Also**  
\texttt{named(1M), rndc-confgen(1M), named.conf(4), rndc.conf(4), attributes(5)}

See the \textit{BIND 9 Administrator’s Reference Manual}. As of the date of publication of this man page, this document is available at \url{https://www.isc.org/software/bind/documentation}. 
The `rndc-confgen` utility generates configuration files for `rndc(1M)`. This utility can be used as a convenient alternative to writing by hand the `rndc.conf(4)` file and the corresponding controls and key statements in `named.conf`. It can also be run with the `-a` option to set up a `rndc.key` file and avoid altogether the need for a `rndc.conf` file and a controls statement.

The following options are supported:

- **-a**
  Perform automatic `rndc` configuration. This option creates a file `rndc.key` in `/etc` (or however `sysconfdir` was specified when BIND was built) that is read by both `rndc` and `named(1M)` on startup. The `rndc.key` file defines a default command channel and authentication key allowing `rndc` to communicate with `named` with no further configuration.

  Running `rndc-confgen` with `-a` specified allows BIND 9 and `rndc` to be used as drop-in replacements for BIND 8 and `ndc`, with no changes to the existing BIND 8 `named.conf` file.

  If a more elaborate configuration than that generated by `rndc-confgen -a` is required, for example if `rndc` is to be used remotely, you should run `rndc-confgen` without the `-a` option and set up `rndc.conf` and `named.conf` files, as directed.

- **-b keysize**
  Specify the size of the authentication key in bits. The `keysize` argument must be between 1 and 512 bits; the default is 128.

- **-c keyfile**
  Used with the `-a` option to specify an alternate location for `rndc.key`.

- **-h**
  Print a short summary of the options and arguments to `rndc-confgen`.

- **-k keyname**
  Specify the key name of the `rndc` authentication key. The `keyname` argument must be a valid domain name. The default is `rndc.key`.

- **-p port**
  Specify the command channel port where `named` listens for connections from `rndc`. The default is 953.

- **-r randomfile**
  Specify a source of random data for generating the authorization. By default, `/dev/random` is used. The `randomdev` argument specifies the name of a character device or file containing random data to be used instead of the default. The special value `keyboard` indicates that keyboard input should be used.
- **s address**
  Specify the IP address where named listens for command channel connections from **rndc**. The default is the loopback address 127.0.0.1.

- **t chrootdir**
  Used with the `-a` option to specify a directory where named will run after the root directory is changed with **chroot(2)**. An additional copy of the **rndc.key** will be written relative to this directory so that it will be found by the **named** in the new directory.

- **u user**
  Used with the `-a` option to set the owner of the **rndc.key** file generated. If `-t` is also specified only the file in the chroot area has its owner changed.

**Examples**

**EXAMPLE 1**  Create Automatic **rndc** Configuration

The following command creates an automatic **rndc** configuration, so that **rndc** can be used immediately.

```
# rndc-confgen -a
```

**EXAMPLE 2**  Print a Sample **rndc.conf** File

The following command prints a sample **rndc.conf** file with corresponding controls and key statements. These statements can subsequently be manually inserted in the file **named.conf**.

```
# rndc-confgen
```

Name  roleadd – administer a new role account on the system

Synopsis  roleadd [-c comment] [-d dir] [-e expire] [-f inactive]
          [-g group] [-G group [ , group... ]] [-m [-k skel_dir]]
          [-u uid [-o]] [-s shell] [-S repository]
          [-A authorization [ , authorization... ]] [-K key=value] role
          roleadd -D [-b base_dir] [-e expire] [-f inactive]
                 [-g group] [-A authorization [ , authorization... ]]
                 [-P profile [ , profile... ] [-K key=value]]

Description  roleadd adds a role entry to the passwd and shadow and user_attr databases specified by the -S option. The default repository is files. The -A and -P options respectively assign authorizations and profiles to the role. Roles cannot be assigned to other roles. The -K option adds a key=value pair to user_attr for a role. Multiple key=value pairs can be added with multiple -K options.

roleadd also creates supplementary group memberships for the role (-G option) and creates the home directory (-m option) for the role if requested. The new role account remains locked until the passwd(1) command is executed.

Specifying roleadd -D with the -g, -b, -f, -e, or -K option (or any combination of these option) sets the default values for the respective fields. See the -D option. Subsequent roleadd commands without the -D option use these arguments.

The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options can exceed this limit.

The role (role) field accepts a string of no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (.), underscore (_), and hyphen (-). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message is written if these restrictions are not met. A future Solaris release might refuse to accept role fields that do not meet these requirements.

The role field must contain at least one character and must not contain a colon (:) or a newline (\n).

An administrator must be granted the User Management Profile to be able to create a new role. The authorizations required to set the various fields in passwd, shadow and user_attr can be found in passwd(4), shadow(4), and user_attr(4). The authorizations required to assign groups can be found in group(4).

Options  The following options are supported:

- A authorization
  One or more comma separated authorizations defined in auth_attr(4). Only a user or role who has grant rights to the authorization can assign it to an account
-b base_dir
   The default base directory for the system if -d dir is not specified. base_dir is concatenated
   with the account name to define the home directory. If the -m option is not used, base_dir
   must exist.

-c comment
   Any text string. It is generally a short description of the role. This information is stored in
   the role's passwd entry.

-d dir|server:dir
   Specifies the home directory path for the new role. If no server name is specified, the
   specified directory is maintained in the passwd(4) database.

   The optional server name specifies the host on which the home directory resides. Entries in
   this form depend on the automounter, and are maintained in the auto_home map. The path
   /home/username is maintained in the passwd(4) database. When the user subsequently
   references /home/username, the automounter will mount the specified directory on
   /home/username.

-D
   Display the default values for group, base_dir, skel_dir, shell, inactive, expire and key=value
   pairs. When used with the -g, -b, -f, or -K options, the -D option sets the default values for
   the specified fields. The default values are:

   group
      other (GID of 1)

   base_dir
      /export/home

   skel_dir
      /etc/skel

   shell
      /bin/pfsh

   inactive
      0

   expire
      Null

   auths
      Null

   profiles
      Null

   key=value (pairs defined in user_attr(4)
      not present
- **e expire**
  Specify the expiration date for a role. After this date, no user is able to access this role. The expire option argument is a date entered using one of the date formats included in the template file /etc/datemsk. See `getdate(3C)`.

  If the date format that you choose includes spaces, it must be quoted. For example, you can enter 10/6/90 or October 6, 1990. A null value (""") defeats the status of the expired date. This option is useful for creating temporary roles.

- **f inactive**
  The maximum number of days allowed between uses of a role ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.

- **g group**
  An existing group's integer ID or character-string name. Without the -D option, it defines the new role's primary group membership and defaults to the default group. You can reset this default value by invoking `roleadd -D -g group`.

- **G group**
  An existing group's integer ID or character-string name. It defines the new role's supplementary group membership. Duplicates between group with the -g and -G options are ignored. No more than NGROUPS_MAX groups can be specified.

- **k skel_dir**
  A directory that contains skeleton information (such as .profile) that can be copied into a new role's home directory. This directory must already exist. The system provides the /etc/skel directory that can be used for this purpose.

- **K key=value**
  A key=value pair to add to the role's attributes. Multiple -K options can be used to add multiple key=value pairs. The generic -K option with the appropriate key can be used instead of the specific implied key options (-A and -P). See `user_attr(4)` for a list of valid key=value pairs. The "type" key is not a valid key for this option. Keys can not be repeated.

- **m**
  Create the new role's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by group, where group is the role's primary group. If the server name specified to the -d option is a remote host then the system will not attempt to create the home directory.

  If the directory does not already exist and the parent directory is the mount point of a ZFS dataset, then a child of that dataset will be created and mounted at the specified location. The role is delegated permissions to create ZFS snapshots and promote them. The newly created dataset will inherit the encryption setting from its parent. If it is encrypted, the role is granted permission to change its wrapping key.

- **o**
  This option allows a UID to be duplicated (non-unique).
-P profile
   One or more comma-separated execution profiles defined in prof_attr(4).

-s shell
   Full pathname of the program used as the user's shell on login. It defaults to an empty field
   causing the system to use /bin/pfsh as the default. The value of shell must be a valid
   executable file.

-S repository
   The valid repositories are files, ldap. The repository specifies which name service will be
   updated. The default repository is files. When the repository is files, the authorizations,
   profiles, and roles can be present in other name service repositories and can be assigned to
   a user in the files repository. When the repository is ldap, all the assignable attributes
   must be present in the ldap repository.

-u uid
   The UID of the new role. This UID must be a non-negative decimal integer below MAXUID
   as defined in <sys/param.h>. The UID defaults to the next available (unique) number
   above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are
   assigned, the next default UID number is 201. (UIDs from 0-99 are reserved for possible
   use in future applications.)

Exit Status  In case of an error, roleadd prints an error message and exits with one of the following values:

1   No permission for attempted operation.
2   The command syntax was invalid. A usage message for the usermod command is
    displayed.
3   An invalid argument was provided to an option.
4   The gid or uid given with the -u option is already in use.
5   The password and shadow files are not consistent with each other. pwconv(1M) might
    be of use to correct possible errors. See passwd(4) and shadow(4).
6   The login to be modified does not exist, the gid or the uid does not exist.
7   The group, passwd, or shadow file is missing.
9   A group or user name is already in use.
10  Cannot update the passwd, shadow, or user_attr file.
11  Insufficient space to move the home directory (-m option).
12  Unable to create, remove, or move the new home directory.
13  Requested login is already in use.
14  Unexpected failure.
16  Unable to update the group database.
Unable to update the project database.
Insufficient authorization.
Does not have role.
Does not have profile.
Does not have privilege.
Does not have label.
Does not have group.
System not running Trusted Extensions.
Does not have project.
Unable to update auto_home.

Files
/etc/datemsk
/etc/passwd
/etc/shadow
/etc/group
/etc/skel
/usr/include/limits.h
/etc/user_attr

Diagnostics
In case of an error, roleadd prints an error message and exits with a non-zero status.

The following indicates that login specified is already in use:
UX: roleadd: ERROR: login is already in use. Choose another.
The following indicates that the `uid` specified with the `-u` option is not unique:
UX: roleadd: ERROR: uid `uid` is already in use. Choose another.

The following indicates that the `group` specified with the `-g` option is already in use:
UX: roleadd: ERROR: group `group` does not exist. Choose another.

The following indicates that the `uid` specified with the `-u` option is in the range of reserved UIDs (from 0-99):
UX: roleadd: WARNING: uid `uid` is reserved.

The following indicates that the `uid` specified with the `-u` option exceeds `MAXUID` as defined in `<sys/param.h>`:
UX: roleadd: ERROR: uid `uid` is too big. Choose another.

The following indicates that the `/etc/passwd` or `/etc/shadow` files do not exist:
UX: roleadd: ERROR: Cannot update system files - login cannot be created.

The following indicates that the user executing the command does not have sufficient authorization to perform the operation:
UX: roleadd: ERROR: Permission denied.
Name  roledel – delete a role’s login from the system

Synopsis  roledel [-r] [-S repository] role

Description  The roledel utility deletes a role account from the system and makes the appropriate
account-related changes to the system file and file system. roledel also removes the role from
each user’s list of assumable roles.

An administrator must be granted the User Management Profile to be able to delete an
existing role.

Options  The following options are supported:

-  r  
   Remove the role’s home directory from the system. This directory must exist. The files and
directories under the home directory will no longer be accessible following successful
execution of the command. The ZFS dataset that was created for the role’s home directory
will be removed.

   The auto_home entry for the role will be deleted.

-  S repository  
   The valid repositories are files, ldap. The repository specifies which name service will be
updated. The default repository is files.

Operands  The following operands are supported:

role  An existing role name to be deleted.

Exit Status  The following exit values are returned:

0  Successful completion.

2  Invalid command syntax. A usage message for the roledel command is displayed.

6  The account to be removed does not exist.

8  The account to be removed is in use.

10  Cannot update the /etc/group or /etc/user_attr file but the login is removed from
the /etc/passwd file.

12  Cannot remove or otherwise modify the home directory.

Files  /etc/passwd  system password file

/etc/shadow  system file containing roles’ encrypted passwords and related
information

/etc/group  system file containing group definitions

/etc/user_attr  system file containing additional role attributes
Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

Notes The roledel utility only deletes an account definition that is in the group, passwd, shadow, and user_attr databases in the repository.
Name
rolemod – modify a role’s login information on the system

Synopsis
rolemod [-u uid [-o]] [-g group] [-G [+|-]group [, group...]]
       [-d dir [-m]] [-s shell] [-c comment] [-l new_name]
       [-f inactive] [-e expire]
       [-A [+|-]authorization [, authorization]]
       [-S repository]
       [-P [+|-]profile [, profile]] [-K key[+|]=value] role

Description
The rolemod utility modifies a role’s login information on the system. It changes the definition
of the specified login and makes the appropriate login-related system file and file system
changes.

The system file entries created with this command have a limit of 512 characters per line.
Specifying long arguments to several options may exceed this limit.

An administrator must be granted the User Security Profile to be able to modify the security
attributes for an existing role. To be able to modify non-security attributes of an existing user
requires the User Management Profile. The authorizations required to set the various fields in
passwd, shadow and user_attr can be found in passwd(4), shadow(4), user_attr(4). The
authorizations required to assign groups can be found in group(4).

Options
The following options are supported:

- A [+|-]authorization
  One or more comma separated authorizations as deined in auth_attr(4). Only role with
grant rights to the authorization can assign it to an account. This replaces any existing
authorization setting. If no authorization list is specified, the existing setting is removed.

  A prefix + adds the authorization to the existing authorization; a prefix - removes the
authorization from the existing authorization. With no prefix, the value for authorization
replaces the existing authorization.

- c comment
  Specify a comment string, comment can be any text string. It is generally a short description
of the login, and is currently used as the field for the user’s full name. This information is
stored in the user’s /etc/passwd entry.

- d dir
  Specify the new home directory of the role. It defaults to base_dir/login, where base_dir is
the base directory for new login home directories, and login is the new login. This creates
or modifies an auto_home entry for the user.

  The argument to the option can be specified as server:dir where server is the hostname of
the machine on which the home directory resides and dir is the path to the user’s home
directory. If the server is a remote host then the home directory needs to be created on the
remote host for the system to mount it, when the user logs in. If no server name is specified
then the home directory will be created on the host where the command is executed, when
the -m option is used.
-e expire
Specify the expiration date for a role. After this date, no role will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file /etc/datemsk. See getdate(3C).

For example, you may enter 10/6/90 or October 6, 1990. A value of "'' defeats the status of the expired date.

-f inactive
Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.

-g group
Specify an existing group's integer ID or character-string name. It redefines the role's primary group membership.

-g [+|-]group
An existing group's integer ID or character-string name. It defines the new user's supplementary group membership. Duplicates between group with the -g and -G options are ignored. No more than NGROUPS_MAX groups can be specified. GIDs 0-99 are reserved for allocation by the Solaris Operating System.

A prefix + adds the group to the existing group; a prefix - removes the group from the existing group. With no prefix, group replaces the existing group.

-K key[+-]=value
Replace existing or add to a role's key=value pair attributes. Multiple -K options can be used to replace or add multiple key=value pairs. However, keys must not be repeated. The generic -K option with the appropriate key may be used instead of the specific implied key options (-A and -P). See user_attr(4) for a list of valid key=value pairs. If no value is specified, the existing key is removed.

The keyword type can be specified with the value role or the value normal. When using the value normal, the account changes from a role user to a normal user; using the value role keeps the account a role user.

A prefix + adds the value to the existing value; a prefix - removes the value from the existing value. With no prefix, value replaces the existing value.

The prefix +/- operation is applicable only to the following keys: auths, profiles, roles, project, limitpriv, and defaultpriv.

-l new_logname
Specify the new login name for the role. The new_logname argument is a string no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hyphen (−). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release
may refuse to accept login fields that do not meet these requirements. The new_logname argument must contain at least one character and must not contain a colon (:) or NEWLINE (\n).

-m Move the role’s home directory to the new directory specified with the -d option. If the directory already exists, it must have permissions read/write/execute by group, where group is the role’s primary group. If the server name specified to the -d option is a remote host then the system will not attempt to create the home directory.

If the directory does not already exist, a new ZFS dataset will be created. In the global zone, the dataset is created as rpool/export/home/rolename. For non-global zones, the dataset will be created as ROOT-dataset/export/home/rolename. The mountpoint for the ZFS dataset is /export/home/rolename by default. If -d path is specified and it is a path on the local machine, the dataset will be mounted at the specified location. The role is delegated permissions to create ZFS snapshots and promote them. The newly created dataset will inherit the encryption setting from its parent. If it is encrypted, the role is granted permission to change its wrapping key.

-o This option allows the specified UID to be duplicated (non-unique).

-P [+]profile
One or more comma-separated execution profiles defined in auth_attr(4). This replaces any existing profile setting. If no profile list is specified, the existing setting is removed.

A prefix + adds the profile to the existing profile; a prefix - removes the profile from the existing profile. With no prefix, profile replaces the existing profile.

-s shell
Specify the full pathname of the program that is used as the role’s shell on login. The value of shell must be a valid executable file.

-S repository
The valid repositories are files, ldap. The repository specifies which name service will be updated. The default repository is files. When the repository is files, the authorizations, profiles, and roles can be present in other name service repositories and can be assigned to a user in the files repository. When the repository is ldap, all the assignable attributes must be present in the ldap repository.

-u uid
Specify a new UID for the role. It must be a non-negative decimal integer less than MAXUID as defined in <param.h>. The UID associated with the role’s home directory is not modified with this option; a role will not have access to their home directory until the UID is manually reassigned using chown(1).
The following operands are supported:

login
   An existing login name to be modified.

Examples  EXAMPLE 1  Setting Root Back to a Normal Account

   The following command sets the root user back to a normal, non-privileged user.
   
   # rolemod -K type=normal root
   Found user in files repository.

Exit Status  In case of an error, rolemod prints an error message and exits with one of the following values:

1   No permission for attempted operation.
2   The command syntax was invalid. A usage message for the usermod command is displayed.
3   An invalid argument was provided to an option.
4   The gid or uid given with the -u option is already in use.
5   The password and shadow files are not consistent with each other. pwconv(1M) might be of use to correct possible errors. See passwd(4) and shadow(4).
6   The login to be modified does not exist, the gid or the uid does not exist.
7   The group, passwd, or shadow file is missing.
9   A group or user name is already in use.
10  Cannot update the passwd, shadow, or user_attr file.
11  Insufficient space to move the home directory (-m option).
12  Unable to create, remove, or move the new home directory.
13  Requested login is already in use.
14  Unexpected failure.
16  Unable to update the group database.
17  Unable to update the project database.
18  Insufficient authorization.
19  Does not have role.
20  Does not have profile.
21  Does not have privilege.
22  Does not have label.
Does not have group.
System not running Trusted Extensions.
Does not have project.
Unable to update auto_home.

**Files**

**root_archive**

**Name**
root_archive – manage bootable miniroot archives

**Synopsis**

```
/boot/solaris/bin/root_archive pack archive root
```

```
/boot/solaris/bin/root_archive unpack archive root
```

**Description**
The `root_archive` utility is used to manipulate boot archives. The utility can pack and unpack boot archives and image miniroots. Both ufs and hsfs (iso9660) format archives can be unpacked, although only ufs format is generated when packing.

For normal, boot-related system administration, `bootadm(1M)` is recommended.

**Subcommands**
The `root_archive` command has the following subcommands:

- **pack** *archive root*
  Pack the contents of the root directory into the boot archive *archive*.

- **unpack** *archive root*
  Unpack the contents of the boot archive named *archive* to the directory named *root*.

**Exit Status**
The following exit values are returned:

- **0** The command completed successfully.
- **1** The command exited due to an error.

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

Name  route – manually manipulate the routing tables

Synopsis  route [-fnvq] sub-command [ modifiers] args

           route [-fnvq] [-p [-R root-dir]] add | delete [modifiers] destination gateway [args]
           route [-fnvq] change | get [modifiers] destination [gateway [args]]
           route [-fn] monitor [modifiers]
           route [-fnvq] flush [modifiers]
           route -p [-R root-dir] show

Description  route manually manipulates the network routing tables. These tables are normally maintained by the system routing daemon, such as in routed(1M) and in.ripngd(1M).

route supports a limited number of general options, but a rich command language. Users can specify an arbitrary request that can be delivered by means of the programmatic interface discussed in route(7P).

route uses a routing socket and the new message types RTM_ADD, RTM_DELETE, RTM_GET, and RTM_CHANGE. While only superusers can modify routing tables, the RTM_GET operation is allowed for non-privileged users.

Options

- f  Flush the routing tables of all gateway entries. If you use the -f option in conjunction with any of the route sub-commands, route flushes the gateways before performing the sub-command. Specify the table to flush by placing the inet or inet6 modifier immediately after the -f option. If unspecified, flushing IPv4 (inet) routes is the default.

- n  Prevent attempts to print host and network names symbolically when reporting actions. This option is useful when name servers are unavailable.

- p  Make changes to the network route tables persistent across system restarts. The operation is applied to the network routing tables first and, if successful, is then applied to the list of saved routes associated with the currently active Network Configuration Profile (refer to netcfg(1M) for more information about network configuration profiles). In determining whether an operation was successful, a failure to add a route that already exists or to delete a route that is not in the routing table is ignored. Particular care should be taken when using host or network names in persistent routes, as network-based name resolution services are not available at the time routes are added at startup.

- q  Suppress all output.

- R root-dir  Specify an alternate root directory where route applies changes. This option is ignored unless used in conjunction with the -p option. When -R is specified, route changes are applied only to the list of saved routes to be used at startup,
not to the network routing tables. In addition, certain checks, such as the
existence of network interfaces used with -ifp, are skipped. This can be useful
from within JumpStart scripts, where the root directory of the system being
modified is in a location other than /.

-v
Print additional details in verbose mode.

Subcommands
The following subcommands are supported:

add Add a route.
change Change aspects of a route (such as its gateway).
delete Delete a specific route.
flush Remove all gateway entries from the routing table.
get Look up and display the route for a destination.
monitor Continuously report any changes to the routing information base, routing
lookup misses, or suspected network partitionings.
show Display the list of routes to be applied at system startup. Can be used only in
conjunction with the -p option.

The add and delete sub-commands have the following syntax:

route [-v] cmd destination gateway [metric/netmask]

where cmd is add or delete, destination is the destination host or network, and gateway is the
next-hop intermediary through which packets should be routed. Modifiers described in
OPERANDS can be placed anywhere on the command line.

The get and change sub-commands have the following syntax:

route [-v] cmd destination [gateway [metric/netmask]]

where cmd is get or change, destination is the destination host or network, and gateway is the
next-hop intermediary through which packets should be routed. Modifiers described in
OPERANDS can be placed anywhere on the command line.

The monitor sub-command has the following syntax:

route monitor [-inet | -inet6]

Operands
route executes its sub-commands on routes to destinations by way of gateways.

Destinations and
Gateways
By default, destination and gateway addresses are interpreted as IPv4 addresses. All symbolic
names are tried first as a host name, using getipnodebyname(3SOCKET). If this lookup fails in
the AF_INET case, getnetbyname(3SOCKET) interprets the name as that of a network.
Including an optional modifier on the command line before the address changes how the route sub-command interprets it.

The following modifiers are supported:

- `inet` Force the address to be interpreted as an IPv4 address, that is, under the AF_INET address family.
- `inet6` Force the address to be interpreted as an IPv6 address, that is, under the AF_INET6 address family.

For IPv4 addresses, routes to a particular host are by default distinguished from those to a network by interpreting the Internet address specified as the destination. If the destination has a local address part (that is, the portion not covered by the netmask) of 0, or if the destination is resolved as the symbolic name of a network, then the route is assumed to be to a network; otherwise, it is presumed to be a route to a host.

You can force this selection by using one of the following modifiers:

- `host` Force the destination to be interpreted as a host.
- `net` Force the destination to be interpreted as a network.

For example:

<table>
<thead>
<tr>
<th>Destination</th>
<th>Destination Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>128.32</td>
<td>-host 128.0.0.32</td>
</tr>
<tr>
<td>128.32.130</td>
<td>-host 128.32.0.130</td>
</tr>
<tr>
<td>net 128.32</td>
<td>128.32.0.0</td>
</tr>
<tr>
<td>net 128.32.130</td>
<td>128.32.130.0</td>
</tr>
</tbody>
</table>

Two modifiers avoid confusion between addresses and keywords (for example, `host` used as a symbolic host name). You can distinguish a destination by preceding it with the `-dst` modifier. You can distinguish a gateway address by using the `-gateway` modifier. If the destination is directly reachable by way of an interface requiring no intermediary IP router to act as a gateway, this can be indicated by using the `-interface` or `-iface` modifier.

In the following example, the route does not refer to an external gateway (router), but rather to one of the machine's interfaces. Packets with IP destination addresses matching the destination and mask on such a route are sent out on the interface identified by the gateway address. For interfaces using the ARP protocol, this type of route is used to specify that all matching destinations are local to the physical link. That is, a host could be configured to ARP for all addresses, without regard to the configured interface netmask, by adding a default route using this command. For example:
example# route add default hostname -interface

where gateway address hostname is the name or IP address associated with the network interface over which all matching packets should be sent. On a host with a single network interface, hostname is usually the same as the nodename returned by the uname -n command. See uname(1).

For backward compatibility with older systems, directly reachable routes can also be specified by placing a 0 after the gateway address:
example# route add default hostname 0

This value was once a route metric, but this metric is no longer used. If the value is specified as 0, then the destination is directly reachable (equivalent to specifying -interface). If it is non-zero but cannot be interpreted as a subnet mask, then a gateway is used (default).

With the AF_INET address family or an IPv4 address, a separate subnet mask can be specified. This can be specified in one of the following ways:

- IP address following the gateway address. This is typically specified in decimal dot notation as for inet_addr(3SOCKET) rather than in symbolic form.
- IP address following the -netmask qualifier.
- Slash character and a decimal length appended to the destination address.

If a subnet mask is not specified, the mask used is the subnet mask of the output interface selected by the gateway address, if the classful network of the destination is the same as the classful network of the interface. Otherwise, the classful network mask for the destination address is used.

Each of the following examples creates an IPv4 route to the destination 192.0.2.32 subnet with a subnet mask of 255.255.255.224:

example# route add 192.0.2.32/27 somegateway
example# route add 192.0.2.32 -netmask 255.255.255.224 somegateway
example# route add 192.0.2.32 somegateway 255.255.255.224

For IPv6, only the slash format is accepted. The following example creates an IPv6 route to the destination 3ffe:: with a netmask of 16 one-bits followed by 112 zero-bits.

example# route add -inet6 3ffe::/16 somegateway

In cases where the gateway does not uniquely identify the output interface (for example, when several interfaces have the same address), you can use the -ifp ifname modifier to specify the interface by name. For example, -ifp lo0 associates the route with the lo0 interface. If the named interface is an underlying interface in an IPMP (IP multipathing) group, then requests to add a route will automatically be translated to the corresponding IPMP IP interface, and requests to delete or change a route on an underlying interface will fail.
When the routing table contains several equal routes, that is, routes for the same destination and mask, then IP attempts to spread the traffic over those routes. The spreading is such that an individual transport connection uses the same route to avoid packet reordering as seen by, for example, TCP. The details of the spreading algorithm is not documented and is likely to evolve over time.

Routing Flags

Routes have associated flags that influence operation of the protocols when sending to destinations matched by the routes. These flags can be set (and in some cases cleared, indicated by ~) by including the following modifiers on the command line:

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-interface</td>
<td>~RTF_GATEWAY</td>
<td>Destination is directly reachable</td>
</tr>
<tr>
<td>-iface</td>
<td>~RTF_GATEWAY</td>
<td>Alias for interface modifier</td>
</tr>
<tr>
<td>-static</td>
<td>RTF_STATIC</td>
<td>Manually added route</td>
</tr>
<tr>
<td>-nostatic</td>
<td>~RTF_STATIC</td>
<td>Pretend route was added by kernel or routing daemon</td>
</tr>
<tr>
<td>-reject</td>
<td>RTF_REJECT</td>
<td>Emit an ICMP unreachable when matched</td>
</tr>
<tr>
<td>-blackhole</td>
<td>RTF_BLACKHOLE</td>
<td>Silently discard packets</td>
</tr>
<tr>
<td>-proto1</td>
<td>RTF_PROTO1</td>
<td>Set protocol specific routing flag #1</td>
</tr>
<tr>
<td>-proto2</td>
<td>RTF_PROTO2</td>
<td>Set protocol specific routing flag #2</td>
</tr>
<tr>
<td>-private</td>
<td>RTF_PRIVATE</td>
<td>Do not advertise this route</td>
</tr>
<tr>
<td>-multirt</td>
<td>RTF_MULTIRT</td>
<td>Creates the specified redundant route</td>
</tr>
<tr>
<td>-setsrc</td>
<td>RTF_SETSRC</td>
<td>Assigns the default source address</td>
</tr>
<tr>
<td>-indirect</td>
<td>RTF_INDIRRECT</td>
<td>Allows adding routes where gateway is not on-link</td>
</tr>
</tbody>
</table>

The optional -indirect modifier allows adding routes where the gateway is not directly reachable. When an indirect route is the best match for a packet to be sent or forwarded, then IP proceeds to look up that gateway to find a route that is directly reachable. The -indirect modifier can be used even if the gateway is directly reachable.

The optional modifiers -rtt, -rttvar, -sendpipe, -recvpipe, -mtu, -hopcount, -expire, and -ssthresh provide initial values to quantities maintained in the routing entry by transport level protocols, such as TCP. These can be individually locked either by preceding each modifier to be locked by the -lock meta-modifier, or by specifying that all ensuing metrics can be locked by the -lockrest meta-modifier.

Some transport layer protocols can support only some of these metrics. The following optional modifiers are supported:

- expire Lifetime for the entry. This optional modifier is not currently supported.
-hopcount  Maximum hop count. This optional modifier is not currently supported.

-mtu  Maximum MTU in bytes.

-receive  Receive pipe size in bytes.

-rtt  Round trip time in microseconds.

-rttvar  Round trip time variance in microseconds.

-sendpipe  Send pipe size in bytes.

-ssthresh  Send pipe size threshold in bytes.

-secattr  Security attributes of the route. This modifier is available only if the system is configured with the Solaris Trusted Extensions feature.

The -secattr modifier has the following format:

\[
\text{min}\_\text{sl}=val,\text{max}\_\text{sl}=val,\text{doi}=val,\text{cipso}
\]

or:

\[
\text{sl}=VAL,\text{doi}=VAL,\text{cipso}
\]

In the first form, above, the \textit{val} for \textit{min\_sl} and \textit{max\_sl} is a sensitivity label in either hex or string form. The \textit{val} for \textit{doi} is a non-negative integer. The route will apply only for packets with the same domain of interpretation as defined by the \textit{doi} value and within the accreditation range defined by the \textit{min\_sl} and \textit{max\_sl} values. The \textit{cipso} keyword is optional and set by default. Valid \textit{min\_sl}, \textit{max\_sl} and \textit{doi} keyword/value pairs are mandatory. Note that if \textit{val} contains a space, it must be protected by double quotes.

The second form, above, is equivalent to specifying the first form with the same \textit{VAL} for \textit{min\_sl} and \textit{max\_sl}. The second form should be used for the \texttt{get} command, because \texttt{get} uses only a single sensitivity label.

### Compatibility

The modifiers \texttt{host} and \texttt{net} are taken to be equivalent to \texttt{-host} and \texttt{-net}. To specify a symbolic address that matches one of these names, use the \texttt{dst} or \texttt{gateway} keyword to distinguish it. For example: \texttt{-dst host}

The following two flags are also accepted for compatibility with older systems, but have no effect.

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>-cloning</td>
<td>RTF_CLONING</td>
</tr>
<tr>
<td>-xresolve</td>
<td>RTF_XRESOLVE</td>
</tr>
</tbody>
</table>
The -ifa hostname modifier is also accepted, but has no effect.

Files

- `/etc/defaultrouter` List of default routers
- `/etc/hosts` List of host names and net addresses
- `/etc/networks` List of network names and addresses

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTETYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>

Diagnostics

add [ host | network ] destination:gateway flags
The specified route is being added to the tables. The values printed are from
the routing table entry supplied in the ioctl(2) call. If the gateway address
used was not the primary address of the gateway (the first one returned by
getipnodebyname(3SOCKET)) the gateway address is printed
numerically as well as symbolically.

delete [ host | network ] destination:gateway flags
As add, but when deleting or changing
an entry.

destination done
When the -f flag is specified, or the
flush sub-command is used, each
routing table entry deleted is indicated
with a message of this form.

Network is unreachable
An attempt to add a route failed
because the gateway listed was not on
a directly-connected network. Give
the next-hop gateway instead.

not in table
A delete operation was attempted for
an entry that is not in the table.

entry exists
An add operation was attempted for a
route that already exists in the kernel.
routing table overflow

An operation was attempted, but the system was unable to allocate memory to create the new entry.

insufficient privileges

An attempt to add, delete, change, or flush a route failed because the calling process does not have appropriate privileges.

Notes

Specifying that destinations are local (with the -interface modifier) assumes that the routers implement proxy ARP, meaning that they respond to ARP queries for all reachable destinations. Normally, using either router discovery or RIP is more reliable and scalable than using proxy ARP. See in.routed(1M) for information related to RIP.

Combining the all destinations are local route with subnet or network routes can lead to unpredictable results. The search order as it relates to the all destinations are local route are undefined and can vary from release to release.
routeadm(1M)

Name    routeadm – IP forwarding and routing configuration

Synopsis  routeadm [-p [option]]
          routeadm [-R root-dir] [-e option ...] [-d option ...]
                   [-r option ...] [-s var=value]
          routeadm [-l fmri]
          routeadm [-m fmri key=value [key=value]...]
          routeadm [-u]

Description  The routeadm command is used to administer system-wide configuration for IP forwarding
              and routing. IP forwarding is the passing of IP packets from one network to another; IP
              routing is the use of a routing protocol to determine routes.

              IP routing functions are also represented as services within the service management facility
              (SMF), and can be administered by means of svcadm(1M) also, using the following fault
              management resource identifiers (FMRIs):

              svc:/network/routing/route:default
              svc:/network/routing/ripng:default

              See EXAMPLES for relevant examples.

              In addition to enabling and disabling routing and forwarding, routeadm is used to interact
              with SMF-based routing daemon services. Routing daemon services are identified by the
              presence of a routeadm application property group, which routeadm uses in administering the
              given service. Routing daemon services can also specify properties relating to their operation
              in the routing application property group; these can be modified by means of routeadm -m. If
              an FMRI for a service without such a property group is specified, an error is issued and the
              operation is not carried out. If a routing daemon has not been converted to SMF, the ipv4/or
              6-routing-daemon, ipv4/or 6-routing-daemon-args, and ipv4/or 6-routing-stop-cmd
              variables can be used to specify the appropriate daemon for IPv4 or IPv6 routing. routeadm
              will then run that daemon using the svc:/network/routing/legacy-routing:ipv4/or 6/
              service as appropriate. This conversion process occurs when you issue an enable (-e), disable
              (-d) or an update (-u) command.

              The first usage, in the SYNOPSIS above, reports the current configuration.

Options  The following command-line options are supported:

            -p [option]
            Print the configuration in parseable format. If option is specified, only the configuration for
            the specified option or variable is displayed.
-R root-dir
Specify an alternate root directory where routeadm applies changes. This can be useful from within JumpStart scripts, where the root directory of the system being modified is mounted elsewhere.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-e option...
Enable the specified option. The effect is to prepare the associated services for enabling. By means of the routing-svcs variable, the routing daemons are specified to be enabled on subsequent boot or when routeadm -u is run.

-d option...
Disable the specified option. The effect is to prepare the associated services for disabling. By means of the routing-svcs variable, the routing daemons are specified to be disabled on subsequent boot or when routeadm -u is run.

-l fmri
List all properties in the routing application property group for the SMF routing daemon service.

-m fmri key=value
Change property value of property key to value in routing application property group for the SMF routing daemon service. For multi-valued properties, the property name can be used multiple times in the modify operation, and each associated value will be added.

-r option...
Revert the specified option to the system default. The system defaults are specified in the description of each option.

-u
Apply the currently configured options to the running system. These options might include enabling or disabling IP forwarding and launching or killing routing daemons, if any are specified. It does not alter the state of the system for those settings that have been set to default. This option is meant to be used by administrators who do not want to reboot to apply their changes. In addition, this option upgrades non-SMF configurations from the invocations of daemon stop commands, which might include a set of arguments, to a simple enabling of the appropriate service.

-s key=value
Specify string values for specific variables in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is displayed and the program exits. The following variables can be specified:
routing-svcs=fmrilist
   Specifies the routing daemon services to be enabled. Routing daemon services are
determined to be IPv4 or IPv6 (and so enabled or disabled when routeadm -e/-d
ipv4(6)-routing is run) on the basis of property values in the routeadm application
property group. Default: route:default ripng:default

ipv4-routing-daemon=<full_path_to_routing_daemon>
   Specifies the routing daemon to be started when ipv4-routing is enabled. The routing
deaemon specified must be an executable binary or shell-script. If the specified program
maps to an SMF service, the service will be used, and daemon arguments to the program
will be transferred to the properties of the service at enable time. Default: ""

ipv4-routing-daemon-args=<args>
   Specifies the startup arguments to be passed to the ipv4-routing-daemon when
ipv4-routing is enabled. Default: no arguments

ipv4-routing-stop-cmd=<command>
   Specifies the command to be executed to stop the routing daemon when ipv4-routing
is disabled. <command> can be an executable binary or shell-script, or a string that can
be parsed by system(3C). Default: ""

ipv6-routing-daemon=<full_path_to_routing_daemon>
   Specifies the routing daemon to be started when ipv6-routing is enabled. The routing
daemon specified must be an executable binary or shell-script. If the specified program
maps to an SMF service, the service will be used, and daemon arguments to the program
will be transferred to the properties of the service at enable time. Default: ""

ipv6-routing-daemon-args=<args>
   Specifies the startup arguments to be passed to the ipv6-routing-daemon when
ipv6-routing is enabled. Default: ""

ipv6-routing-stop-cmd=<command>
   Specifies the command to be executed to stop the routing daemon when ipv6-routing
is disabled. <command> can be an executable binary or shell-script, or a string that can
be parsed by system(3C). Default: ""

Multiple -e, -d, and -r options can be specified on the command line. Changes made by -e,
-d, and -r are persistent, but are not applied to the running system unless routeadm is called
later with the -u option.

Use the following options as arguments to the -e, -d, and -r options (shown above as option...).

ipv4-forwarding
   Controls the global forwarding configuration for all IPv4 interfaces. The system default is
disabled. If enabled, IP will forward IPv4 packets to and from interfaces when
appropriate. If disabled, IP will not forward IPv4 packets to and from interfaces when
appropriate.
ipv4-routing
Determine whether an IPv4 routing daemon is run. The system default is enabled unless the /etc/defaultrouter file exists (see defaultrouter(4)), in which case the default is disabled. The value of this option reflects the state of all IPv4 routing services, such that if any IPv4 routing service is enabled, ipv4-routing is enabled. This allows users to interact with routing services using svcadm(1M), as well as through routeadm. IPv4 routing services, specified by means of the routing-svcs variable, will be prepared for enable on next boot when the user explicitly enables ipv4-routing. The SMF routing daemon service for in.routed (svc:/network/routing/route:default) is specified by default.

ipv6-forwarding
Controls the global forwarding configuration for all IPv6 interfaces. The system default is disabled. If enabled, IP will forward IPv6 packets to and from interfaces when appropriate. If disabled, IP will not forward IPv6 packets to and from interfaces when appropriate.

ipv6-routing
Determine whether an IPv6 routing daemon is run. The system default is disabled. The value of this option reflects the state of all IPv6 routing services, such that, if any IPv6 routing service is enabled, ipv6-routing is enabled. This allows users to interact with routing services via svcadm(1M) as well as through routeadm. IPv6 routing services, specified by means of the routing-svcs variable, will be prepared for enable on next boot when the user explicitly enables ipv6-routing. The SMF routing daemon service for in.ripngd (svc:/network/routing/ripng:default) is specified by default.

The forwarding and routing settings are related but not mutually dependent. For example, a router typically forwards IP packets and uses a routing protocol, but nothing would prevent an administrator from configuring a router that forwards packets and does not use a routing protocol. In that case, the administrator would enable forwarding, disable routing, and populate the router's routing table with static routes.

The forwarding settings are global settings. Each interface also has an IFF_ROUTER forwarding flag that determines whether packets can be forwarded to or from a particular interface. That flag can be independently controlled by means of ifconfig(1M)'s router option. When the global forwarding setting is changed (that is, -u is issued to change the value from enabled to disabled or vice-versa), all interface flags in the system are changed simultaneously to reflect the new global policy. Interfaces configured by means of DHCP automatically have their interface-specific IFF_ROUTER flag cleared.

When a new interface is plumbed by means of ifconfig, the value of the interface-specific forwarding flag is set according to the current global forwarding value. Thus, the forwarding value forms the “default” for all new interfaces.

Examples

EXAMPLE 1  Enabling IPv4 Forwarding
IPv4 forwarding is disabled by default. The following command enables IPv4 forwarding:

example# routeadm -e ipv4-forwarding
Apply Configured Settings to the Running System

In the previous example, a system setting was changed, but will not take effect until the next reboot unless a command such as the following is used:

```
example# routeadm -u
```

Making a Setting Revert to its Default

To make the setting changed in the first example revert to its default, enter the following:

```
example# routeadm -r ipv4-forwarding
example# routeadm -u
```

Starting `in.routed` with the `-q` Flag

Setting the `-q` flag is represented in the SMF service by setting the `quiet_mode` property to true. The following sequence of commands starts `in.routed` with the `-q` flag:

```
example# routeadm -m route:default quiet_mode=true
example# routeadm -e ipv4-routing -u
```

See `in.routed(1M)` for details of property names and how they relate to daemon behavior.

Exit Status

The following exit values are returned:

- `0` Successful completion.
- `!=0` An error occurred while obtaining or modifying the system configuration.

Files

`/etc/inet/routing.conf` Parameters for IP forwarding and routing. (Not to be edited.)

rpcbind (1M)

**Name**  rpcbind – universal addresses to RPC program number mapper

**Synopsis**  rpcbind [-d] [-w]

**Description**  rpcbind is a server that converts RPC program numbers into universal addresses. It must be running on the host to be able to make RPC calls on a server on that machine.

When an RPC service is started, it tells rpcbind the address at which it is listening, and the RPC program numbers it is prepared to serve. When a client wishes to make an RPC call to a given program number, it first contacts rpcbind on the server machine to determine the address where RPC requests should be sent.

rpcbind should be started before any other RPC service. Normally, standard RPC servers are started by port monitors, so rpcbind must be started before port monitors are invoked.

When rpcbind is started, it checks that certain name-to-address translation-calls function correctly. If they fail, the network configuration databases can be corrupt. Since RPC services cannot function correctly in this situation, rpcbind reports the condition and terminates.

rpcbind maintains an open transport end for each transport that it uses for indirect calls. This is the UDP port on most systems.

The rpcbind service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/bind

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). rpcbind can only be started by the superuser.

The configuration properties of this service can be modified with svccfg(1M).

The following SMF property is used to allow or disallow access to rpcbind by remote clients:

`config/local_only = true`

The default value, `true`, shown above, disallows remote access; a value of `false` allows remote access. See EXAMPLES.

The FMRI `svc:network/rpc/bind` property group `config` contains the following property settings:

`enable_tcpwrappers`  Specifies that the TCP wrappers facility is used to control access to TCP services. The value `true` enables checking. The default value for `enable_tcpwrappers` is `false`. If the `enable_tcpwrappers` parameter is enabled, then all calls to `rpcbind` originating from non-local addresses are automatically wrapped by the TCP wrappers facility. The `syslog` facility code daemon is used to log allowed connections (using the `info` severity level) and denied
traffic (using the warning severity level). See syslog.conf(4) for a
description of syslog codes and severity levels. The Interface
Stability of the TCP wrappers facility and its configuration files is
Volatile. As the TCP wrappers facility is not controlled by Sun,
intrarelease incompatibilities are not uncommon. See
attributes(5).

verbose_logging
Specifies whether the TCP wrappers facility logs all calls or just the
denied calls. The default is false. This option has no effect if TCP
wrappers are not enabled.

allow_indirect
Specifies whether rpcbind allows indirect calls at all. By default,
rpcbind allows most indirect calls, except to a number of standard
services (keyserv, automount, mount, nfs, rquota, and selected NIS
and rpcbind procedures). Setting allow_indirect to false causes
all indirect calls to be dropped. The default is true. NIS broadcast
clients rely on this functionality on NIS servers.

Options  The following options are supported:

-\(d\)  Run in debug mode. In this mode, rpcbind does not fork when it starts. It prints
additional information during operation, and aborts on certain errors. With this
option, the name-to-address translation consistency checks are shown in detail.

-\(w\)  Do a warm start. If rpcbind aborts or terminates on SIGINT or SIGTERM, it writes the
current list of registered services to /var/run/portmap.file and
/var/run/rpcbind.file. Starting rpcbind with the -\(w\) option instructs it to look for
these files and start operation with the registrations found in them. This allows
rpcbind to resume operation without requiring all RPC services to be restarted.

Examples  EXAMPLE 1  Allowing Remote Access

The following sequence of commands allows remote access to rpcbind.

# svccfg -s svc:/network/rpc/bind setprop config/local_only = false
# svcadm refresh svc:/network/rpc/bind

Files  /var/run/portmap.file Stores the information for RPC services registered over IP based
transports for warm start purposes.

/var/run/rpcbind.file Stores the information for all registered RPC services for warm
start purposes.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
</tbody>
</table>
TCP wrappers is Volatile.

See Also  smf(5), rpcinfo(1M), svcadm(1M), svccfg(1M), rpcbind(3NSL), syslog.conf(4), attributes(5), smf(5)

For information on the TCP wrappers facility, see the hosts_access(4) man page, delivered as part of the Solaris operating environment in /usr/sfw/man and available in the security/tcp-wrapper package.

Notes  Terminating rpcbind with SIGKILL prevents the warm-start files from being written.

All RPC servers are restarted if the following occurs: rpcbind crashes (or is killed with SIGKILL) and is unable to to write the warm-start files; rpcbind is started without the -w option after a graceful termination. Otherwise, the warm start files are not found by rpcbind.
rpc.bootparamd(1M)

Name  rpc.bootparamd, bootparamd – boot parameter server

Synopsis  /usr/sbin/rpc.bootparamd [-d]

Description  rpc.bootparamd is a server process that provides information from a bootparams database to diskless clients at boot time. See bootparams(4)

The source for the bootparams database is determined by the nsswitch.conf(4) file (on the machine running the rpc.bootparamd process).

Options  The following options are supported:
           -d     Display debugging information.

Files  /etc/bootparams   boot parameter database
       /etc/nsswitch.conf configuration file for the name-service switch

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/boot/network</td>
</tr>
</tbody>
</table>

See Also  svc(1), svcadm(1M), bootparams(4), nsswitch.conf(4), attributes(5), smf(5)

Notes  A diskless client requires service from at least one rpc.bootparamd process running on a server that is on the same IP subnetwork as the diskless client.

Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.

The rpc.bootparamd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/bootparams

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
Name  rpcinfo – report RPC information

Synopsis  rpcinfo [-m | -s] [host]
           rpcinfo -p [host]
           rpcinfo -T transport host prognum [versnum]
           rpcinfo -l [-T transport] host prognum versnum
           rpcinfo [-n portnum] -u host prognum [versnum]
           rpcinfo [-n portnum] -t host prognum [versnum]
           rpcinfo -a serv_address -T transport prognum [versnum]
           rpcinfo -b [-T transport] prognum versnum
           rpcinfo -d [-T transport] prognum versnum

Description  rpcinfo makes an RPC call to an RPC server and reports what it finds.

In the first synopsis, rpcinfo lists all the registered RPC services with rpcbind on host. If host is not specified, the local host is the default. If -s is used, the information is displayed in a concise format.

In the second synopsis, rpcinfo lists all the RPC services registered with rpcbind, version 2. Note that the format of the information is different in the first and the second synopsis. This is because the second synopsis is an older protocol used to collect the information displayed (version 2 of the rpcbind protocol).

The third synopsis makes an RPC call to procedure 0 of prognum and versnum on the specified host and reports whether a response was received. transport is the transport which has to be used for contacting the given service. The remote address of the service is obtained by making a call to the remote rpcbind.

The prognum argument is a number that represents an RPC program number (see rpc(4)).

If a versnum is specified, rpcinfo attempts to call that version of the specified prognum. Otherwise, rpcinfo attempts to find all the registered version numbers for the specified prognum by calling version 0, which is presumed not to exist; if it does exist, rpcinfo attempts to obtain this information by calling an extremely high version number instead, and attempts to call each registered version. Note that the version number is required for -b and -d options.

The EXAMPLES section describe other ways of using rpcinfo.

Options  -T transport Specify the transport on which the service is required. If this option is not specified, rpcinfo uses the transport specified in the NETPATH environment variable, or if that is unset or NULL, the transport in the netconfig(4) database is used. This is a generic option, and can be used in conjunction with other options as shown in the SYNOPSIS.
-a serv_address  Use serv_address as the (universal) address for the service on transport to ping procedure 0 of the specified prognum and report whether a response was received. The -T option is required with the -a option. If versnum is not specified, rpcinfo tries to ping all available version numbers for that program number. This option avoids calls to remote rpcbind to find the address of the service. The serv_address is specified in universal address format of the given transport.

-b  Make an RPC broadcast to procedure 0 of the specified prognum and versnum and report all hosts that respond. If transport is specified, it broadcasts its request only on the specified transport. If broadcasting is not supported by any transport, an error message is printed. Use of broadcasting should be limited because of the potential for adverse effect on other systems.

-d  Delete registration for the RPC service of the specified prognum and versnum. If transport is specified, unregister the service on only that transport, otherwise unregister the service on all the transports on which it was registered. Only the owner of a service can delete a registration, except the superuser, who can delete any service.

-l  Display a list of entries with a given prognum and versnum on the specified host. Entries are returned for all transports in the same protocol family as that used to contact the remote rpcbind.

-m  Display a table of statistics of rpcbind operations on the given host. The table shows statistics for each version of rpcbind (versions 2, 3 and 4), giving the number of times each procedure was requested and successfully serviced, the number and type of remote call requests that were made, and information about RPC address lookups that were handled. This is useful for monitoring RPC activities on host.

-n portnum  Use portnum as the port number for the -t and -u options instead of the port number given by rpcbind. Use of this option avoids a call to the remote rpcbind to find out the address of the service. This option is made obsolete by the -a option.

-p  Probe rpcbind on host using version 2 of the rpcbind protocol, and display a list of all registered RPC programs. If host is not specified, it defaults to the local host. This option is not useful for IPv6; use -s (see below) instead. Note that version 2 of the rpcbind protocol was previously known as the portmapper protocol.

-s  Display a concise list of all registered RPC programs on host. If host is not specified, it defaults to the local host.
-t Make an RPC call to procedure 0 of prognum on the specified host using TCP, and report whether a response was received. This option is made obsolete by the -T option as shown in the third synopsis.

-u Make an RPC call to procedure 0 of prognum on the specified host using UDP, and report whether a response was received. This option is made obsolete by the -T option as shown in the third synopsis.

**Examples**

**Example 1** RPC services.

To show all of the RPC services registered on the local machine use:

```
example% rpcinfo
```

To show all of the RPC services registered with rpcbind on the machine named klaxon use:

```
example% rpcinfo klaxon
```

The information displayed by the above commands can be quite lengthy. Use the -s option to display a more concise list:

```
example% rpcinfo -s klaxon
```

<table>

</tbody>
</table>

To show whether the RPC service with program number prognum and version versnum is registered on the machine named klaxon for the transport TCP use:

```
example% rpcinfo -T tcp klaxon prognum versnum
```
To show all RPC services registered with version 2 of the rpcbind protocol on the local machine use:

example% rpcinfo -p

To delete the registration for version 1 of the walld (program number 100008) service for all transports use:

example# rpcinfo -d 100008 1

or

example# rpcinfo -d walld 1

rpc.mdcommd – multi-node disk set services

**Synopsis**
/usr/sbin/rpc.mdcommd

**Description**
rpc.mdcommd is an rpc(4) daemon that functions as a server process. rpc.mdcommd manages communication among hosts participating in a multi-node disk set configuration.

rpc.mdcommd is invoked by inetd(1M).

**Exit Status**
The following exit values are returned:

- 0  Successful completion.
- >0  An error occurred.

**Attributes**
See attributes(5) for descriptions of the following attributes:

*Solaris Volume Manager Administration Guide*

**Notes**
The rpc.mdcommd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/rpc/mdcomm
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.
**rpc.metad(1M)**

**Name**  rpc.metad – remote metaset services

**Synopsis**  /usr/sbin/rpc.metad

**Description**  rpc.metad is an rpc(4) daemon (functioning as a server process) that is used to manage local copies of metadevice diskset information. The rpc.metad daemon is controlled by inetadm(1M).

**Exit Status**  The following exit values are returned:

<table>
<thead>
<tr>

**Notes**  The rpc.metad service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/rpc/meta:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.
Name \texttt{rpc.metamedd} – remote mediator services

Synopsis \texttt{/usr/sbin/rpc.metamedd}

Description \texttt{rpc.metamedd} is an \texttt{rpc(4)} server which is used to manage mediator information for use in 2-string HA configurations. The \texttt{rpc.metamedd} daemon is controlled by \texttt{inetadm(1M)}.

Exit Status The following exit values are returned:

\begin{itemize}
  \item 0 \hspace{1cm} Successful completion.
  \item >0 \hspace{1cm} An error occurred.
\end{itemize}

Attributes See \texttt{attributes(5)} for descriptions of the following attributes:

\begin{center}
\begin{tabular}{|l|l|}
\hline
\multicolumn{2}{|c|}{ATTRIBUTE TYPE} & \multicolumn{1}{|c|}{ATTRIBUTE VALUE} \\

Sun Cluster documentation, \textit{Solaris Volume Manager Administration Guide}

Notes The \texttt{rpc.metamedd} service is managed by the service management facility, \texttt{smf(5)}, under the service identifier:

\texttt{svc:/network/rpc/metamed:default}

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using \texttt{svcadm(1M)}. Responsibility for initiating and restarting this service is delegated to \texttt{inetd(1M)}. Use \texttt{inetadm(1M)} to make configuration changes and to view configuration information for this service. The service's status can be queried using the \texttt{svcs(1)} command.
**rpc.metamhd(1M)**

**Name**
rpc.metamhd – remote multihost disk services

**Synopsis**
/usr/sbin/rpc.metamhd

**Description**
`rpc.metamhd` is an `rpc(4)` daemon (functioning as a server process) that is used to manage multi-hosted disks. The `rpc.metamhd` daemon is controlled by `inetadm(1M)`.

**Exit Status**
The following exit values are returned:
- 0 Successful completion.
- >0 An error occurred.

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTETYPE</th>
<th>ATTRIBUTEVALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>storage/svm</td>
</tr>
</tbody>
</table>

**See Also**

**Solaris Volume Manager Administration Guide**

**Notes**
The `rpc.metamhd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/metamh/default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.
**rpc.rexd(1M)**

**Name**
rpc.rexd, rexd – RPC-based remote execution server

**Synopsis**
/usr/sbin/rpc.rexd [-s]

**Description**
rpc.rexd is the Oracle Sun RPC server for remote program execution. This daemon is started by `inetd(1M)` whenever a remote execution request is made.

For non-interactive programs, the standard file descriptors are connected directly to TCP connections. Interactive programs involve pseudo-terminals, in a fashion that is similar to the login sessions provided by `rlogin(1)`. This daemon may use NFS to mount file systems specified in the remote execution request.

There is a 10240 byte limit for arguments to be encoded and passed from the sending to the receiving system.

**Options**
The following option is supported:

- `-s` Secure. When specified, requests must have valid DES credentials. If the request does not have a DES credential it is rejected. The default publickey credential is rejected. Only newer `on(1)` commands send DES credentials.

If access is denied with an authentication error, you may have to set your publickey with the `chkey(1)` command.

Specifying the `-s` option without presenting secure credentials will result in an error message: Unix too weak auth (DesONLY)!

**Security**
rpc.rexd uses `pam(3PAM)` for account and session management. The PAM configuration policy, configured in `/etc/pam.conf` or per-service files in `/etc/pam.d/`, specifies the modules to be used for rpc.rexd. Here is a partial `pam.conf` file with `rpc.rexd` entries for account and session management using the UNIX module:

```
rpc.rexd account requisite pam_roles.so.1
rpc.rexd account required pam_projects.so.1
rpc.rexd account required pam_unix_account.so.1
rpc.rexd session required pam_unix_session.so.1
```

The equivalent PAM configuration in `/etc/pam.d/` would be the following entries in `/etc/pam.d/rpc.rexd`:

```
account requisite pam_roles.so.1
account required pam_projects.so.1
account required pam_unix_account.so.1
session required pam_unix_session.so.1
```

If there are no entries for the `rpc.rexd` service in `/etc/pam.conf` and no `/etc/pam.d/rpc.rexd` file exists, then the entries for the “other” service in `/etc/pam.conf`
will be used. If there are not any entries in /etc/pam.conf for the “other” service, then the entries in /etc/pam.d/other will be used. rpc.rexd uses the getpwuid() call to determine whether the given user is a legal user.

Files
/dev/pts
Pseudo-terminals used for interactive mode
/etc/passwd
Authorized users
/tmp_rex/rexd?????
Temporary mount points for remote file systems

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

Diagnostics
Diagnostic messages are normally printed on the console, and returned to the requestor.

Notes
Root cannot execute commands using rexd client programs such as on(1).

The rpc.rexd service is managed by the service management facility, smf(5), under the service identifier:
svc:/network/rpc/rex:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service’s status can be queried using the svcs(1) command.
rpc.rstatd(1M)

Name  rpc.rstatd, rstatd – kernel statistics server

Synopsis  /usr/lib/netsvc/rstat/rpc.rstatd

Description  rpc.rstatd is a server which returns performance statistics obtained from the kernel. rup(1) uses rpc.rstatd to collect the uptime information that it displays.

rpc.rstatd is an RPC service.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

See Also  rup(1), svcs(1), inetadm(1M), inetd(1M), svcadm(1M), services(4), attributes(5), smf(5)

Notes  The rpc.rstatd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/rstat:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service’s status can be queried using the svcs(1) command.
rpc.rusersd(1M)

Name  rpc.rusersd, rusersd – network username server

Synopsis /usr/lib/netsvc/rusers/rpc.rusersd

Description rpc.rusersd is a server that returns a list of users on the host. The rpc.rusersd daemon may be started by inetd(1M).

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/network/network-servers</td>
</tr>
</tbody>
</table>

See Also svcs(1), inetadm(1M), inetd(1M), svcadm(1M), attributes(5), smf(5)

Notes The rpc.rusersd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/rusers:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.
rpc.rwalld(1M)

Name  rpc.rwalld, rwalld – network rwall server

Synopsis  /usr/lib/netsvc/rwall/rpc.rwalld

Description  rpc.rwalld is a server that handles rwall(1M) requests. It is implemented by calling wall(1M) on all the appropriate network machines. The rpc.rwalld daemon may be started by inetd(1M).

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/network/network-servers</td>
</tr>
</tbody>
</table>

See Also  svcs(1), inetadm(1M), inetd(1M), rwall(1M), svcadm(1M), wall(1M), attributes(5), smf(5)

Notes  The rpc.rwalld service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/rpc/wall:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetd(1M) to make configuration changes and to view configuration information for this service. The service’s status can be queried using the svcs(1) command.
rpc.smserverd(1M)

Name  rpc.smserverd – removable media device server

Synopsis  
/usr/lib/smedia/rpc.smserverd

Description  rpc.smserverd is a server that handles requests from client applications, such as volume management software, for access to removable media devices. In addition to volume management software, `rmformat(1)` and the CDE Filemanager (when performing removable media operations) are `rpc.smserverd` clients. The `rpc.smserverd` daemon is started by `inetd(1M)` when a client makes a call to a Solaris-internal library to access a SCSI, IDE, or USB device. The daemon is not started if a client attempts to access a PCMCIA device. Once started, the daemon remains active until such time as it is idle for three minutes or more.

The `rpc.smserverd` daemon is provided for the exclusive use of the client applications mentioned above. It has no external, customer-accessible interfaces, including no configuration file.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/storage/removable-media</td>
</tr>
</tbody>
</table>

See Also  `svcs(1), inetadm(1M), inetd(1M), svcadm(1M), attributes(5), smf(5)`

Notes  The `rpc.smserverd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/smserver
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.
rpc.sprayd(1M)

Name  rpc.sprayd, sprayd – spray server

Synopsis  /usr/lib/netsvc/spray/rpc.sprayd

Description  rpc.sprayd is a server that records the packets sent by spray(1M). The rpc.sprayd daemon may be started by inetd(1M).

The service provided by rpc.sprayd is not useful as a networking benchmark as it uses unreliable connectionless transports, (udp for example). It can report a large number of packets dropped when the drops were caused by the program sending packets faster than they can be buffered locally (before the packets get to the network medium).

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

<td>service/network/network-servers</td>
</tr>
</tbody>
</table>

See Also  svcs(1), inetadm(1M), inetd(1M), spray(1M), svcadm(1M), attributes(5), smf(5)

Notes  The rpc.sprayd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/spray:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service’s status can be queried using the svcs(1) command.
Description
rpc.yppasswdd is a server that handles password change requests from yppasswd(1). It changes a password entry in the passwd, shadow, and security/passwd.adjunct files. The passwd and shadow files provide the basis for the passwd.byname and passwd.byuid maps. The passwd.adjunct file provides the basis for the passwd.adjunct.byname and passwd.adjunct.byuid maps. Entries in the passwd, shadow or passwd.adjunct files are changed only if the password presented by yppasswd(1) matches the encrypted password of the entry. All password files are located in the PWDIR directory.

If the -D option is given, the passwd, shadow, or passwd.adjunct files are placed under the directory path that is the argument to -D.

If the -noshell, -nogecos or -nopw options are given, these fields cannot be changed remotely using chfn, chsh, or passwd(1).

If the -m option is given, a make(1S) is performed in /var/yp after any of the passwd, shadow, or passwd.adjunct files are modified. All arguments following the flag are passed to make.

The second of the listed syntaxes is provided only for backward compatibility. If the second syntax is used, the passwordfile is the full pathname of the password file and adjunctfile is the full pathname of the optional passwd.adjunct file. If a shadow file is found in the same directory as passwordfile, the shadowfile is used as described above. Use of this syntax and the discovery of a shadowfile file generates diagnostic output. The daemon, however, starts normally.

The first and second syntaxes are mutually exclusive. You cannot specify the full pathname of the passwd, passwd.adjunct files and use the -D option at the same time.

The daemon is started automatically on the master server of the passwd map by ypstart(1M), which is invoked at boot time by the svcs:/network/nis/server:default service.

The server does not insist on the presence of a shadow file unless there is no -D option present or the directory named with the -D option is /etc. In addition, a passwd.adjunct file is not necessary. If the -D option is given, the server attempts to find a passwd.adjunct file in the security subdirectory of the named directory. For example, in the presence of -D /var/yp the server checks for a /var/yp/security/passwd.adjunct file.
If only a passwd file exists, then the encrypted password is expected in the second field. If both a passwd and a passwd.adjunct file exist, the encrypted password is expected in the second field of the adjunct file with #username in the second field of the passwd file. If all three files are in use, the encrypted password is expected in the shadow file. Any deviation causes a password update to fail.

If you remove or add a shadow or passwd.adjunct file after rpc.yppasswd has started, you must stop and restart the daemon to enable it to recognize the change. See ypstart(1M) for information on restarting the daemon.

The rpc.yppasswd daemon considers a shell that has a name that begins with ‘r’ to be a restricted shell. By default, the daemon does not check whether a shell begins with an ‘r’. However, you can tell it to do so by uncommenting the check_restricted_shell_name=1 line in /etc/default/yppasswd. The result will be to restrict a user’s ability to change from his default shell. See yppasswd(4).

On start up, yppasswd checks for the existence of a NIS to LDAP (N2L) configuration file, /var/yp/NISLDAPmapping. If the configuration file is present, the daemon runs in N2L mode. If the file is not present, yppasswd runs in traditional, non-N2L mode.

In N2L mode, changes are written directly to the Directory Information Tree (DIT). If the changes are written successfully, the NIS map is updated. The NIS source files, passwd, shadow, and passwd.adjunct, for example, are not updated. Thus, in N2L mode, the -D option is meaningless. In N2L mode, yppasswd propagates changes by calling yppush(1M) instead of ypmake(1M). The -m option is thus unused.

During an NIS-to-LDAP transition, the yppasswd daemon uses the N2L-specific map, ageing.byname, to read and write password aging information to the DIT. If you are not using password aging, then the ageing.byname mapping is ignored.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/network/nis</td>
</tr>
</tbody>
</table>

See Also  svcs(1), make(1S), passwd(1), yppasswd(1), inetd(1M), svcadm(1M), yppasswd(4), ypstart(1M), NISLDAPmapping(4), passwd(4), shadow(4), ypfiles(4), yppasswd(4), ypserv(4), attributes(5), smf(5)

Notes  If make has not been installed and the -m option is given, the daemon outputs a warning and proceeds, effectively ignoring the -m flag.

When using the -D option, you should make sure that the PWDIR of the /var/yp/Makefile is set accordingly.

The second listed syntax is supplied only for backward compatibility and might be removed in a future release of this daemon.
The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and cannot be used without permission.

The NIS server service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svcs:/network/nis/server:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
rpc.ypupdated, ypupdated – server for changing NIS information

 Synopsis /usr/lib/netsvc/yp/rpc.ypupdated [-is]

 Description ypupdated is a daemon that updates information in the Network Information Service (NIS). ypupdated consults the updaters(4) file in the /var/yp directory to determine which NIS maps should be updated and how to change them.

 By default, the daemon requires the most secure method of authentication available to it, either DES (secure) or UNIX (insecure).

 On start up, ypupdated checks for the existence of a NIS to LDAP (N2L) configuration file, /var/yp/NISLDAPmapping. If the file is present, ypupdated generates an informational message and exits. ypupdated is not supported in N2L mode.

 Options -i Accept RPC calls with the insecure AUTH_UNIX credentials. This allows programmatic updating of the NIS maps in all networks.
 -s Accept only calls authenticated using the secure RPC mechanism (AUTH_DES authentication). This disables programmatic updating of the NIS maps unless the network supports these calls.

 Files /var/yp/updaters Configuration file for rpc.ypupdated command.
 /var/yp/NISLDAPmapping Configuration file for N2L

 Oracle Solaris Administration: Naming and Directory Services

 Notes The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two services remains the same. Only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and it must not be used without permission.
rquotad(1M)

Name  rquotad – remote quota server

Synopsis  /usr/lib/nfs/rquotad

Description  rquotad is an rpc(4) server which returns quotas for a user of a local file system which is
mounted by a remote machine over the NFS. The results are used by quota(1M) to display
user quotas for remote file systems. The rquotad daemon is normally invoked by inetd(1M).

Usage  See largefile(5) for the description of the behavior of rquotad when encountering files
greater than or equal to 2 Gbyte (2^{31} bytes).

Files  quotas  quota file at a UFS file system root

Attributes  See attributes(5) for descriptions of the following attributes:

share_nfs(1M), svcadm(1M), rpc(4), services(4), attributes(5), largefile(5), smf(5)

Installing Oracle Solaris 11.1 Systems

Notes  The rquotad service is managed by the service management facility, smf(5), under the service
identifier:

svc:/network/nfs/rquota

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be
performed using svcadm(1M). Responsibility for initiating and restarting this service is
delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view
configuration information for this service. The service's status can be queried using the
svc(1) command.

If it is disabled, it is enabled by mount_nfs(1M), share_nfs(1M), and automountd(1M) unless
its application/auto_enable property is set to false.
rsh, restricted_shell – restricted shell command interpreter

**Synopsis**

/usr/lib/rsh [-acefhiknrstuvx] [argument]...

**Description**

rsh is a limiting version of the standard command interpreter sh, used to restrict logins to execution environments whose capabilities are more controlled than those of sh (see sh(1) for complete description and usage).

When the shell is invoked, it scans the environment for the value of the environmental variable, SHELL. If it is found and rsh is the file name part of its value, the shell becomes a restricted shell.

The actions of rsh are identical to those of sh, except that the following are disallowed:

- changing directory (see cd(1)),
- setting the value of $PATH,
- specifying path or command names containing /,
- redirecting output (>& and >>).

The restrictions above are enforced after .profile is interpreted.

A restricted shell can be invoked in one of the following ways:

1. rsh is the file name part of the last entry in the /etc/passwd file (see passwd(4));
2. the environment variable SHELL exists and rsh is the file name part of its value; the environment variable SHELL needs to be set in the .login file;
3. the shell is invoked and rsh is the file name part of argument 0;
4. the shell is invoke with the -r option.

When a command to be executed is found to be a shell procedure, rsh invokes sh to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the .profile (see profile(4)) has complete control over user actions by performing guaranteed setup actions and leaving the user in an appropriate directory (probably not the login directory).

The system administrator often sets up a directory of commands (that is, /usr/rbin) that can be safely invoked by a restricted shell. Some systems also provide a restricted editor, red.

**Exit Status**

Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed.
Attributes

See attributes(5) for descriptions of the following attributes:

<table>

Notes

The restricted shell, /usr/lib/rsh, should not be confused with the remote shell, /usr/bin/rsh, which is documented in rsh(1).
Name rtc - provide all real-time clock and UTC-lag management

Synopsis /usr/sbin/rtc [-c] [-z zone-name]

Description On x86 systems, the rtc command reconciles the difference in the way that time is established between UNIX and MS-DOS systems. UNIX systems utilize Universal Coordinated Time (UTC), while MS-DOS systems utilize local time.

Without arguments, rtc displays the currently configured time zone string. The currently configured time zone string is based on what was last recorded by rtc -z zone-name.

The rtc command is not normally run from a shell prompt; it is generally invoked by the system. Commands such as date(1) and rdate(1M), which are used to set the time on a system, invoke /usr/sbin/rtc -c to ensure that daylight savings time (DST) is corrected for properly.

Options
- c This option checks for DST and makes corrections if necessary. It is normally run once a day by a cron job.

If there is no RTC time zone or /etc/rtc_config file, this option will do nothing.

- z zone-name This option, which is normally run by the system at software installation time, is used to specify the time zone in which the RTC is to be maintained. It updates the configuration file /etc/rtc_config with the name of the specified zone and the current UTC lag for that zone. If there is an existing rtc_config file, this command will update it. If not, this command will create it.

Files /etc/rtc_config The data file used to record the time zone and UTC lag. This file is completely managed by /usr/sbin/rtc, and it is read by the kernel.

**Name**
rtquery – query routing daemons for their routing tables

**Synopsis**
rtquery [-np] [-w timeout] [-r addr] [-a secret] host...

rtquery [-t operation] host...

**Description**
The `rtquery` command is used to query a RIP network routing daemon, `in.routed(1M)` or `GateD`, for its routing table by sending a request or poll command. The routing information in any routing response packets returned is displayed numerically and symbolically.

By default, `rtquery` uses the request command. When the `-p` option is specified, `rtquery` uses the poll command, an undocumented extension to the RIP protocol supported by `GateD`. When querying `GateD`, the poll command is preferred over the request command because the response is not subject to Split Horizon and/or Poisoned Reverse, and because some versions of `GateD` do not answer the request command. `in.routed` does not answer the poll command, but recognizes requests coming from `rtquery` and so answers completely.

The `rtquery` command is also used to turn tracing on or off in `in.routed`.

**Options**
The following options are supported:

- `a passwd=XXX`  
  - `a md5_passwd=XXX` | KeyID
  
  Causes the query to be sent with the indicated cleartext or MD5 password.

- `n`
  Displays only the numeric network and host addresses instead of both numeric and symbolic names.

- `p`
  Uses the poll command to request full routing information from `GateD`. This is an undocumented extension RIP protocol supported only by `GateD`.

- `-r addr`
  Asks about the route to destination `addr`.

- `-t operation`
  Changes tracing, where `operation` is one of the actions listed below. Requests from processes not running with UID 0 or on distant networks are generally ignored by the daemon except for a message in the system log. `GateD` is likely to ignore these debugging requests.

  - `on=tracefile`
    Turns tracing on, directing tracing into the specified file. That file must have been specified when the daemon was started or have the name, `/var/log/in.routed.trace`.

  - `more`
    Increases the debugging level.

  - `off`
    Turns off tracing.
dump            Dumps the daemon’s routing table to the
current trace file.

-w timeout     Changes the delay for an answer from each host. By default,
each host is given 15 seconds to respond.

-1             Queries using RIP version 1 instead of RIP version 2.

Exit Status    The following exit values are returned:

  0       Successful completion.
  >0      An error occurred.

Routing Information Protocol, RIPv1, RFC 1058

Routing Information Protocol, RIPv2, RFC 2453, STD 0056
runacct is the main daily accounting shell procedure. It is normally initiated using cron. runacct processes connect, fee, disk, and process accounting files. It also prepares summary files for prdaily or billing purposes. runacct is distributed only to source code licensees.

runacct takes care not to damage active accounting files or summary files in the event of errors. It records its progress by writing descriptive diagnostic messages into active. When an error is detected, a message is written to /dev/console, mail (see mail(1)) is sent to root and adm, and runacct terminates. runacct uses a series of lock files to protect against re-invocation. The files lock and lock1 are used to prevent simultaneous invocation, and lastdate is used to prevent more than one invocation per day.

runacct breaks its processing into separate, restartable states using statefile to remember the last state completed. It accomplishes this by writing the state name into statefile. runacct then looks in statefile to see what it has done and to determine what to process next. states are executed in the following order:

- **SETUP**: Move active accounting files into working files.
- **WTMPFIX**: Verify integrity of wtmpx file, correcting date changes if necessary.
- **CONNECT**: Produce connect session records in tacct.h format.
- **PROCESS**: Convert process accounting records into tacct.h format.
- **MERGE**: Merge the connect and process accounting records.
- **FEES**: Convert output of chargefee into tacct.h format, merge with connect, and process accounting records.
- **DISK**: Merge disk accounting records with connect, process, and fee accounting records.
- **MERGETACCT**: Merge the daily total accounting records in daytacct with the summary total accounting records in /var/adm/acct/sum/tacct.
- **CMS**: Produce command summaries.
- **USEREXIT**: Any installation dependent accounting programs can be included here.
- **CLEANUP**: Clean up temporary files and exit. To restart runacct after a failure, first check the active file for diagnostics, then fix any corrupted data files, such as pacct or wtmpx. The lock, lock1, and lastdate files must be removed before runacct can be restarted. The argument mmdd is necessary if runacct is being restarted. mmdd specifies the month and day for which runacct will rerun the accounting. The entry point for processing is based on the contents of statefile; to override this, include the desired state on the command line to designate where processing should begin.
**Examples**

**EXAMPLE 1**  Starting runacct

The following example starts runacct:

```
example% nohup runacct 2> /var/adm/acct/nite/fd2log &
```

**EXAMPLE 2**  Restarting runacct

The following example restarts runacct:

```
example% nohup runacct 0601 2>> /var/adm/acct/nite/fd2log &
```

**EXAMPLE 3**  Restarting runacct at a Specific State

The following example restarts runacct at a specific state:

```
example% nohup runacct 0601 MERGE 2>> /var/adm/acct/nite/fd2log &
```

**Files**

- `/var/adm/wtmpx`  History of user access and administration information
- `/var/adm/pacctincr`
- `/var/adm/acct/nite/active`
- `/var/adm/acct/nite/daytacct`
- `/var/adm/acct/nite/lock`
- `/var/adm/acct/nite/lock1`
- `/var/adm/acct/nite/lastdate`
- `/var/adm/acct/nite/statefile`

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/accounting/legacy-accounting</td>
</tr>
</tbody>
</table>

**See Also**

`acctcom(1), mail(1), acct(1M), acctcms(1M), acctcon(1M), acctmerg(1M), acctprc(1M), acctsh(1M), cron(1M), fwtmp(1M), acct(2), acct.h(3HEAD), utmpx(4), attributes(5)`

**Notes**

It is not recommended to restart `runacct` in the SETUP state. Run SETUP manually and restart using:

```
runacct mmdd WTMPFIX
```

If `runacct` failed in the PROCESS state, remove the last `ptacct` file because it will not be complete.

The `runacct` command can process a maximum of

- 6000 distinct sessions
1000 distinct terminal lines
2000 distinct login names
during a single invocation of the command. If at some point the actual number of any one of
these items exceeds the maximum, the command will not succeed.

Do not invoke `runacct` at the same time as `ckpacct`, as there may be a conflict if both scripts
attempt to execute `turnacct switch` simultaneously.
rwall – write to all users over a network

**Synopsis**

```
/usr/sbin/rwall hostname...
/usr/sbin/rwall -n netgroup...
/usr/sbin/rwall -h hostname -n netgroup
```

**Description**

rwall reads a message from standard input until EOF. It then sends this message, preceded by the line:

```
Broadcast Message . . .
```

to all users logged in on the specified host machines. With the `-n` option, it sends to the specified network groups.

**Options**

- `n netgroup` Send the broadcast message to the specified network groups.
- `h hostname` Specify the `hostname`, the name of the host machine.

**Attributes**

See [attributes(5)](attributes(5)) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/network/network-clients</td>
</tr>
</tbody>
</table>

**See Also**

inetd(1M), wall(1M), attributes(5)

**Notes**
The timeout is fairly short to allow transmission to a large group of machines (some of which may be down) in a reasonable amount of time. Thus the message may not get through to a heavily loaded machine.
System activity data can be accessed at the special request of a user (see sar(1)) and automatically, on a routine basis, as described here. The operating system contains several counters that are incremented as various system actions occur. These include counters for CPU utilization, buffer usage, disk and tape I/O activity, TTY device activity, switching and system-call activity, file-access, queue activity, inter-process communications, and paging. For more general system statistics, use iostat(1M), sar(1), or vmstat(1M).

sadc and two shell procedures, sa1 and sa2, are used to sample, save, and process this data.

sadc, the data collector, samples system data \( n \) times, with an interval of \( t \) seconds between samples, and writes in binary format to outile or to standard output. The sampling interval \( t \) should be greater than 5 seconds; otherwise, the activity of \( \text{sadc} \) itself may affect the sample. If \( t \) and \( n \) are omitted, a special record is written. This facility can be used at system boot time, when booting to a multi-user state, to mark the time at which the counters restart from zero.

For example, when accounting is enabled, the \( \text{svc:/system/sar:default} \) service writes the restart mark to the daily data file using the command entry:

\[
\text{su sys -c } "\text{/usr/lib/sa/sadc /var/adm/sa/sa date +%d" }
\]

The shell script sa1, a variant of \( \text{sadc} \), is used to collect and store data in the binary file \( /var/adm/sa/sadd \), where \( dd \) is the current day. The arguments \( t \) and \( n \) cause records to be written \( n \) times at an interval of \( t \) seconds, or once if omitted. The following entries in \( /var/spool/cron/crontabs/sys \) will produce records every 20 minutes during working hours and hourly otherwise:

\[
0 * * * 0-6 /usr/lib/sa/sa1
20,40 8-17 * * 1-5 /usr/lib/sa/sa1
\]

See crontab(1) for details.

The shell script sa2, a variant of sar, writes a daily report in the file \( /var/adm/sa/sar dd \). See the OPTIONS section in sar(1) for an explanation of the various options. The following entry in \( /var/spool/cron/crontabs/sys \) will report important activities hourly during the working day:

\[
5 18 * * 1-5 /usr/lib/sa/sa2 -s 8:00 -e 18:01 -i 1200 -A
\]

**Files**

- \( /tmp/sa.adrfl \) address file
- \( /var/adm/sa/sadd \) daily data file
- \( /var/adm/sa/sar dd \) daily report file
/var/spool/cron/crontabs/sys used for performance collection

**Attributes** See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/accounting/legacy-accounting</td>
</tr>
</tbody>
</table>

*Oracle Solaris Administration: Common Tasks*

**Notes** The sar service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/sar
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
sasinfo − Serial Attached SCSI HBA port command line interface

Synopsis
sasinfo hba [-v] [HBA_Name]...
sasinfo hba-port [-lvy] [-a HBA_Name] [HBA_port_Name]...
sasinfo expander [-vt] [-p HBA_port_Name] [Expander_SAS_Addr]...
sasinfo target-port [-s | -v] [Target_port_SAS_Addr]...
sasinfo logical-unit | lu [-v] [device_path]...
sasinfo [-V]
sasinfo [-?] 

Description
The sasinfo utility is a command line interface that collects administrative information on Serial Attached SCSI−2 (SAS−2) host bus adapter (HBA) that supports the Storage Management HBA API (SM−HBA). The utility reports attributes of HBA ports and of expander devices and SCSI target devices that might be connected to those HBA ports.

sasinfo is implemented as a set of subcommands, described below.

Sub-commands
The following subcommands are supported by sasinfo.

hba
Lists information for the HBA referenced by the specified HBA_name. If HBA_name is not specified, all HBAs on the host will be listed.

hba-port
Lists information for the HBA port referenced by the specified HBA_port_Name. If HBA_port_Name is not specified, all HBA ports on the host will be listed. Note that HBA ports can be dynamically configured/unconfigured so that the number of HBA ports on an HBA can change as connections to target devices are established. With no connections to a storage device, no HBA port is configured.

expander
Lists hierarchical view of the expander referenced by the specified Expander_SAS_Addr. If no argument is specified, all expanders that are visible across all HBA ports on the host will be listed.

target-port
Lists information for those target ports referenced by Target_port_SAS_Addr address. If no argument is specified, all target ports that are visible on the host will be listed.

logical-unit | lu
Lists the logical unit referenced by the specified device_path. If device_path is not specified, all SAS logical units will be listed, including the SAS Management Protocol (SMP) target port.
Options

The following options are supported.

- ?, - help
  Displays usage information

-a, -hba HBA_Name
  Retrieve HBA port information from the HBA_Name of an HBA on the host. The -a option can only be used with the hba-port subcommand.

-l, -phy.linkstat
  Lists the link error statistics information for the phys on the HBA port referenced by the specified HBA_port_Name or all HBA ports if no HBA port is specified. This option is used only with the hba-port subcommand.

-p HBA_port_SAS_Addr, -port HBA_port_SAS_Addr
  Retrieve remote port information from the HBA_port_SAS_Addr of the local HBA port on the host. The -p option can be used only with the expander subcommand.

-s, -scsi
  Lists SCSI attributes for target ports that are requested for display. This option is only used for the target-port subcommand.

-v, -verbose
  Display details on hardware information, such as SAS address, topology device, and so forth, based on which subcommand is invoked.

-V, --version
  Displays the version information.

-y, -phy
  Lists the phy information on the HBA port specified by HBA_port_Name or all HBA ports if no HBA port is specified. This option is used only with the hba-port subcommand.

Examples

EXAMPLE 1  Listing All HBAs

The following command lists all HBAs on the host.

# sasinfo hba
HBA Name: SUNW-pmc6-0
HBA Name: SUNW-pmc6-1

EXAMPLE 2  Listing All HBAs with Details

The following command lists all HBAs on the host, along with related details. Note that each HBA has two HBA ports configured, with each HBA port connected to a storage device.

# sasinfo hba -v
HBA Name: SUNW-pmc6-0
  Manufacturer: sun
  Model: SAS Gen-2
  Firmware Version: 1.1
EXAMPLE 2  Listing All HBAs with Details  (Continued)

    FCode/BIOS Version: 1.1
    Serial Number: 111-11111
    Driver Name: smvsl
    Driver Version: 1.1
    Number of HBA Ports: 2
    HBA Name: SUNW-pmcs-1
    Manufacturer: sun
    Model: SAS Gen-2
    Firmware Version: 1.1
    FCode/BIOS Version: 1.1
    Serial Number: 111-11111
    Driver Name: smvsl
    Driver Version: 1.1
    Number of HBA Ports: 2

EXAMPLE 3  Listing All HBA Ports

The following command lists all HBA ports on the host.

    # sasinfo hba-port
    HBA Name: SUNW-pmcs-0
      HBA Port Name: /dev/cfg/c1
      HBA Port Name: /dev/cfg/c2
    HBA Name: SUNW-pmcs-1
      HBA Port Name: /dev/cfg/c3
      HBA Port Name: /dev/cfg/c4

EXAMPLE 4  Listing all HBA Portswith Details

The following command lists all HBA ports, with accompanying details.

    # sasinfo hba-port -v
    HBA Name: SUNW-pmcs-0
      HBA Port Name: /dev/cfg/c1
        Type: sas-device
        State: online
        Local SAS Address: 5000c50000d756aa
        Attached Port SAS Address: 50800201a5a502bf
        Number of Phys: 4
      HBA Port Name: /dev/cfg/c25000c50000d756cc
        Type: sas-device
        State: online
        Local SAS Address: 5000c50000d756aa
        Attached Port SAS Address: 50800201a5a503bf
        Number of Phys: 4
    HBA Name: SUNW-pmcs-1
      HBA Port Name: /dev/cfg/c3
        Type: sas-device
EXAMPLE 4  Listing all HBA Ports with Details  (Continued)

State: online
Local SAS Address: 5000c50000d756cc
Attached Port SAS Address: 50800201a5a504bf
Number of Phys: 4
HBA Port Name: /dev/cfg/c4
  Type: sas-device
  State: online
Local SAS Address: 5000c50000d756cc
Attached Port SAS Address: 50800201a5a505bf
Number of Phys: 4

EXAMPLE 5  Listing phy Information for All HBA Ports

The following command lists phy information for all HBA ports.

```bash
# sasinfo hba-port -y
HBA Name: SUNW-pmcs-0
  HBA Port Name: /dev/cfg/c1
    Phy Information:
      Identifier: 0
        State: enabled
        HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
        ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
        NegotiatedLinkRate: 3Gbit
      Identifier: 1
        State: enabled
        HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
        ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
        NegotiatedLinkRate: 3Gbit
      Identifier: 2
        State: enabled
        HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
        ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
        NegotiatedLinkRate: 3Gbit
      Identifier: 3
        State: enabled
        HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
        ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
        NegotiatedLinkRate: 3Gbit
  HBA Port Name: /dev/cfg/c2
    Phy Information:
      Identifier: 4
        State: enabled
        HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
        ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
        NegotiatedLinkRate: 3Gbit
      Identifier: 5
```

System Administration Commands - Part 2
EXAMPLE 5 Listing PHY Information for All HBA Ports  (Continued)

State: enabled
HardwareLinkRate (Min/Max): 1.5Gbit/3Gbit
ProgrammedLinkRate (Min/Max): 1.5Gbit/3Gbit

  Identifier: 2
    State: enabled
    HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
    ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
    NegotiatedLinkRate: 3Gbit
EXAMPLE 6  Listing phy Link Error Statistics for a Specific HBA Port  (Continued)

Link Error Statistics:
Invalid Dword: 0
Running Disparity Error: 0
Loss of Dword Sync: 0
Reset Problem: 0
Identifier: 3
State: enabled
HardwareLinkRate (Min/Max): 1.5Gbit/3Gbit
ProgrammedLinkRate (Min/Max): 1.5Gbit/3Gbit
NegotiatedLinkRate: 3Gbit
Link Error Statistics:
Invalid Dword: 0
Running Disparity Error: 0
Loss of Dword Sync: 0
Reset Problem: 0

EXAMPLE 7  Listing Expanders Connected to an HBA Port

The following command lists all expanders that are visible through the specified HBA port.

# sasinfo expander -p /dev/cfg/c1
HBA Name: SUNW-pmcs-0
HBA Port Name: /dev/cfg/c1
   Expander SAS Address (Tier 1): 50800201a5a502bf
   Expander SAS Address (Tier 2): 5000c5000d2da812
   Expander SAS Address (Tier 1): 50800201a5a503bf
   Expander SAS Address (Tier 2): 5000c5000d2da823
   Expander SAS Address (Tier 2): 5000c5000d2da812

EXAMPLE 8  Listing Detailed Information on Expanders

The following command lists detailed information on all expanders that are visible through the specified HBA port.

# sasinfo expander -v -p /dev/cfg/c1
HBA Name: SUNW-pmcs-0
HBA Port Name: /dev/cfg/c1
   Expander SAS Address (Tier 1): 50800201a5a502bf
      OS Device Name: /dev/smp/expd0
      State: online
   Expander SAS Address (Tier 2): 5000c5000d2da812
      OS Device Name: /dev/smp/expd3
      State: online
   Expander SAS Address (Tier 1): 50800201a5a503bf
      OS Device Name: /dev/smp/expd2
      State: online
   Expander SAS Address (Tier 2): 5000c5000d2da823
      OS Device Name: /dev/smp/expd3
      State: online
   Expander SAS Address (Tier 2): 5000c5000d2da812
      OS Device Name: /dev/smp/expd3
      State: online
EXAMPLE 8  Listing Detailed Information on Expanders  (Continued)

OS Device Name: /dev/smp/expd1
State: online
  Expander SAS Address (Tier 2): 50800201a5a502d2
    OS Device Name: /dev/smp/expd3
    State: online
  Expander SAS Address (Tier 2): 5000c5000d2da823
EXAMPLE 9  Listing Target Ports Attached to Expanders

The following command lists all target ports that are attached to expanders connected to a specified HBA port.

# sasinfo expander -t -p /dev/cfg/c1
HBA Name: SUNW-pmcs-0
  HBA Port Name: /dev/cfg/c1
    Expander SAS Address (Tier 1): 50800201a5a502bf
      Target Port SAS Address: 50800201a5a504f1
      Expander SAS Address (Tier 2): 50800201a5a50233
        Target Port SAS Address: 50800201a5a502be
        Target Port SAS Address: 5000c5000d2da8b2
        Expander SAS Address (Tier 2): 5000c5000d2da812
          Target Port SAS Address: 50800201a5a502be
          Target Port SAS Address: 50800201a5a508b2
          Expander SAS Address (Tier 1): 50800201a5a503bf
            Target Port SAS Address: 50800201a5a50421
            Expander SAS Address (Tier 2): 50800201a5a502d2
              Target Port SAS Address: 5000c5000d2da7be
              Expander SAS Address (Tier 2): 5000c5000d2da823
                Target Port SAS Address: 50800201a5a503be
                Target Port SAS Address: 5000c5000d2da7be
EXAMPLE 10  Listing Target Port Information

The following command lists all target ports discovered on the host.

# sasinfo target-port
Target Port SAS Address: 5000c5000bae4009
Target Port SAS Address: 5000c5000baef4b1
Target Port SAS Address: 5000c5000bae3fe1
Target Port SAS Address: 5000c5000bae40d9
Target Port SAS Address: 5000c5000bae36c5
LISTING TARGET PORT INFORMATION WITH TOPOLOGY DETAILS

The following command lists all target ports with the HBA port and expander that they are connected to.

# sasinfo target-port -v
Target Port SAS Address: 5000c5000bae4009
  Type: SAS Device
  HBA Port Name: /dev/cfg/c7
  Expander Device SAS Address: 500e004aaaaaaa3f
  HBA Port Name: /dev/cfg/c5
  Expander Device SAS Address: 500e004aaaaaaa3f
Target Port SAS Address: 5000c5000baef4b1
  Type: SAS Device
  HBA Port Name: /dev/cfg/c7
  Expander Device SAS Address: 500e004aaaaaaa3f
  HBA Port Name: /dev/cfg/c5
  Expander Device SAS Address: 500e004aaaaaaa3f
Target Port SAS Address: 5000c5000bae3fe1
  Type: SAS Device
  HBA Port Name: /dev/cfg/c7
  Expander Device SAS Address: 500e004aaaaaaa3f
  HBA Port Name: /dev/cfg/c5
  Expander Device SAS Address: 500e004aaaaaaa3f
Target Port SAS Address: 5000c5000bae49d9
  Type: SAS Device
  HBA Port Name: /dev/cfg/c7
  Expander Device SAS Address: 500e004aaaaaaa3f
  HBA Port Name: /dev/cfg/c5
  Expander Device SAS Address: 500e004aaaaaaa3f
Target Port SAS Address: 5000c5000bae36c5
  Type: SAS Device
  HBA Port Name: /dev/cfg/c7
  Expander Device SAS Address: 500e004aaaaaaa3f
  HBA Port Name: /dev/cfg/c5
  Expander Device SAS Address: 500e004aaaaaaa3f

LISTING TARGET PORTS WITH SCSI INFORMATION

The following command lists all target port details, including SCSI information for each target port.

# sasinfo target-port -s 5000c5000bae4009
Target Port SAS Address: 5000c5000bae4009
  Type: SAS Device
  HBA Port Name: /dev/cfg/c7
  Expander Device SAS Address: 500e004aaaaaaa3f
  LUN: 0
  OS Device Name: /dev/rdsk/c6t5000C5000BAE4000Bd0s2
  Vendor: Sun
EXAMPLE 12  Listing Target Ports with SCSI Information  (Continued)

Product: J4400
Device Type: Disk
HBA Port Name: /dev/cfg/c5
  Expander Device SAS Address: 500e004aaaaaa3f
  LUN : 0
  OS Device Name : /dev/rdsk/c6t5000C5000BAE400Bd0s2
  Vendor: Sun
  Product: J4400
  Device Type: Disk

EXAMPLE 13  Listing the Logical Units

The following command lists the logical units on a host.

# sasinfo logical-unit
OS Device Name: /dev/rdsk/c4t50020F2300B4904Ed0s2
OS Device Name: /dev/rdsk/c4t50020F230000B4AFd0s2

EXAMPLE 14  Listing Additional Information on Logical Units

The following command displays additional logical unit information using the -v option for device /dev/rmt/On.

# sasinfo lu -v
OS Device Name: /dev/rdsk/c4t50020F2300B4904Ed0s2
  HBA Port Name: /dev/cfg/c1
    Target Port SAS Address: 50020f2300b4904e
    LUN: 0
    Vendor: Sun
    Product: J4400
    Device Type: Disk
OS Device Name: /dev/rdsk/c4t50020F230000B4AFd0s2
  HBA Port Name: /dev/cfg/c1
    Target Port SAS Address: 50020f230063100b
    LUN: 0
    Vendor: Sun
    Product: J4400
    Device Type: Disk

The `savecore` utility saves a crash dump of the kernel (assuming that one was made) and writes a reboot message in the shutdown log. It is invoked by the `dumpadm` service each time the system boots.

`savecore` can be configured by `dumpadm(1M)` to save crash dump data in either a compressed or uncompressed format. For the compressed format, `savecore` saves the crash dump data in the file `directory/vmdump.N`, where `N` in the pathname is replaced by a number which increments by one each time `savecore` is run in `directory`. The compressed file can be uncompressed in a separate step using the `-f dumpfile` option. For the uncompressed format, `savecore` saves the crash dump data in the file `directory/vmcore.N` and the kernel’s namelist in `directory/unix.N`.

Before writing out a crash dump, `savecore` reads a number from the file `directory/minfree`. This is the minimum number of kilobytes that must remain free on the file system containing `directory`. If after saving the crash dump the file system containing `directory` would have less free space the number of kilobytes specified in `minfree`, the crash dump is not saved. If the `minfree` file does not exist, `savecore` assumes a `minfree` value of 1 megabyte.

The `savecore` utility also logs a reboot message using facility `LOG_AUTH` (see `syslog(3C)`). If the system crashed as a result of a panic, `savecore` logs the panic string too.

### Options

The following options are supported:

- `-d`
  Disregard dump header valid flag. Force `savecore` to attempt to save a crash dump even if the header information stored on the dump device indicates the dump has already been saved.

- `-f dumpfile`
  Save a crash dump from the specified file instead of from the system’s current dump device. When given `directory/vmdump.N`, uncompress the file to `vmcore.N` and `unix.N`, where `N` is the same number as in the compressed name.

  This option may also be useful if the information stored on the dump device has been copied to an on-disk file by means of the `dd(1M)` command.

- `-L`
  Save a crash dump of the live running Solaris system, without actually rebooting or altering the system in any way. This option forces `savecore` to save a live snapshot of the system to the dump device, and then immediately to retrieve the data and to write it out to a new set of crash dump files in the specified directory. Live system crash dumps can only be performed if you have configured your system to have a dedicated dump device using `dumpadm(1M)`.
savecore -L does not suspend the system, so the contents of memory continue to change while the dump is saved. This means that live crash dumps are not fully self-consistent.

- v
  Verbose. Enables verbose error messages from savecore.

Operands
The following operands are supported:
  directory
  Save the crash dump files to the specified directory. If directory is not specified, savecore saves the crash dump files to the default savecore directory, configured by dumpadm(1M).

Files
  directory/vmcore.N
  directory/unix.N
  directory/bounds
  directory/minfree
  /var/crash/’uname -n’ (default crash dump directory)

adb(1), mdb(1), svcs(1), dd(1M), dumpadm(1M), svcadm(1M), syslog(3C), attributes(5), smf(5)

Notes
The system crash dump service is managed by the service management facility, smf(5), under the service identifier:
  svc:/system/dumpadm:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

If the dump device is also being used as a swap device, you must run savecore very soon after booting, before the swap space containing the crash dump is overwritten by programs currently running.

When savecore creates a file it appends the suffix .partial. After the file is completed, it is renamed without the suffix. If files are found in the dump directory with this suffix, it means that either savecore is still busy, or that it was interrupted before completely writing the file. In the former case, use ps(1) to find the PID of the running savecore process and wait for it to complete. In the latter case, remove the partial file and recreate it by running savecore -d.
**Name**  
sbdadm – SCSI Block Disk command line interface

**Synopsis**  
sbdadm create-lu [-s, --size size] filename

sbdadm delete-lu filename

sbdadm import-lu filename

sbdadm list-lu

sbdadm modify-lu [-s, --size size] lu_name | filename

**Description**  
The sbdadm command creates and manages SCSI-block-device-based logical units that are registered with the SCSITarget Mode Framework (STMF).

**Sub-commands**  
The sbdadm command supports the subcommands listed below. Note that if you enter a question mark as an argument to the command (sbdadm ?), sbdadm responds with a help display.

`create-lu [-s, --size size] filename`
Create a logical unit that can be registered with the STMF. For the `-s` option, `size` is an integer followed by one of the following letters, to indicate a unit of size:

- k kilobyte
- m megabyte
- g gigabyte
- t terabyte
- p petabyte
- e exabyte

If you do not specify `size`, the size defaults to the size of `filename`.

The size specified can exceed the size of the file or device.

`delete-lu filename`
Deletes an existing logical unit that was created using sbdadm create-`lu`. This effectively unloads the logical unit from the STMF framework. Any existing data on the logical unit remains intact.

`import-lu filename`
Imports and loads a logical unit into the STMF that was previously created using sbdadm create-`lu` and was since deleted from the STMF using sbdadm delete-`lu`. On success, the logical unit is again made available to the STMF. `filename` is the filename used in the sbdadm create-`lu` command for this logical unit.

`list-lu`
List all logical units that were created using the sbdadm create-`lu` command.
modify-lu [-s, --size size] lu_name filename

Modifies attributes of a logical unit created using the `sbdadm create-lu` command. For the -s option, size is an integer value followed by a unit specifier. The unit specifiers are as described above under create-lu. When this option is specified, the existing size of the logical unit is changed to the new size.

The size specified can exceed the size of the file or device represented by `lu_name`.

**Operands**
sbdadm use the following operands:

`filename`
Name of an existing file or a fully qualified path to a raw block device.

`lu_name`
The 32-byte hexadecimal representation of the logical unit.

**Examples**

**EXAMPLE 1** Creating a Logical Unit

The following series of commands creates a 10-gigabyte logical unit.

```
# touch /export/lun/0
# sbdadm create-lu -s 10g /export/lun/0
# sbdadm create-lu /dev/rdsk/c1t1d0s0
```

**EXAMPLE 2** Listing Logical Units

The following command lists all logical units.

```
# sbdadm list-lu
```

**Exit Status**

- **0**
  Successful completion.

- **non-zero**
  An error occurred.

sckmd(1M)

Name  sckmd – Sun cryptographic key management daemon

Synopsis  /usr/platform/sun4u/lib/sckmd

Description  sckmd is a server process that resides on a high-end system domain to maintain the Internet Protocol Security (IPsec) Security Associations (SAs) needed to secure communications between a Service Processor or System Controller (SC) and platform management software running within a domain. The dcs(1M) daemon uses these Security Associations. See ipsec(7P) for a description of Security Associations.

The sckmd daemon receives SAs from the Service Processor or SC and installs these SAs in a domain’s Security Association Database (SADB) using pf_key(7P).

sckmd starts up at system boot time as an SMF service. The FMRI for the sckmd service is:

svc:/platform/sun4u/sckmd:default

A domain supports only one running sckmd process at a time.

Attributes  See attributes(5) for descriptions of the following attributes:

</tbody>
</table>

See Also  dcs(1M), ipseccnf(1M), ipsecalgs(1M), attributes(5), ipsec(7P), ipsecah(7P),

ipsecesp(7P), pf_key(7P)

Notes  The sckmd service is used only on Sun Fire high-end systems and the SPARC Enterprise Server family. It provides a mechanism for exchanging IPsec keys between a domain and its System Controller (SC) or Service Processor. These platforms use IPsec to secure the communications between the SC or Service Processor and certain platform-specific daemons in the domain. dcs(1M) is such a daemon.

The documentation for each platform that supports sckmd describes how to configure its use of IPsec for such communications. Also, the documentation for each specific application describes how to configure its security policies and IPsec options in a manner appropriate for the target platform. Refer to the platform- and application-specific documentation for detailed information.
The `scmadm` command provides various options for controlling and gathering information about a storage device cache.

**Options**

If no options are specified, `scmadm` displays a list of configured cache descriptors with disknames, options, and global options. The `scmadm` command supports the following options:

- **-h**
  Displays usage information for the `scmadm` command.

- **-e**
  Reads the configuration and enables the storage device cache with those parameters. See `dscfg`(1M).

- **-d**
  Shuts down the storage device cache.

- **-v**
  Displays the cache version number.

- **-C [parameter [= value]] ...**
  Sets or displays the configuration parameters. If the `-C` option is specified with no arguments the current cache configuration parameters are displayed. If `parameter` is specified, the current value of `parameter` is displayed. If `parameter=value` is specified, the current value of `parameter` is displayed and the parameter is changed to `value`. If `value` is omitted, or if `value` is specified as the null string, "", or as ",", the parameter is deleted from the configuration and the system uses the default value. Multiple parameters can be specified in a single invocation of the `scmadm` command. A change in a configuration parameter takes effect only when the cache is next restarted.

- **-o { system | cd | diskname } [option]**
  Sets or displays the options for the system or for the cache device specified by `cd` or `diskname`. If the `option` `rdcache` or `nordcache` is specified, the system or specified cache device is set to that option. The option is saved as part of the configuration so that the option persists. See `dscfg`(1M). To notify the system to "forget" about a saved option, use
the forget option. This does not change the option; it just removes the option from the saved configuration. If no option is specified, current options are displayed. The rdcache option is set as the default. The options are defined as follows:

rdcache
Data blocks are likely to be referenced again and should remain in cache.

nordcache
Data blocks are unlikely to be referenced again and should be treated as least recently used, so that other blocks can remain in the cache longer.

-m { cd | diskname | all }
Displays the cache descriptor and diskname map for the device specified by cd or diskname or, if you specify all, displays the cache descriptors and diskname map for all storage devices on the system.

Exit Status
The scadm command returns 0 for success, non-zero for error.

Files /dev/sdbc

Diagnostics
scadm fails if there is insufficient contiguous memory.
Name  sconadm – register system information

Synopsis  
```
/usr/sbin/sconadm register [-a
    [-e softwareUpdate | -E softwareUpdate]
    [-h hostname] [-l logfile] [-N]
    [-p proxy_host[:proxy_port]]
    [-r registration_profile] [-u username]
    [-x proxy_username]
```
```
/usr/sbin/sconadm proxy [-l logfile]
    [-p proxy_host[:proxy_port]]
    [-r registration_profile] [-x proxy_username]
```

Description  The sconadm utility is a command-line version of the Basic Registration GUI. In the first form of the command in the SYNOPSIS, sconadm uses the register subcommand to register a host with a registration server. In the second form, sconadm uses the proxy subcommand to configure all of the components for software update to use an HTTP web proxy.

The parameters specified with -u, -e (or -E), -h, -p, and -x override values specified in your registration profile. A template for this profile, owned by root, with read-only permissions, is stored in `/usr/lib/breg/data/RegistrationProfile.properties`. See `registration_profile(4)`.

For the proxy subcommand, the proxy password is stored in the RegistrationProfile.properties file, available if proxy authentication is needed. Storage in the profile prevents proxy passwords from being exposed as part of a listing of processes on a system.

Options  The following options are supported:

- **-a**  
  Accept "Terms of Use and Binary Code License". Absence of this option means that you do not accept the license.

- **-e softwareUpdate**  
  Enable client to be managed at the Sun-hosted Update Connection Service.

- **-E softwareUpdate**  
  Disable client’s ability to be managed at the Sun-hosted Update Connection Service.

- **-h hostname**  
  Hostname of the machine you want to register.

- **-l logfile**  
  Pathname of log file.

- **-N**  
  Never register.

- **-p proxy_host[:proxy_port]**  
  Proxy host name and optional proxy port number.

- **-r registration_profile**  
  Pathname to a registration profile.

- **-u username**  
  User name (a Sun Online Account).

- **-x proxy_username**  
  User name on the proxy host.
Examples

Unless specified otherwise, the commands below require root privileges or privileges equivalent to root. See privileges(5).

EXAMPLE 1  Registering a New System

Assume a file registrationprofile.properties in /tmp that contains the following:

```plaintext
userName=user123
gassword=abc123
hostName=
scriptionKey=
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

To register a new system using the profile above, you enter:

```
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties
```

EXAMPLE 2  Reregistering a System with a Different User

Assume a file registrationprofile.properties in /tmp with the contents shown below. Note the changed specification for userName and password.

```plaintext
userName=newuser
gassword=newpassword
hostName=
scriptionKey=
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

To reregister a new system using the profile above, you enter the same command you entered to register the system:

```
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties
```

EXAMPLE 3  Reregistering a System, Adding a Sun Subscription Key

Modify registrationprofile.properties as follows:

```plaintext
userName=newuser
gassword=newpassword
hostName=
scriptionKey=abc12345678
portalEnabled=false
proxyHostName=
```
EXAMPLE 3  Reregistering a System, Adding a Sun Subscription Key  (Continued)

proxyPort=
proxyUserName=
proxyPassword=

Run the command:

/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties

EXAMPLE 4  Reregistering and Enabling Access to all Update Connection Services
Modify registrationprofile.properties as follows:

userName=newuser
password=newpassword
hostName=
subscriptionKey=abc12345678
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=

Note that portalEnabled is set to false. Run the command:

/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties \ -e softwareUpdate

EXAMPLE 5  Never Registering
To never register a system, enter:

/usr/sbin/sconadm register -N

EXAMPLE 6  Using a Proxy Server With Proxy Authentication
Edit registrationprofile.properties as follows:

userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=webcache.mycompany.com
proxyPort=8880
proxyUserName=myCompanyProxyUserName
proxyPassword=myCompanyProxyPassword

Run the command:
EXAMPLE 6  Using a Proxy Server With Proxy Authentication  (Continued)

/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties

EXAMPLE 7  Changing Proxy Host Settings
Edit registrationprofile.properties as follows:

userNa
password=
hostNa
subscriptionKey=
portalEnabled=
proxyHostName=webcache.mycompany.com
proxyPort=8080
proxyUserName=myCompanyProxyUserName
proxyPassword=myCompanyProxyPassword

Run the command:

/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties

Then, change the proxyHostName value by running the following command:

/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties \
-p newproxy.mycompany.com

After the preceding command all proxies use newproxy.mycompany.com.

EXAMPLE 8  Resetting a System Not to Use a Proxy
Edit registrationprofile.properties as follows:

userNa
password=
hostNa
subscriptionKey=
portalEnabled=
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=

Note that values for all proxy fields are null.

Run the command:

/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties
Exit Status   0    Success.
            >0    An error occurred.

Files    /usr/lib/breg/data/RegistrationProfile.properties
          Registration profile template.

Attributes    See attributes(5) for descriptions of the following attributes:

<table>

# sendmail

## Synopsis

```
 [-Option =value] [-o xvalue] [-p protocol]
 [-Q [reason]] [-q [time]] [-q Xstring] [-R ret]
 [-r name] [-t] [-V envid] [-v] [-X logfile]
 [address]...
```

## Description

The `sendmail` utility sends a message to one or more people, routing the message over whatever networks are necessary. `sendmail` does internetwork forwarding as necessary to deliver the message to the correct place.

`sendmail` is not intended as a user interface routine. Other programs provide user-friendly front ends. `sendmail` is used only to deliver pre-formatted messages.

With no flags, `sendmail` reads its standard input up to an EOF, or a line with a single dot, and sends a copy of the letter found there to all of the addresses listed. It determines the network to use based on the syntax and contents of the addresses.

Local addresses are looked up in the local `aliases` file, or in a name service as defined by the `nsswitch.conf` file, and aliased appropriately. In addition, if there is a `.forward` file in a recipient's home directory, `sendmail` forwards a copy of each message to the list of recipients that file contains. Refer to the NOTES section for more information about `.forward` files. Aliasing can be prevented by preceding the address with a backslash.

There are several conditions under which the expected behavior is for the alias database to be either built or rebuilt. This cannot occur under any circumstances unless root owns and has exclusive write permission to the `/etc/mail/aliases*` files.

If a message is found to be undeliverable, it is returned to the sender with diagnostics that indicate the location and nature of the failure; or, the message is placed in a `dead.letter` file in the sender's home directory.

## Service Management

The `sendmail` service is managed by the service management facility, `smf(5)`, under the service identifiers:

```
svc:/network/smtp:sendmail
svc:/network/sendmail-client:default
```

Administrative actions on these services, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The services' status can be queried using the `svcs(1)` command.

These are separate services rather than instances of the same service so that other services can properly express any dependencies. In particular, here are some guidelines about which service/instance should be depended on for which purposes:
For a service that uses sendmail to send mail, an optional dependency on the service `svc:/network/sendmail-client` might be in order.

- For a service that needs to receive mail in general, but does not depend on sendmail being the particular SMTP receiver, a dependency on the service `svc:/network/smtp` might be in order.
- For a service that needs to interact with sendmail in particular, such as a Milter, a dependency on the instance `svc:/network/smtp:sendmail` might be in order.

For the last two, note the difference, as the latter has the ":sendmail" instance specification, whereas the former does not, thus representing the more general service.

**Enabling Access to Remote Clients**

On an unmodified system, access to sendmail by remote clients is enabled and disabled through the service management facility (see `smf(5)`). In particular, remote access is determined by the value of the `local_only` SMF property:

```
svc:/network/smtp:sendmail/config/local_only = true
```

A setting of true, as above, disallows remote access; false allows remote access. The default value is true.

The following example shows the sequence of SMF commands used to enable sendmail to allow access to remote systems:

```
# svccfg -s svc:/network/smtp:sendmail setprop config/local_only = false
# svcadm refresh svc:/network/smtp:sendmail
# svcadm restart svc:/network/smtp:sendmail
```

See `svcadm(1M)` and `svccfg(1M)`.

Note, however, on a system where any of the `sendmail(4)` files have been customized, setting this property might not have the intended effect. See `sendmail(4)` for details.

**Automated Rebuilding of Configuration Files**

See `sendmail(4)` for details on which service properties can be set to automate (re)building of configuration files when the service is started.

**Restricting Host Access**

Sendmail uses TCP Wrappers to restrict access to hosts. It uses the service name of sendmail for `hosts_access()`. For more information on TCP Wrappers, see `tcpd(1M)` and `hosts_access(4)` in the `security/tcp-wrapper` package. `tcpd(1M)` and `hosts_access(4)` are not part of the Solaris man pages.

**Startup Options**

The `/etc/default/sendmail` file stores startup options for sendmail so that the options are not removed when a host is upgraded. See also `sendmail(4)` for details on which service properties can be set to automate (re)building of configuration files when the service is started.

You can use the following variables in the `/etc/default/sendmail` startup file:
CLIENTOPTIONS=string
Selects additional options to be used with the client daemon, which looks in the client-only queue (/var/spool/clientmqueue) and acts as a client queue runner. No syntax checking is done, so be careful when making changes to this variable.

CLIENTQUEUEINTERVAL=#
Similar to the QUEUEINTERVAL option, CLIENTQUEUEINTERVAL sets the time interval for mail queue runs. However, the CLIENTQUEUEINTERVAL option controls the functions of the client daemon, instead of the functions of the master daemon. Typically, the master daemon is able to deliver all messages to the SMTP port. However, if the message load is too high or the master daemon is not running, then messages go into the client-only queue, /var/spool/clientmqueue. The client daemon, which checks in the client-only queue, then acts as a client queue processor.

ETRN_HOSTS=string
Enables an SMTP client and server to interact immediately without waiting for the queue run intervals, which are periodic. The server can immediately deliver the portion of its queue that goes to the specified hosts. For more information, refer to the etrn(1M) man page.

MODE=-bd
Selects the mode to start sendmail with. Use the -bd option or leave it undefined.

OPTIONS=string
Selects additional options to be used with the master daemon. No syntax checking is done, so be careful when making changes to this variable.

QUEUEINTERVAL=#
Sets the interval for mail queue runs on the master daemon. # can be a positive integer that is followed by either s for seconds, m for minutes, h for hours, d for days, or w for weeks. The syntax is checked before sendmail is started. If the interval is negative or if the entry does not end with an appropriate letter, the interval is ignored and sendmail starts with a queue interval of 15 minutes.

QUEUEOPTIONS=p
Enables one persistent queue runner that sleeps between queue run intervals, instead of a new queue runner for each queue run interval. You can set this option to p, which is the only setting available. Otherwise, this option is not set.

Mail Filter API
sendmail supports a mail filter API called “milter”. For more information, see /usr/include/libmilter/README and http://www.milter.org

Options
The following options are supported:

- Ac
  Uses submit.cf even if the operation mode does not indicate an initial mail submission.

- Am
  Uses sendmail.cf even if the operation mode indicates an initial mail submission.
-ba
  Goes into ARPANET mode. All input lines must end with a RETURN-LINEFEED, and all
  messages are generated with a RETURN-LINEFEED at the end. Also, the From: and
  Sender: fields are examined for the name of the sender.

-bd
  Runs as a daemon in the background, waiting for incoming SMTP connections.

- bD
  Runs as a daemon in the foreground, waiting for incoming SMTP connections.

-bi
  Initializes the aliases(4) database. Root must own and have exclusive write permission to
  the /etc/mail/aliases* files for successful use of this option.

-bl
  Runs as a daemon (like -bd) but accepts only loopback SMTP connections.

-bm
  Delivers mail in the usual way (default).

-bp
  Prints a summary of the mail queues.

-bP
  Prints the number of entries in the queues. This option is only available with shared
  memory support.

-bs
  Uses the SMTP protocol as described in RFC 2821. This flag implies all the operations of
  the -ba flag that are compatible with SMTP.

-bt
  Runs in address test mode. This mode reads addresses and shows the steps in parsing; it is
  used for debugging configuration tables.

-bv
  Verifies names only. Does not try to collect or deliver a message. Verify mode is normally
  used for validating users or mailing lists.

-B type
  Indicates body type (7BIT or 8BITMIME).

-C file
  Uses alternate configuration file.

-d logfile
  Send debugging output to the indicated log file instead of stdout.

-d X
  Sets debugging value to X.
-f name
  Sets the name of the “from” person (that is, the sender of the mail).

-F fullname
  Sets the full name of the sender.

-G
  When accepting messages by way of the command line, indicates that they are for relay (gateway) submission. When this flag is set, sendmail might complain about syntactically invalid messages, for example, unqualified host names, rather than fixing them. sendmail does not do any canonicalization in this mode.

-h N
  Sets the hop count to N. The hop count is incremented every time the mail is processed. When it reaches a limit, the mail is returned with an error message, the victim of an aliasing loop.

-L tag
  Sets the identifier used in syslog messages to the supplied tag.

-M x=value
  Sets macro x to the specified value.

-n
  Does not do aliasing.

-N notifications
  Tags all addresses being sent as wanting the indicated notifications, which consists of the word “NEVER” or a comma-separated list of “SUCCESS”, “FAILURE”, and “DELAY” for successful delivery, failure and a message that is stuck in a queue somewhere. The default is “FAILURE,DELAY”.

-ox=value
  Sets option x to the specified value. Processing Options are described below.

-Option=value
  Sets option to the specified value (for long from names). Processing Options are described below.

-p protocol
  Sets the sending protocol. The protocol field can be in form protocol: host to set both the sending protocol and the sending host. For example: -pUUCP: uunet sets the sending protocol to UUCP and the sending host to uunet. Some existing programs use -oM to set the r and s macros; this is equivalent to using -p.

-q[time]
  Processes saved messages in the queue at given intervals. If time is omitted, processes the queue once. time is given as a tagged number, where s is seconds, m is minutes, h is hours, d is days, and w is weeks. For example, -q1h30m or -q90m would both set the timeout to one hour thirty minutes.
By default, sendmail runs in the background. This option can be used safely with -bd.

-qp[\(time\)-]
  Similar to -q[\(time\)], except that instead of periodically forking a child to process the queue, sendmail forks a single persistent child for each queue that alternates between processing the queue and sleeping. The sleep time (\(time\)) is specified as the argument; it defaults to 1 second. The process always sleeps at least 5 seconds if the queue was empty in the previous queue run.

-qf
  Processes saved messages in the queue once and does not fork(2), but runs in the foreground.

-qG\(name\)
  Processes jobs in queue group called \(name\) only.

-q[!]I\(substr\)
  Limits processed jobs to those containing \(substr\) as a substring of the queue ID or not when ! is specified.

-q[!]Q\(substr\)
  Limits processed jobs to those quarantined jobs containing \(substr\) as a substring of the quarantine reason or not when ! is specified.

-q[!]R\(substr\)
  Limits processed jobs to those containing \(substr\) as a substring of one of the recipients or not when ! is specified.

-q[!]S\(substr\)
  Limits processed jobs to those containing \(substr\) as a substring of the sender or not when ! is specified.

-Q[reason]
  Quarantines a normal queue item with the given reason or unquarantines a quarantined queue item if no reason is given. This should only be used with some sort of item matching as described above.

-r \(name\)
  An alternate and obsolete form of the -f flag.

-R \(ret\)
  Identifies the information you want returned if the message bounces. \(ret\) can be HDRS for headers only or FULL for headers plus body.

-t
  Reads message for recipients. To:,Cc:, and Bcc: lines are scanned for people to send to. The Bcc: line is deleted before transmission. Any addresses in the argument list is suppressed. The NoRecipientAction Processing Option can be used to change the behavior when no legal recipients are included in the message.
Goes into verbose mode. Alias expansions are announced, and so forth.

-V
The indicated \textit{envid} is passed with the envelope of the message and returned if the message bounces.

-X \textit{logfile}
Logs all traffic in and out of \texttt{sendmail} in the indicated \texttt{logfile} for debugging \texttt{mailer} problems. This produces a lot of data very quickly and should be used sparingly.

There are a number of “random” options that can be set from a configuration file. Options are represented by a single character or by multiple character names. The syntax for the single character names of is:

\texttt{0xvalue}

This sets option \texttt{x} to be \texttt{value}. Depending on the option, \texttt{value} may be a string, an integer, a boolean (with legal values \texttt{t}, \texttt{T}, \texttt{f}, or \texttt{F}; the default is \texttt{TRUE}), or a time interval.

The multiple character or long names use this syntax:

\texttt{Longname=argument}

This sets the option \texttt{Longname} to be \texttt{argument}. The long names are beneficial because they are easier to interpret than the single character names.

Not all processing options have single character names associated with them. In the list below, the multiple character name is presented first followed by the single character syntax enclosed in parentheses.

\textbf{AliasFile} (\texttt{Afile})
Specifies possible alias files.

\textbf{AliasWait} (a \texttt{N})
If set, waits up to \texttt{N} minutes for an “@:@” entry to exist in the \texttt{aliases(4)} database before starting up. If it does not appear in \texttt{N} minutes, issues a warning. Defaults to 10 minutes.

\textbf{AllowBogusHELO}
Allows a \texttt{HELO} SMTP command that does not include a host name. By default this option is disabled.

\textbf{BadRcptThrottle=N}
If set and more than the specified number of recipients in a single SMTP envelope are rejected, sleeps for one second after each rejected RCPT command.

\textbf{BlankSub} (\texttt{Bc})
Sets the blank substitution character to \texttt{c}. Unquoted spaces in addresses are replaced by this character. Defaults to \texttt{SPACE} (that is, no change is made).
CACertFile
   File containing one CA cert.

CACertPath
   Path to directory with certs of CAs.

CheckAliases (n)
   Validates the RHS of aliases when rebuilding the aliases(4) database.

CheckpointInterval (CN)
   Checkpoints the queue every N (default 10) addresses sent. If your system crashes during delivery to a large list, this prevents retransmission to any but the last N recipients.

ClassFactor (zfact)
   The indicated factor fact is multiplied by the message class (determined by the Precedence: field in the user header and the P lines in the configuration file) and subtracted from the priority. Thus, messages with a higher Priority: are favored. Defaults to 1800.

ClientCertFile
   File containing the cert of the client, that is, this cert is used when sendmail acts as client.

ClientKeyFile
   File containing the private key belonging to the client cert.

ClientPortOptions
   Sets client SMTP options. The options are key=value pairs. Known keys are:

      Addr Address Mask
      Address Mask defaults to INADDR_ANY. The address mask can be a numeric address in dot notation or a network name.

      Family
      Address family (defaults to INET).

      Listen
      Size of listen queue (defaults to 10).

      Port
      Name/number of listening port (defaults to smtp).

      RcvBufSize
      The size of the TCP/IP receive buffer.

      SndBufSize
      The size of the TCP/IP send buffer.

      Modifier
      Options (flags) for the daemon. Can be:

         h
         Uses name of interface for HELO command.
If h is set, the name corresponding to the outgoing interface address (whether chosen by
tools of the Connection parameter or the default) is used for the HELO/EHLO command.

ColonOkInAddr
If set, colons are treated as a regular character in addresses. If not set, they are treated as the
introducer to the RFC 822 “group” syntax. This option is on for version 5 and lower
configuration files.

ConnectionCacheSize (kN)
The maximum number of open connections that are to be cached at a time. The default is 1.
This delays closing the current connection until either this invocation of sendmail needs to
connect to another host or it terminates. Setting it to 0 defaults to the old behavior, that is,
connections are closed immediately.

ConnectionCacheTimeout (Ktimeout)
The maximum amount of time a cached connection is permitted to idle without activity. If
this time is exceeded, the connection is immediately closed. This value should be small (on
the order of ten minutes). Before sendmail uses a cached connection, it always sends a
NOOP (no operation) command to check the connection. If the NOOP command fails, it
reopens the connection. This keeps your end from failing if the other end times out. The
point of this option is to be a good network neighbor and avoid using up excessive
resources on the other end. The default is five minutes.

ConnectionRateThrottle
The maximum number of connections permitted per second. After this many connections
are accepted, further connections are delayed. If not set or <= 0, there is no limit.

ConnectionRateWindowSize
Define the length of the interval for which the number of incoming connections is
maintained. The default is 60 seconds.

ControlSocketName
Name of the control socket for daemon management. A running sendmail daemon can be
controlled through this Unix domain socket. Available commands are: help, restart,
shutdown, and status. The status command returns the current number of daemon
children, the free disk space (in blocks) of the queue directory, and the load average of the
machine expressed as an integer. If not set, no control socket is available. For the sake of
security, this Unix domain socket must be in a directory which is accessible only by root;
/var/spool/mqueue/.smcontrol is recommended for the socket name.

CRLFile
File containing certificate revocation status, useful for X.509v3 authentication.

DaemonPortOptions (Ooptions)
Sets server SMTP options. The options are key=value pairs. Known keys are:

Name
User-definable name for the daemon (defaults to “daemon#”). Used for error messages
and logging.
Addr
   Address mask (defaults INADDR_ANY).
   The address mask may be a numeric address in dot notation or a network name.

Family
   Address family (defaults to INET).

InputMailFilters
   List of input mail filters for the daemon.

Listen
   Size of listen queue (defaults to 10).

Modifier
   Options (flags) for the daemon; can be a sequence (without any delimiters) of:
   a  Requires authentication.
   b  Binds to interface through which mail has been received.
   c  Performs hostname canonification (.cf).
   f  Requires fully qualified hostname (.cf).
   h  Uses name of interface for HELO command.
   u  Allows unqualified addresses (.cf).
   C  Does not perform hostname canonification.
   E  Disallows ETRN (see RFC 2476).

Name
   User-definable name for the daemon (defaults to Daemon#). Used for error messages and logging.

Port
   Name/number of listening port (defaults to smtp).

ReceiveSize
   The size of the TCP/IP receive buffer.

SendSize
   The size of the TCP/IP send buffer.
children
  Maximum number of children per daemon. See MaxDaemonChildren.

DeliveryMode
  Delivery mode per daemon. See DeliveryMode.

refuseLA
  RefuseLA per daemon.

delayLA
  DelayLA per daemon.

queueLA
  QueueLA per daemon.

sendmail listens on a new socket for each occurrence of the DaemonPortOptions option in
a configuration file.

DataFileBufferSize
  Sets the threshold, in bytes, before a memory-bases queue data file becomes disk-based.
The default is 4096 bytes.

DeadLetterDrop
  Defines the location of the system-wide dead.letter file, formerly hard-coded to
  /var/tmp/dead.letter. If this option is not set (the default), sendmail does not attempt to
  save to a system-wide dead.letter file in the event it cannot bounce the mail to the user or
  postmaster. Instead, it renames the qf file as it has in the past when the dead.letter file
  could not be opened.

DefaultCharSet
  Sets the default character set to use when converting unlabeled 8bit input to MIME.

DefaultUser (gid) or (uid)
  Sets the default group ID for mailers to run in to gid or set the default userid for mailers to
  uid. Defaults to 1. The value can also be given as a symbolic group or user name.

DelayLA=LA
  When the system load average exceeds LA, sendmail sleeps for one second on most SMTP
  commands and before accepting connections.

DeliverByMin=time
  Sets minimum time for Deliver By SMTP Service Extension (RFC 2852). If 0, no time is
  listed, if less than 0, the extension is not offered, if greater than 0, it is listed as minimum
  time for the EHLO keyword DELIVERBY.

DeliveryMode (dx)
  Delivers in mode x. Legal modes are:
    i
      Delivers interactively (synchronously).
Delivers in background (asynchronously).

Deferred mode. Database lookups are deferred until the actual queue run.

Just queues the message (delivers during queue run).

Defaults to `b` if no option is specified, `i` if it is specified but given no argument (that is, `Od` is equivalent to `Odi`).

**DHParameters**
File containing the DH parameters.

**DialDelay**
If a connection fails, waits this many seconds and tries again. Zero means “do not retry”.

**DontBlameSendmail**
If set, overrides the file safety checks. This compromises system security and should not be used. See [http://www.sendmail.org/tips/dontBlameSendmail](http://www.sendmail.org/tips/dontBlameSendmail) for more information.

**DontExpandCnames**
If set, $[ ... $] lookups that do DNS-based lookups do not expand CNAME records.

**DontInitGroups**
If set, the `initgroups(3C)` routine is never invoked. If you set this, agents run on behalf of users only have their primary (`/etc/passwd`) group permissions.

**DontProbeInterfaces**
If set, `sendmail` does not insert the names and addresses of any local interfaces into the `$=w` class. If set, you must also include support for these addresses, otherwise mail to addresses in this list bounces with a configuration error.

**DontPruneRoutes (R)**
If set, does not prune route-addr syntax addresses to the minimum possible.

**DoubleBounceAddress**
If an error occurs when sending an error message, sends that “double bounce” error message to this address.

**EightBitMode (8)**
Uses 8-bit data handling. This option requires one of the following keys. The key can selected by using just the first character, but using the full word is better for clarity.

- **mimify**
  Does any necessary conversion of 8BITMIME to 7-bit.

- **pass**
  Passes unlabeled 8-bit input through as is.
strict
   Rejected unlabeled 8-bit input.

ErrorHeader (Efile/message)
   Appends error messages with the indicated message. If it begins with a slash, it is assumed
   to be the pathname of a file containing a message (this is the recommended setting).
   Otherwise, it is a literal message. The error file might contain the name, email address,
   and/or phone number of a local postmaster who could provide assistance to end users. If
   the option is missing or NULL, or if it names a file which does not exist or which is not
   readable, no message is printed.

ErrorMode (ex)
   Disposes of errors using mode x. The values for x are:

   e
      Mails back errors and gives 0 exit status always.

   m
      Mails back errors.

   p
      Prints error messages (default).

   q
      No messages, just gives exit status.

   w
      Writes back errors (mail if user not logged in).

FallbackMXhost (Vfallbackhost)
   If specified, the fallbackhost acts like a very low priority MX on every host. This is intended
   to be used by sites with poor network connectivity.

FallBackSmartHost
   If specified, the fallBackSmartHost is used in a last-ditch effort for each host. This is
   intended to be used by sites with “fake internal DNS”. That is, a company whose DNS
   accurately reflects the world inside that company’s domain but not outside.

FastSplit
   If set to a value greater than zero (the default is one), it suppresses the MX lookups on
   addresses when they are initially sorted, that is, for the first delivery attempt. This usually
   results in faster envelope splitting unless the MX records are readily available in a local
   DNS cache. To enforce initial sorting based on MX records set FastSplit to zero. If the
   mail is submitted directly from the command line, then the value also limits the number of
   processes to deliver the envelopes; if more envelopes are created they are only queued up
   and must be taken care of by a queue run. Since the default submission method is by way of
   SMTP (either from a MUA or by way of the Message Submission Program [MSP]), the
   value of FastSplit is seldom used to limit the number of processes to deliver the
   envelopes.
ForkEachJob (Y)
If set, delivers each job that is run from the queue in a separate process. Use this option if you are short of memory, since the default tends to consume considerable amounts of memory while the queue is being processed.

ForwardPath (Jpath)
Sets the path for searching for users’ .forward files. The default is $z/.forward. Some sites that use the automounter may prefer to change this to /var/forward/$u to search a file with the same name as the user in a system directory. It can also be set to a sequence of paths separated by colons; sendmail stops at the first file it can successfully and safely open. For example, /var/forward/$u:$z/.forward searches first in /var/forward/username and then in ~username/.forward (but only if the first file does not exist). Refer to the NOTES section for more information.

HeloName=name
Sets the name to be used for HELO/EHLO (instead of $j).

HelpFile (Hfile)
Specifies the help file for SMTP.

HoldExpensive (c)
If an outgoing mailer is marked as being expensive, does not connect immediately.

HostsFile
Sets the file to use when doing “file” type access of host names.

HostStatusDirectory
If set, host status is kept on disk between sendmail runs in the named directory tree. If a full path is not used, then the path is interpreted relative to the queue directory.

IgnoreDots (i)
Ignores dots in incoming messages. This is always disabled (that is, dots are always accepted) when reading SMTP mail.

LogLevel (Ln)
Sets the default log level to n. Defaults to 9.

(Mx value)
Sets the macro x to value. This is intended only for use from the command line.

MailboxDatabase
Type of lookup to find information about local mail boxes, defaults to pw which uses getpwnam(3C). Other types can be introduced by adding them to the source code, see libsm/mbdb.c for details.

MatchGECOS (G)
Tries to match recipient names using the GECOS field. This allows for mail to be delivered using names defined in the GECOS field in /etc/passwd as well as the login name.
MaxDaemonChildren
The maximum number of children the daemon permits. After this number, connections are rejected. If not set or <=0, there is no limit.

MaxHopCount (hN)
The maximum hop count. Messages that have been processed more than N times are assumed to be in a loop and are rejected. Defaults to 25.

MaxMessageSize
The maximum size of messages that are accepted (in bytes).

MaxMimeHeaderLength=M[\(\frac{1}{N}\)]
Sets the maximum length of certain MIME header field values to M characters. For some of these headers which take parameters, the maximum length of each parameter is set to N if specified. If \(\frac{1}{N}\) is not specified, one half of M is used. By default, these values are 0, meaning no checks are done.

MaxNOOPCommands=N
Overrides the default of 20 for the number of useless commands.

MaxQueueChildren=N
When set, this limits the number of concurrent queue runner processes to N. This helps to control the amount of system resources used when processing the queue. When there are multiple queue groups defined and the total number of queue runners for these queue groups would exceed MaxQueueChildren then the queue groups are not all run concurrently. That is, some portion of the queue groups run concurrently such that MaxQueueChildren is not be exceeded, while the remaining queue groups are run later (in round robin order). See MaxRunnersPerQueue.

MaxQueueRunSize
If set, limits the maximum size of any given queue run to this number of entries. This stops reading the queue directory after this number of entries is reached; job priority is not used. If not set, there is no limit.

MaxRunnersPerQueue=N
This sets the default maximum number of queue runners for queue groups. Up to N queue runners work in parallel on a queue group's messages. This is useful when the processing of a message in the queue might delay the processing of subsequent messages. Such a delay can be the result of non-erroneous situations such as a low bandwidth connection. The can be overridden on a per queue group basis by setting the Runners option. The default is 1 when not set.

MeToo (m)
Sends to me too, even if I am in an alias expansion.

MaxRecipientsPerMessage
If set, allows no more than the specified number of recipients in an SMTP envelope. Further recipients receive a 452 error code and are deferred for the next delivery attempt.
MinFreeBlocks (bN/M)
Insists on at least \( N \) blocks free on the file system that holds the queue files before accepting email by way of SMTP. If there is insufficient space, sendmail gives a 452 response to the MAIL command. This invites the sender to try again later. The optional \( M \) is a maximum message size advertised in the ESMTP EHLO response. It is currently otherwise unused.

MinQueueAge
Specifies the amount of time a job must sit in the queue between queue runs. This allows you to set the queue run interval low for better responsiveness without trying all jobs in each run. The default value is 0.

MustQuoteChars
Specifies the characters to be quoted in a full name phrase. \&, ; : \()\[]\] are quoted automatically.

NiceQueueRun
Specifies the priority of queue runners. See nice(1).

NoRecipientAction
Sets action if there are no legal recipient files in the message. The legal values are:
- add-apparently-to
  Adds an Apparently-to: header with all the known recipients (which may expose blind recipients).
- add-bcc
  Adds an empty Bcc: header.
- add-to
  Adds a To: header with all the known recipients (which may expose blind recipients).
- add-to-undisclosed
  Adds a To: undisclosed-recipients: header.
- none
  Does nothing, that is, leaves the message as it is.

OldStyleHeaders (o)
Assumes that the headers may be in old format, that is, spaces delimit names. This actually turns on an adaptive algorithm: if any recipient address contains a comma, parenthesis, or angle bracket, it is assumed that commas already exist. If this flag is not on, only commas delimit names. Headers are always output with commas between the names.

OperatorChars or $o
Defines the list of characters that can be used to separate the components of an address into tokens.

PidFile
Specifies the filename of the pid file. The default is /var/run/sendmail.pid. The filename is macro-expanded before it is opened, and unlinked when sendmail exits.

sendmail(1M)
**PostmasterCopy** *(Ppostmaster)*

If set, copies of error messages are sent to the named *postmaster*. Only the header of the failed message is sent. Since most errors are user problems, this is probably not a good idea on large sites, and arguably contains all sorts of privacy violations, but it seems to be popular with certain operating systems vendors.

**PrivacyOptions** *(popt,opt,...)*

Sets privacy options. Privacy is really a misnomer; many of these options are just a way of insisting on stricter adherence to the SMTP protocol.

The `goaway` pseudo-flag sets all flags except `noreceipts`, `restrictmailq`, `restrictqrun`, `restrictexpand`, `noetrn`, and `nobodyreturn`. If `mailq` is restricted, only people in the same group as the queue directory can print the queue. If queue runs are restricted, only root and the owner of the queue directory can run the queue. The `restrict-expand` pseudo-flag instructs `sendmail` to drop privileges when the `-bv` option is given by users who are neither root nor the TrustedUser so users cannot read private aliases, forwards, or :include: files. It adds the NonRootSafeAddr to the “DontBlame-Sendmail” option to prevent misleading unsafe address warnings. It also overrides the `-v` (verbose) command line option to prevent information leakage. Authentication Warnings add warnings about various conditions that may indicate attempts to fool the mail system, such as using an non-standard queue directory.

The options can be selected from:

- **authwarnings**
  - Puts X-Authentication-Warning: headers in messages.
- **goaway**
  - Disallows essentially all SMTP status queries.
- **needexpnhelo**
  - Insists on HELO or EHLO command before EXPN.
- **needmailhelo**
  - Insists on HELO or EHLO command before MAIL.
- **needvrfyhelo**
  - Insists on HELO or EHLO command before VRFY.
- **noactualrecipient**
  - Do not put an X-Actual-Recipient line in a DNS that reveals the actual account to which an address is mapped.
- **noetrn**
  - Disallows ETRN entirely.
- **noexpn**
  - Disallows EXPN entirely.
noreceipts
    Prevents return receipts.
nobodyreturn
    Does not return the body of a message with DSNs.
novrfy
    Disallows VRFY entirely.
public
    Allows open access.
restrictexpand
    Restricts -bv and -v command line flags.
restrictmailq
    Restricts mailq command.
restrictqrun
    Restricts -q command line flag.

ProcessTitlePrefix string
    Prefixes the process title shown on "/usr/ucb/ps auxww" listings with string. The string is macro processed.

QueueDirectory (Qdir)
    Uses the named dir as the queue directory.

QueueFactor (qfactor)
    Uses factor as the multiplier in the map function to decide when to just queue up jobs rather than run them. This value is divided by the difference between the current load average and the load average limit (x flag) to determine the maximum message priority to be sent. Defaults to 600000.

QueueFileMode=mode
    Defaults permissions for queue files (octal). If not set, sendmail uses 0600 unless its real and effective uid are different in which case it uses 0644.

QueueLA (xLA)
    When the system load average exceeds LA, just queues messages (that is, does not try to send them). Defaults to eight times the number of processors online when sendmail starts.

QueueSortOrder=algorithm
    Sets the algorithm used for sorting the queue. Only the first character of the value is used. Legal values are host (to order by the name of the first host name of the first recipient), filename (to order by the name of the queue file name), time (to order by the submission/creation time), random (to order randomly), modification (to order by the modification time of the qf file (older entries first)), none (to not order), and priority (to order by message priority). Host ordering makes better use of the connection cache, but may tend to process low priority messages that go to a single host over high priority.
messages that go to several hosts; it probably shouldn’t be used on slow network links. Filename and modification time ordering saves the overhead of reading all of the queued items before starting the queue run. Creation (submission) time ordering is almost always a bad idea, since it allows large, bulk mail to go out before smaller, personal mail, but may have applicability on some hosts with very fast connections. Random is useful if several queue runners are started by hand which try to drain the same queue since odds are they are working on different parts of the queue at the same time. Priority ordering is the default.

**QueueTimeout** (**Trtime/wtime**)
Sets the queue timeout to *rtime*. After this interval, messages that have not been successfully sent are returned to the sender. Defaults to five days (5d). The optional *wtime* is the time after which a warning message is sent. If it is missing or 0, then no warning messages are sent.

**RandFile**
File containing random data (use prefix *file:* ) or the name of the UNIX socket if EGD is used (use prefix *egd:* ). Note that Solaris supports random(7D), so this does not need to be specified.

**RecipientFactor** (**yfact**)
The indicated factor *fact* is added to the priority (thus lowering the priority of the job) for each recipient, that is, this value penalizes jobs with large numbers of recipients. Defaults to 30000.

**RefuseLA** (**XLA**)
When the system load average exceeds *LA*, refuses incoming SMTP connections. Defaults to 12 times the number of processors online when *sendmail* starts.

**RejectLogInterval**
Log interval when refusing connections for this long (default: 3h).

**ResolverOptions** (**I**)
Tunes DNS lookups.

**RetryFactor** (**Zfact**)
The indicated factor *fact* is added to the priority every time a job is processed. Thus, each time a job is processed, its priority is decreased by the indicated value. In most environments this should be positive, since hosts that are down are all too often down for a long time. Defaults to 90000.

**RrtImpliesDsn**
If this option is set, a Return-Receipt-To: header causes the request of a DSN, which is sent to the envelope sender as required by RFC 1891, not to the address given in the header.

**RunAsUser**
If set, becomes this user when reading and delivering mail. Intended for use of firewalls where users do not have accounts.
SafeFileEnvironment
   If set, sendmail does a chroot into this directory before writing files.

SaveFromLine (f)
   Saves Unix-style From lines at the front of headers. Normally they are assumed redundant and discarded.

SendMimeErrors (j)
   If set, sends error messages in MIME format (see RFC 2045 and RFC 1344 for details). If disabled, sendmail does not return the DSN keyword in response to an EHLO and does not do Delivery Status Notification processing as described in RFC 1891.

ServerCertFile
   File containing the cert of the server, that is, this cert is used when sendmail acts as server.

ServerKeyFile
   File containing the private key belonging to the server cert.

ServiceSwitchFile
   Defines the path to the service-switch file. Since the service-switch file is defined in the Solaris operating environment this option is ignored.

SevenBitInput (7)
   Strips input to seven bits for compatibility with old systems. This should not be necessary.

SharedMemoryKey
   Specifies key to use for shared memory segment. If not set (or 0), shared memory is not be used. If this option is set, sendmail can share some data between different instances. For example, the number of entries in a queue directory or the available space in a file system. This allows for more efficient program execution, since only one process needs to update the data instead of each individual process gathering the data each time it is required.

SharedMemoryKeyFile=file
   If SharedMemoryKeyFile is set to -1, the automatically selected shared memory key will be stored in the specified file.

SingleLineFromHeader
   If set, From: lines that have embedded newlines are unwrapped onto one line.

SingleThreadDelivery
   If this option and the HostStatusDirectory option are both set, uses single thread deliveries to other hosts.

SmtpGreetingMessage or $e
   Specifies the initial SMTP greeting message.

SoftBounce
   If set, issue temporary errors (4xy) instead of permanent errors (5xy). This can be useful during testing of a new configuration to avoid erroneous bouncing of mail.
StatusFile ($file)
Logs statistics in the named file. By default, this is /etc/mail/sendmail.st. As root, you must touch(1) this file to enable mailstats(1).

SuperSafe (s)
This option can be set to True, False, Interactive, or PostMilter. If set to True, sendmail is set to super-safe when running things, that is, always instantiate the queue file, even if you are going to attempt immediate delivery. sendmail always instantiates the queue file before returning control to the client under any circumstances. This should really always be set to True. The Interactive value has been introduced in 8.12 and can be used together with DeliveryMode=i. It skips some synchronization calls which are effectively doubled in the code execution path for this mode. If set to PostMilter, sendmail defers synchronizing the queue file until any milters have signaled acceptance of the message. PostMilter is useful only when sendmail is running as an SMTP server; in all other situations it acts the same as True.

TempFileMode (Fmode)
Specifies the file mode for queue files.

Timeout (timeouts)
Timeout reads after time interval. The timeouts argument is a list of keyword=value pairs. All but command apply to client SMTP. For backward compatibility, a timeout with no keyword= part is set all of the longer values. The recognized timeouts and their default values, and their minimum values specified in RFC 1123 section 5.3.2 are:

- aconnect: all connections for a single delivery attempt [0, unspecified]
- command: command read [1h, 5m]
- connect: initial connect [0, unspecified]
- control: complete control socket transaction [2m, none]
- datablock: data block read [1h, 3m]
- datafinal: reply to final . in data [1h, 10m]
- datainit: reply to DATA command [5m, 2m]
- fileopen: file open [60sec, none]
- helo: reply to HELO or EHLO command [5m, none]
hoststatus
  host retry [30m, unspecified]

iconnect
  first attempt to connect to a host [0, unspecified]

ident
  IDENT protocol timeout [5s, none]

initial
  wait for initial greeting message [5m, 5m]

lhlo
  wait for reply to an LMTP LHLO command [2m, unspecified]

mail
  reply to MAIL command [10m, 5m]

misc
  reply to NOOP and VERB commands [2m, none]

queue return
  undeliverable message returned [5d]

queue warn
  deferred warning [4h]

quit
  reply to QUIT command [2m, none]

rcpt
  reply to RCPT command [1h, 5m]

resolver.retrans
  Resolver's retransmission time interval (in seconds) [varies]. Sets both
  Timeout.resolver.retrans.first and Timeout.resolver.retrans.normal.

resolver.retrans.first
  Resolver's retransmission time interval (in seconds) for the first attempt to deliver a
  message [varies].

resolver.retrans.normal
  Resolver's retransmission time interval (in seconds) for all look-ups except the first
  delivery attempt [varies].

resolver.retry
  Number of times to retransmit a resolver query [varies]. Sets both
  Timeout.resolver.retry.first and Timeout.resolver.retry.normal.

resolver.retry.first
  Number of times to retransmit a resolver query for the first attempt to deliver a message
  [varies].
resolver.retry.normal
   Number of times to retransmit a resolver query for all look-ups except the first delivery attempt [varies].

rset
   reply to RSET command [5m, none]

starttls
   response to an SMTP STARTTLS command [1h]

TimeZoneSpec (tzinfo)
   Sets the local time zone info to tzinfo, for example, “PST8PDT”. Actually, if this is not set, the TZ environment variable is cleared (so the system default is used); if set but null, the user’s TZ variable is used, and if set and non-null, the TZ variable is set to this value.

TLSSrvOptions
   If this option is ‘V’, then no client verification is performed, that is, the server does not ask for a certificate.

TrustedUser
   The user parameter can be a user name (looked up in the passwd map) or a numeric user id. Trusted user for file ownership and starting the daemon. If set, generated alias databases and the control socket (if configured) are automatically owned by this user.

TryNullMXList (w)
   If you are the “best” (that is, lowest preference) MX for a given host, you should normally detect this situation and treat that condition specially, by forwarding the mail to a UUCP feed, treating it as local, or whatever. However, in some cases (such as Internet firewalls) you may want to try to connect directly to that host as though it had no MX records at all. Setting this option causes sendmail to try this. The downside is that errors in your configuration are likely to be diagnosed as “host unknown” or “message timed out” instead of something more meaningful. This option is deprecated.

UnixFromLine or $l
   The “From” line used when sending to files or programs.

UnsafeGroupWrites
   If set, group-writable :include: and .forward files are considered “unsafe”, that is, programs and files cannot be directly referenced from such files.

UseErrorsTo (l)
   If there is an Errors-To: header, sends error messages to the addresses listed there. They normally go to the envelope sender. Use of this option causes sendmail to violate RFC 1123. This option is not recommended and deprecated.

UseMSP
   Uses as mail submission program, that is, allows group writable queue files if the group is the same as that of a set-group-id sendmail binary.
UserDatabaseSpec (U)
Defines the name and location of the file containing User Database information.

Verbose (v)
Runs in verbose mode. If this is set, sendmail adjusts the HoldExpensive and DeliveryMode options so that all mail is delivered completely in a single job so that you can see the entire delivery process. The Verbose option should never be set in the configuration file; it is intended for command line use only.

XScriptFileBufferSize
Sets the threshold, in bytes, before a memory-bases queue transcript file becomes disk-based. The default is 4096 bytes.

If the first character of the user name is a vertical bar, the rest of the user name is used as the name of a program to pipe the mail to. It may be necessary to quote the name of the user to keep sendmail from suppressing the blanks from between arguments.

If invoked as newaliases, sendmail rebuilds the alias database, so long as the /etc/mail/aliases* files are owned by root and root has exclusive write permission. If invoked as mailq, sendmail prints the contents of the mail queue.

Operands
address
address of an intended recipient of the message being sent.

Usage
See largefile(5) for the description of the behavior of sendmail when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

Exit Status
sendmail returns an exit status describing what it did. The codes are defined in /usr/include/sysexits.h.

EX_OK
Successful completion on all addresses.

EX_NOUSER
User name not recognized.

EX_UNAVAILABLE
Catchall. Necessary resources were not available.

EX_Syntax
Syntax error in address.

EX_SOFTWARE
Internal software error, including bad arguments.

EX_OSERR
Temporary operating system error, such as “cannot fork”.

EX_NOHOST
Host name not recognized.
EX_TEMPFAIL
Message could not be sent immediately, but was queued.

Environment Variables
No environment variables are used. However, sendmail's start-up script, invoked by
svcadm(1M), reads /etc/default/sendmail. In this file, if the variable ETRN_HOSTS is set, the
start-up script parses this variable and invokes etrn(1M) appropriately. ETRN_HOSTS should
be of the form:
"s1:c1.1,c1.2 s2:c2.1 s3:c3.1,c3.2,c3.3"

That is, white-space separated groups of server:client where client can be one or more
comma-separated names. The :client part is optional. server is the name of the server to prod; a
mail queue run is requested for each client name. This is comparable to running:
/usr/lib/sendmail -qR client

on the host server.

Files
dead.letter
Unmailable text
/etc/default/sendmail
Contains default settings. You can override some of the settings by command line options.
/etc/mail/aliases
Mail aliases file (ASCII)
/etc/mail/aliases.db
Database of mail aliases (binary)
/etc/mail/aliases.dir
Database of mail aliases (binary)
/etc/mail/aliases.pag
Database of mail aliases (binary)
/etc/mail/sendmail.cf
Defines environment for sendmail
/etc/mail/submit.cf
Defines environment for MSP
/etc/mail/trusted-users
Lists users that are "trusted", that is, able to set their envelope from address using -f
without generating a warning message. Note that this file is consulted by the default
sendmail.cf, but not by the default submit.cf, in which the line referring to
/etc/mail/trusted-users is commented out. See sendmail(4) for instructions on
making changes to submit.cf and sendmail.cf.

Notes

The sendmail program requires a fully qualified host name when starting. A script has been included to help verify if the host name is defined properly (see check-hostname(1M)).

The permissions and the ownership of several directories have been changed in order to increase security. In particular, access to /etc/mail and /var/spool/mqueue has been restricted.

Security restrictions have been placed users using .forward files to pipe mail to a program or redirect mail to a file. The default shell (as listed in /etc/passwd) of these users must be listed in /etc/shells. This restriction does not affect mail that is being redirected to another alias.

Additional restrictions have been put in place on .forward and :include: files. These files and the directory structure that they are placed in cannot be group- or world-writable. See check-permissions(1M).

If you have interfaces that map to domains that have MX records that point to non-local destinations, you might need to enable the Don'tProbeInterfaces option to enable delivery to those destinations. In its default startup behavior, sendmail probes each interface and adds an
interface’s IP addresses, as well as any domains that those addresses map to, to its list of domains that are considered local. For domains thus added, being on the list of local domains is equivalent to having a 0-preference MX record, with \texttt{localhost} as the MX value. If this is not the result you want, enable \texttt{DontProbeInterfaces}. 
Name  sftp-server – SFTP server subsystem

Synopsis  /usr/lib/ssh/sftp-server [-f log_facility] [-l log_level]

Description  sftp-server implements the server side of the SSH File Transfer Protocol as defined in the IETF draft-ietf-secsh-filexfer.

sftp-server is a subsystem for sshd(1M) and must not be run directly. Command-line flags to sftp-server should be specified in the Subsystem declaration. See sshd_config(4) for more information.

To enable the sftp-server subsystem for sshd add the following to /etc/ssh/sshd_config:

Subsystem sftp /usr/lib/ssh/sftp-server

To run sftp-server in a chroot configuration, use internal-sftp instead of /usr/lib/ssh/sftp-server. Otherwise, the chroot directory must contain the necessary files and directories to support the user’s session. See the ChrootDirectory and Subsystem options in sshd_config(4)) for more information on how sshd and sftp-server work with chroot(2).

See sshd_config(4) for a description of the format and contents of that file.

There is no relationship between the protocol used by sftp-server and the FTP protocol (RFC 959) provided by in.ftpd.

For logging to work, sftp-server must be able to access /dev/log. Use of sftp-server in a chroot configuration therefore requires that syslogd(1M) establish a logging socket inside the chroot directory.

Options  Valid options are listed below. As stated above, these options, if used, are specified in the Subsystem declaration of sshd_config.

- f log_facility
  Specifies the facility code that is used when logging messages from sftp-server. The possible values are: DAEMON, USER, AUTH, LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, LOCAL5, LOCAL6, LOCAL7. The default is AUTH.

- l log_level
  Specifies which messages will be logged by sftp-server. The possible values are: QUIET, FATAL, ERROR, INFO, VERBOSE, DEBUG, DEBUG1, DEBUG2, and DEBUG3. INFO and VERBOSE log transactions that sftp-server performs on behalf of the client. DEBUG and DEBUG1 are equivalent. DEBUG2 and DEBUG3 each specify higher levels of debugging output. The default is ERROR.

- u umask
  Sets an explicit umask(2) to be applied to newly-created files and directories, instead of the user’s default mask.
Exit Status  The following exit values are returned:

0    Successful completion.
>0   An error occurred.

Files  /usr/lib/ssh/sftp-server  Server-side binary.

shadowd(1M)

**Name**
shadowd – shadow migration daemon

**Synopsis**
/usr/lib/fs/shadowd
svc:/system/filesystem/shadowd:default

**Description**
shadowd is a daemon that provides background worker threads to migrate data for a shadow migration. A shadow migration gradually moves data from a source file system into a new “shadow” file system. Users can access and change their data within the shadow file system while migration is occurring.

The shadowd service is managed by the service management facility, smf(5). Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service’s status can be queried using the svcs(1) command.

The svccfg(1M) command can be used to manage the following parameter related to shadowd:

```
config_params/shadow_threads
```

Number of threads to devote to background migration of data. These threads are global to the entire system, and increasing the number can increase concurrency and the overall speed of migration at the expense of increased resource consumption (network, I/O, and CPU).

**Attributes**
See attributes(5) for descriptions of the following attributes:

<td>Unstable</td>
</tr>
</tbody>
</table>

**See Also**
shadowstat(1M), zfs(1M), attributes(5)
Name  shadowstat – report shadow migration statistics

Synopsis  /usr/sbin/shadowstat [count]

Description  The shadowstat utility reports statistics on in-progress shadow migrations. A line of output is presented for each migrating file system; the output looks similar to the following:

<table>
<thead>
<tr>
<th>DATASET</th>
<th>EST</th>
<th>XFRD</th>
<th>LEFT</th>
<th>ERRORS</th>
<th>TIME</th>
</tr>
</thead>
<tbody>
<tr>
<td>pool/newfs</td>
<td>2.10M</td>
<td>28.8G</td>
<td>-</td>
<td></td>
<td>00:02:45</td>
</tr>
</tbody>
</table>

Each line identifies bytes transferred thus far, a rough estimate of bytes left to transfer, number of migration errors, and the time elapsed since the migration was started.

If count is unspecified, updated values are presented every few seconds until the program is terminated. If count is specified, updates only occur count times, after which the program exits.

share (1M)

**Name**
share – display file system shares or make local file system available for mounting by remote systems

**Synopsis**
share [-F protocol] [-a]

share [-F protocol] [-o options] [-d description] pathname [sharename]

share [-F protocol] [-A]

**Description**
The `share` command defines and publishes a file system share, which means the file system is available for mounting through a sharing protocol.

If the `-F protocol` option is omitted, the first file sharing protocol listed in `/etc/dfs/fstypes` is used as the default.

For a description of NFS-specific share options, see `share_nfs(1M)`. For a description of SMB specific share options, see `share_smb(1M)`.

Using the `share` command to define and publish an NFS or SMB share of a ZFS file system is considered a legacy operation. Consider setting the `share.nfs` property or using the `zfs share` command to define and publish an NFS or an SMB share of a ZFS file system. For more information, see `share_nfs(1M)` and `share_smb(1M)`.

In the third form of `share` command, as shown in the Synopsis above, `share` displays published shares or, with the `-A` option, displays all configured (defined) shares.

**Options**
- `-F protocol`
  Specify the file sharing protocol.
- `-o specific_options`
  - `r` Share `pathname` is published with read and write access to all clients. This is the default behavior.
  - `rw` Share `pathname` is published with read and write access only to the listed clients. No other systems can access the share `pathname`.
  - `ro` Share `pathname` is published with read-only access to all clients.
  - `r=client[:client]...` Share `pathname` is published with read-only access only to the listed clients. No other systems can access the share `pathname`.
  - `ro=client[:client]...` Share `pathname` is published with read-only access only to the listed clients. No other systems can access the share `pathname`.

Separate multiple options with commas. Separate multiple operands for an option with colons. See EXAMPLES.

- `-d`
  Provide a comment that describes the file system share to be published.
-a
  Publish all defined shares.
-A
  Display all defined shares.

Examples  
**EXAMPLE 1**  Publishing an NFS Share With Read-Only Access  
The following command defines and publishes an NFS share of /ufsfs with read-only access.

```bash
# share -F nfs -o ro /ufsfs
```

**EXAMPLE 2**  Publishing an NFS Share with Multiple Share Options  
The following command defines and publishes an NFS share of the /export/manuals file system with a netgroup called users_nfs who have read-only access and users from specified hosts who have read and write access.

```bash
# share -F nfs -o ro=users_nfs,rw=host1:host2:host3 /export/manuals
```

Files  
/etc/dfs/dfstab  
This file is obsolete. An SMF service publishes NFS or SMB shares at boot time.

/etc/dfs/fstypes  
List of file-sharing protocols. NFS is the default file sharing protocol.

Attributes  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcs</td>
</tr>
</tbody>
</table>

See Also  
mountd(1M), nfsd(1M), share_nfs(1M), share_smb(1M), shareall(1M), unshare(1M), zfs(1M), zfs(1M)attributes(5)

Notes  
If share commands are invoked multiple times on the same file system, the last share invocation supersedes the previous invocation. The options set by the last share command replace the old options. For example, if read-write permission was granted to usera on the legacy /somefs file system, then you want to grant read-write permission also to userb on /somefs, use the following syntax:

```bash
example% share -F nfs -o rw=usera:userb /somefs
```
Name  shareall, unshareall – publish or unpublish multiple shares

Synopsis  shareall [-F FSType [,FSType]...] [-] file
unshareall [-F FSType [,FSType]...]

Description  When used with no arguments, shareall publishes shares from a specified file that contains a list of share command lines. If the operand is a hyphen (-), then the share command lines are obtained from standard input. Otherwise, if neither a file nor a hyphen is specified, then shares are published from the SMF shares repository.

Shares can be specified by identifying the file system type in a comma-separated list as an argument to -F.

The unshareall command unpublishes all published file system shares. Without an -F flag, it unpublishes all distributed file system shares.

Options  -F FSType  Specify file system type. Defaults to the first entry in /etc/dfs/fstypes.

Files  /etc/dfs/dfstab

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcs</td>
</tr>
</tbody>
</table>

### Name
```
sharectl – configure and manage file sharing service
```

### Synopsis
```
sharectl [-h]

sharectl status [-h] [protocol]

sharectl get [-h] [-p property] ... protocol

sharectl set [-h] [-p property=value] ... protocol
```

### Description
The `sharectl` command operates on file-sharing protocols, such as NFS and SMB. The command sets the client and server operational properties, takes and restores configuration snapshots, and gets status of the protocol service.

The `get` and `set` subcommands (see below) require root privileges. An authorized user can use `sharectl` to set global values for NFS and SMB properties in the Solaris server management facility. See `nfs(4)` and `smb(4)`.

### Interaction with Location Profiles
The `nfsmapid_domain` property is managed in Location profiles (refer to `netcfg(1M)`) for more information about location profiles). These profiles are either fixed, meaning the network configuration is being managed in the traditional way, or reactive, meaning the network configuration is being managed automatically, reacting to changes in the network environment according to policy rules specified in the profiles.

When a fixed location (there can currently be only one, the `DefaultFixed` location) is active, changes made to the SMF repository, including those made by `sharectl`, will be applied to the location when it is disabled, and thus will be restored if that location is later re-enabled.

When a reactive location is active, changes should not be applied directly to the SMF repository; these changes will not be preserved in the location profile, and will thus be lost if the location is disabled, or if the system’s network configuration, as managed by `svc:/network/physical:default` and `svc:/network/location:default`, is refreshed or restarted. Changes should instead be applied to the location itself, using the `netcfg(1M)` command; this will save the change to the location profile repository, and will also apply it to the SMF repository (if the change is made to the currently active location).

The `nfsmapid_domain` setting is stored in the `nfsv4-domain` property of a location profile.

### Options
The following options are supported:

- `-h`
  Displays usage message.

- `-p property [=value]`
  Specifies a property. See “Subcommands,” below.

### Subcommands
`sharectl` supports the subcommands described below. The form of a `sharectl` command is:
```
# sharectl subcommand [option]
```
get [-p property] protocol

Get the property values for the specified protocol. If no -p option is provided, get all the properties for the specified protocol.

set [-p property=value]... protocol

Set properties for the specified file sharing protocol.

status [protocol]

Display status of the specified protocol, or, if no protocol is specified, of all file-sharing protocols.

**Examples**

**EXAMPLE 1**  Getting Properties

The following command gets the properties for the NFS protocol.

```
% sharectl get nfs
servers=1024
lockd_listen_backlog=32
lockd_servers=1024
lockd_retransmit_timeout=5
grace_period=90
server_versmin=2
server_versmax=4
client_versmin=2
client_versmax=4
server_delegation=on
nfsmapid_domain=oracle.com
max_connections=-1
protocol=ALL
listen_backlog=32
device=
```

The following command gets the value of the grace_period property for the NFS protocol.

```
% sharectl get -p grace_period nfs
grace_period=90
```

**EXAMPLE 2**  Setting a Property

Note in the preceding example that the minimum version of the server NFS protocol (server_versmin) is set to 2. The following command sets the minimum version number to version 3.

```
% sharectl set -p server_versmin=3 nfs
```

**EXAMPLE 3**  Obtaining Status

The following command obtains the status of all file-sharing protocols on a system.

```
% sharectl status
nfs enabled
```
EXAMPLE 4  Setting Property for SMB Server

The following command sets the value of the `server_signing_required` property for the SMB protocol.

```
% sharectl set -p server_signing_required=true smb
```

EXAMPLE 5  Setting Property for SMB Client

The following command sets the value of the `client_signing_required` property for the SMB protocol.

```
% sharectl set -p client_signing_required=true smb
```

EXAMPLE 6  Setting Tracing of RPC Calls for `autofs`

The following command expands each RPC call to `autofs` and logs it to the location specified for that service in `automountd(1M)`.

```
# sharectl set trace=1 autofs
```

Exit Status 0  Successful completion.
non-zero Command failed.

Files `/usr/include/libshare.h` Error codes used for exit status.

share_nfs(1M)

Name
share_nfs – make NFS shares available for mounting by remote systems

Synopsis
share -F nfs [-a [-o specific_options] [-d description]]
pathname [sharename] [-A]

zfs set share.nfs=on | off filesystem|share
zfs share -o share.nfs=on | off specific_options
filesystem|filesystem%share

Description
The share utility defines and publishes a NFS share, which makes a local file system available for mounting by remote systems. It starts the nfsd(1M) and mountd(1M) daemons if they are not already running.

You can use the share command to create and publish a ZFS file system share, but this is considered a legacy operation. See zfs(1M) for information about setting the share.nfs property or using the zfs share command to create and publish NFS shares.

Options
The following options are supported:

-F nfs
Specify the NFS file sharing protocol.

-a
Publish all defined shares.

-o specific_options
Specify specific_options in a comma-separated list of keywords and attribute-value-assertions for interpretation by the NFS protocol. By default, a share is published with read-write access to all clients, unless a specific option overrides the default access. specific_options can be any combination of the following:

aclok
Allows the NFS server to do access control for NFS Version 2 clients. When aclok is set on the server, maximal access is given to all clients. For example, with aclok set, if anyone has read permissions, then everyone does. If aclok is not set, minimal access is given to all clients.

anon=uid
Set uid to be the effective user ID of unknown users. By default, unknown users are given the effective user ID UID_NOPRINT. If uid is set to −1, access is denied.

charset
All clients will be assumed to be using the specified character set (see list in following description) and file and path names will be converted to UTF-8 for the server.

charset=access_list
Where charset is one of: euc-cn, euc-jp, euc-jpms, euc-kr, euc-tw, iso8859-1, iso8859-2, iso8859-5, iso8859-6, iso8859-7, iso8859-8, iso8859-9, iso8859-13, iso8859-15, koi8-r.
Clients that match the *access_list* for one of these properties will be assumed to be using that character set and file and path names will be converted to UTF-8 for the server.

**index=file**
Load file rather than a listing of the directory containing this file when the directory is referenced by an NFS URL.

**log[=tag]**
Enables NFS server logging for the specified file system. The optional tag determines the location of the related log files. The *tag* is defined in `/etc/nfs/nfslog.conf`. If no *tag* is specified, the default values associated with the *global tag* in `/etc/nfs/nfslog.conf` is used. Support of NFS server logging is only available for NFS Version 2 and Version 3 requests.

**noaclfab**
Allows NFS servers to not return fabricated ACLs to NFS clients. The default behavior for NFS servers is to fabricate ACLs. If *noaclfab* is set, then the NFS server does not fabricate ACLs, which is the appropriate choice if the underlying filesystem does not support the POSIX Draft ACL.

**none**
Access is disallowed to all clients. The *ro* or *rw* options can override *none*.

**none=access_list**
Access is not allowed to any client that matches the access list. The exception is when the access list is an asterisk (*), in which case *ro* or *rw* can override *none*.

**nosub**
Prevents clients from mounting subdirectories of shared directories. For example, if `/export` is shared with the *nosub* option on server *fooe* then a NFS client cannot do:

```
    mount -F nfs fooey:/export/home/mnt
```

NFS Version 4 does not use the MOUNT protocol. The *nosub* option only applies to NFS Version 2 and Version 3 requests.

**nosuid**
By default, clients are allowed to create files on the shared file system with the setuid or setgid mode enabled. Specifying *nosuid* causes the server file system to silently ignore any attempt to enable the setuid or setgid mode bits.

**public**
Moves the location of the public file handle from *root (/)* to the exported directory for WebNFS-enabled browsers and clients. This option does not enable WebNFS service. WebNFS is always on. Only one file system per server may use this option. Any other option, including the `-ro=list` and `-rw=list` options can be included with the *public* option.

**ro**
Share is published with read-only access to all clients.
ro=access_list
  Share is published with read-only access to the clients listed in access_list; overrides the rw suboption for the clients specified. See access_list below.

root
  Root users from all hosts have root access.

root=access_list
  Only root users from the hosts specified in access_list have root access. See access_list below. By default, no host has root access, so root users are mapped to an anonymous user ID (see the anon=uid option described above). Netgroups can be used if the file system shared is using UNIX authentication (AUTH_SYS).

root_mapping=uid
  For a client that is allowed root access, map the root UID to the specified user id.

rw
  Share is published with read and write access to all clients.

rw=access_list
  Share is published with read and write access to the clients listed in access_list; overrides the ro suboption for the clients specified. See access_list below.

sec=mode[:mode]... 
  Publishes a share by using one or more of the specified security modes. The mode in the sec=mode option must be a node name supported on the client. If the sec= option is not specified, the default security mode used is AUTH_SYS. Multiple sec= options can be specified on the command line, although each mode can appear only once. The security modes are defined in nfssec(5).

  Each sec= option specifies modes that apply to any subsequent window=, rw, ro, rw=, ro= and root= options that are provided before another sec=option. Each additional sec= resets the security mode context, so that more window=, rw, ro, rw=, ro= and root= options can be supplied for additional modes.

sec=none
  If the option sec=none is specified when the client uses AUTH_NONE, or if the client uses a security mode that is not one that the file system is shared with, then the credential of each NFS request is treated as unauthenticated. See the anon=uid option for a description of how unauthenticated requests are handled.

secure
  This option has been deprecated in favor of the sec=dh option.

window=value
  When a share is published with sec=dh, set the maximum life time (in seconds) of the RPC request's credential (in the authentication header) that the NFS server allows. If a credential arrives with a life time larger than what is allowed, the NFS server rejects the request. The default value is 30000 seconds (8.3 hours).
- d description
  Provide a comment that describes the file system to be shared.

- A
  Display all defined shares.

access_list The access_list argument is either the string “*” to represent all hosts or a colon-separated list
whose components may be any number of the following:

hostname
  The name of a host. With a server configured for DNS or LDAP naming in the nsswitch
hosts entry, any hostname must be represented as a fully qualified DNS or LDAP name.
  The hostname specified must be the canonical name for this host and must match the
  hostname returned on the reverse lookup of the incoming IP address of the NFS client.

netgroup
  A netgroup contains a number of hostnames. With a server configured for DNS or LDAP
  naming in the nsswitch hosts entry, any hostname in a netgroup must be represented as a
  fully qualified DNS or LDAP name.

domain name suffix
  To use domain membership the server must use DNS or LDAP to resolve hostnames to IP
  addresses; that is, the hosts entry in the /etc/nsswitch.conf must specify dns or ldap
  ahead of nis, since only DNS and LDAP return the full domain name of the host. Other
  name services like NIS cannot be used to resolve hostnames on the server because when
  mapping an IP address to a hostname they do not return domain information. For
  example,

  NIS   172.16.45.9  --> "myhost"
    and:

  DNS or LDAP 172.16.45.9  -->
      "myhost.mydomain.mycompany.com"

  The domain name suffix is distinguished from hostnames and netgroups by a prefixed dot.
  For example,

  rw = .mydomain.mycompany.com

  A single dot can be used to match a hostname with no suffix. For example,

  rw = .

  matches mydomain but not mydomain.mycompany.com. This feature can be used to match
  hosts resolved through NIS rather than DNS and LDAP.

network
  The network or subnet component is preceded by an at-sign (@). It can be either a name or
  a dotted address. If a name, it is converted to a dotted address by
  getnetbyname(3SOCKET). For example,
would be equivalent to:

@172.16 or @172.16.0.0

The network prefix assumes an octet-aligned netmask determined from the zeroth octet in the low-order part of the address up to and including the high-order octet, if you want to specify a single IP address (see below). In the case where network prefixes are not byte-aligned, the syntax allows a mask length to be specified explicitly following a slash (/) delimiter. For example,

@172.16.132/22

...where the mask is the number of leftmost contiguous significant bits in the corresponding IP address.

When specifying individual IP addresses, use the same notation described above, without a netmask specification. For example:

@172.16.132.14

Multiple, individual IP addresses would be specified, for example, as:

root=@172.16.132.20:@172.16.134.20

A prefixed minus sign (−) denies access to that component of access_list. The list is searched sequentially until a match is found that either grants or denies access, or until the end of the list is reached. For example, if host terra is in the engineering netgroup, then

rw=terra:engineering

denies access to terra but

rw=engineering:-terra

grants access to terra.

Operands

The following operands are supported:

pathname

The pathname of the file system to be shared.

Examples

EXAMPLE 1 Define and Publish an NFS Share

The following example shows how to use the legacy share command to define and publish the /export/manuals file system share.

# share -F NFS /export/manuals

The following example shows how to use the zfs set command to share a ZFS file system.

# zfs set share.nfs=on tank/data
EXAMPLE 1  Define and Publish an NFS Share  (Continued)

The following example shows how to create a named NFS share, tank/public%pubshare, with the share.nfs.public option rather than setting this option on the ZFS file system, tank/public, because this property is not inheritable.

```
# zfs create -o mountpoint=/pub tank/public
# zfs share -o share.nfs=on -o share.nfs.public=on tank/public%pubshare
```

Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Files  /etc/dfs/fstypes
      list of system types, NFS by default

/etc/dfs/sharetab
      system record of shared file systems

/etc/nfs/nfslogtab
      system record of logged file systems

/etc/nfs/nfslog.conf
      logging configuration file

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/file-system/nfs</td>
</tr>
</tbody>
</table>

See Also  mount(1M), mountd(1M), nfsd(1M), nfslogd(1M), share(1M), unshare(1M),
zfs_share(1M), getnetbyname(3SOCKET), nfslog.conf(4), netgroup(4), attributes(5),
nfssec(5)

Notes  Creating and publishing an NFS share with the share command is permanent until the share is unshared. Publishing NFS shares is managed by the following SMF service:

```
$ svcs | grep share
online  Mar_07  svc:/network/shares:default
```

If the file system being shared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) are shared. For example, if /export/foo is a symbolic link to /export/bar (/export/foo -> /export/bar), the following share command results in /export/bar as the shared pathname (and not /export/foo).

```
# share -F nfs /export/foo
```
An NFS mount of `server:/export/foo` results in `server:/export/bar` really being mounted.

The `mountd(1M)` process allows the processing of a path name the contains a symbolic link. This allows the processing of paths that are not themselves explicitly shared with `share nfs`. For example, `/export/foo` might be a symbolic link that refers to `/export/bar` which has been specifically shared. When the client mounts `/export/foo` the `mountd` processing follows the symbolic link and responds with the `/export/bar`. The NFS Version 4 protocol does not use the `mountd` processing and the client’s use of `/export/foo` does not work as it does with NFS Version 2 and Version 3 and the client receives an error when attempting to mount `/export/foo`. 
Name

share_smb – make SMB shares available for mounting by remote systems

Synopsis

share -F smb [-a [-o specific-options] [-d description]

pathname sharename | [-A]]

zfs set share.smb=on | off filesystem|filesystem%share

zfs share -o share.smb=on | off specific_options

filesystem|filesystem%share

Description

The share command defines and publishes a SMB share, which makes a local file system available for mounting by remote systems.

You can modify the behavior of SMB shares by setting property values with either the share, the zfs set command or the zfs share command. See the share(1M) and zfs(1M) man pages.

The share command has the following options:

- F smb
  Share SMB file sharing protocol.

- a
  Publish all defined shares.

- o specific-options
  Specify specific-options in a comma-separated list of keywords and attribute-value-assertions for interpretation by the SMB protocol. By default, a share is published with read-write access to all clients, unless a specific option overrides the default access. specific-options can be any combination of the properties supported by a given file system.

- d description
  Provide a comment that describes the file system to be shared.

- A
  Display all defined shares.

Share Properties

The following SMB share properties are supported and can be set by the zfs and share commands:

abe=boolean
  Sets the access-based enumeration (ABE) policy for a share. When set to true, ABE filtering is enabled on this share and directory entries to which the requesting user has no access will be omitted from directory listings returned to the client. When set to false or not defined, ABE filtering will not be performed on this share. This property is not defined by default.

false
  Disable ABE for this share.
true
   Enable ABE for this share.

ad-container
   Specifies the AD container in which to publish shares.

   The AD container is specified as a comma-separated list of attribute name-value pairs
   using the LDAP distinguished name (DN) or relative distinguished name (RDN) format.

   The following example uses the share command to specify the AD container:
   ```
   $ share -F smb -o abe=true,ad-container=cn=sales,ou=mycompany,dc=com /export/home
   ```

   The following example uses the zfs share command to specify the AD container:
   ```
   $ zfs share -o share.smb=on -o share.smb.ad-container=cn=sales,ou=mycompany,dc=com -o share.smb.abe=on rpool/
   ```

   The DN or RDN must be specified in LDAP format using the cn=, ou=, and dc= prefixes:
   - cn represents the common name
   - ou represents the organizational unit
   - dc represents the domain component

   cn=, ou= and dc= are attribute types. The attribute type used to describe an object’s RDN is
called the naming attribute, which, for ADS, includes the following object classes:
   - cn for the user object class
   - ou for the organizational unit (OU) object class
   - dc for the domainDns object class

   catia=boolean
   Specifies whether to perform CATIA character substitution. CATIA V4 uses characters in
   file names that are considered to be invalid by Windows. A CATIA V4 file could be
   inaccessible to Windows clients if the file name contains any of the characters that are
   considered illegal in Windows. By default, CATIA character substitution is not performed.

   If the catia property is set to true, the following character substitution is applied to file
   names.

<table>
<thead>
<tr>
<th>CATIA</th>
<th>V4 UNIX</th>
<th>CATIA</th>
<th>V5 Windows</th>
</tr>

</tr>
</tbody>
</table>
**csc=value**
Sets the client-side caching policy for a share. Client-side caching is a client feature and offline files are managed entirely by the clients.

The following are valid values for the **csc** property:
- **manual** – Clients are permitted to cache files from the specified share for offline use as requested by users. However, automatic file-by-file reintegration is not permitted. manual is the default value.
- **auto** – Clients are permitted to automatically cache files from the specified share for offline use and file-by-file reintegration is permitted.
- **vdo** – Clients are permitted to automatically cache files from the specified share for offline use, file-by-file reintegration is permitted, and clients are permitted to work from their local cache even while offline.
- **disabled** – Client-side caching is not permitted for this share.

**dfsroot=boolean**
Marks a share as a distributed file system (DFS) root share to distinguish it from a regular share. By default, **dfsroot** is not defined. If **dfsroot** is **false** or not defined, the share is not a DFS root share.

**guestok=boolean**
Sets the guest access policy for the share. When set to **true** guest access is allowed on this share. When set to **false** or not defined guest access is not allowed on this share. This property is not defined by default.

An **idmap(1M)** name-based rule can be used to map guest to any local user name, such as **guest** or **nobody**. If the local account has a password in **/var/smb/smbpasswd** the guest connection will be authenticated against that password. Any connection made using an account that maps to the local guest account will be treated as a guest connection.

The following name-based rule maps the Windows **Guest** user to the UNIX **guest** user:

```
# idmap add winname:Guest unixuser:guest
```

**none=access-list**
Specifies that access is not allowed to any client that matches the access list. The exception is when the access list is an asterisk (***”), in which case **ro** or **rw** can override **none**.

**ro=access-list**
Specifies that sharing is read-only to the clients listed in **access-list**. Overrides the **rw** suboption for the clients specified. See **access-list**.

**rw=access-list**
Specifies that sharing is read-write to the clients listed in **access-list**. Overrides the **ro** suboption for the clients specified. See **access-list**.
The access-list argument is either the string "+" to represent all hosts or a colon-separated list whose components may be any number of the following:

**hostname**
Specifies the name of a host. hostname must be a fully qualified DNS or LDAP name when the host specifies these naming schemes in the hosts portion of the /etc/nsswitch.conf file.

**netgroup**
A netgroup contains a number of host names. Any hostname in a netgroup must be a fully qualified DNS or LDAP name when the host specifies these naming schemes in the hosts portion of the /etc/nsswitch.conf file.

**domainname.suffix**
To use domain membership, the server must use DNS or LDAP to resolve host names to IP addresses. This means that the hosts entry of the /etc/nsswitch.conf file must specify dns or ldap before nis. You must do this because only DNS and LDAP return the full domain name of the host.

Other naming services, such as NIS, cannot be used to resolve host names on the server because these naming services do not return domain information. For example, the following shows how NIS, DNS, and LDAP return host name information for the 172.16.45.9 IP address:

NIS Returns: myhost
DNS or LDAP Returns: myhost.mydomain.mycompany.com

The domain name suffix is distinguished from host names and netgroups by a prefixed dot. For example, rw=.mydomain.mycompany.com matches all host names in mydomain.mycompany.com.

The rw=. notation uses a single dot to match a host name that has no suffix. This notation matches mydomain but not mydomain.mycompany.com. This feature can be used to match hosts that are resolved by NIS rather than by DNS and LDAP.

**network**
The network or subnet component is preceded by an at-sign character (@). It can be either a network name or a dotted address.

A network name is converted to a dotted address by using getnetbyname(3SOCKET). For example, =@mynet is equivalent to =@172.16 or =@172.16.0.0.

The network prefix assumes an octet-aligned netmask. The netmask is determined from the zeroth octet in the low-order part of the address up to and including the high-order octet. If network prefixes are not byte-aligned, the syntax permits a mask length to be explicitly specified following a slash delimiter (/). For example, =@ethernext/17 or =@172.16.132/22 where the mask is the number of leftmost contiguous significant bits in the corresponding IP address.
When specifying individual IP addresses, use the same @ notation described previously, but do not use a netmask specification. For example, =@172.16.132.14.

You can use a colon character (:) to separate multiple, individual IP addresses. For example, root=@172.16.132.20:@172.16.134.20.

A prefixed minus sign (−) denies access to that component of access-list. The list is searched sequentially until a match is found that either grants or denies access, or until the end of the list is reached. For example, if host terra is in the engineering netgroup, specifying rw=-terra:engineering denies access to terra. However, specifying rw=engineering:-terra grants access to terra.

**Examples**

**EXAMPLE 1** Setting a Share Property

The following examples use the `zfs share` and `share` commands to create and publish an SMB share.

- The following example shows how to use the `zfs share` command to create and publish an SMB share that also enables guest access:
  
  ```
  # zfs share -o share.smb=on -o share.smb.guestok=on tank/home%hshare
  ```

- The following example shows how to use the `share` command to enable guest access on a share:
  
  ```
  # share -F smb -o guestok=true /tank/home
  ```

**EXAMPLE 2** Viewing the Share Properties

The following examples show how to use the `zfs get` command and the `/etc/dfs/sharetab` file to view share properties:

- The `zfs get` command enables you to view share properties on the tank/home dataset:
  
  ```
  # zfs get share.smb tank/home%hshare
  NAME    PROPERTY     VALUE     SOURCE
  tank/home%hshare share.smb on local
  ```

- The `/etc/dfs/sharetab` file shows all the active shares on the system. The entry for each share shows the properties set and their values:
  
  ```
  # grep home /etc/dfs/sharetab
  /tank/home  hshare  smb  guestok
  ```

**Files**

`/etc/dfs/sharetab`

System record of shared file systems

showmount(1M)

Name showmount – show remote mounts

Synopsis /usr/sbin/showmount [-ade] [hostname]

Description showmount lists the clients that have remotely mounted a filesystem from host. This information is maintained by the mountd(1M) server on host, and is saved across crashes in the file /etc/rmtab. The default value for host is the value returned by hostname(1).

The showmount command does not display the names of NFS Version 4 clients.

Options -a Print all remote mounts in the format:
    hostname : directory

    where hostname is the name of the client, and directory is the root of the file system that has been mounted.

    -d List directories that have been remotely mounted by clients.

    -e Print the list of shared file systems.

Files /etc/rmtab

Installing Oracle Solaris 11.1 Systems

Bugs If a client crashes, its entry is removed from the list of remote mounts on the server.
shutdown is executed by the super user to change the state of the machine. In most cases, it is used to change from the multi-user state (state 2) to another state.

By default, shutdown brings the system to a state where only the console has access to the operating system. This state is called single-user.

Before starting to shut down daemons and killing processes, shutdown sends a warning message and, by default, a final message asking for confirmation. message is a string that is sent out following the standard warning message:

The system will be shut down in ...

If the string contains more than one word, it should be contained within single (') or double ("), quotation marks.

The warning message and the user provided message are output when there are 7200, 3600, 1800, 1200, 600, 300, 120, 60, and 30 seconds remaining before shutdown begins. See EXAMPLES.

System state definitions are:

state 0 Stop the operating system.

state 1 State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.

state s, S State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.

state 5 Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The rc0 procedure is called to perform this task.

state 6 Stop the operating system and reboot to the state defined by the initdefault entry in /etc/inittab. The rc6 procedure is called to perform this task.

Options -y

Pre-answer the confirmation question so the command can be run without user intervention.
-g grace-period
   Allow the super user to change the number of seconds from the 60-second default.

-i init-state
   If there are warnings, init-state specifies the state init is to be in. By default, system state ‘s’ is used.

-r
   Equivalent to specifying -16.

Examples

   EXAMPLE 1 Using shutdown

   In the following example, shutdown is being executed on host foo and is scheduled in 120 seconds. The warning message is output 2 minutes, 1 minute, and 30 seconds before the final confirmation message.

   example# shutdown -i S -g 120 "====== disk replacement ======
   Shutdown started. Tue Jun 7 14:51:40 PDT 1994

   Broadcast Message from root (pts/1) on foo Tue Jun 7 14:51:41. . .
   The system will be shut down in 2 minutes
   ====== disk replacement ======
   Broadcast Message from root (pts/1) on foo Tue Jun 7 14:52:41. . .
   The system will be shut down in 1 minutes
   ====== disk replacement ======
   Broadcast Message from root (pts/1) on foo Tue Jun 7 14:53:41. . .
   The system will be shut down in 30 seconds
   ====== disk replacement ======
   Do you want to continue? (y or n):

Attributes

   See attributes(5) for descriptions of the following attributes:

   +--------------------------------+------------------+
   | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
   +--------------------------------+------------------+
   | Availability | system/core-os |
   +--------------------------------+------------------+

See Also

   boot(1M), halt(1M), init(1M), killall(1M), reboot(1M), ufsdump(1M), init.d(4),
   inittab(4), nologin(4), attributes(5)

Notes

   When a system transitions down to the S or s state, the /etc/nologin file (see nologin(4)) is created. Upon subsequent transition to state 2 (multi-user state), this file is removed by a script in the /etc/rc2.d directory.
slpd – Service Location Protocol Daemon

/usr/lib/inet/slpd [-f configuration-file]

The slpd daemon provides common server functionality for the Service Location Protocol ("SLP") versions 1 and 2, as defined by IETF in RFC 2165 and RFC 2608. SLP provides a scalable framework for the discovery and selection of network services.

slpd provides the following framework services:

Directory Agent
This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. slpd does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained.

Service Agent Server
All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, slpd is a service agent server.

Passive Directory Agent Discovery
This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query slpd, obviating the need to perform discovery by means of multicast. By default, slpd performs this service.

Proxy Registration
This service can act as a proxy service agent for services that cannot register themselves. slpd reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.

All configuration options are available from the configuration file. slpd reads its configuration file upon startup.

Stop and start the slpd daemon using svcadm(1M). Use the command svcadm enable network/slp to start the slpd daemon. Use the command svcadm disable network/slp to stop it.

The file /etc/inet/slp.conf must exist before the slp service can start the daemon. Only the example file /etc/inet/slp.conf.example is present by default. To enable SLP, copy /etc/inet/slp.conf.example to /etc/inet/slp.conf.
The following options are supported:

- `-f configuration-file` Specify an alternate configuration file

Examples

**Example 1** Stopping the slpd daemon

The following command stops the slpd daemon:

```
example# svcadm disable network/slp
```

**Example 2** Restarting the slpd daemon

The following command restarts the slpd daemon:

```
example# svcadm restart network/slp
```

Files

- `/etc/inet/slp.conf` The default configuration file
- `/slpd.reg` The proxy registration file

*Oracle Solaris Administration: Network Services*

Notes

The slpd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/slp
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
Name: smattrpop – populate security attribute databases in a name service

Description: The smattrpop command updates the auth_attr(4), exec_attr(4), prof_attr(4), and user_attr(4) role-based access control databases in a target NIS, LDAP, or local /etc files nameservice from the corresponding databases in a source name service or files.

This command processes the table entries from the source database and merges each source entry field into the same field in the corresponding table entry in the target database. If a source entry does not exist in the target database, the entry is created. If the source entry exists in the target database, the fields are merged or replaced according to the command options.

Any errors encountered while updating the target entry are reported to stdout, and the command continues with the next source database entry.

Options: The following options are supported:

- **-c**  Performs cross-table checking. If you specify this option and a check error occurs, a message identifying the check error is written to stdout.

  The target entry values are checked against entries in related databases:
  - **auths** values — Each value must exist as the name of an authorization in the auth_attr(4) database.
  - **profiles** values — Each value must exist as a name of a profile in the prof_attr(4) database.
  - **roles** values — Each value must exist as the name of a role identity in the user_attr(4) database.
    - For each exec_attr(4) entry in the source database, the name must exist as the name of a profile in the prof_attr(4) database.

- **-f**  Specifies that the value in each field in the source entry replaces the value in the corresponding field in the target entry, if the source entry field has a non-empty value.

- **-m**  For the auths, profiles, and roles attributes, specifies that the values in each field in the source entry are merged with the values in the corresponding target entry field. If a source value does not exist in the target field, the value is appended to the set of target values. If the target field is empty, the source values replace the target field. The attribute values that merge depend on the database being updated:
  - **prof_attr(4)** — the auths and profiles attribute values are merged.
  - **user_attr(4)** — the auths, profiles, and roles attribute values are merged.
  - **exec_attr(4)** — the uid, gid, euid, and egid values are merged.
-p policy  Specifies the value of the policy field in the exec_attr(4) database. Valid values are suser (standard Solaris superuser) and tsol (Trusted Solaris). If you specify this option, only the entries in the source exec_attr database with the specified policy are processed. If you omit this option, all entries in the source exec_attr database are processed.

-r  Specifies that role identities in the user_attr(4) database in the source name service are processed. If you omit this option, only the normal user entries in the user_attr source database are processed.

-s scope  Specifies the source name service or local file directory for database updates, using the following syntax:

```
type:/server/domain
```

where type indicates the type of name service. Valid values for type are:

- file — local files
- nis — NIS name service
- ldap — LDAP name service

server indicates the local host name of the Solaris system on which the smattrpop command is executed, and on which both the source and target databases exist.

domain specifies the management domain name for the name service.

You can use two special cases of scope values:

- To indicate the databases in the /etc/security local system directory, use the scope file:/server, where server is the name of the local system.
- To load from databases in an arbitrary directory on the Solaris server, use the scope file:/server/pathname, where where server is the name of the local system and pathname is the fully-qualified directory path name to the database files.

-t scope  Specifies the target name service or local file directory for database updates, using the following syntax:

```
type:/server/domain
```

where type indicates the type of name service. Valid values for type are:

- file — local files
- nis — NIS name service
- ldap — LDAP name service

server indicates the local host name of the Solaris system on which the smattrpop command is executed, and on which both the source and target databases exist.

domain specifies the management domain name for the name service.
You can use two special cases of `scope` values:

- To indicate the databases in the `/etc/security` local system directory, use the scope file: `/server`, where `server` is the name of the local system.
- To update to databases in an arbitrary directory on the Solaris server, use the scope file: `/server/pathname`, where `server` is the name of the local system and `pathname` is the fully-qualified directory path name to the database files.

`-v` Specifies that verbose messages are written. A message is written to `stdout` for each entry processed.

**Operands**

The following operands are supported:

- `database`: Populates one or all databases. You can specify either the name of the database you want to process (for example, `auth_attr`), or `all` to process all databases. If you specify `all`, the databases are processed in the following order:
  1. `auth_attr`
  2. `prof_attr`
  3. `exec_attr`
  4. `user_attr`

**Examples**

**EXAMPLE 1** Populating all tables in the NIS name service

The following example merges the values from all four attribute databases in the `/etc/security` directory of the local system into the corresponding tables in the NIS domain, `east.example.com`. The command is executed on the master server, `hoosier`, for the NIS domain and the source files are in the `/etc` and `/etc/security` directories on the NIS master server. No cross-table checking is performed. A summary message indicating the number of entries processed and updated for each table is written to `stdout`.

```
/usr/sadm/bin/smattrpop -s file:/hoosier \ 
    -t nis:/hoosier/east.example.com all
```

**Environment Variables**

See `environ(5)` for a description of the JAVA_HOME environment variable, which affects the execution of the smattrpop command. If this environment variable is not specified, the `/usr/java` location is used.

**Exit Status**

Any errors encountered while updating the target entry are reported to `stdout`. The following exit values are returned:

- 0 The specified tables were updated. Individual entries may have encountered checking errors.
- 1 A syntax error occurred in the command line.
- 2 A fatal error occurred and the tables were not completely processed. Some entries may have been updated before the failure.

smbadm join -u username [-o organizational-unit] domain

smbadm join -w workgroup

smbadm lookup-server //server

smbadm lookup-user [-u username] name | SID

smbadm print [-u username] //server/share {print_file| -}

smbadm remove-key [-u username ]

smbadm remove-member -m member [[-m member] ...] group

smbadm rename-group group new-group

smbadm set-group -p property=value [[-p property=value] ...] group

smbadm show-connections [-t] [-u username] [-c computename | -s sharename] server

smbadm show-domains

smbadm show-files [-t] [-u username] server

smbadm show-groups [-m] [-p] [group]

smbadm show-sessions [-t] [-u username] server

smbadm show-shares [-t] [-A | -u username] server

**Description**

The `smbadm` command is used to configure SMB local groups, to manage domain membership, to manage persistent password information, and issue various commands. You can also use the `smbadm` command to enable or disable SMB password generation for individual local users.

SMB local groups can be used when Windows accounts must be members of some local groups and when Windows-style privileges must be granted. Solaris local groups cannot provide these functions.
There are two types of local groups: user defined and built-in. Built-in local groups are predefined local groups to support common administration tasks.

In order to provide proper identity mapping between SMB local groups and Solaris groups, an SMB local group must have a corresponding Solaris group. This requirement has two consequences: first, the group name must conform to the intersection of the Windows and Solaris group name rules. Thus, an SMB local group name can be up to eight (8) characters long and contain only lowercase characters and numbers. Second, a Solaris local group has to be created before an SMB local group can be created.

Built-in groups are standard Windows groups and are predefined by the SMB service. The built-in groups cannot be added, removed, or renamed, and these groups do not follow the SMB local group naming conventions.

When the SMB server is started, the following built-in groups are available:
- **Administrators**
  Group members can administer the system.
- **Backup Operators**
  Group members can bypass file access controls to back up and restore files.
- **Power Users**
  Group members can share directories.

Solaris local users must have an SMB password for authentication and to gain access to SMB resources. This password is created by using the `passwd(1)` command when the `pam_smb_password` module is added to the system’s PAM configuration. See the `pam_smb_passwd(5)` man page.

The `disable-user` and `enable-user` subcommands control SMB password-generation for a specified local user. When disabled, the user is prevented from connecting to the Solaris SMB service. By default, SMB password-generation is enabled for all local users.

To reenable a disabled user, you must use the `enable-user` subcommand and then reset the user’s password by using the `passwd` command. The `pam_smb_password.so.1` module must be added to the system’s PAM configuration to generate an SMB password.

**Escaping Backslash Character**

For the `add-member`, `remove-member`, and `join` (with `-u`) subcommands, the backslash character (`\`) is a valid separator between member or user names and domain names. The backslash character is a shell special character and must be quoted. For example, you might escape the backslash character with another backslash character: `domain\username`. For more information about handling shell special characters, see the man page for your shell.

**Operands**

The `smbadm` command uses the following operands:

- **domain**
  Specifies the name of an existing Windows domain to join.
**group**
Specifies the name of the SMB local group.

**username**
Specifies the name of a Windows user. *username* can be specified in any of the following formats:

- `domain\username[+password]`
- `domain/username[+password]`
- `username@domain`
- `username`

...where *domain* can be the NetBIOS or DNS domain name.

**server**
Specifies the name or IP address of the local host.

---

**Sub-commands**

The `smbadm` command includes these subcommands:

**add-key [-u username]**
Specifies persistent password information to be used for an SMB server user account. When you specify this information, mounts can be done without a password prompt in non-Kerberos configurations. Kerberos sites should use Kerberos automatically, not prompt for a password. If a default domain is available in SMF, the domain can be omitted. If a user name is not specified, the Solaris user account name is used. An encrypted (hashed) password can also be used, see the `crypt` subcommand. The command can also read a password from standard input, prompting if standard input is a TTY.

Passwords can also be stored for a specific server by using a server name in place of the domain name.

The persistent password information will also be stored in `/var/smb/smbfspasswd` for the user running the command.

**add-member -m member [-m member] ... group**
Adds the specified member to the specified SMB local group. The `-m member` option specifies the name of an SMB local group member. The member name must include an existing user name and an optional domain name.

Specify the member name in either of the following formats:

- `domain\username`
- `domain/username`

For example, a valid member name might be `sales\terry` or `sales/terry`, where `sales` is the Windows domain name and `terry` is the name of a user in the `sales` domain.

**create-group [-d description] group**
Creates an SMB local group with the specified name. You can optionally specify a description of the group by using the `-d` option.
crypt
Creates a hash of a password. This subcommand prompts for a password and writes the hash to standard output. This hash value is suitable for use as a value for the encrypted password option for smbios mount and various smbadm subcommands.

delete-group group
Deletes the specified SMB local group. The built-in groups cannot be deleted.

disable-user username
Disables SMB password-generation capabilities for the specified local user. A disabled local user is prevented from accessing the system by means of the SMB service. When a local user account is disabled, you cannot use the passwd command to modify the user’s SMB password until the user account is reenabled.

enable-user username
Enables SMB password-generation capabilities for the specified local user. After the password-generation capabilities are reenabled, you must use the passwd command to generate the SMB password for the local user before he can connect to the SMB service.

The passwd command manages both the Solaris password and SMB password for this user if the pam_smb_passwd module has been added to the system’s PAM configuration.

get-group [...] group
Retrieves property values for the specified group. If no property is specified, all property values are shown.

join -u username [-o organizational-unit] domain
Joins a Windows domain or a workgroup.

The default mode for the SMB service is workgroup mode, which uses the default workgroup name, WORKGROUP.

An authenticated user account is required to join a domain, so you must specify a Windows user name with the -u option. If the password is not specified on the command line, the user is prompted for it. The following users are allowed to perform domain join:

- Domain administrator. Can join any number of systems to the domain with machine trust accounts placed in any containers.
- Delegated administrator with authority over one or more OUs. Can join any number of systems to a domain with machine account location designated in the OUs they are responsible for.
- Normal user with machine accounts pre-staged by administrator. Can join a system to the domain as pre-authorized by an administrator.
- Normal user. Normally authorized to join a limited number of systems. For more details see the Active Directory documentation and consult the Active Directory domain administrator.

username and domain can be entered in any of the following formats:
username[+password] domain
domain\username[+password]
domain/username[+password]
username@domain

...where domain can be the NetBIOS or DNS domain name.

By default, a machine trust account for the system will be automatically created in the
default container for computer accounts (cn=Computers) as part of the domain join
operation if the account does not already exist in Active Directory.

The -o organizational-unit option specifies an alternative organizational unit in which the
system’s machine trust account will be created.

If the system’s computer account already exists, you do not need to specify the -o option. A
warning will be given if the OU specified is not the one that the account is in.

The organizational-unit is specified as a comma-separated list of one or more name-value
pairs using the domain-relative distinguished name (DN) format, for example,
'ou=innerOU,ou=outerOU'.

The following reserved characters when specified in an attribute value must be escaped
using the backslash character (\). The backslash character is a shell special character and so
distinguished names that contain the following reserved characters must be quoted. It is
recommended to use single quotes as opposed to double quotes because backslash enclosed
by double quotes can retain its special meaning in some cases. For more information about
handling shell special characters, see the man page for your shell.

<table>
<thead>
<tr>
<th>Reserved</th>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>comma</td>
<td>,</td>
<td></td>
</tr>
<tr>
<td>plus</td>
<td>+</td>
<td></td>
</tr>
<tr>
<td>double quote</td>
<td>*</td>
<td></td>
</tr>
<tr>
<td>backslash</td>
<td>\</td>
<td></td>
</tr>
<tr>
<td>left angle bracket</td>
<td>&lt;</td>
<td></td>
</tr>
<tr>
<td>right angle bracket</td>
<td>&gt;</td>
<td></td>
</tr>
<tr>
<td>semicolon</td>
<td>;</td>
<td></td>
</tr>
<tr>
<td>equals sign</td>
<td>=</td>
<td></td>
</tr>
<tr>
<td># character at the beginning of a string</td>
<td>#</td>
<td></td>
</tr>
</tbody>
</table>

For example, in the following hierarchy:

dc=com
dc=mycompany
ou=Departments
ou=Engineering
ou=Payables, Receivables, and Payroll
If the machine trust account is intended to be created in the sub-OU named engineering, the organizational-unit should be specified as:

```
ou=Engineering,ou=Departments
```

If the machine trust account is intended to be created in the second sub-OU, the organizational-unit should be specified with backslashes and enclosed in single quotes as follows:

```
ou=Payables\,Receivables\,and Payroll,ou=Departments'
```

**join -w workgroup**

Joins a Windows domain or a workgroup.

The `-w workgroup` option specifies the name of the workgroup to join when using the `join` subcommand.

**lookup-server //server**

Resolves the specified server to IP address, NetBIOS domain, and NetBIOS server name. `server` can be one of the following:

- NetBIOS hostname
- DNS hostname
- IP address

**lookup-user [ -u username] name | SID**

Resolves information about the name or SID of an account in the current domain or any trusted domain.

**print [ -u username] //server/share {print_file|}**

Print file to the specified remote printer. If `print_file` is a hyphen (`-`), read standard input. If a default domain is available in SMF, the domain can be omitted. If a user name is not specified, the Solaris user account name is used. An encrypted (hashed) password can also be used, see `crypt` subcommand. The command can also take a password through redirection.

**remove-key [ -u username]**

Erases the passwords for the user running the command. The passwords in `/var/smb/smbfspasswd` will also be deleted for the user running the command.

The username and domain name portions of the name are optional. If a default domain is available in SMF, the domain can be omitted. If a `username` is not specified, all of the keys that are stored for the user who is running the command will be deleted.

If the user's password is stored for a specific server, the server name should be specified in place of the domain name.
remove -m member [[-m member] …] group
Removes the specified member from the specified SMB local group. The -m member option specifies the name of an SMB local group member. The member name must include an existing user name and an optional domain name.

Specify the member name in either of the following formats:
[domain\]username
[domain/]username
For example, a valid member name might be sales\terry or sales/terry, where sales is the Windows domain name and terry is the name of a user in the sales domain.

rename -g group new-group
Renames the specified SMB local group. The group must already exist. The built-in groups cannot be renamed.

set -g -p property=value [[-p property=value] …] group
Sets configuration properties for an SMB local group. The description and the privileges for the built-in groups cannot be changed.

The -p property=value option specifies the list of properties to be set on the specified group.

The group-related properties are as follows:
backup=[on|off]
Specifies whether members of the SMB local group can bypass file access controls to backup file system objects.
description=description-text
Specifies a text description for the SMB local group.
restore=[on|off]
Specifies whether members of the SMB local group can bypass file access controls to restore file system objects.
take-ownership=[on|off]
Specifies whether members of the SMB local group can take ownership of file system objects.

show-domains
Shows information about the current workgroup or domain. The information typically includes the workgroup name or the primary domain name. When in domain mode, the information includes domain controller names and trusted domain names.

Each entry in the output is identified by one of the following tags:
- [*] Primary domain
- [.] Local domain
- [-] Other domains
- [+ ] Selected domain controller
show-groups [-m] [-p] [group]
Shows information about the specified SMB local group or groups. If no group is specified, information is shown for all groups. If the -m option is specified, the group members are also shown. If the -p option is specified, the group privileges are also shown.

The following set of subcommands shows information about the user shares, sessions, connections, and open files on a local or a remote server.

An authenticated user account is required to show the types of data listed above, so you must specify the Windows administrative user name with the -u option. If the password is not specified on the command line, the user is prompted for it. This user should be the domain administrator or a user who has administrative privileges for the target domain. If a user name is not specified, the Solaris user account name is used.

The \textit{username} can be in any of the formats described under “Operands”.

\begin{Verbatim}
show-connections [-t] [-u username] [-c computename] [-s sharename] server
\end{Verbatim}
Shows information about the SMB tree connections made on the server. The -c option specifies the computer name for connections of interest to the client. The -s option specifies the share name for connections of interest to the client. The -t option specifies the command header to be displayed.

\begin{Verbatim}
show-files [-t] [-u username] server
\end{Verbatim}
Shows information about the files open over SMB on the server. The -t option specifies the command header to be displayed.

\begin{Verbatim}
show-sessions [-t] [-u username] server
\end{Verbatim}
Shows information about the SMB user sessions on the server. The -t option specifies command header to be displayed.

\begin{Verbatim}
show-shares [-t] [-A] [-u username] server
\end{Verbatim}
Shows information about the SMB shares on the server. The -t option specifies the command header to be displayed. The -A option specifies anonymous user.

\textbf{Exit Status}  The following exit values are returned:

\begin{itemize}
\item \textbf{0}  Successful completion.
\item \textbf{>0}  An error occurred.
\end{itemize}

smbd(1M)

Name smbd – SMB server daemon

Synopsis /usr/lib/smbd

Description The smbd daemon handles CIFS/SMB requests from SMB clients, such as Windows clients. Only processes with (PRIV_SYS_SMB) and sufficient privileges to write the /var/run directory can run this daemon.

The smbd daemon is automatically invoked by using the share(1M) command or the zfs(1M) set share command over all available transports. By default, smbd starts over the NetBIOS-Over-TCP (NBT) and TCP transports.

When smbd is started over NBT, the following services are started:
- The NetBIOS name service is started on UDP port 137.
- The NetBIOS datagram service is started on UDP port 138.
- The NetBIOS session service is started on TCP port 139.

When the smbd daemon is started over TCP, the SMB service is started on TCP port 445.

Only one instance of smbd may be running at a time.

Exit Status The following exit values are returned:

- 0 Daemon exited cleanly.
- 95 Daemon exited with a fatal error.
- 96 Daemon exited with a configuration error.

Attributes See the attributes(5) man page for descriptions of the following attributes:

Notes Use the svcadm command to perform administrative actions on the smbd service, such as enabling, disabling, or restarting the service. Use the svcs command to query the service status.

The smbd service is managed by the service management facility under the service identifier svc:/network/smb/server.

If the smbd service is disabled, it will be enabled by the share(1M) command or the zfs set share command, unless its auto_enable property is set to false.
**Name**  
smbiod, smbid-svc – SMB client I/O daemon

**Synopsis**  
/usr/lib/smbfs/smbiod  
/usr/lib/smbfs/smbiod-svc

**Description**  
smbiod and smbid-svc are internal components of the SMB client. They have no external, customer-accessible interfaces. For more information about the SMB client, see the `mount_smbfs(1M)` man pages.

smbiod-svc is run by the SMF service, svc:/network/smb/client:default, and starts and manages the smbid processes that are required by the SMB client.

smbiod is started by smbid-svc, which runs as a separate process for each user who requests SMB client connections. These smbid processes continue to run until the owning user no longer has any SMB client connections.

**Files**  
/usr/lib/smbfs/smbiod  
SMB I/O daemon.

/usr/lib/smbfs/smbiod-svc  
SMF service program.

/var/run/smbiod/.*  
File on which smbid-svc instantiates a door.

/var/run/smbiod/$UID  
File on which a user’s smbid process instantiates a door. $UID is the numeric representation of the owner’s user ID.

**Attributes**  
See the `attributes(5)` man page for descriptions of the following attributes:

smbios(1M)

Name  

smbios – display the contents of a System Management BIOS image

Synopsis  

smbios [-BeOsx] [-i id] [-t type] [-w file] [file]

Description  
The smbios utility displays the contents of the System Management BIOS (SMBIOS) image exported by the current system or stored in a file. SMBIOS is an industry-standard mechanism for low-level system software to export hardware configuration information to higher-level system management software. The SMBIOS data format itself is defined by the Distributed Management Task Force (DMTF). Refer to http://www.dmtf.org for more information about SMBIOS and to obtain a copy of the SMBIOS specification and implementation guidelines.

The SMBIOS image consists of a table of structures, each describing some aspect of the system software or hardware configuration. By default, smbios displays the entire contents of the current SMBIOS image. If the -s option is specified, smbios displays a summary of the structures that are present in the image. If the -w option is specified, smbios writes a copy of the SMBIOS image to the specified file. smbios can then be applied to the resulting file to display its content.

smbios attempts to display each structure and its content in a human-readable fashion. If smbios does not recognize a structure's type or content, the raw hexadecimal data for the structure is displayed.

Options  
The following options are supported:

-B  
Disable header validation for broken BIOSes.

By default, smbios attempts to validate the SMBIOS header by verifying the anchor strings, header checksums, and version number. This option might be necessary when a BIOS has a non-compliant header.

-e  
Display the contents of the SMBIOS entry point rather than the contents of the SMBIOS structure table.

-i id  
Display only the specified structure, named by its integer id.

-O  
Display obsolete structure types.

By default, smbios elides output for structures whose type is marked as obsolete in the DMTF SMBIOS specification.

-s  
Display only a summary listing of the structure identifiers and types, instead of the content of each selected structure.

-t type  
Display only those structures whose type matches the specified integer type, as defined the DMTF SMBIOS specification.

-w file  
Write a copy of the SMBIOS image to the specified file and exit.
The SMBIOS entry point is written to the start of the file with its structure table address set to the file offset of the structure table, and a new entry point checksum is computed.

-x   Display raw hexadecimal data for the selected structures in addition to human-readable output.

By default, hexadecimal data is only displayed if `smbios` cannot display human-readable output for the selected structures.

**Operands**
The following operands are supported:

`file` Specifies an alternate SMBIOS image to display instead of the current system’s SMBIOS image.

**Exit Status**
The following exit values are returned:

0  Successful completion. All structures in the SMBIOS image were examined successfully.
1  A fatal error occurred, such as failure to open the specified file or device, or corruption in the image.
2  Invalid command-line options were specified.

**Files**
/`dev/smbios` Kernel SMBIOS image device. This device special file is used to export a snapshot of the current system SMBIOS image.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/core-os</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The command-line options are Committed. The human-readable output is Uncommitted.

**See Also**
prtdiag(1M), attributes(5), smbios(7D)

*System Management BIOS Reference Specification* (see [http://www.dmtf.org](http://www.dmtf.org))

**Notes**
The implementation of a System Management BIOS image is entirely at the discretion of the system and BIOS vendors. Not all systems export an SMBIOS. The SMBIOS structure content varies widely between systems and BIOS vendors and frequently does not comply with the guidelines included in the specification. Some structure fields might not be filled in by the BIOS at all, and others might be filled in with non-conforming values.
**Name**  
smbstat – show Solaris SMB file server statistics

**Synopsis**  
smbstat [-r [-n [-a | -z]] [-t] [-u] [-c] interval

**Description**  
The `smbstat` command shows statistical information for the `smbd(1M)` server. `smbstat` has a number of options, described below, and a single operand, `interval`. If `interval` is specified, the first display captures statistics since the server started, up to the moment the command was entered. Subsequent displays capture statistics for the last `interval`.

By default, the `smbstat` command shows all statistics.

**Options**  
The `smbstat` command includes the following options:

- `c`  
  Display counters.

- `r`  
  Display the statistics of the requests. You can combine `-r` with the following options.

  - `a`  
    Display statistics for all the types of server requests, whether valid or not. Note that there are 256 types of server requests. The `-a` and `-z` options are mutually exclusive.

  - `n`  
    Display in alphabetic order.

- `z`  
  Display statistics for requests actually received. The `-a` and `-z` options are mutually exclusive.

- `t`  
  Display the throughput of the SMB server.

- `u`  
  Display the utilization of the SMB server.

**Extended Description**  
The `smbstat` command displays the headings shown below. The headings displayed for a given command vary according to which option(s) are specified. There are four categories of headings, corresponding to categories of statistics: counters, throughput, utilization, and (server) requests.

**Counters**

- `nbt`  
  Number of SMB NetBIOS-over-TCP (NBT) sessions.

- `tcp`  
  Number of SMB TCP sessions.

- `users`  
  Number of users logged in.

- `trees`  
  Number of trees connected.
files
Number of open files.

pipes
Number of open pipes.

Throughput

rbytes/s
Number of bytes received per second.

bytes/s
Number of bytes transmitted per second.

reqs/s
Number of requests handled per second.

reads/s
Number of read requests per second. This would be an aggregation of the following requests: SMB_COM_READ, SMB_COM_LOCK_AND_READ, SMB_COM_READ_RAW, and SMB_COM_READ_ANDX.

writes/s
Number of write requests per second. This would ba an aggregation of the following requests: SMB_COM_WRITE, SMB_COM_WRITE_AND_UNLOCK, SMB_COM_WRITE_RAW, and SMB_COM_WRITE_AND_CLOSE.

Utilization

wcnt
Average number of requests received but waiting for an SMB worker thread to execute them.

rcnt
Average number of requests being simultaneously executed by an SMB worker thread.

wtime
Average time a request waits before an SMB worker thread starts executing it.

rtime
Average execution time of a request.

w%
Percentage of the time during which at least one request was waiting.

r%
Percentage of the time during which at least one request was being executed.

u%
Percentage of utilization of the SMB server. This number is defined as: rcnt / (max_worker_threads).

sat
Flag indicating if the server has been saturated in the past. Saturation is defined as: u% == 100%.
usr%
    Percentage of the time the processor(s) spent in user space.

sys%
    Percentage of the time the processor(s) spent in kernel space.

idle%
    Percentage of the time the processor(s) was(were) idle.

The following headings are displayed for each type of request.

code
    Code of the request, in hexadecimal.

%    Percentage of a given type of request.

count
    Number of requests received.

rbytes/s
    Number of bytes received per second.

tbytes/s
    Number of bytes received per second.

req/s
    Number of requests handled per second.

rt-mean
    Average response time in seconds.

rt-stddev
    Standard deviation of the response time.

Examples

EXAMPLE 1  Combining Options

The following command combines the -c, -t, and -u options.

% smbsstat -ctu
nbt   tcp  users  trees  files  pipes
  0   1   1   2   20   0

rbytes/s   tbytes/s   reqs/s   reads/s   writes/s
  1.036e+02  1.298e+00   0.000e+00   0.000e+00   0.000e+00

wcnt   rcnt   wtime   rtime   w%   r%   u%   sat   usr%   sys%   idle%
  4.317e-01  7.410e+00  2.461e-05  4.224e-04  31   100   0   no   0   76   24
Exit Status  The following exit values are returned:

0    Successful completion.

>0   An error occurred.

The smrsh program is intended as a replacement for the sh command in the prog mailer in sendmail(1M) configuration files. The smrsh program sharply limits commands that can be run using the |program syntax of sendmail. This improves overall system security. smrsh limits the set of programs that a programmer can execute, even if sendmail runs a program without going through an alias or forward file.

Briefly, smrsh limits programs to be in the directory /var/adm/sm.bin, allowing system administrators to choose the set of acceptable commands. It also rejects any commands with the characters ., <, >, |, ;, $, \r (RETURN), or \n (NEWLINE) on the command line to prevent end run attacks.

Initial pathnames on programs are stripped, so forwarding to /usr/ucb/vacation, /usr/bin/vacation, /home/server/mydir/bin/vacation, and vacation all actually forward to /var/adm/sm.bin/vacation.

System administrators should be conservative about populating /var/adm/sm.bin. Reasonable additions are utilities such as vacation(1) and procmail. Never include any shell or shell-like program (for example, perl) in the sm.bin directory. This does not restrict the use of shell or perl scrips in the sm.bin directory (using the #! syntax); it simply disallows the execution of arbitrary programs.

The following options are supported:

- `-c command` Where command is a valid command, executes command.

Attributes

See Also sendmail(1M), attributes(5)
smtp-notify is a daemon that subscribes to software events and Fault Management lifecycle events and produces email notifications based on a set of notification preferences that are stored in the SMF service configuration repository.

Email notification preferences are set using `svccfg(1M)`.

smtp-notify is managed by the service management facility, `smf(5)`, under the service FMRI:

```
svc:/system/fm/smtp-notify:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

The following service properties can be set:

```
config/rootdir
```

This is a string property that defaultsto `/`. When set, the specified root directory will be used for all pathnames evaluated by `smtp-notify`.

By default, the body of the email event notification will be based on a set of localized message templates that are delivered with the Oracle Solaris operating system. `smtp-notify` will lookup the appropriate template (based on the event class) and fill in the template using elements from the event payload.

A user-supplied message body template can be substituted by specifying the `msg_template` notification preference. Refer to `svccfg(1M)` for more information about setting notification preferences on a per-service or per-event-class basis.

The message body template can contain the expansion macros listed below. These macros will be expanded by `smtp-notify` before sending the message.

<table>
<thead>
<tr>
<th>Macro</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%%</td>
<td>expands to a literal % character</td>
</tr>
<tr>
<td>%&lt;HOSTNAME&gt;</td>
<td>expands to the hostname on which the event occurred</td>
</tr>
<tr>
<td>%&lt;URL&gt;</td>
<td>expands to the URL of the knowledge article associated with this event</td>
</tr>
<tr>
<td>%&lt;CLASS&gt;</td>
<td>expands to the event class</td>
</tr>
<tr>
<td>%&lt;UUID&gt;</td>
<td>expands to the UUID of the event</td>
</tr>
<tr>
<td>%&lt;CODE&gt;</td>
<td>expands to the knowledge article message ID</td>
</tr>
<tr>
<td>%&lt;SEVERITY&gt;</td>
<td>expands to the severity of the event</td>
</tr>
</tbody>
</table>

For SMF service state transition events, the following additional macros can be specified in a message template:
To facilitate email filtering, `smtp-notify` will create X-headers for the following components of the event payload for all event classes:

<table>
<thead>
<tr>
<th>Header name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>X-FMEV-HOSTNAME</td>
<td>the name of the host on which the event occurred</td>
</tr>
<tr>
<td>X-FMEV-CLASS</td>
<td>the event class</td>
</tr>
<tr>
<td>X-FMEV-CODE</td>
<td>the Knowledge article message ID</td>
</tr>
<tr>
<td>X-FMEV-SEVERITY</td>
<td>the severity of the event</td>
</tr>
<tr>
<td>X-FMEV-UUID</td>
<td>the UUID of the event</td>
</tr>
</tbody>
</table>

SMF service state transition events will also include the following additional X-headers:

<table>
<thead>
<tr>
<th>Header name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>X-FMEV-FMRI</td>
<td>the FMRI of the affected SMF service</td>
</tr>
<tr>
<td>X-FMEV-FROM-STATE</td>
<td>the previous state of the service</td>
</tr>
<tr>
<td>X-FMEV-TO-STATE</td>
<td>the new state of the service</td>
</tr>
</tbody>
</table>

### Examples

**EXAMPLE 1** Configuring Notification Preferences

The following command configures notification preferences for SMF service state transition events.

```
# svccfg -s svc:/system/svc/global:default setnotify -g \ 
    from-online,to-maintenance mailto:admin@somehost.com
```

**EXAMPLE 2** Enabling Email Notifications

The following command enables email notifications for Fault Management problem diagnosis events.

```
# svccfg setnotify problem-diagnosed mailto:admin@somehost.com
```

**EXAMPLE 3** Listing Notification Settings

The following command lists all notification settings for Fault Management problem diagnosis events.

```
# svccfg listnotify problem-diagnosed
```

sndradm [options] -R C tag [sndr_set]
The /usr/sbin/sndradm command is the administrative command line interface for the Sun StorageTek Availability Suite Remote Mirror software. Remote Mirror enables you to replicate disks between different physically-separate Sun servers in real time. Remote Mirror is conceptually similar to the local disk mirroring scheme of RAID 1 but it performs its replication operations over longer distances.

If you do not specify a Remote Mirror set (sndr_set) on the command line, sndradm operates on all configured Remote Mirror sets.

The sndradm command generates an entry in the Availability Suite log file, /var/adm/ds.log (see ds.log(4)), for all operations except print (-p, -P and -i), help (-h), and version (-v).

The sndradm utility supports the following options:

- **-f volset-file**
  Specifies a file containing the sndr_set information for one or more Remote Mirror sets in the same format as the fully specified command line sndr_set documented below.

- **-g io_groupname**
  Limits operations to only those Remote Mirror sets belonging to io_groupname.
  The io_groupname for a given set must be consistent across both the primary and the secondary hosts.

- **-C tag**
  On a clustered node, limits operations to only those Remote Mirror sets belonging to the cluster resource group or disk group name specified by tag. This option is not valid on a system that is not clustered.

- **-n**
  Does not prompt the user after starting a Remote Mirror operation using sndradm. For all but the printing, help, and version options, the default behavior is to prompt for a response. For example, after starting a full synchronization from the primary to the secondary volume, Remote Mirror prompts: "Overwrite secondary with primary? (Y/N) [N].".

**sndr_set**
Specifies the Remote Mirror set. For a set that has already been enabled, this can be a set_name in the format phost:pdev. You can supply a fully specified Remote Mirror set in the same format as a configuration file:

```
phost pdev pbitmap shost sdev sbitmap ip {sync | async} \
[g io_groupname] [C tag]
```
These parameters are described as follows:

**phost**
Specifies the server on which the primary volume resides.

**pdev**
Specifies the primary volume partition to be replicated. Specify full pathnames only (for example, `/dev/rdsk/c0t1d0s2`).

**pbitmap**
Specifies the volume partition on which the bitmap (scoreboard log) of the primary partition is stored. Specify full pathnames only (for example, `/dev/rdsk/c0t1d0s3`).

**shost**
Specifies the server on which the secondary volume resides.

**sdev**
Specifies the secondary volume partition. Specify full path names only (for example, `/dev/rdsk/c0t1d0s4`).

**sbitmap**
Specifies the volume partition on which the bitmap (scoreboard log) of the secondary partition is stored. Specify full path names only (for example, `/dev/rdsk/c0t1d0s5`).

**ip**
Specifies the network transfer protocol.

**sync | async**
Specifies the Remote Mirror operating mode. **sync** is the Remote Mirror mode where the I/O operation is not confirmed as complete until the remote volume has been updated. **async** is the Remote Mirror mode where the primary host I/O operation is confirmed as complete before updating the remote volume.

**io_groupname**
Specifies the name of the Remote Mirror consistency group to which the Remote Mirror set belongs. In asynchronous mode, write ordering must be preserved across all replicating volumes in a Remote Mirror consistency group. This ensures that the secondary volumes belonging to the group contain a valid point-in-time copy of the corresponding primary volumes.

When adding an existing set to a consistency group or when enabling a set to be in a group, the set must be configured with the same group name on both the primary and the secondary hosts.

**tag**
For operation within a cluster, this specifies the disk group name or resource tag of the local data and bitmap volumes in cases where this is not implied by the name of the volume (for example, `/dev/rdsk/md/dg/vol` and `/dev/vx/rdsk/dg/vol` both indicate a disk group name of `dg`). It is the responsibility of the user to ensure that the cluster tag specified to the Remote Mirror matches the appropriate cluster resource group tag, and
to keep all the Availability Suite services up to date in the event of cluster resource group reconfigurations. It is illegal to specify the cluster resource tag on a system that is not clustered.

**Parameters**  
A valid `sndadm` command must specify one of the parameters listed below.

- **-I a master shadow bitmap**  
  Add an `ndr_ii` entry with the specified master, shadow, and bitmap to the Availability Suite configuration file. See `sndrsyncd(1M)`. If the corresponding Point-in-Time Copy set does not exist, it is enabled when the next sync command is issued on the related volume(s). When no longer required, this Point-in-Time Copy set can be disabled by `iidadm -d`. See `iidadm(1M)`.

- **-I d master shadow bitmap**  
  Delete the `ndr_ii` entry with the specified master, shadow, and bitmap from the Availability Suite configuration file. Use the `dscfg` command to list `ndr_ii` configuration entries.

- **-a value**  
  Specifies the value, on or off, of the automatic sync variable for the set. Once `autosync` has been requested for a set, the functionality is active from the time a sync operation is requested until the set is manually put into logging mode. Once the set is manually put into logging mode, the `autosync` functionality is not active and remains inactive until the next time a sync request is made. To check whether `autosync` is active, use `sndadm -P`. To check whether `autosync` has been requested for a set, look for the "auto=on; " tag for the set in the output of `dscfg -l`. See `sndrsyncd(1M)`.

- **-A value**  
  Specifies the maximum number of threads that can be created to process the asynchronous queue when a set is replicating in asynchronous mode. The default is 2.

- **-W value**  
  Specifies the maximum number of writes that can be queued to a set replicating in asynchronous mode. The default is 4096. For example, set this value to 1 to ensure that the secondary volume is never more than one write operation behind the primary volume.

  Tuning the maximum number of writes is only valid for sets using memory-based async I/O queues. This value is ignored when disk based I/O queues are used.

- **-D {block | noblock}**  
  Toggles the `block|noblock` attribute of a disk-based queue. The default setting is `block`. If the I/O fill rate is larger than the drain rate for enough time for the queue to fill, incoming I/O is blocked until there is adequate space on the queue for it. This is to preserve write ordering whether it is one volume or across many volumes in the same consistency group. If `noblock` is set, and incoming I/O fills the queue, the I/O is not blocked. Instead, the set is put into logging and the disk queue contents are disregarded. An ensuing update sync synchronizes the latest data to the secondary site.
- F value
Specifies the maximum number of 512-byte FBAs that can be queued in kernel memory to a set replicating in asynchronous mode. The default is 16384.

Tuning the maximum number of FBAs is valid only for sets using memory-based async I/O queues. This value is ignored when disk-based I/O queues are used.

-h
Prints the sndradm usage summary.

-v
Prints the Remote Mirror version number.

-e
 Enables Remote Mirror for the set and enables scoreboard logging. The scoreboard is set to indicate that a full synchronization is required. Details of the set are saved in the current configuration. See dscfg(1M). The local volume and the bitmap volume are enabled for the Storage Volume driver (see sv(7D)).

-E
 Enables Remote Mirror for the set and enables scoreboard logging. The scoreboard is cleared to indicate that the primary and secondary volumes are already guaranteed to be fully synchronized. Details of the set are saved in the current configuration. See dscfg(1M). The local volume and the bitmap volume are enabled for the Storage Volume driver (see sv(7D)).

-d
 Disables Remote Mirror for the set and halts any current synchronization operations. sndradm -d also discards any active scoreboards that track temporary differences between primary and secondary volumes.

-l
 Stops Remote Mirror replication and copy operations between primary and secondary volumes and starts independent Remote Mirror scoreboard logging on these volumes. When all the sets in a consistency group are replicating, it means that the secondary volumes contain a valid point-in-time copy of the corresponding primary volumes. Under this condition, as soon as one Remote Mirror set drops into logging mode, the rdc kernel module drops all the other sets in the group into logging mode automatically. This ensures that the secondary volumes still contains a valid point-in-time copy. To resume the Remote Mirror after using the -l parameter, use the -n parameter to perform a full resynchronization or the -u parameter to perform an update resynchronization (based on the scoreboard).

This option does not work on the secondary for any volumes that are currently synchronizing.

-w
 Waits for a synchronization copy to complete or abort, or returns immediately if invoked on the secondary system.
-H  
Reports on the health of the network link used by the specified volume set. The health of the link is reported as active or inactive. Active means that the network link is actively being used for replicating or resynchronizing data, and is therefore in good health. Inactive means that the network link is not actively being used for replicating or resynchronizing data, which might indicate a problem with the link.

-p  
Displays a list of configured Remote Mirror volumes or sets.

-P  
Displays a list of configured Remote Mirror volumes or sets with extra details. (See state descriptions, below.)

-q a volume  
Add a disk queue to a set or group. This operation is valid when the set or group is in logging mode.

-q d  
Remove a disk queue from a set or group. This operation is valid when the set or group is in logging mode.

-q r volume  
Replace a disk queue for a group or set. The queue is removed from the set or group as in the queue-disable operation and the new disk queue is added as in the queue-add operation. This operation is valid when the set or group is in logging mode.

-i  
Displays a list of configured Remote Mirror volumes or sets in the same format as the volset-file.

-R  
Attempt to reset a Remote Mirror set’s error condition such as failed bitmaps.

-R b p bitmap  
Reconfigure a Remote Mirror set’s primary bitmap. This command should be entered on both primary and secondary servers. It is only possible to reconfigure the primary bitmap for one set at a time.

-R b s bitmap  
Reconfigure a Remote Mirror set’s secondary bitmap. This command should be entered on both primary and secondary servers. It is only possible to reconfigure the secondary bitmap for one set at a time.

-R C tag
