Preface

Both novice users and those familiar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question “What does it do?” The man pages in general comprise a reference manual. They are not intended to be a tutorial.

Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.
- Section 9E describes the DDI (Device Driver Interface)/DKI (Driver/Kernel Interface), DDI-only, and DKI-only entry-point routines a developer can include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report,
there is no BUGS section. See the Intro pages for more information and detail about each section, and man(1) for more information about man pages in general.

NAME
This section gives the names of the commands or functions documented, followed by a brief description of what they do.

SYNOPSIS
This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.

The following special characters are used in this section:

[] Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.

... Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, “filename...”.

| Separator. Only one of the arguments separated by this character can be specified at a time.

{} Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.

PROTOCOL
This section occurs only in subsection 3R to indicate the protocol description file.

DESCRIPTION
This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are described under USAGE.

IOCTL
This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the ioctl(2) system call is called ioctl and generates its own heading. ioctl calls for a specific device are listed alphabetically (on the man page for that specific device).
ioctl calls are used for a particular class of devices all of which have an io ending, such as mtio(7I).

OPTIONS
This section lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.

OPERANDS
This section lists the command operands and describes how they affect the actions of the command.

OUTPUT
This section describes the output – standard output, standard error, or output files – generated by the command.

RETURN VALUES
If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.

ERRORS
On failure, most functions place an error code in the global variable errno indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph under the error code.

USAGE
This section lists special rules, features, and commands that require in-depth explanations. The subsections listed here are used to explain built-in functionality:

- Commands
- Modifiers
- Variables
- Expressions
- Input Grammar

EXAMPLES
This section provides examples of usage or of how to use a command or function. Wherever possible a complete

Preface
example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as example%, or if the user must be superuser, example#. Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.

ENVIRONMENT VARIABLES
This section lists any environment variables that the command or function affects, followed by a brief description of the effect.

EXIT STATUS
This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.

FILES
This section lists all file names referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.

ATTRIBUTES
This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See attributes(5) for more information.

SEE ALSO
This section lists references to other man pages, in-house documentation, and outside publications.

DIAGNOSTICS
This section lists diagnostic messages with a brief explanation of the condition causing the error.

WARNINGS
This section lists warnings about special conditions which could seriously affect your working conditions. This is not a list of diagnostics.

NOTES
This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.

BUGS
This section describes known bugs and, wherever possible, suggests workarounds.
REFERENCE

Introduction
Intro – introduction to kernel data structures and properties

Section 9P describes kernel properties used by device drivers. Section 9S describes the data structures used by drivers to share information between the driver and the kernel. See Intro(9E) for an overview of device driver interfaces.

In Section 9S, reference pages contain the following headings:

- **NAME** summarizes the purpose of the structure or property.
- **SYNOPSIS** lists the include file that defines the structure or property.
- **INTERFACE LEVEL** describes any architecture dependencies.
- **DESCRIPTION** provides general information about the structure or property.
- **STRUCTURE MEMBERS** lists all accessible structure members (for Section 9S).
- **SEE ALSO** gives sources for further information.

Of the preceding headings, Section 9P reference pages contain the **NAME**, **DESCRIPTION**, and **SEE ALSO** fields.

Every driver MUST include `<sys/ddi.h>` and `<sys/sunddi.h>`, in that order, and as final entries.

The following table summarizes the STREAMS structures described in Section 9S.

Notes    Do not declare arrays of structures as the size of the structures can change between releases. Rely only on the structure members listed in this chapter and not on unlisted members or the position of a member in a structure.
REFERENCE

Data Structures for Drivers
**Name**  
aio_req – asynchronous I/O request structure

**Synopsis**  
#include <sys/uio.h>  
#include <sys/aio_req.h>  
#include <sys/ddi.h>  
#include <sys/sunddi.h>

**Interface Level**  
Solaris DDI specific (Solaris DDI)

**Description**  
An aio_req structure describes an asynchronous I/O request.

**Structure Members**  
struct uio*aio_uio;  /* uio structure describing the I/O request */

The aio_uio member is a pointer to a uio(9S) structure, describing the I/O transfer request.

**See Also**  
aread(9E), awrite(9E), aphsio(9F), uio(9S)
An `audio_engine_ops` structure defines vectors that an audio driver exports to the Sun audio framework. One such vector is used for each DMA or PIO engine (sometimes referred to as a "stream") supported on the device.

The audio framework provides the following synchronization guarantees for audio engines:

- only one thread will be executing an audio engine entry point for a given audio device at any one time
- no threads will be executing any audio engine entry points for a given audio device if that device is suspended. See `audio_dev_suspend(9F)`.

Each entry point receives as its first argument the driver private state that was registered with `audio_engine_set_private(9F)`.

### Structure Members

<table>
<thead>
<tr>

</tbody>
</table>

---

**Synopsis**

`#include <sys/audio/audio_driver.h>`

**Interface Level**

Solaris DDI specific (Solaris DDI)

**Description**

An `audio_engine_ops` structure defines vectors that an audio driver exports to the Sun audio framework.
audio_engine_channels  Function entry to get the number of channels of the engine.
audio_engine_rate    Function entry to get the sample rate of the engine.
audio_engine_sync    Function entry to synchronize the DMA cache for the buffer associated with the engine.
audio_engine_glen    Function entry to determine the on-device FIFO len for the engine.
audio_engine_chinfo  Function entry to determine number and layout channels for device.
audio_engine_playahead Function entry to determine minimum number of frames that should be queued to the engine.

### Name
buf – block I/O data transfer structure

### Synopsis
```
#include <sys/ddi.h>
#include <sys/sunddi.h>
```

### Interface Level
Architecture independent level 1 (DDI/DKI)

### Description
The buf structure is the basic data structure for block I/O transfers. Each block I/O transfer has an associated buffer header. The header contains all the buffer control and status information. For drivers, the buffer header pointer is the sole argument to a block driver `strategy(9E)` routine. Do not depend on the size of the buf structure when writing a driver.

A buffer header can be linked in multiple lists simultaneously. Because of this, most of the members in the buffer header cannot be changed by the driver, even when the buffer header is in one of the driver’s work lists.

Buffer headers are also used by the system for unbuffered or physical I/O for block drivers. In this case, the buffer describes a portion of user data space that is locked into memory.

Block drivers often chain block requests so that overall throughput for the device is maximized. The `av_forw` and the `av_back` members of the buf structure can serve as link pointers for chaining block requests.

```c
int b_flags; /* Buffer status */
struct buf *av_forw; /* Driver work list link */
struct buf *av_back; /* Driver work list link */
size_t b_bcount; /* # of bytes to transfer */
union {
    caddr_t b_addr; /* Buffer's virtual address */
} b_un;
daddr_t b_blkno; /* Block number on device */
diskaddr_t b_lblkno; /* Expanded block number on dev. */
size_t b_resid; /* # of bytes not xferred */
size_t b_bufsize; /* size of alloc. buffer */
int (*b_iiodone)(struct buf *); /* function called */
    /* by iodone */
int b_error; /* expanded error field */
void *b_private; /* "opaque" driver private area */
dev_t b_edev; /* expanded dev field */
```

The members of the buffer header available to test or set by a driver are as follows:

- `b_flags` stores the buffer status and indicates to the driver whether to read or write to the device. The driver must never clear the `b_flags` member. If this is done, unpredictable results can occur including loss of disk sanity and the possible failure of other kernel processes.

- All `b_flags` bit values not otherwise specified above are reserved by the kernel and may not be used.

Valid flags are as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>b_flags</td>
<td>Buffer status</td>
</tr>
<tr>
<td>av_forw</td>
<td>Driver work list link</td>
</tr>
<tr>
<td>av_back</td>
<td>Driver work list link</td>
</tr>
<tr>
<td>b_bcount</td>
<td># of bytes to transfer</td>
</tr>
<tr>
<td>b_addr</td>
<td>Buffer's virtual address</td>
</tr>
<tr>
<td>b_blkno</td>
<td>Block number on device</td>
</tr>
<tr>
<td>b_lblkno</td>
<td>Expanded block number on dev.</td>
</tr>
<tr>
<td>b_resid</td>
<td># of bytes not xferred</td>
</tr>
<tr>
<td>b_bufsize</td>
<td>Size of alloc. buffer</td>
</tr>
<tr>
<td>b_iiodone</td>
<td>Function called by iodone</td>
</tr>
<tr>
<td>b_error</td>
<td>Expanded error field</td>
</tr>
<tr>
<td>b_private</td>
<td>&quot;Opaque&quot; driver private area</td>
</tr>
<tr>
<td>b_edev</td>
<td>Expanded dev field</td>
</tr>
</tbody>
</table>
B_BUSY  Indicates the buffer is in use. The driver must not change this flag unless it allocated the buffer with `getrbuf(9F)` and no I/O operation is in progress.

B_DONE   Indicates the data transfer has completed. This flag is read-only.

B_ERROR  Indicates an I/O transfer error. It is set in conjunction with the `b_error` field. `bioerror(9F)` should be used in preference to setting the B_ERROR bit.

B_READ   Indicates that data is to be read from the peripheral device into main memory.

B_WRITE  Indicates that the data is to be transferred from main memory to the peripheral device. B_WRITE is a pseudo flag and cannot be directly tested; it is only detected as the NOT form of B_READ.

`av_forw` and `av_back` can be used by the driver to link the buffer into driver work lists.

`b_count` specifies the number of bytes to be transferred in both a paged and a non-paged I/O request.

`b_un.b_addr` must only be referenced after calling `bp_mapin(9F)`. After `bp_mapin()`, `b_un.b_addr` is the virtual address of the buffer data associated with the I/O request. To efficiently check buffer data alignment, without calling `bp_mapin()`, a driver should use `bioaligned(9F)`.

`b_blkno` identifies which logical block on the device (the device is defined by the device number) is to be accessed. The driver might have to convert this logical block number to a physical location such as a cylinder, track, and sector of a disk. This is a 32-bit value. The driver should use `b_blkno` or `b_lblkno`, but not both.

`b_lblkno` identifies which logical block on the device (the device is defined by the device number) is to be accessed. The driver might have to convert this logical block number to a physical location such as a cylinder, track, and sector of a disk. This is a 64-bit value. The driver should use `b_lblkno` or `b_blkno`, but not both.

`b_resid` should be set to the number of bytes not transferred because of an error.

`b_bufsize` contains the size of the allocated buffer.

`b_iiodone` identifies a specific `biiodone` routine to be called by the driver when the I/O is complete.

`b_error` can hold an error code that should be passed as a return code from the driver. `b_error` is set in conjunction with the B_ERROR bit set in the `b_flags` member. `bioerror(9F)` should be used in preference to setting the `b_error` field.

`b_private` is for the private use of the device driver.
b_e.dev contains the major and minor device numbers of the device accessed.

**See Also** strategy(9E), aphysio(9F), bioaligned(9F), bioclone(9F), biodone(9F), bioerror(9F), bioinit(9F), bp_mapin(9F), clrbuf(9F), getrbuf(9F), physio(9F), iovec(9S), uio(9S)

*Writing Device Drivers*

**Warnings** Buffers are a shared resource within the kernel. Drivers should read or write only the members listed in this section. Drivers that attempt to use undocumented members of the buf structure risk corrupting data in the kernel or on the device.
cb_ops(9S)

Name cb_ops – character/block entry points structure

Synopsis
#include <sys/conf.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>

Solaris DDI specific (Solaris DDI)

Description
The cb_ops structure contains all entry points for drivers that support both character and block entry points. All leaf device drivers that support direct user process access to a device should declare a cb_ops structure.

All drivers that safely allow multiple threads of execution in the driver at the same time must set the D_MP flag in the cb_flag field. See open(9E).

If the driver properly handles 64-bit offsets, it should also set the D_64BIT flag in the cb_flag field. This specifies that the driver will use the uio_loffset field of the uio(9S) structure.

If the driver returns EINTR from open(9E), it should also set the D_OPEN_RETURNS_EINTR flag in the cb_flag field. This lets the framework know that it is safe for the driver to return EINTR when waiting, to provide exclusion for a last-reference close(9E) call to complete before calling open(9E).

The mt-streams(9F) function describes other flags that can be set in the cb_flag field.

The cb_rev is the cb_ops structure revision number. This field must be set to CB_REV.

Non-STREAMS drivers should set cb_str to NULL.

The following DDI/DKI or DKI-only or DDI-only functions are provided in the character/block driver operations structure.

STREAMS Programming Guide
Name | datab, dblk – STREAMS message data structure
--- | ---
Synopsis | #include <sys/stream.h>

### Interface Level

Architecture independent level 1 (DDI/DKI).

### Description

The datab structure describes the data of a STREAMS message. The actual data contained in a STREAMS message is stored in a data buffer pointed to by this structure. A msgb (message block) structure includes a field that points to a datab structure.

Because a data block can have more than one message block pointing to it at one time, the db_ref member keeps track of a data block’s references, preventing it from being deallocated until all message blocks are finished with it.

#### Structure Members

- unsigned char *db_base; /* first byte of buffer */
- unsigned char *db_lim; /* last byte (+1) of buffer */
- unsigned char db_ref; /* # of message pointers to this data */
- unsigned char db_type; /* message type */

A datab structure is defined as type dblk_t.

Solaris DDI specific (Solaris DDI)

The ddi_device_acc_attr structure describes the data access characteristics and requirements of the device.

**Structure Members**

- `ushort_t devacc_attr_version;`
- `uchar_t devacc_attr_endian_flags;`
- `uchar_t devacc_attr_dataorder;`
- `uchar_t devacc_attr_access;`

The `devacc_attr_version` member identifies the version number of this structure. The current version number is DDI_DEVICE_ATTR_V0.

The `devacc_attr_endian_flags` member describes the endian characteristics of the device. Specify one of the following values:

- `DDI_NEVERSWAP_ACC` Data access with no byte swapping
- `DDI_STRUCTURE_BE_ACC` Structural data access in big-endian format
- `DDI_STRUCTURE_LE_ACC` Structural data access in little endian format

`DDI_STRUCTURE_BE_ACC` and `DDI_STRUCTURE_LE_ACC` describe the endian characteristics of the device as big-endian or little-endian, respectively. Although most of the devices have the same endian characteristics as their buses, examples of devices that have opposite endian characteristics of the buses do exist. When `DDI_STRUCTURE_BE_ACC` or `DDI_STRUCTURE_LE_ACC` is set, byte swapping is automatically performed by the system if the host machine and the device data formats have opposite endian characteristics. The implementation can take advantage of hardware platform byte swapping capabilities.

When you specify `DDI_NEVERSWAP_ACC`, byte swapping is not invoked in the data access functions.

The `devacc_attr_dataorder` member describes the order in which the CPU references data. Specify one of the following values:

- `DDI_STRICTORDER_ACC` Data references must be issued by a CPU in program order. Strict ordering is the default behavior.
- `DDI_UNORDERED_OK_ACC` The CPU can reorder the data references. This includes all kinds of reordering. For example, a load followed by a store might be replaced by a store followed by a load.
- `DDI_MERGING_OK_ACC` The CPU can merge individual stores to consecutive locations. For example, the CPU can turn two consecutive byte stores into one half-word store. It can also batch
individual loads. For example, the CPU might turn two consecutive byte loads into one half-word load.

DDI_MERGING_OK_ACC also implies reordering.

**DDI_LOADCACHING_OK_ACC**

The CPU can cache the data it fetches and reuse it until another store occurs. The default behavior is to fetch new data on every load. DDI_LOADCACHING_OK_ACC also implies merging and reordering.

**DDI_STORECACHING_OK_ACC**

The CPU can keep the data in the cache and push it to the device, perhaps with other data, at a later time. The default behavior is to push the data right away. DDI_STORECACHING_OK_ACC also implies load caching, merging, and reordering.

These values are advisory, not mandatory. For example, data can be ordered without being merged, or cached, even though a driver requests unordered, merged, and cached together.

The values defined for `devacc_attr_access` are:

**DDI_DEFAULT_ACC**

If an I/O fault occurs, the system will take the default action, which might be to panic.

**DDI_FLAGERR_ACC**

Using this value indicates that the driver is hardened: able to cope with the incorrect results of I/O operations that might result from an I/O fault. The value also indicates that the driver will use `ddi_fm_acc_err_get(9F)` to check access handles for faults on a regular basis.

If possible, the system should not panic on such an I/O fault, but should instead mark the I/O handle through which the access was made as having faulted.

This value is advisory: it tells the system that the driver can continue in the face of I/O faults. The value does not guarantee that the system will not panic, as that depends on the nature of the fault and the capabilities of the system. It is quite legitimate for an implementation to ignore this flag and panic anyway.

**DDI_CAUTIOUS_ACC**

This value indicates that an I/O fault is anticipated and should be handled as gracefully as possible. For example, the framework should not print a console message.

This value should be used when it is not certain that a device is physically present: for example, when probing. As such, it provides an alternative within the DDI access framework to the existing peek/poke
functions, which don't use access handles and cannot be integrated easily into a more general I/O fault handling framework.

In order to guarantee safe recovery from an I/O fault, it might be necessary to acquire exclusive access to the parent bus, for example, or to synchronize across processors on an MP machine. “Cautious” access can be quite expensive and is only recommended for initial probing and possibly for additional fault-recovery code.

**Examples** The following examples illustrate the use of device register address mapping setup functions and different data access functions.

**EXAMPLE 1 Using ddi_device_acc_attr() in ddi_regs_map_setup()**

This example demonstrates the use of the `ddi_device_acc_attr()` structure in `ddi_regs_map_setup()`. It also shows the use of `ddi_getw()` and `ddi_putw()` functions in accessing the register contents.

```c
dev_info_t *dip;
uint_t rnumber;
ushort_t *dev_addr;
offset_t offset;
offset_t len;
ushort_t dev_command;
ddi_device_acc_attr_t dev_attr;
ddi_acc_handle_t handle;

/* setup the device attribute structure for little endian,
 * strict ordering and 16-bit word access. */
dev_attr.devacc_attr_version = DDI_DEVICE_ATTR_V0;
dev_attr.devacc_attr_endian_flags = DDI_STRUCTURE_LE_ACC;
dev_attr.devacc_attr_dataorder = DDI_STRICTORDER_ACC;

/* set up the device registers address mapping */
ddi_regs_map_setup(dip, rnumber, (caddr_t *)&dev_addr, offset, len,
 &dev_attr, &handle);

/* read a 16-bit word command register from the device */
dev_command = ddi_getw(handle, dev_addr);

dev_command |= DEV_INTR_ENABLE;
/* store a new value back to the device command register */
```

Data Structures for Drivers 29
ddi_device_acc_attr(9S)

EXAMPLE 1 Using ddi_device_acc attr() in ddi_regs_map_setup(9F)  (Continued)

ddi_putw(handle, dev_addr, dev_command);

EXAMPLE 2 Accessing a Device with Different Apertures

The following example illustrates the steps used to access a device with different apertures. Several apertures are assumed to be grouped under one single "reg" entry. For example, the sample device has four different apertures, each 32 Kbyte in size. The apertures represent YUV little-endian, YUV big-endian, RGB little-endian, and RGB big-endian. This sample device uses entry 1 of the "reg" property list for this purpose. The size of the address space is 128 Kbyte with each 32 Kbyte range as a separate aperture. In the register mapping setup function, the sample driver uses the offset and len parameters to specify one of the apertures.

ulong_t *dev_addr;
ddi_device_acc attr_t dev_attr;
ddi_acc_handle_t handle;
uchar_t buf[256];
...

/*
 * setup the device attribute structure for never swap,
 * unordered and 32-bit word access.
 */
dev_attr.devacc attr_version = DDI_DEVICE_ATTR_V0;
dev_attr.devacc attr_endian_flags = DDI_NEVERSWAP_ACC;
dev_attr.devacc attr_dataorder = DDI_UNORDERED_OK_ACC;

/*
 * map in the RGB big-endian aperture
 * while running in a big endian machine
 * - offset 96K and len 32K
 */
ddi_regs_map_setup(dip, 1, (caddr_t *)&dev_addr, 96*1024, 32*1024, &dev_attr, &handle);

/*
 * Write to the screen buffer
 * first 1K bytes words, each size 4 bytes
 */
ddi_rep_putl(handle, buf, dev_addr, 256, DDI_DEV_AUTOINCR);

EXAMPLE 3 Functions That Call Out the Data Word Size

The following example illustrates the use of the functions that explicitly call out the data word size to override the data size in the device attribute structure.
EXAMPLE 3 Functions That Call Out the Data Word Size  (Continued)

```c
struct device_blk {
    ushort_t  d_command;  /* command register */
    ushort_t  d_status;   /* status register */
    ulong     d_data;     /* data register */
} *dev_blkp;
dev_info_t *dip;
caddr_t   dev_addr;
ssize_t   dev_attr;
diacc_handle_t handle;
uchar_t buf[256];

/*
 * setup the device attribute structure for never swap,
 * strict ordering and 32-bit word access.
 */
dev_attr.devacc_attr_version = DDIDEVICEATTR_V0;
dev_attr.devacc_attr_endian_flags = DDI_NEVERSWAP_ACC;
dev_attr.devacc_attr_dataorder = DDI_STRICTORDER_ACC;

ddi_regs_map_setup(dip, 1, (caddr_t *)&dev_blkp, 0, 0,
                    &dev_attr, &handle);

/* write command to the 16-bit command register */
ddi_putw(handle, &dev_blkp->d_command, START_XFER);

/* Read the 16-bit status register */
status = ddi_getw(handle, &dev_blkp->d_status);

if ((status & DATA_READY)
    /* Read 1K bytes off the 32-bit data register */
    ddi_rep_getl(handle, buf, &dev_blkp->d_data,
                 256, DDI_DEV_NO_AUTOINCR);

Writing Device Drivers

Data Structures for Drivers 31
ddi_dma_attr – DMA attributes structure

Synopsis
#include <sys/ddidmareq.h>

Description
A ddi_dma_attr_t structure describes device- and DMA engine-specific attributes necessary to allocate DMA resources for a device. The driver might have to extend the attributes with bus-specific information, depending on the bus to which the device is connected.

Structure Members

- uint_t dma_attr_version; /* version number */
- uint64_t dma_attr_addr_lo; /* low DMA address range */
- uint64_t dma_attr_addr_hi; /* high DMA address range */
- uint64_t dma_attr_count_max; /* DMA counter register */
- uint64_t dma_attr_align; /* DMA address alignment */
- uint_t dma_attr_burstsizes; /* DMA burst sizes */
- uint32_t dma_attr_minxfer; /* min effective DMA size */
- uint64_t dma_attr_maxxfer; /* max DMA xfer size */
- int dma_attr_seg; /* segment boundary */
- int dma_attr_sgl_len; /* s/g list length */
- uint32_t dma_attr_granular; /* granularity of device */
- uint_t dma_attr_flags; /* DMA transfer flags */

The dma_attr_version stores the version number of this DMA attribute structure. It should be set to DMA_ATTR_V0.

The dma_attr_addr_lo and dma_attr_addr_hi fields specify the address range the device's DMA engine can access. The dma_attr_addr_lo field describes the inclusive lower 64-bit boundary. The dma_attr_addr_hi describes the inclusive upper 64-bit boundary. The system ensures that allocated DMA resources are within the range specified. See ddi_dma_cookie(9S).

The dma_attr_count_max describes an inclusive upper bound for the device's DMA counter register. For example, 0xFFFFFFFF would describe a DMA engine with a 24-bit counter register. DMA resource allocation functions have to break up a DMA object into multiple DMA cookies if the size of the object exceeds the size of the DMA counter register.

The dma_attr_align specifies alignment requirements for allocated DMA resources. This field can be used to force more restrictive alignment than imposed by dma_attr_burstsizes or dma_attr_minxfer, such as alignment at a page boundary. Most drivers set this field to 1, indicating byte alignment.

The dma_attr_align only specifies alignment requirements for allocated DMA resources. The buffer passed to ddi_dma_addr_bind_handle(9F) or ddi_dma_buf_bind_handle(9F) must have an equally restrictive alignment (see ddi_dma_mem_alloc(9F)).

The dma_attr_burstsizes field describes the possible burst sizes the DMA engine of a device can accept. The format of the data sizes is binary, encoded in terms of powers of two. When
DMA resources are allocated, the system can modify the burstsizes value to reflect the system limits. The driver must use the allowable burstsizes to program the DMA engine. See ddi_dma_burstsizes(9F).

The dma_attr_minxfer field describes the minimum effective DMA access size in units of bytes. DMA resources can be modified, depending on the presence and use of I/O caches and write buffers between the DMA engine and the memory object. This field is used to determine alignment and padding requirements for ddi_dma_mem_alloc(9F).

The dma_attr_maxxfer field describes the maximum effective DMA access size in units of bytes.

The dma_attr_seg field specifies segment boundary restrictions for allocated DMA resources. The system allocates DMA resources for the device so that the object does not span the segment boundary specified by dma_attr_seg. For example, a value of 0xFFFF means DMA resources must not cross a 64-Kbyte boundary. DMA resource allocation functions might have to break up a DMA object into multiple DMA cookies to enforce segment boundary restrictions. In this case, the transfer must be performed using scatter-gather I/O or multiple DMA windows.

The dma_attr_sgllen field describes the length of the DMA scatter/gather list of a device. Possible values are as follows:

- `< 0` Device DMA engine is not constrained by the size, for example, with DMA chaining.
- `= 0` Reserved.
- `= 1` Device DMA engine does not support scatter/gather such as third party DMA.
- `> 1` Device DMA engine uses scatter/gather. The dma_attr_sgllen value is the maximum number of entries in the list.

The dma_attr_granular field describes the granularity of the device transfer size in units of bytes. When the system allocates DMA resources, the size of a single segment is a multiple of the device granularity. If dma_attr_sgllen is larger than 1 within a window, the sum of the sizes for a subgroup of segments is a multiple of the device granularity.

All driver requests for DMA resources must be a multiple of the granularity of the device transfer size.

The dma_attr_flags field can be set to a combination of:

- DDI_DMA_FORCE_PHYSICAL

Some platforms, such as SPARC systems, support what is called Direct Virtual Memory Access (DVMA). On these platforms, the device is provided with a virtual address by the system in order to perform the transfer. In this case, the underlying platform provides an IOMMU, which translates accesses to these virtual addresses into the proper physical addresses. Some of these platforms also support DMA. DDI_DMA_FORCE_PHYSICAL indicates that the system should return physical rather than virtual I/O addresses if the
system supports both. If the system does not support physical DMA, the return value from
\texttt{ddi_dma_alloc_handle(9F)} is \texttt{DDI_DMA_BADATTR}. In this case, the driver has to clear
\texttt{DDI_DMA_FORCE_PHYSICAL} and retry the operation.

\textbf{DDI_DMA_FLAGERR}

Using this value indicates that the driver is hardened: able to cope with the incorrect results
of DMA operations that might result from an I/O fault. The value also indicates that the
driver will use \texttt{ddi_fm_dma_err_get(9F)} to check DMA handles for faults on a regular
basis.

If a DMA error is detected during a DMA access to an area mapped by such a handle, the
system should not panic if possible, but should instead mark the DMA handle as having
faulted.

This value is advisory: it tells the system that the driver can continue in the face of I/O
faults. It does not guarantee that the system will not panic, as that depends on the nature of
the fault and the capabilities of the system. It is quite legitimate for an implementation to
ignore this flag and panic anyway.

\textbf{DDI_DMA_RELAXED_ORDERING}

This optional flag can be set if the DMA transactions associated with this handle are not
required to observe strong DMA write ordering among themselves, nor with DMA write
transactions of other handles.

The flag allows the host bridge to transfer data to and from memory more efficiently and
might result in better DMA performance on some platforms.

Drivers for devices with hardware support, such as marking the bus transactions relaxed
ordered, should not use this flag. Such drivers should use the hardware capability instead.

\textbf{Examples}

\textbf{EXAMPLE 1} Initializing the ddi_dma_attr_t Structure

Assume a device has the following DMA characteristics:

- Full 32-bit range addressable
- 24-bit DMA counter register
- Byte alignment
- 4- and 8-byte burst sizes support
- Minimum effective transfer size of 1 bytes
- 64 Mbyte minus 1 (26-bit) maximum transfer size limit
- Maximum segment size of 32 Kbyte
- 17 scatter/gather list elements
- 512-byte device transfer size granularity

The corresponding \texttt{ddi_dma_attr_t} structure is initialized as follows:

```c
static ddi_dma_attr_t dma_attrs = {
    DMA_ATTR_V0,  /* version number */
    (uint64_t)0x0, /* low address */
```

EXAMPLE 1 Initializing the ddi_dma_attr_t Structure  (Continued)

    (uint64_t)0xffffffff, /* high address */
    (uint64_t)0xffffffff, /* DMA counter max */
    (uint64_t)0x1 /* alignment */
    0x0c, /* burst sizes */
    0x1, /* minimum transfer size */
    (uint64_t)0x3fffffff, /* maximum transfer size */
    (uint64_t)0x7fff, /* maximum segment size */
    17, /* scatter/gather list lgth */
    512 /* granularity */
    0 /* DMA flags */
};

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

See Also  attributes(5), ddi_dma_addr_bind_handle(9F), ddi_dma_alloc_handle(9F),
ddi_dma_buf_bind_handle(9F), ddi_dma_burstsizes(9F), ddi_dma_mem_alloc(9F),
ddi_dma_nextcookie(9F), ddi_dma_cookie(9S)

Writing Device Drivers
#include <sys/sunddi.h>

Solaris DDI specific (Solaris DDI).

The ddi_dma_cookie_t structure contains DMA address information required to program a DMA engine. The structure is filled in by a call to ddi_dma_getwin(9F), ddi_dma_addr_bind_handle(9F), or ddi_dma_buf_bind_handle(9F), to get device-specific DMA transfer information for a DMA request or a DMA window.

typedef struct {
    union {
        uint64_t _dmac_ll; /* 64 bit DMA add. */
        uint32_t _dmac_la[2]; /* 2 x 32 bit add. */
    } _dmu;
    size_t dmac_size; /* DMA cookie size */
    uint_t dmac_type; /* bus spec. type bits */
} ddi_dma_cookie_t;

You can access the DMA address through the #defines: dmac_address for 32-bit addresses and dmac_laddress for 64-bit addresses. These macros are defined as follows:

#define dmac_laddress _dmu._dmac_ll
#ifdef _LONG_LONG_HTOL
#define dmac_notused _dmu._dmac_la[0]
#define dmac_address _dmu._dmac_la[1]
#else
#define dmac_address _dmu._dmac_la[0]
#define dmac_notused _dmu._dmac_la[1]
#endif

dmac_laddress specifies a 64-bit I/O address appropriate for programming the device's DMA engine. If a device has a 64-bit DMA address register a driver should use this field to program the DMA engine. dmac_address specifies a 32-bit I/O address. It should be used for devices that have a 32-bit DMA address register. The I/O address range that the device can address and other DMA attributes have to be specified in a ddi_dma_attr(9S) structure.

dmac_size describes the length of the transfer in bytes.

dmac_type contains bus-specific type bits, if appropriate. For example, a device on a PCI bus has PCI address modifier bits placed here.

ddi_dma_buf_bind_handle(9F), ddi_dma_getwin(9F), ddi_dma_nextcookie(9F),
ddi_dma_attr(9S)

Writing Device Drivers
### Name

ddi_dmae_req – DMA engine request structure

### Synopsis

```
#include <sys/dma_engine.h>
```

### Interface Level

Solaris x86 DDI specific (Solaris x86 DDI).

### Description

A device driver uses the ddi_dmae req structure to describe the parameters for a DMA channel. This structure contains all the information necessary to set up the channel, except for the DMA memory address and transfer count. The defaults, as specified below, support most standard devices. Other modes might be desirable for some devices, or to increase performance. The DMA engine request structure is passed to `ddi_dmae_prog(9F)`.

### Structure Members

The ddi_dmae_req structure contains several members, each of which controls some aspect of DMA engine operation. The structure members associated with supported DMA engine options are described here.

- `uchar_t der_command; /* Read / Write */`
- `/uchar_t der_bufprocess; /* Standard / Chain */`
- `uchar_t der_path; /* 8 / 16 / 32 */`
- `uchar_t der_cycles; /* Compat / Type A / Type B / Burst */`
- `uchar_t der_trans; /* Single / Demand / Block */`
- `ddi_dma_cookie_t* (*proc)(); /* address of nextcookie routine */`
- `void* procparms; /* parameter for nextcookie call */`

- **der_command**
  
  Specifies what DMA operation is to be performed. The value `DMAE_CMD_WRITE` signifies that data is to be transferred from memory to the I/O device. The value `DMAE_CMD_READ` signifies that data is to be transferred from the I/O device to memory. This field must be set by the driver before calling `ddi_dmae_prog()`.

- **der_bufprocess**
  
  On some bus types, a driver can set `der_bufprocess` to the value `DMAE_BUF_CHAIN` to specify that multiple DMA cookies will be given to the DMA engine for a single I/O transfer. This action causes a scatter/gather operation. In this mode of operation, the driver calls `ddi_dmae_prog()` to give the DMA engine the DMA engine request structure and a pointer to the first cookie. The proc structure member must be set to the address of a driver nextcookie routine. This routine takes one argument, specified by the procparms structure member, and returns a pointer to a structure of type `ddi_dma_cookie_t` that specifies the next cookie for the I/O transfer. When the DMA engine is ready to receive an additional cookie, the bus nexus driver controlling that DMA engine calls the routine specified by the proc structure member to obtain the next cookie from the driver. The driver’s nextcookie routine must then return the address of the next cookie (in static storage) to the bus nexus routine that called it. If there are no more segments in the current DMA window, then `(*proc)()` must return the `NULL` pointer.

---

Data Structures for Drivers 37
A driver can specify the `DMAE_BUF_CHAIN` flag only if the particular bus architecture supports the use of multiple DMA cookies in a single I/O transfer. A bus DMA engine can support this feature either with a fixed-length scatter/gather list, or by an interrupt chaining feature. A driver must determine whether its parent bus nexus supports this feature by examining the scatter/gather list size returned in the `dlim_sgllen` member of the DMA limit structure returned by the driver’s call to `ddi_dmae_getlim()`. (See `ddi_dmae_getlim()`.) If the size of the scatter/gather list is 1, then no chaining is available. The driver must not specify the `DMAE_BUF_CHAIN` flag in the `ddi_dmae_req` structure it passes to `ddi_dmae_prog()`, and the driver need not provide a `nextcookie` routine.

If the size of the scatter/gather list is greater than 1, then DMA chaining is available, and the driver has two options. Under the first option, the driver chooses not to use the chaining feature. In this case (a) the driver must set the size of the scatter/gather list to 1 before passing it to the DMA setup routine, and (b) the driver must not set the `DMAE_BUF_CHAIN` flag.

Under the second option, the driver chooses to use the chaining feature, in which case, (a) it should leave the size of the scatter/gather list alone, and (b) it must set the `DMAE_BUF_CHAIN` flag in the `ddi_dmae_req` structure. Before calling `ddi_dmae_prog()`, the driver must `prefetch` cookies by repeatedly calling `ddi_dma_nextseg()` and `ddi_dma_segtocookie()` until either (1) the end of the DMA window is reached (`ddi_dma_nextseg()` returns `NULL`), or (2) the size of the scatter/gather list is reached, whichever occurs first. These cookies must be saved by the driver until they are requested by the nexus driver calling the driver’s `nextcookie` routine. The driver’s `nextcookie` routine must return the prefetched cookies in order, one cookie for each call to the `nextcookie` routine, until the list of prefetched cookies is exhausted. After the end of the list of cookies is reached, the `nextcookie` routine must return the `NULL` pointer.

The size of the scatter/gather list determines how many discontiguous segments of physical memory can participate in a single DMA transfer. ISA bus DMA engines have no scatter/gather capability, so their scatter/gather list sizes are 1. Other finite scatter/gather list sizes would also be possible. For performance reasons, drivers should use the chaining capability if it is available on their parent bus.

As described above, a driver making use of DMA chaining must `prefetch` DMA cookies before calling `ddi_dmae_prog()`. The reasons for this are:
First, the driver must have some way to know the total I/O count with which to program the I/O device. This I/O count must match the total size of all the DMA segments that will be chained together into one DMA operation. Depending on the size of the scatter/gather list and the memory position and alignment of the DMA object, all or just part of the current DMA window might be able to participate in a single I/O operation. The driver must compute the I/O count by adding up the sizes of the prefetched DMA cookies. The number of cookies whose sizes are to be summed is the lesser of (a) the size of the scatter/gather list, or (b) the number of segments remaining in the window.

Second, on some bus architectures, the driver's nextcookie routine can be called from a high-level interrupt routine. If the cookies were not prefetched, the nextcookie routine would have to call ddi_dma_nextseg() and ddi_dma_segtocookie() from a high-level interrupt routine, which is not recommended.

When breaking a DMA window into segments, the system arranges for the end of every segment whose number is an integral multiple of the scatter/gather list size to fall on a device-granularity boundary, as specified in the dlim_granular field in the ddi_dma_lim_x86(9S) structure.

If the scatter/gather list size is 1 (either because no chaining is available or because the driver does not want to use the chaining feature), then the total I/O count for a single DMA operation is the size of DMA segment denoted by the single DMA cookie that is passed in the call to ddi_dmae_prog(). In this case, the system arranges for each DMA segment to be a multiple of the device-granularity size.

der_path
Specifies the DMA transfer size. The default of zero (DMAE_PATH_DEF) specifies ISA compatibility mode. In that mode, channels 0, 1, 2, and 3 are programmed in 8-bit mode (DMAE_PATH_8), and channels 5, 6, and 7 are programmed in 16-bit, count-by-word mode (DMAE_PATH_16).

der_cycles
Specifies the timing mode to be used during DMA data transfers. The default of zero (DMAE_CYCLES_1) specifies ISA compatible timing. Drivers using this mode must also specify DMAE_TRANS_SNGL in the der_trans structure member.

der_trans
Specifies the bus transfer mode that the DMA engine should expect from the device. The default value of zero (DMAE_TRANS_SNGL) specifies that the device performs one transfer for each bus arbitration cycle. Devices that use ISA compatible timing (specified by a value of zero, which is the default, in the der_cycles structure member) should use the
DMAE_TRANS_SNGL mode.

ddi_dma_lim_sparc(9S)

Name    ddi_dma_lim_sparc, ddi_dma_lim – SPARC DMA limits structure
Synopsis #include <sys/ddidmareq.h>

Interface Level Solaris SPARC DDI specific (Solaris SPARC DDI). These interfaces are obsolete.

Description This page describes the SPARC version of the ddi_dma_lim structure. See ddi_dma_lim_x86(9S) for a description of the x86 version of this structure.

A ddi_dma_lim structure describes in a generic fashion the possible limitations of a device’s DMA engine. This information is used by the system when it attempts to set up DMA resources for a device.

Structure Members

uint_t dlim_addr_lo; /* low range of 32 bit
    addressing capability */
uint_t dlim_addr_hi; /* inclusive upper bound of address.
    capability */
uint_t dlim_cntr_max; /* inclusive upper bound of
    dma engine address limit */
uint_t dlim_burstsizes; /* binary encoded dma burst sizes */
uint_t dlim_minxfer; /* minimum effective dma xfer size */
uint_t dlim_dmaspeed; /* average dma data rate (kb/s) */

The dlim_addr_lo and dlim_addr_hi fields specify the address range the device’s DMA engine can access. The dlim_addr_lo field describes the lower 32-bit boundary of the device’s DMA engine, the dlim_addr_hi describes the inclusive upper 32-bit boundary. The system allocates DMA resources in a way that the address for programming the device’s DMA engine (see ddi_dma_cookie(9S) or ddi_dma_htoc(9F)) is within this range. For example, if your device can access the whole 32-bit address range, you may use [0, 0xFFFFFFFF]. If your device has just a 16-bit address register but will access the top of the 32-bit address range, then [0xFFFF0000, 0xFFFFFFFF] is the right limit.

The dlim_cntr_max field describes an inclusive upper bound for the device’s DMA engine address register. This handles a fairly common case where a portion of the address register is only a latch rather than a full register. For example, the upper 8 bits of a 32-bit address register can be a latch. This splits the address register into a portion that acts as a true address register (24 bits) for a 16 Mbyte segment and a latch (8 bits) to hold a segment number. To describe these limits, specify 0x0FF0000 in the dlim_cntr_max structure.

The dlim_burstsizes field describes the possible burst sizes the device’s DMA engine can accept. At the time of a DMA resource request, this element defines the possible DMA burst cycle sizes that the requester’s DMA engine can handle. The format of the data is binary encoding of burst sizes assumed to be powers of two. That is, if a DMA engine is capable of doing 1-, 2-, 4-, and 16-byte transfers, the encoding is 0x17. If the device is an SBus device and can take advantage of a 64-bit SBus, the lower 16 bits are used to specify the burst size for 32-bit transfers and the upper 16 bits are used to specify the burst size for 64-bit transfers. As the resource request is handled by the system, the burstsizes value can be modified. Prior to
enabling DMA for the specific device, the driver that owns the DMA engine should check (using ddi_dma_burstsizes(9F)) what the allowed burst sizes have become and program the DMA engine appropriately.

The dlim_minxfer field describes the minimum effective DMA transfer size (in units of bytes). It must be a power of two. This value specifies the minimum effective granularity of the DMA engine. It is distinct from dlim_burstsizes in that it describes the minimum amount of access a DMA transfer will effect. dlim_burstsizes describes in what electrical fashion the DMA engine might perform its accesses, while dlim_minxfer describes the minimum amount of memory that can be touched by the DMA transfer. As a resource request is handled by the system, the dlim_minxfer value can be modified contingent upon the presence (and use) of I/O caches and DMA write buffers in between the DMA engine and the object that DMA is being performed on. After DMA resources have been allocated, the resultant minimum transfer value can be gotten using ddi_dma_devalign(9F).

The field dlim_dmaspeed is the expected average data rate for the DMA engine (in units of kilobytes per second). Note that this should not be the maximum, or peak, burst data rate, but a reasonable guess as to the average throughput. This field is entirely optional and can be left as zero. Its intended use is to provide some hints about how much of the DMA resource this device might need.

ddi_dma_lim_x86 – x86 DMA limits structure

Synopsis  

#include <sys/ddidmareq.h>

Interface Level  

Solaris x86 DDI specific (Solaris x86 DDI). This interface is obsolete.

Description  

A ddi_dma_lim structure describes in a generic fashion the possible limitations of a device or its DMA engine. This information is used by the system when it attempts to set up DMA resources for a device. When the system is requested to perform a DMA transfer to or from an object, the request is broken up, if necessary, into multiple sub-requests. Each sub-request conforms to the limitations expressed in the ddi_dma_lim structure.

This structure should be filled in by calling the routine ddi_dmae_getlim(). This routine sets the values of the structure members appropriately based on the characteristics of the DMA engine on the driver’s parent bus. If the driver has additional limitations, it can further restrict some of the values in the structure members. A driver should not relax any restrictions imposed by ddi_dmae_getlim().

</tbody>
</table>

The dlim_addr_lo and dlim_addr_hi fields specify the address range that the device’s DMA engine can access. The dlim_addr_lo field describes the lower 32-bit boundary of the device’s DMA engine. The dlim_addr_hi member describes the inclusive, upper 32-bit boundary. The system allocates DMA resources in a way that the address for programming the device’s DMA engine will be within this range. For example, if your device can access the whole 32-bit address range, you can use [0, 0xFFFFFFFF]. See ddi_dma_cookie(9S) or ddi_dma_segtocookie(9F).

The dlim_minxfer field describes the minimum effective DMA transfer size (in units of bytes), which must be a power of two. This value specifies the minimum effective granularity of the DMA engine and describes the minimum amount of memory that can be touched by the DMA transfer. As a resource request is handled by the system, the dlim_minxfer value can be modified. This modification is contingent upon the presence (and use) of I/O caches and DMA write buffers between the DMA engine and the object that DMA is being performed on. After DMA resources have been allocated, you can retrieve the resultant minimum transfer value using ddi_dma_devalign(9F).
The `dlim_version` field specifies the version number of this structure. Set this field to `DMALIM_VER0`.

The `dlim_adreg_max` field describes an inclusive upper bound for the device's DMA engine address register. This bound handles a fairly common case where a portion of the address register is simply a latch rather than a full register. For example, the upper 16 bits of a 32-bit address register might be a latch. This splits the address register into a portion that acts as a true address register (lower 16 bits) for a 64-kilobyte segment and a latch (upper 16 bits) to hold a segment number. To describe these limits, you specify `0xFFFF` in the `dlim_adreg_max` structure member.

The `dlim_ctreg_max` field specifies the maximum transfer count that the DMA engine can handle in one segment or cookie. The limit is expressed as the maximum count minus one. This transfer count limitation is a per-segment limitation. Because the limitation is used as a bit mask, it must be one less than a power of two.

The `dlim_granular` field describes the granularity of the device's DMA transfer ability, in units of bytes. This value is used to specify, for example, the sector size of a mass storage device. DMA requests are broken into multiples of this value. If there is no scatter/gather capability, then the size of each DMA transfer will be a multiple of this value. If there is scatter/gather capability, then a single segment cannot be smaller than the minimum transfer value, but can be less than the granularity. However, the total transfer length of the scatter/gather list is a multiple of the granularity value.

The `dlim_sglplen` field specifies the maximum number of entries in the scatter/gather list. This value is the number of segments or cookies that the DMA engine can consume in one I/O request to the device. If the DMA engine has no scatter/gather list, set this field to one.

The `dlim_reqsize` field describes the maximum number of bytes that the DMA engine can transmit or receive in one I/O command. This limitation is only significant if it is less than `(dlim_ctreg_max +1)*dlim_sglplen`. If the DMA engine has no particular limitation, set this field to `0xFFFFFFFF`.

The `ddi_dma_req` structure describes a request for DMA resources. A driver can use it to describe forms of allocations and ways to allocate DMA resources for a DMA request.

```c
#include <sys/ddidmareq.h>

Solaris DDI specific (Solaris DDI). This interface is obsolete.
```

### Description

A `ddi_dma_req` structure describes a request for DMA resources. A driver can use it to describe forms of allocations and ways to allocate DMA resources for a DMA request.

```c
struct ddi_dma_req {
    struct ddi_dma_lim_t *dmar_limits; /* Caller's dma engine constraints */
    uint_t dmar_flags; /* Contains info for mapping routines */
    int (*dmar_fp)(caddr_t);/* Callback function */
    caddr_t dmar_arg; /* Callback function's argument */
    ddi_dma_obj_t dmar_object; /* Descrip. of object to be mapped */
};
```

For the definition of the DMA limits structure, which `dmar_limits` points to, see `ddi_dma_lim_sparc(9S)` or `ddi_dma_lim_x86(9S)`.

Valid values for `dmar_flags` are:

- **DDI_DMA_WRITE** /* Direction memory --> IO */
- **DDI_DMA_READ** /* Direction IO --> memory */
- **DDI_DMA_RDWR** /* Both read and write */
- **DDI_DMA_REDZONE** /* Establish MMU redzone at end of mapping */
- **DDI_DMA_PARTIAL** /* Partial mapping is allowed */
- **DDI_DMA_CONSISTENT** /* Byte consistent access wanted */
- **DDI_DMA_SBUS_64BIT** /* Use 64 bit capability on SBus */

**DDI_DMA_WRITE**, **DDI_DMA_READ**, and **DDI_DMA_RDWR** describe the intended direction of the DMA transfer. Some implementations might explicitly disallow **DDI_DMA_RDWR**.

**DDI_DMA_REDZONE** asks the system to establish a protected red zone after the object. The DMA resource allocation functions do not guarantee the success of this request, as some implementations might not have the hardware ability to support it.

**DDI_DMA_PARTIAL** lets the system know that the caller can accept partial mapping. That is, if the size of the object exceeds the resources available, the system allocates only a portion of the object and returns status indicating this partial allocation. At a later point, the caller can use `ddi_dma_curwin(9F)` and `ddi_dma_movwin(9F)` to change the valid portion of the object that has resources allocated.

**DDI_DMA_CONSISTENT** gives a hint to the system that the object should be mapped for byte consistent access. Normal data transfers usually use a streaming mode of operation. They start at a specific point, transfer a fairly large amount of data sequentially, and then stop, usually on an aligned boundary. Control mode data transfers for memory-resident device control blocks...
(for example, Ethernet message descriptors) do not access memory in such a sequential fashion. Instead, they tend to modify a few words or bytes, move around and maybe modify a few more.

Many machine implementations make this non-sequential memory access difficult to control in a generic and seamless fashion. Therefore, explicit synchronization steps using `ddi_dma_sync(9F)` or `ddi_dma_free(9F)` are required to make the view of a memory object shared between a CPU and a DMA device consistent. However, proper use of the `DDI_DMA_CONSISTENT` flag can create a condition in which a system will pick resources in a way that makes these synchronization steps are as efficient as possible.

`DDI_DMA_SBUS_64BIT` tells the system that the device can perform 64–bit transfers on a 64–bit SBus. If the SBus does not support 64–bit data transfers, data will be transferred in 32–bit mode.

The callback function specified by the member `dmar_fp` indicates how a caller to one of the DMA resource allocation functions wants to deal with the possibility of resources not being available. (See `ddi_dma_setup(9F)`.) If `dmar_fp` is set to `DDI_DMA_DONTWAIT`, then the caller does not care if the allocation fails, and can deal with an allocation failure appropriately. Setting `dmar_fp` to `DDI_DMA_SLEEP` indicates the caller wants to have the allocation routines wait for resources to become available. If any other value is set, and a DMA resource allocation fails, this value is assumed to be a function to call later, when resources become available. When the specified function is called, it is passed the value set in the structure member `dmar_arg`. The specified callback function must return either:

0  Indicating that it attempted to allocate a DMA resource but failed to do so, again, in which case the callback function will be put back on a list to be called again later.

1  Indicating either success at allocating DMA resources or that it no longer wants to retry.

The callback function is called in interrupt context. Therefore, only system functions and contexts that are accessible from interrupt context are available. The callback function must take whatever steps necessary to protect its critical resources, data structures, and queues.

It is possible that a call to `ddi_dma_free(9F)`, which frees DMA resources, might cause a callback function to be called and, unless some care is taken, an undesired recursion can occur. This can cause an undesired recursive `mutex_enter(9F)`, which makes the system panic.

The `dmar_object` member of the `ddi_dma_req` structure is itself a complex and extensible structure:

```c
typedef struct dmar_object {
    uint_t dmao_size; /* size, in bytes, of the object */
    ddi_dma_atyp_t dmao_type; /* type of object */
    ddi_dma_aobj_t dmao_obj; /* the object described */
} dmar_object_t;
```

The `dmao_size` element is the size, in bytes, of the object resources allocated for DMA.
The dmao_type element selects the kind of object described by dmao_obj. It can be set to DMA_OTYP_VADDR, indicating virtual addresses.

The last element, dmao_obj, consists of the virtual address type:

```c
struct v_address virt_obj;
```

It is specified as:

```c
struct v_address {
    caddr_t  v_addr; /* base virtual address */
    struct as *v_as; /* pointer to address space */
    void     *v_priv; /* priv data for shadow I/O */
};
```

*Writing Device Drivers*
ddi_fm_error - I/O error status structure

Synopsis

#include <sys/ddifm.h>

Description

A ddi_fm_error_t structure contains common data necessary for I/O error handling. A pointer to a ddi_fm_error_t structure is passed to error handling callbacks where it can then be used in a call to pci_ereport_post(). The same structure is also returned to callers of ddi_fm_acc_err_get() and ddi_fm_dma_err_get().

Structure Members

int fme_version;
uint64_t fme_ena;
int fme_status;
int fme_flag;

The fme_version is the current version of ddi_fm_error_t. Valid values for the version are: DDI_FME_VER0 and DDI_FME_VER1.

The fme_ena is the FMA event protocol Format 1 Error Numeric Association (ENA) for this error condition.

The fme_flag field is set to DDI_FM_ERR_EXPECTED if the error is the result of a DDI_ACC_CAUTIOUS protected operation. In this case, fme_acc_handle is valid and the driver should check for and report only errors not associated with the DDI_ACC_CAUTIOUS protected access operation. This field can also be set to DDI_FM_ERR_POKE or DDI_FM_ERR_PEEK if the error is the result of a ddi_peek(9F) or ddi_poke(9F) operation. The driver should handle these in a similar way to DDI_FM_ERR_EXPECTED. Otherwise, fme_flag is set to DDI_FM_ERR_UNEXPECTED and the driver must perform the full range of error handling tasks.

The fme_status indicates current status of an error handler callback or resource handle:

DDI_FM_OK No errors were detected.
DDI_FM_FATAL An error which is considered fatal to the operational state of the system was detected.
DDI_FM_NONFATAL An error which is not considered fatal to the operational state of the system was detected.
DDI_FM_UNKNOWN An error was detected, but the driver was unable to determine the impact of the error on the operational state of the system.

The fme_acc_handle is the valid access handle associated with the error that can be returned from pci_ereport_post().

The fme_dma_handle is the valid DMA handle associated with the error that can be returned from pci_ereport_post().

Writing Device Drivers
Solaris device drivers are attached by `devfsadm(1M)` and by the kernel in response to `open(2)` requests from applications. Drivers not currently in use can be detached when the system experiences memory pressure. The `ddi-forceattach` and `ddi-no-autodetach` properties can be used to customize driver attach/detach behavior.

The `ddi-forceattach` is an integer property, to be set globally by means of the `driver.conf(4)` file. Drivers with this property set to 1 are loaded and attached to all possible instances during system startup. The driver will not be auto-detached due to system memory pressure.

The `ddi-no-autodetach` is an integer property to be set globally by means of the `driver.conf(4)` file or created dynamically by the driver on a per-instance basis with `ddi_prop_update_int(9F)`. When this property is set to 1, the kernel will not auto-detach driver due to system memory pressure.

Note that `ddi-forceattach` implies `ddi-no-autodetach`. Neither the `ddi-forceattach` nor `ddi-no-autodetach` properties prevent driver detaching in response to reconfiguration requests, such as executing commands `cfgadm(1M)`, `modunload(1M)`, `rem_drv(1M)`, and `update_drv(1M)`.

The `ddi-no-modunload` is an integer property to be set globally by means of the `driver.conf(4)` file. When this property is set to 1, the driver module is locked in memory and cannot be unloaded by `modunload`, `rem_drv`, or `update_drv`; the operation of `cfgadm`, however, remains unaffected.

Setting any of these properties to a non-integer value or an integer value not equal to 1 produces undefined results.

`cfgadm(1M)`, `modunload(1M)`, `rem_drv(1M)`, `update_drv(1M)`, `driver.conf(4)`

### Writing Device Drivers

### Warnings
Clearing the `ddi-no-modunload` property in a vendor-delivered `driver.conf` file could cause system instability.

The use of the `ddi-no-modunload` property is indicative that the delivered driver is broken in some way and that a cleaner version of the driver should be pursued. Thus, the use of this property is a temporary workaround which should be removed when the driver is fixed.
ddi_idevice_cookie(9S)

Name  ddi_idevice_cookie – device interrupt cookie

Synopsis  
#include <sys/ddi.h>
#include <sys/sunddi.h>

Interface Level  Solaris DDI specific (Solaris DDI). This interface is obsolete. Use the new interrupt interfaces referenced in Intro(9F). Refer to Writing Device Drivers for more information.

Description  The ddi_idevice_cookie_t structure contains interrupt priority and interrupt vector information for a device. This structure is useful for devices having programmable bus-interrupt levels. ddi_add_intr(9F) assigns values to the ddi_idevice_cookie_t structure members.

Writing Device Drivers
# devmap_callback_ctl

## Name

devmap_callback_ctl – device mapping-control structure

## Synopsis

```
#include <sys/ddidevmap.h>
```

## Interface Level

Solaris DDI specific (Solaris DDI).

## Description

A `devmap_callback_ctl` structure describes a set of callback routines that are called by the system to notify a device driver to manage events on the device mappings created by `devmap_setup(9F)` or `ddi_devmap_segmap(9F)`.

Device drivers pass the initialized `devmap_callback_ctl` structure to either `devmap_devmem_setup(9F)` or `devmap_umem_setup(9F)` in the `devmap(9E)` entry point during the mapping setup. The system makes a private copy of the structure for later use. Device drivers can specify different `devmap_callback_ctl` for different mappings.

A device driver should allocate the device mapping control structure and initialize the following fields, if the driver wants the entry points to be called by the system:

- `devmap_rev`: Version number. Set this to `DEVMAP_OPS_REV`.
- `devmap_map`: Set to the address of the `devmap_map(9E)` entry point or to `NULL` if the driver does not support this callback. If set, the system calls the `devmap_map(9E)` entry point during the `mmap(2)` system call. The drivers typically allocate driver private data structure in this function and return the pointer to the private data structure to the system for later use.
- `devmap_access`: Set to the address of the `devmap_access(9E)` entry point or to `NULL` if the driver does not support this callback. If set, the system calls the driver’s `devmap_access(9E)` entry point during memory access. The system expects `devmap_access(9E)` to call either `devmap_do_ctxmgt(9F)` or `devmap_default_access(9F)` to load the memory address translations before it returns to the system.
- `devmap_dup`: Set to the address of the `devmap_dup(9E)` entry point or to `NULL` if the driver does not support this call. If set, the system calls the `devmap_dup(9E)` entry point during the `fork(2)` system call.
- `devmap_unmap`: Set to the address of the `devmap_unmap(9E)` entry point or to `NULL` if the driver does not support this call. If set, the system will call the `devmap_unmap(9E)` entry point during the `munmap(2)` or `exit(2)` system calls.

## Structure Members

```
int devmap_rev;

int (*devmap_map)(devmap_cookie_t dhp, dev_t dev,
    uint_t flags, offset_t off, size_t len, void **pvtp);

int (*devmap_access)(devmap_cookie_t dhp, void *pvtp,
    offset_t off, size_t len, uint_t type, uint_t rw);

int (*devmap_dup)(devmap_cookie_t dhp, void *pvtp,
    devmap_cookie_t new_dhp, void **new_pvtp);
```
void (*devmap_unmap)(devmap_cookie_t dhp, void *pvtp,
    offset_t off, size_t len, devmap_cookie_t new_dhp1,
    void **new_pvtp1, devmap_cookie_t new_dhp2, void **new_pvtp2);

  Writing Device Drivers
## Name

dev_ops – device operations structure

## Synopsis

```
#include <sys/conf.h>
#include <sys/devops.h>
```

## Interface Level

Solaris DDI specific (Solaris DDI).

## Description

`dev_ops` contains driver common fields and pointers to the `bus_ops` and `cb_ops(9S)`.

Following are the device functions provided in the device operations structure. All fields must be set at compile time.

- `devo_rev` (Driver build version. Set this to DEVO_REV).
- `devo_refcnt` (Driver reference count. Set this to 0).
- `devo_getinfo` (Get device driver information (see `getinfo(9E)`)).
- `devo_identify` (This entry point is obsolete. Set to nulldev).
- `devo_probe` (Probe device. See `probe(9E)`).
- `devo_attach` (Attach driver to dev_info. See `attach(9E)`).
- `devo_detach` (Detach/prepare driver to unload. See `detach(9E)`).
- `devo_reset` (Reset device. (Not supported in this release.) Set this to nodev).
- `devo_cb_ops` (Pointer to `cb_ops(9S)` structure for leaf drivers).
- `devo_bus_ops` (Pointer to bus operations structure for nexus drivers. Set this to NULL if this is for a leaf driver).
- `devo_power` (Power a device attached to system. See `power(9E)`).
- `devo_quiesce` (Quiesce a device attached to system (see `quiesce(9E)` for more information). This can be set to `ddi_quiesce_not_needed()` if the driver does not need to implement quiesce.

## Structure Members

- `struct dev_ops {
  int devo_rev;
  int devo_refcnt;
  int (*devo_getinfo)(dev_info_t *dip, ddi_info_cmd_t infocmd, void *arg, void **result);
  int (*devo_identify)(dev_info_t *dip);
  int (*devo_probe)(dev_info_t *dip);
  int (*devo_attach)(dev_info_t *dip, ddi_attach_cmd_t cmd);
  int (*devo_detach)(dev_info_t *dip, ddi_detach_cmd_t cmd);
  int (*devo_reset)(dev_info_t *dip, ddi_reset_cmd_t cmd);
  struct cb_ops *devo_cb_ops;
  struct bus_ops *devo_bus_ops;
  int (*devo_power)(dev_info_t *dip, int component, int level);
} dev_ops;`
int (*devo_quiesce)(dev_info_t *dip);

Writing Device Drivers
Name  

fmodsw – STREAMS module declaration structure

Synopsis  

#include <sys/stream.h>
#include <sys/conf.h>

Interface Level  

Solaris DDI specific (Solaris DDI)

Description  

The fmodsw structure contains information for STREAMS modules. All STREAMS modules must define a fmodsw structure.

f_name must match mi_idname in the module_info structure. See module_info(9S). f_name should also match the module binary name. (See WARNINGS.)

All modules must set the f_flag to D_MP to indicate that they safely allow multiple threads of execution. See mt-streams(9F) for additional flags.

Structure  

char f_name[FMNAMESZ + 1]; /* module name */

Members  

struct streamtab *f_str; /* streams information */

int f_flag; /* flags */

See Also  

mt-streams(9F), modlstrmod(9S), module_info(9S)

STREAMS Programming Guide

Warnings  

If f_name does not match the module binary name, unexpected failures can occur.
**Name**
free_rtn – structure that specifies a driver’s message-freeing routine

**Synopsis**
#include <sys/stream.h>

**Interface Level**
Architecture independent level 1 (DDI/DKI).

**Description**
The free_rtn structure is referenced by the datab structure. When freeb(9F) is called to free the message, the driver’s message-freeing routine (referenced through the free_rtn structure) is called, with arguments, to free the data buffer.

<table>
<thead>
<tr>
<th>Structure Members</th>
</tr>
</thead>
<tbody>
<tr>
<td>void (<em>free_func)(); /</em> user’s freeing routine */</td>
</tr>
<tr>
<td>char <em>free_arg /</em> arguments to free_func() */</td>
</tr>
</tbody>
</table>

The free_rtn structure is defined as type frtn_t.

**See Also**
esballoc(9F), freeb(9F), datab(9S)

STREAMS Programming Guide
The Generic LAN Driver (GLD) Media Access Control (MAC) information (gld_mac_info) structure is the main data interface between the device-specific driver and GLD. It contains data required by GLD and a pointer to an optional additional driver-specific information structure.

Drivers can make no assumptions about the length of this structure, which might be different in different releases of Solaris and/or GLD. Structure members private to GLD, not documented here, should not be set or read by the device-specific driver.

</table>
Below is a description of the members of the `gld_mac_info` structure that are visible to the device driver.

`gldm_private` This structure member is private to the device-specific driver and is not used or modified by GLD. Conventionally, this is used as a pointer to private data, pointing to a driver-defined and driver-allocated per-instance data structure.

The following group of structure members must be set by the driver before calling `gld_register()`, and should not thereafter be modified by the driver; `gld_register()` can use or cache the values of some of these structure members, so changes made by the driver after calling `gld_register()` might cause unpredictable results.

`gldm_reset` Pointer to driver entry point; see `gld(9E)`.

`gldm_start` Pointer to driver entry point; see `gld(9E)`.

`gldm_stop` Pointer to driver entry point; see `gld(9E)`.

`gldm_set_mac_addr` Pointer to driver entry point; see `gld(9E)`.

`gldm_set_multicast` Pointer to driver entry point; see `gld(9E)`.

`gldm_set_promiscuous` Pointer to driver entry point; see `gld(9E)`.

`gldm_send` Pointer to driver entry point; see `gld(9E)`.

`gldm_intr` Pointer to driver entry point; see `gld(9E)`.

`gldm_get_stats` Pointer to driver entry point; see `gld(9E)`.

`gldm_ioctl` Pointer to driver entry point; can be NULL; see `gld(9E)`.

`gldm_ident` Pointer to a string containing a short description of the device. It is used to identify the device in system messages.

`gldm_type` The type of device the driver handles. The values currently supported by GLD are `DL_ETHER` (IEEE 802.3 and Ethernet Bus), `DL_TPR` (IEEE 802.5 Token Passing Ring), and `DL_FDDI` (ISO 9314-2 Fibre Distributed Data Interface). This structure member must be correctly set for GLD to function properly.

Support for the `DL_TPR` and `DL_FDDI` media types is obsolete and may be removed in a future release of Solaris.
### gldm_minpkt
Minimum *Service Data Unit* size — the minimum packet size, not including the MAC header, that the device will transmit. This can be zero if the device-specific driver can handle any required padding.

### gldm_maxpkt
Maximum *Service Data Unit* size — the maximum size of packet, not including the MAC header, that can be transmitted by the device. For Ethernet, this number is 1500.

### gldm_addrlen
The length in bytes of physical addresses handled by the device. For Ethernet, Token Ring, and FDDI, the value of this structure member should be 6.

### gldm_saplen
The length in bytes of the *Service Access Point* (SAP) address used by the driver. For GLD-based drivers, this should always be set to -2, to indicate that two-byte SAP values are supported and that the SAP appears after the physical address in a DLSAP address. See the description under “Message DL_INFO_ACK” in the DLPI specification for more details.

### gldm_broadcast_addr
Pointer to an array of bytes of length `gldm_addrlen` containing the broadcast address to be used for transmit. The driver must allocate space to hold the broadcast address, fill it in with the appropriate value, and set `gldm_broadcast_addr` to point at it. For Ethernet, Token Ring, and FDDI, the broadcast address is normally 0xFF-FF-FF-FF-FF-FF.

### gldm_vendor_addr
Pointer to an array of bytes of length `gldm_addrlen` containing the vendor-provided network physical address of the device. The driver must allocate space to hold the address, fill it in with information read from the device, and set `gldm_vendor_addr` to point at it.

### gldm_ppa
The Physical Point of Attachment (PPA) number for this instance of the device. Normally this should be set to the instance number, returned from `ddi_get_instance(9F)`.

### gldm_devinfo
Pointer to the dev_info node for this device.

### gldm_cookie
The interrupt block cookie returned by `ddi_get_iblock_cookie(9F), ddi_add_intr(9F), ddi_get_soft_iblock_cookie(9F), or ddi_add_softintr(9F)`. This must correspond to the device’s receive interrupt, from which `gld_recv()` is called.

### gldm_margin
Drivers set this value to the amount of data in bytes that the device can transmit beyond `gldm_maxpkt`. For example, if an Ethernet device can handle packets whose payload section is no
greater than 1522 bytes and the `gldm_maxpkt` is set to 1500 (as is typical for Ethernet), then `gldm_margin` is set to 22. The registered `gldm_margin` value is reported in acknowledgements of the DLIOCMARGININFO ioctl (see `dlpi(7P)`).

`gldm_capabilities` Bit-field of device capabilities. If the device is capable of reporting media link state, the GLD_CAP_LINKSTATE bit should be set.

**See Also** `gld(7D), dlpi(7P), attach(9E), gld(9E), ddi_add_intr(9F), gld(9F), gld_stats(9S)`

*Writing Device Drivers*
Name gld_stats – Generic LAN Driver statistics data structure
Synopsis #include <sys/gld.h>

Interface Level Solaris architecture specific (Solaris DDI).

Description The Generic LAN Driver (GLD) statistics (gld_stats) structure is used to communicate statistics and state information from a GLD-based driver to GLD when returning from a driver's gldm_get_stats() routine as discussed in gld(9E) and gld(7D). The members of this structure, filled in by the GLD-based driver, are used when GLD reports the statistics. In the tables below, the name of the statistics variable reported by GLD is noted in the comments. See gld(7D) for a more detailed description of the meaning of each statistic.

Drivers can make no assumptions about the length of this structure, which might be different in different releases of Solaris and/or GLD. Structure members private to GLD, not documented here, should not be set or read by the device specific driver.

Structure Members The following structure members are defined for all media types:

```
uint64_t glds_speed; /* ifspeed */
uint32_t glds_media; /* media */
uint32_t glds_intr; /* intr */
uint32_t glds_norcvbuf; /* norcvbuf */
uint32_t glds_errrcv; /* ierrors */
uint32_t glds_errxmt; /* oerrors */
uint32_t glds_missed; /* missed */
uint32_t glds_underflow; /* uflo */
uint32_t glds_overflow; /* oflo */
```

The following structure members are defined for media type DL_ETHER:

```
uint32_t glds_frame; /* align_errors */
uint32_t glds_crc; /* fcs_errors */
uint32_t glds_duplex; /* duplex */
uint32_t glds_nocarrier; /* carrier_errors */
uint32_t glds_collisions; /* collisions */
uint32_t glds_excoll; /* ex_collisions */
uint32_t glds_xmtlatecoll; /* tx_late_collisions */
uint32_t glds_defer; /* defer_xmts */
uint32_t glds_dot3_first_coll; /* first_collisions */
uint32_t glds_dot3_multi_coll; /* multi_collisions */
uint32_t glds_dot3_sqe_error; /* sqe_errors */
uint32_t glds_dot3_mac_xmt_error; /* macxmt_errors */
uint32_t glds_dot3_mac_rcv_error; /* macrcv_errors */
uint32_t glds_dot3_frame_too_long; /* toolong_errors */
uint32_t glds_short; /* runt_errors */
```

The following structure members are defined for media type DL_TPR:
uint32_t glds_dot5_line_error /* line_errors */
uint32_t glds_dot5_burst_error /* burst_errors */
uint32_t glds_dot5_signal_loss /* signal_losses */
uint32_t glds_dot5_ace_error /* ace_errors */
uint32_t glds_dot5_internal_error /* internal_errors */
uint32_t glds_dot5_lost_frame_error /* lost_frame_errors */
uint32_t glds_dot5_frame_copied_error /* frame_copied_errors */
uint32_t glds_dot5_token_error /* token_errors */
uint32_t glds_dot5_freq_error /* freq_errors */

Note – Support for the DL_TPR media type is obsolete and may be removed in a future release of Solaris.

The following structure members are defined for media type DL_FDDI:

uint32_t glds_fddi_mac_error; /* mac_errors */
uint32_t glds_fddi_mac_lost; /* mac_lost_errors */
uint32_t glds_fddi_mac_token; /* mac_tokens */
uint32_t glds_fddi_mac_tvx_expired; /* mac_tvx_expired */
uint32_t glds_fddi_mac_late; /* mac_late */
uint32_t glds_fddi_mac_ring_op; /* mac_ring_ops */

Note – Support for the DL_FDDI media type is obsolete and may be removed in a future release of Solaris.

Most of the above statistics variables are counters denoting the number of times the particular event was observed. Exceptions are:

glds_speed An estimate of the interface’s current bandwidth in bits per second. For interfaces that do not vary in bandwidth or for those where no accurate estimation can be made, this object should contain the nominal bandwidth.

glds_media The type of media (wiring) or connector used by the hardware. Currently supported media names include GLDM_AUI, GLDM_BNC, GLDM_TP, GLDM_10BT, GLDM_100BT, GLDM_100BTX, GLDM_100BT4, GLDM_RING4, GLDM_RING16, GLDM_FIBER, and GLDM_PHYMII. GLDM_UNKNOWN can also be specified.

glds_duplex Current duplex state of the interface. Supported values are GLD_DUPLEX_HALF and GLD_DUPLEX_FULL. GLD_DUPLEX_UNKNOWN can also be specified.

See Also gld(7D), gld(9F), gld(9E), gld_mac_info(9S)

Writing Device Drivers
Name  hook_nic_event – data structure describing events related to network interfaces

Synopsis  
#include <sys/neti.h>
#include <sys/hook.h>
#include <sys/hook_event.h>

Interface Level  Solaris DDI specific (Solaris DDI).

Description  The hook_nic_event structure contains fields that relate to an event that has occurred and belongs to a network interface. This structure is passed through to callbacks for NE_PLUMB, NE_UNPLUMB, NE_UP, NE_DOWN and NE_ADDRESS_CHANGE events.

A callback may not alter any of the fields in this structure.

Structure Members  
net_data_t  hne_family;
phy_if_t  pkt_private;
lif_if_t  hne_lif;
nic_event_t  hne_event;
nic_event_data_t  hne_data;
size_t  hne_datalen;

The following fields are set for each event:

hne_family  A valid reference for the network protocol that owns this network interface and can be in calls to other netinfo(9F) functions.

hne_nic  The physical interface to which an event belongs.

hne_event  A value that indicates the respective event. The current list of available events is:

NE_PLUMB  an interface has just been created.

NE_UNPLUMB  An interface has just been destroyed and no more events should be received for it.

NE_UP  An interface has changed the state to “up” and may now generate packet events.

NE_DOWN  An interface has changed the state to “down” and will no longer generate packet events.
**NE_ADDRESS_CHANGE**
An address on an interface has changed. *hne_lif* refers to the logical interface for which the change is occurring, *hne_data* is a pointer to a `sockaddr` structure that is *hne_datalen* bytes long and contains the new network address.

**NE_IFINDEX_CHANGE**
An interface index has changed. *hne_lif* refers to the logical interface for which the change is occurring, *hne_data* is a new `ifindex` value.

**Attributes**

**Name**

`hook_pkt_event` – packet event structure passed through to hooks

**Synopsis**

```c
#include <sys/neti.h>
#include <sys/hook.h>
#include <sys/hook_event.h>
```

**Interface Level**

Solaris DDI specific (Solaris DDI).

**Description**

The `hook_pkt_event` structure contains fields that relate to a packet in a network protocol handler. This structure is passed through to a callback for `NH_PRE_ROUTING`, `NH_POST_ROUTING`, `NH_FORWARDING`, `NH_LOOPBACK_IN`, and `NH_LOOPBACK_OUT` events.

A callback may only modify the `hpe_hdr`, `hpe_mp`, and `hpe_mb` fields.

The following table documents which fields can be safely used as a result of each event.

<table>
<thead>
<tr>
<th>Event</th>
<th>hpe_ifp</th>
<th>hpe_ofp</th>
<th>hpe_hdr</th>
<th>hpe_mp</th>
<th>hpe_mb</th>
</tr>
</thead>
<tbody>
<tr>
<td>NH_PRE_ROUTING</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>NH_POST_ROUTING</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>NH_FORWARDING</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>NH_LOOPBACK_IN</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>NH_LOOPBACK_OUT</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
</tr>
</tbody>
</table>

**Structure Members**

- `net_data_t hne_family;`
- `phy_if_t hpe_ifp;`
- `phy_if_t hpe_ofp;`
- `void *hpe_hdr;`
- `mblk_t *hpe_mp;`
- `mblk_t *hpe_mb;`
- `uint32_t hpe_flags;`

The following fields are set for each event:

- `hne_family` - The protocol family for this packet. This value matches the corresponding value returned from a call to `net_protocol_lookup(9F)`.
- `hpe_ifp` - The inbound interface for a packet.
- `hpe_ofp` - The outbound interface for a packet.
- `hpe_hdr` - Pointer to the start of the network protocol header within an `mblk_t` structure.
- `hpe_mp` - Pointer to the `mblk_t` pointer that points to the first `mblk_t` structure in this packet.
- `hpe_mb` - Pointer to the `mblk_t` structure that contains `hpe_hdr`.
- `hpe_flags` - This field is used to carry additional properties of packets. The current collection of defined bits available is:
HPE_BROADCAST  This bit is set if the packet was recognized as a broadcast packet from the link layer. The bit cannot be set if HPE_MULTICAST is set, currently only possible with physical in packet events.

HPE_MULTICAST  This set if the packet was recognized as a multicast packet from the link layer. This bit cannot be set if HPE_BROADCAST is set, currently only possible with physical in packet events.

hook_t – callback structure for subscribing to netinfo events

Synopsis

#include <sys/hook.h>

The hook_t data structure defines a callback that is to be inserted into a networking event. This data structure must be allocated with a call to hook_alloc() and released with a call to hook_free().

Structure Members

hook_func_t h_func; /* callback function to invoke */
char *h_name; /* unique name given to the hook */
int h_flags;
hook_hint_t h_hint; /* insertion hint type */
uintptr_t h_hintvalue; /* used with h_hint */
void *h_arg; /* value to pass into h_func */

typedef int (*hook_func_t)(net_event_t token, hook_data_t info,
void *);

HINT TYPES

Hook hints are hints that are used at the time of insertion and are not rules that enforce where a hook lives for its entire lifetime on an event. The valid values for the h_hint field are:

HH_NONE Insert the hook wherever convenient.
HH_FIRST Place the hook first on the list of hooks.
HH_LAST Place the hook last on the list of hooks.
HH_BEFORE Place the hook before another hook on the list of hooks. The value in h_hintvalue must be a pointer to the name of another hook.
HH_AFTER Place the hook after another hook on the list of hooks. The value in h_hintvalue must be a pointer to the name of another hook.

netinfo(9F)
### Name

### Description
These are optional properties, typically created by the system, for SCSI target devices. References to these properties should use their `sys/scsi/impl/inquiry.h` defined names.

**inquiry-device-type** is an integer property. When present, the least significant byte of the value indicates the device type as defined by the SCSI standard. Consumers of this property should compare the property values with `DTYPE_*` values defined in `sys/scsi/generic/inquiry.h`.

**inquiry-vendor-id** is a string property. When present, it contains the vendor information. This information typically comes from the `scsi_inquiry(9S)` “inq_vid” field.

**inquiry-product-id** is a string property. When present, it contains the product identification. This information typically comes from the `scsi_inquiry(9S)` “inq_pid” field.

**inquiry-revision-id** is a string property. When present, it contains the product revision. This revision typically comes from the `scsi_inquiry(9S)` “inq_rev” field.

**inquiry-serial-no** is a string property. When present, it contains the serial number. The serial number is typically obtained from the EVPD “Unit Serial Number” SCSI INQUIRY data (page 0x80).

### See Also
`scsi_inquiry(9S)`

*Writing Device Drivers*

### Notes
Values established at `tran_tgt_init(9E)` time by an HBA driver take precedence over values established by the system, and HBA driver values may not be the same length as the typical `scsi_inquiry(9S)` field.
iocblk(9S)

Name
iocblk – STREAMS data structure for the M_IOCTL message type

Synopsis
#include <sys/stream.h>

Interface Level
Architecture independent level 1 (DDI/DKI).

Description
The iocblk data structure is used for passing M_IOCTL messages.

Structure Members
int ioc_cmd; /* ioctl command type */
cred_t *ioc_cr; /* full credentials */
uint_t ioc_id; /* ioctl id */
uint_t ioc_flag; /* ioctl flags */
uint_t ioc_count; /* count of bytes in data field */
int ioc_rval; /* return value */
int ioc_error; /* error code */

*Writing Device Drivers*
**Synopsis**

```
#include <sys/types.h>
#include <sys/kstat.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>
```

Each kernel statistic (kstat) exported by device drivers consists of a header section and a data section. The kstat structure is the header portion of the statistic.

A driver receives a pointer to a kstat structure from a successful call to `kstat_create(9F)`. Drivers should never allocate a kstat structure in any other manner.

After allocation, the driver should perform any further initialization needed before calling `kstat_install(9F)` to actually export the kstat.

### Structure Members

```c
void *ks_data; /* kstat type-specif. data */
ulong_t ks_ndata; /* # of type-specif. data records */
ulong_t ks_data_size; /* total size of kstat data section */
int (*ks_update)(struct kstat *, int);
void *ks_private; /* arbitrary provider-private data */
void *ks_lock; /* protects kstat's data */
```

The members of the kstat structure available to examine or set by a driver are as follows:

- **ks_data**
  Points to the data portion of the kstat. Either allocated by `kstat_create(9F)` for the drivers use, or by the driver if it is using virtual kstats.

- **ks_ndata**
  The number of data records in this kstat. Set by the `ks_update(9E)` routine.

- **ks_data_size**
  The amount of data pointed to by `ks_data`. Set by the `ks_update(9E)` routine.

- **ks_update**
  Pointer to a routine that dynamically updates kstat. This is useful for drivers where the underlying device keeps cheap hardware statistics, but where extraction is expensive. Instead of constantly keeping the kstat data section up to date, the driver can supply a `ks_update(9E)` function that updates the kstat data section on demand. To take advantage of this feature, set the `ks_update` field before calling `kstat_install(9F)`.

- **ks_private**
  Is a private field for the driver’s use. Often used in `ks_update(9E)`. 
ks_lock
Is a pointer to a mutex that protects this kstat. kstat data sections are optionally protected by the per-kstat ks_lock. If ks_lock is non-NULL, kstat clients (such as /dev/kstat) will acquire this lock for all of their operations on that kstat. It is up to the kstat provider to decide whether guaranteeing consistent data to kstat clients is sufficiently important to justify the locking cost. Note, however, that most statistic updates already occur under one of the provider’s mutexes. If the provider sets ks_lock to point to that mutex, then kstat data locking is free. ks_lock is really of type (kmutex_t*) and is declared as (void*) in the kstat header. That way, users do not have to be exposed to all of the kernel’s lock-related data structures.

See Also   kstat_create(9F)

Writing Device Drivers
### kstat_intr(9S)

**Name**

kstat_intr – structure for interrupt kstats

**Synopsis**

```c
#include <sys/types.h>
#include <sys/kstat.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>
```

Solaris DDI specific (Solaris DDI)

**Description**

Interrupt statistics are kept in the kstat_intr structure. When `kstat_create()` creates an interrupt kstat, the ks_data field is a pointer to one of these structures. The macro `KSTAT_INTR_PTR()` is provided to retrieve this field. It looks like this:

```c
#define KSTAT_INTR_PTR(kptr) ((kstat_intr_t *)(kptr)->ks_data)
```

An interrupt is a hard interrupt (sourced from the hardware device itself), a soft interrupt (induced by the system through the use of some system interrupt source), a watchdog interrupt (induced by a periodic timer call), spurious (an interrupt entry point was entered but there was no interrupt to service), or multiple service (an interrupt was detected and serviced just prior to returning from any of the other types).

Drivers generally report only claimed hard interrupts and soft interrupts from their handlers, but measurement of the spurious class of interrupts is useful for auto-vectored devices in order to pinpoint any interrupt latency problems in a particular system configuration.

Devices that have more than one interrupt of the same type should use multiple structures.

**Structure Members**

```c
ulong_t intrs[KSTAT_NUM_INTRS]; /* interrupt counters */
```

The only member exposed to drivers is the intrs member. This field is an array of counters. The driver must use the appropriate counter in the array based on the type of interrupt condition.

The following indexes are supported:

- `KSTAT_INTR_HARD` – Hard interrupt
- `KSTAT_INTR_SOFT` – Soft interrupt
- `KSTAT_INTR_WATCHDOG` – Watchdog interrupt
- `KSTAT_INTR_SPURIOUS` – Spurious interrupt
- `KSTAT_INTR_MULTSVC` – Multiple service interrupt

**See Also**

- `kstat(9S)`

*Writing Device Drivers*
### Name
kstat_io – structure for I/O kstats

### Synopsis
```c
#include <sys/types.h>
#include <sys/kstat.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>
```

### Interface Level
Solaris DDI specific (Solaris DDI)

### Description
I/O kstat statistics are kept in a kstat_io structure. When `kstat_create(9F)` creates an I/O kstat, the `ks_data` field is a pointer to one of these structures. The macro `KSTAT_IO_PTR()` is provided to retrieve this field. It looks like this:

```c
#define KSTAT_IO_PTR(kptr) ((kstat_io_t *)(kptr)->ks_data)
```

The `nread` field should be updated by the driver with the number of bytes successfully read upon completion.

The `nwritten` field should be updated by the driver with the number of bytes successfully written upon completion.

The `reads` field should be updated by the driver after each successful read operation.

The `writes` field should be updated by the driver after each successful write operation.

Other I/O statistics are updated through the use of the `kstat_queue(9F)` functions.

### Structure Members

*Writing Device Drivers*
Name  kstat_named – structure for named kstats

Synopsis  #include <sys/types.h>
          #include <sys/kstat.h>
          #include <sys/ddi.h>
          #include <sys/sunddi.h>

Interface Level  Solaris DDI specific (Solaris DDI)

Description  Named kstats are an array of name-value pairs. These pairs are kept in the kstat_named
structure. When a kstat is created by kstat_create(9F), the driver specifies how many of
these structures will be allocated. The structures are returned as an array pointed to by the
ks_data field.

Structure  union {
           char            c[16];
           long            l;
           ulong_t         ul;
           longlong_t      ll;
           u_longlong_t    ull;
        } value; /* value of counter */

The only member exposed to drivers is the value member. This field is a union of several data
types. The driver must specify which type it will use in the call to kstat_named_init().

See Also  kstat_create(9F), kstat_named_init(9F)

Writing Device Drivers
### Name
linkblk – STREAMS data structure sent to multiplexor drivers to indicate a link

### Synopsis
```c
#include <sys/stream.h>
```

### Interface Level
Architecture independent level 1 (DDI/DKI)

### Description
The `linkblk` structure is used to connect a lower Stream to an upper STREAMS multiplexor driver. This structure is used in conjunction with the `I_LINK`, `I_UNLINK`, `P_LINK`, and `P_UNLINK` ioctl commands. See `streamio(7I)`. The `M_DATA` portion of the `M_IOCTL` message contains the `linkblk` structure. Note that the `linkblk` structure is allocated and initialized by the Stream head as a result of one of the above ioctl commands.

### Structure Members
```
queue_t *l_qtop; /* lowest level write queue of upper stream */
/* (set to NULL for persistent links) */
queue_t *l_qbot; /* highest level write queue of lower stream */
int l_index; /* index for lower stream. */
```

mac_callbacks(9S)

**Name**
mac_callbacks – MAC callbacks data structure

**Synopsis**
#include <sys/mac_provider.h>

**Interface Level**
Solaris architecture specific (Solaris DDI)

**Description**
The mac_callbacks data structure is used by MAC device drivers to expose their entry points to the MAC layer. A pointer to an instance of the mac_callbacks structure is passed through the m_callbacks field of the mac_register(9S) structure as part of the registration of a device driver instance through mac_register(9F).

**Structure**

```c
uint_t mc_callbacks; /* Denotes which callbacks are set */
mac_getstat_t mc_getstat; /* Get the value of a statistic */
mac_start_t mc_start; /* Start the device */
mac_stop_t mc_stop; /* Stop the device */
mac_setpromisc_t mc_setpromisc; /* Enable or disable promiscuous mode */
mac_multicst_t mc_multicst; /* Enable or disable a multicast addr */
mac_unicst_t mc_unicst; /* Set the unicast MAC address */
mac_tx_t mc_tx; /* Transmit a packet */
mac_ioctl_t mc_ioctl; /* Process an unknown ioctl */
m_getcapab_t mc_getcapab; /* Get capability information */
m_setprop_t mc_setprop; /* Set property value */
m_getprop_t mc_getprop; /* Get property value */
m_propinfo_t mc_propinfo; /* Get property attributes */
```

Below are descriptions of the members of the mac_callbacks structure that are visible to the device driver.

**mc_callbacks**

Flags specifying which ones of the optional entry points are implemented by the driver. The following flags are supported:

**MC_IOCTL**
Set by the driver when the mc_ioctl() entry point is present.

**MC_GETCAPAB**
Set by the driver when the mc_getcapab() entry point is present.

**MC_SETPROP**
Set by the driver when the mc_setprop() entry point is present.

**MC_GETPROP**
Set by the driver when the mc_getprop() entry point is present.

**MC_PROPINFO**
Set by the driver when the mc_propinfo() entry point is present.

**MC_PROPERTIES**
Set by a driver which implements all properties entry points (mc_setprop(), mc_getprop(), and mc_propinfo()). Setting MC_PROPERTIES is the equivalent of setting
the three flags MC_SETPROP, MC_GETPROP, and MC_PROPINFO.

\textit{mc_getstat}

pointer to driver entry point

\textit{mc_start}

pointer to driver entry point

\textit{mc_stop}

pointer to driver entry point

\textit{mc_setpromisc}

pointer to driver entry point

\textit{mc_multicast}

mac_capab_lso(9S)

Name       mac_capab_lso, lso_basic_tcp_ipv4 - LSO capability data structure
Synopsis    #include <sys/mac_provider.h>

Interface Level Solaris architecture specific (Solaris DDI)

Description The mac_capab_lso and lso_basic_tcp_ipv4 structures are used by a device driver to
describe its LSO capability. The structure is used as the argument to the mc_getcapab(9E)
driver entry point when querying the MAC_CAPAB_LSO capability.

Structure Members The mac_capab_lso data structure has the following members:

t uscalar_t     lso_flags;
lso_basic_tcp_ipv4_t lso_basic_tcp_ipv4;

The fields must be set as follows:

lso_flags
   Flag indicating the LSO capability supported by the device driver instance. The following
   flags are currently supported:

   LSO_TX_BASIC_TCP_IPV4   LSO for TCP on IPv4

lso_basic_tcp_ipv4
   Parameters for TCP LSO over IPv4

The lso_basic_tcp_ipv4 data structure is used by the device driver to advertise specific
parameters when the LSO_TX_BASIC_TCP_IPV4 lso_flag is set. This data structure has the
following elements:

t uscalar_t     lso_max;

The lso_max field contains the maximum payload size supported by the driver instance.

mac_capab_rings – rings capability data structure

Synopsis
#include <sys/mac_provider.h>

Interface Level
Solaris architecture specific (Solaris DDI)

Description
The mac_capab_rings structure is used by a network device driver to describe its rings capability. The structure is used as the argument to the mc_getcapab(9E) driver entry point when querying the MAC_CAPAB_RINGS capability.

Structure Members
mac_ring_type_t mr_type;
mac_group_type_t mr_group_type;
uint32_t mr_flags;
mac_rings_version_t mr_version;
uint_t mr_rnum;
uint_t mr_gnum;
mac_get_ring_t mr_rget;
mac_get_group_t mr_gget;
mac_group_add_ring_t mr_gaddring;
mac_group_rem_ring_t mr_gremring;

The following fields of the mac_capab_rings structure are set to indicate the device's rings capability:

mr_type
Set by MAC layer to indicate which driver resources is being queried. Possible ring types are MAC_RING_TYPE_RX or MAC_RING_TYPE_TX.

mr_group_type
Set by the driver to indicate whether the device is capable of static or dynamic ring grouping. Possible grouping types for the driver are MAC_GROUP_TYPE_STATIC or MAC_GROUP_TYPE_DYNAMIC. If the driver can dynamically grow and shrink ring groups, then it should advertise the MAC_GROUP_TYPE_DYNAMIC group type and implement mr_gaddring() and mr_gremring() entry points.

mr_flags
Set by the driver to indicate various conditions. Currently, MAC_RINGS_VLAN_TRANSPARENT is the possible value to indicate the hardware is capable of transparent VLANs.

mr_version
Set by the driver to indicate the version of the rings capability that the driver implements. The current revision level is MAC_RINGS_VERSION_1.

mr_rnum
Set by the driver to indicate the total number of RX or TX rings the driver implements.

mr_gnum
Set by the driver to indicate the total number of RX or TX ring groups the hardware implements.

mr_rget
A driver entry point to get specific ring information for each RX and TX ring the hardware implements.
`mac_capab_rings(9S)`

- **mr_gget**: A driver entry point to get the specific information for each RX and TX ring group the driver implements.
- **mr_gaddring**: A driver entry point to add a ring to a driver ring group. This entry point is implemented for drivers who support dynamic ring grouping.
- **mr_gremring**: A driver entry point to remove a specific ring from a driver ring group.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

</tr>
</tbody>
</table>

The following fields of mac_register_t must be set by the device driver before invoking the mac_register() entry point:

m_version
Set by mac_alloc(9F), device drivers should not modify this field.

m_type_ident
Must be set to one of the following depending on the type of device being registered.

MAC_PLUGIN_IDENT_ETHER Ethernet driver

m_driver
Driver handle, opaque to the framework, usually points to a per-driver instance data structure. Passed back as argument to driver's entry points invoked by the framework.

m_dip
Pointer to the driver instance dev_info structure, see attach(9E).

m_instance
Used by the driver to specify the instance number to be associated with the MAC being registered. This value should always be specified by 0.

m_src_addr
Pointer to the primary MAC address value of the MAC instance.

m_dst_addr
Pointer to the destination MAC address value of a fixed destination MAC address. This field is optional and should be set to NULL for regular device drivers.

m_callbacks
Pointer to an instance of the mac_callbacks(9S) structure.
Minimum Service Data Unit size, the minimum packet size, not including the MAC header, that the device can transmit. This can be zero if the device driver can handle any required padding.

Maximum Service Data Unit size, the maximum packet size, not including the MAC header, that can be transmitted by the device. For Ethernet, this number is commonly referred to as the MTU (maximum transmission unit.)

Array of driver-private property names, terminated by a null pointer.

Drivers set this value to the amount of data in bytes that the device can transmit beyond m_max_sdu. For example, if an Ethernet device can handle packets whose payload section is no greater than 1522 bytes and m_max_sdu is set to 1500 (as is typical for Ethernet), then m_margin is set to 22.

See mac_register(9F) for more information about the use of these fields.

The driver is responsible for allocating the memory pointed to by the fields m_priv_props, m_src_addr, and m_dst_addr. The driver can free this memory after the call to mac_register() returns.

mac_ring_info – ring information data structure

#include <sys/mac_provider.h>

Solaris architecture specific (Solaris DDI)

The `mac_ring_info` structure is used by a network device driver to describe its RX and TX rings. The structure is used as an argument to the `mr_rget(9E)` driver entry point when querying the ring.

### Structure Members

- `mac_ring_driver_t mri_driver;`  
  Filled by the driver as handle to the driver’s ring structure.
- `mac_ring_start_t mri_start;`  
  The driver entry point for starting a driver’s ring.
- `mac_ring_stop_t mri_stop;`  
  The driver entry point for stopping a driver ring.
- `mac_ring_stat_t mri_stat;`  
  The driver entry point for getting statistics for ring.
- `mac_intr_enable_t mri_intr_enable;`  
  The driver entry point for transmitting packet for TX rings.
- `mac_intr_disable_t mri_intr_disable;`  
  The driver entry point for polling RX ring for packets.
- `mac_intr_ddi_handle_t mri_intr_ddi_handle;`  
  A set of flags for describing ring behavior.
- `mac_intr_enable_t mri_intr_enable;`  
  The DDI interrupt handle associated with the interrupt for this ring.
- `mac_intr_disable_t mri_intr_disable;`  
  For RX rings, this driver entry point will enable interrupts again and transition the driver polling to interrupt mode.
- `mac_intr_disable_t mri_intr_disable;`  
  For RX rings, this driver entry point will disable interrupts and place the driver into polling mode.

**modlstrmod(9S)**

**Name**  modlstrmod – linkage structure for loadable STREAMS modules

**Synopsis**  
```c
#include <sys/modctl.h>
```

**Interface Level**  Solaris DDI specific (Solaris DDI)

**Description**  The `modlstrmod` structure is used by STREAMS modules to export module specific information to the kernel.

**Structure Members**

- `struct mod_ops *strmod_modops;`  
  Must always be initialized to the address of `mod_strmodops`. This identifies the module as a loadable STREAMS module.

- `char *strmod_linkinfo;`  
  Can be any string up to `MODMAXNAMELEN`, and is used to describe the module. This string is usually the name of the module, but can contain other information (such as a version number).

- `struct fmodsw *strmod_fmodsw;`  
  Is a pointer to a template of a class entry within the module that is copied to the kernel’s class table when the module is loaded.

**See Also**  `modload(1M)`

*Writing Device Drivers*
**Name**  
module_info – STREAMS driver identification and limit value structure

**Synopsis**  
#include <sys/stream.h>

**Interface Level**  
Architecture independent level 1 (DDI/DKI).

**Description**  
When a module or driver is declared, several identification and limit values can be set. These values are stored in the module_info structure.

The module_info structure is intended to be read-only. However, the flow control limits (mi_hiwat and mi_lowat) and the packet size limits (mi_minpsz and mi_maxpsz) are copied to the QUEUE structure, where they can be modified.

For a driver, mi_idname must match the name of the driver binary file. For a module, mi_idname must match the.fname field of the fmodsw structure. See fmodsw(9S) for details.

**Structure Members**

- ush ort_t mi_idnum; /* module ID number */
- char *mi_idname; /* module name */
- ssize_t mi_minpsz; /* minimum packet size */
- ssize_t mi_maxpsz; /* maximum packet size */
- size_t mi_hiwat; /* high water mark */
- size_t mi_lowat; /* low water mark */

The constant FMNAMESZ, limiting the length of a module's name, is set to eight in this release.

STREAMS Programming Guide
# msgb(9S)

## Name
msgb, mblk – STREAMS message block structure

## Synopsis
```c
#include <sys/stream.h>
```

## Interface Level
Architecture independent level 1 (DDI/DKI)

## Description
A STREAMS message is made up of one or more message blocks, referenced by a pointer to a `msgb` structure. The `b_next` and `b_prev` pointers are used to link messages together on a QUEUE. The `b_cont` pointer links message blocks together when a message consists of more than one block.

Each `msgb` structure also includes a pointer to a `datab(9S)` structure, the data block (which contains pointers to the actual data of the message), and the type of the message.

```c
struct msgb *b_next; /* next message on queue */
struct msgb *b_prev; /* previous message on queue */
struct msgb *b_cont; /* next message block */
unsigned char *b_rptr; /* 1st unread data byte of buffer */
unsigned char *b_wptr; /* 1st unwritten data byte of buffer */
struct datab *b_datap; /* pointer to data block */
unsigned char b_band; /* message priority */
unsigned short b_flag; /* used by stream head */
```

Valid flags are as follows:

- MSGMARK: Last byte of message is marked.
- MSGDELIM: Message is delimited.

The `msgb` structure is defined as type `mblk_t`.

**Name**  
net_inject_t – structure for describing how to transmit a packet

**Synopsis**  
#include <sys/neti.h>

**Interface Level**  
Solaris DDI specific (Solaris DDI).

**Description**  
The net_inject_t data structure passes information into net_inject about how to transmit a packet. Transmit includes sending the packet up into the system as well as out of it.

**Structure Members**

- mblk_t *ni_packet; /* start of the packet */
- struct sockaddr_storage ni_addr; /* address of next hop */
- phy_if_t ni_physical; /* network interface to use */

- **ni_packet**  
  Pointer to the first the mblk_t data structure that makes up this packet.

- **ni_addr**  
  This field is only required to be initialized if NI_DIRECT_OUT is being used to transmit the packet. The sockaddr_storage field must be set to indicate whether the destination address contained in the structure is IPv4 (cast ni_addr to struct sockaddr_in) or IPv6 (cast ni_addr to struct sockaddr_in6).

- **ni_physical**  
  The physical interface where the packet will be injected.

Name  net_instance_t– packet event structure passed through to hooks

Synopsis  
```c
#include <sys/neti.h>
```

Interface Level  Solaris DDI specific (Solaris DDI).

Description  The net_instance_t data structure defines a collection of instances to be called when relevant events happen within IP. The value returned by the nin_create() function is stored internally and passed back to both the nin_destroy() and nin_shutdown() functions as the second argument. The netid_t passed through to each function can be used to uniquely identify each instance of IP.

Structure Members  
```c
char *nin_name;
void *(*nin_create)(const netid_t);
void (*nin_destroy)(const netid_t, void *);
void (*nin_shutdown)(const netid_t, void *);
```

nin_name  Name of the owner of the instance.
nin_create  Function to be called when a new instance of IP is created.
nin_destroy  Function to be called when an instance of IP is being destroyed.
nin_shutdown  Function to be called when an instance of IP is being shutdown. nin_shutdown() is called before nin_destroy() is called.

no-involuntary-power-cycles(9P)

**Name**
no-involuntary-power-cycles – device property to prevent involuntary power cycles

**Description**
A device that might be damaged by power cycles should export the boolean (zero length) property `no-involuntary-power-cycles` to notify the system that all power cycles for the device must be under the control of the device driver.

The presence of this property prevents power from being removed from a device or any ancestor of the device while the device driver is detached, unless the device was voluntarily powered off as a result of the device driver calling `pm_lower_power(9F)`.

The presence of `no-involuntary-power-cycles` also forces attachment of the device driver during a CPR suspend operation and prevents the suspend from taking place, unless the device driver returns `DDI_SUCCESS` when its `detach(9E)` entry point is called with `DDI_SUSPEND`.

The presence of `no-involuntary-power-cycles` does not prevent the system from being powered off due to a `halt(1M)` or `uadmin(1M)` invocation, except for CPR suspend.

This property can be exported by a device that is not power manageable, in which case power is not removed from the device or from any of its ancestors, even when the driver for the device and the drivers for its ancestors are detached.

**Examples**
**EXAMPLE 1**  Use of Property in Driver's Configuration File
The following is an example of a `no-involuntary-power-cycles` entry in a driver's `.conf` file:

```
no-involuntary-power-cycles=1;
```

**EXAMPLE 2**  Use of Property in `attach()` Function
The following is an example of how the preceding `.conf` file entry would be implemented in the `attach(9E)` function of a driver:

```
xxattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
  ...
  if (ddi_prop_create(DDI_DEV_T_NONE, dip, DDI_PROP_CANSLEEP, 
                   "no-involuntary-power-cycles", NULL, 0) != DDI_PROP_SUCCESS)
    goto failed;
  ...
}
```

Writing Device Drivers
pm – Power Management properties

The pm-hardware-state property can be used to influence the behavior of the Power Management framework. Its syntax and interpretation is described below.

Note that this property is only interpreted by the system immediately after the device has successfully attached. Changes in the property made by the driver after the driver has attached will not be recognized.

pm-hardware-state is a string-valued property. The existence of the pm-hardware-state property indicates that a device needs special handling by the Power Management framework with regard to its hardware state.

If the value of this property is needs-suspend-resume, the device has a hardware state that cannot be deduced by the framework. The framework definition of a device with hardware state is one with a reg property. Some drivers, such as SCSI disk and tape drivers, have no reg property but manage devices with “remote” hardware. Such a device must have a pm-hardware-state property with a value of needs-suspend-resume for the system to identify it as needing a call to its detach(9E) entry point with command DDI_SUSPEND when system is suspended, and a call to attach(9E) with command DDI_RESUME when system is resumed. For devices using original Power Management interfaces (which are now obsolete) detach(9E) is also called with DDI_PM_SUSPEND before power is removed from the device, and attach(9E) is called with DDI_PM_RESUME after power is restored.

A value of no-suspend-resume indicates that, in spite of the existence of a reg property, a device has no hardware state that needs saving and restoring. A device exporting this property will not have its detach() entry point called with command DDI_SUSPEND when system is suspended, nor will its attach() entry point be called with command DDI_RESUME when system is resumed. For devices using the original (and now obsolete) Power Management interfaces, detach(9E) will not be called with DDI_PM_SUSPEND command before power is removed from the device, nor attach(9E) will be called with DDI_PM_RESUME command after power is restored to the device.

A value of parental-suspend-resume indicates that the device does not implement the detach(9E) DDI_SUSPEND semantics, nor the attach() DDI_RESUME semantics, but that a call should be made up the device tree by the framework to effect the saving and/or restoring of hardware state for this device. For devices using original Power Management interfaces (which are now obsolete), it also indicates that the device does not implement the detach(9E) DDI_PM_SUSPEND semantics, nor the attach(9E) DDI_PM_RESUME semantics, but that a call should be made up the device tree by the framework to effect the saving and/or restoring the hardware state for this device.

pm(7D), attach(9E), detach(9E), pm_busy_component(9F), pm_idle_component(9F), pm-components(9P)

Writing Device Drivers
A device is power manageable if the power consumption of the device can be reduced when it is idle. In general, a power manageable device consists of a number of power manageable hardware units called components. Each component is separately controllable and has its own set of power parameters.

An example of a one-component power manageable device is a disk whose spindle motor can be stopped to save power when the disk is idle. An example of a two-component power manageable device is a frame buffer card with a connected monitor. The frame buffer electronics (with power that can be reduced when not in use) comprises the first component. The second component is the monitor, which can enter in a lower power mode when not in use. The combination of frame buffer electronics and monitor is considered as one device by the system.

In the Power Management framework, all components are considered equal and completely independent of each other. If this is not true for a particular device, the device driver must ensure that undesirable state combinations do not occur. Each component is created in the idle state.

The `pm-components` property describes the Power Management model of a device driver to the Power Management framework. It lists each power manageable component by name and lists the power level supported by each component by numerical value and name. Its syntax and interpretation is described below.

This property is only interpreted by the system immediately after the device has successfully attached, or upon the first call into Power Management framework, whichever comes first. Changes in the property made by the driver after the property has been interpreted will not be recognized.

The `pm-components` property is a string array property. The existence of the `pm-components` property indicates that a device implements power manageable components and describes the Power Management model implemented by the device driver. The existence of `pm-components` also indicates to the framework that device is ready for Power Management if automatic device Power Management is enabled.

The `pm-components` property syntax is:

```
pm-components="NAME=component name","numeric power level=power level name",
"numeric power level=power level name"
[,"numeric power level=power level name"...] 
[,"NAME=component name","numeric power level=power level name",
"numeric power level=power level name"
[,"numeric power level=power level name"...]...];
```

The start of each new component is represented by a string consisting of `NAME=` followed by the name of the component. This should be a short name that a user would recognize, such as “Monitor” or “Spindle Motor.” The succeeding elements in the string array must be strings...
consisting of the numeric value (can be decimal or 0x<hexadecimal number>) of a power level the component supports, followed by an equal sign followed by a short descriptive name for that power level. Again, the names should be descriptive, such as "On," "Off," "Suspend," "Standby," etc. The next component continues the array in the same manner, with a string that starts out NAME=, specifying the beginning of a new component (and its name), followed by specifications of the power levels the component supports.

The components must be listed in increasing order according to the component number as interpreted by the driver’s power(9E) routine. (Components are numbered sequentially from 0). The power levels must be listed in increasing order of power consumption. Each component must support at least two power levels, or there is no possibility of power level transitions. If a power level value of 0 is used, it must be the first one listed for that component. A power level value of 0 has a special meaning (off) to the Power Management framework.

Examples An example of a pm-components entry from the .conf file of a driver which implements a single power managed component consisting of a disk spindle motor is shown below. This is component 0 and it supports 2 power level, which represent spindle stopped or full speed.

```
pm-components="NAME=Spindle Motor", "0=Stopped", "1=Full Speed";
```

Below is an example of how the above entry would be implemented in the attach(9E) function of the driver.

```
static char *pmcomps[] = {
    "NAME=Spindle Motor",
    "0=Stopped",
    "1=Full Speed"
};
...

xxattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    ...
    if (ddi_prop_update_string_array(DDI_DEV_T_NONE, dip, "pm-components",
                                        &pmcomp[0], sizeof (pmcomps) / sizeof (char *)) != DDI_PROP_SUCCESS)
        goto failed;
}
```

Below is an example for a frame buffer which implements two components. Component 0 is the frame buffer electronics which supports four different power levels. Component 1 represents the state of Power Management of the attached monitor.

```
pm-components="NAME=Frame Buffer", "0=Off"
    "1=Suspend", "2=Standby", "3=On",
    "NAME=Monitor", "0=Off", "1=Suspend", "2=Standby,"
    "3=On;"

Writing Device Drivers
### Name
qband – STREAMS queue flow control information structure

### Synopsis
```
#include <sys/stream.h>
```

### Interface Level
Architecture independent level 1 (DDI/DKI)

### Description
The qband structure contains flow control information for each priority band in a queue.

The qband structure is defined as type qband_t.

```
struct qband* qb_next; /* next band's info */
size_t qb_count /* number of bytes in band */
struct msgb *qb_first; /* start of band's data */
struct msgb *qb_last; /* end of band's data */
size_t qb_hiwat; /* band's high water mark */
size_t qb_lowat; /* band's low water mark */
uint_t qb_flag; /* see below */
```

Valid flags are as follows:

- **QB_FULL** Band is considered full.
- **QB_WANTW** Someone wants to write to band.

### See Also
strqget(9F), strqset(9F), msgb(9S), queue(9S)

### STREAMS Programming Guide

### Notes
All access to this structure should be through strqget(9F) and strqset(9F). It is logically part of the queue(9S) and its layout and partitioning with respect to that structure might change in future releases. If portability is a concern, do not declare or store instances of or references to this structure.
Here's the plain text representation of the document:

**Name**  
qinit – STREAMS queue processing procedures structure

**Synopsis**  
#include <sys/stream.h>

**Interface Level**  
Architecture independent level 1 (DDI/DKI)

**Description**  
The qinit structure contains pointers to processing procedures for a QUEUE. The streamtab structure for the module or driver contains pointers to one queue(9S) structure for both upstream and downstream processing.

**Structure Members**  
- int (*qi_putp)(); /* put procedure */
- int (*qi_srvp)(); /* service procedure */
- int (*qi_qopen)(); /* open procedure */
- int (*qi_qclose)(); /* close procedure */
- int (*qi_qadmin)(); /* unused */
- struct module_info *qi_minfo; /* module parameters */
- struct module_stat *qi_mstat; /* module statistics */

**See Also**

*Writing Device Drivers*

*STREAMS Programming Guide*

**Notes**  
This release includes no support for module statistics.
queclass – a STREAMS macro that returns the queue message class definitions for a given message block

**Synopsis**

```c
#include <sys/stream.h>

queclass(mblk_t *bp);
```

**Interface Level**  
Solaris DDI specific (Solaris DDI)

**Description**  
queclass returns the queue message class definition for a given data block pointed to by the message block `bp` passed in.

The message can be either QNORM, a normal priority message, or QPCTL, a high priority message.

**See Also**  
STREAMS Programming Guide
interface

Architecture independent level 1 (DDI/DKI)

A STREAMS driver or module consists of two queue structures: read for upstream processing and write for downstream processing. The queue structure is the major building block of a stream.

The queue structure is defined as type queue_t. The structure can be accessed at any time from inside a STREAMS entry point associated with that queue.

```
struct qinit *q_qinfo; /* queue processing procedure */
struct msgb *q_first; /* first message in queue */
struct msgb *q_last; /* last message in queue */
struct queue *q_next; /* next queue in stream */
void *q_ptr; /* module-specific data */
size_t q_count; /* number of bytes on queue */
uint_t q_flag; /* queue state */
ssize_t q_minpsz; /* smallest packet OK on queue */
ssize_t q_maxpsz; /* largest packet OK on queue */
size_t q_hiwat; /* queue high water mark */
size_t q_lowat; /* queue low water mark */
```

Constraints and restrictions on the use of q_flag and queue_t fields and the q_next values are detailed in the following sections.

q_flag Field
The q_flag field must be used only to check the following flag values.

QFULL Queue is full.
QREADR Queue is used for upstream (read-side) processing.
QUSE Queue has been allocated.
QENAB Queue has been enabled for service by qenable(9F).
QNOENB Queue will not be scheduled for service by putq(9F).
QWANTR Upstream processing element wants to read from queue.
QWANTW Downstream processing element wants to write to queue.

queue_t Fields
Aside from q_ptr and q_qinfo, a module or driver must never assume that a queue_t field value will remain unchanged across calls to STREAMS entry points. In addition, many fields can change values inside a STREAMS entry point, especially if the STREAMS module or driver has perimeters that allow parallelism. See mt-streams(9F). Fields that are not documented below are private to the STREAMS framework and must not be accessed.
- The values of the \texttt{q\_hiwat}, \texttt{q\_lowat}, \texttt{q\_minpsz}, and \texttt{q\_maxpsz} fields can be changed at the discretion of the module or driver. As such, the stability of their values depends on the perimeter configuration associated with any routines that modify them.
- The values of the \texttt{q\_first}, \texttt{q\_last}, and \texttt{q\_count} fields can change whenever \texttt{putq(9F)}, \texttt{put bq(9F)}, \texttt{getq(9F)}, \texttt{insq(9F)}, or \texttt{rmvq(9F)} is used on the queue. As such, the stability of their values depends on the perimeter configuration associated with any routines that call those STREAMS functions.
- The \texttt{q\_flag} field can change at any time.
- The \texttt{q\_next} field will not change while inside a given STREAMS entry point. Additional restrictions on the use of the \texttt{q\_next} value are described in the next section.

A STREAMS module or driver can assign any value to \texttt{q\_ptr}. Typically \texttt{q\_ptr} is used to point to module-specific per-queue state, allocated in \texttt{open(9E)} and freed in \texttt{close(9E)}. The value or contents of \texttt{q\_ptr} is never inspected by the STREAMS framework.

The initial values for \texttt{q\_minpsz}, \texttt{q\_maxpsz}, \texttt{q\_hiwat}, and \texttt{q\_lowat} are set using the \texttt{module\_info(9S)} structure when \texttt{mod\_install(9F)} is called. A STREAMS module or driver can subsequently change the values of those fields as necessary. The remaining visible fields, \texttt{q\_qinfo}, \texttt{q\_first}, \texttt{q\_last}, \texttt{q\_next}, \texttt{q\_count}, and \texttt{q\_flag}, must never be modified by a module or driver.

The Solaris DDI requires that STREAMS modules and drivers obey the rules described on this page. Those that do not follow the rules can cause data corruption or system instability, and might change in behavior across patches or upgrades.

\section*{q\_next Restrictions}

There are additional restrictions associated with the use of the \texttt{q\_next} value. In particular, a STREAMS module or driver:

- Must not access the data structure pointed to by \texttt{q\_next}.
- Must not rely on the value of \texttt{q\_next} before calling \texttt{qproc\_son(9F)} or after calling \texttt{qproc\_soff(9F)}.
- Must not pass the value into any STREAMS framework function other than \texttt{put(9F)}, \texttt{canput(9F)}, \texttt{bcanput(9F)}, \texttt{putct\_1(9F)}, \texttt{putct\_1(9F)}. However, in all cases the "next" version of these functions, such as \texttt{putnext(9F)}, should be preferred.
- Must not use the value to compare against queue pointers from other streams. However, checking \texttt{q\_next} for NULL can be used to distinguish a module from a driver in code shared by both.

Writing Device Drivers

STREAMS Programming Guide
removable-media – removable media device property

Description A device that supports removable media—such as CDROM, JAZZ, and ZIP drives—and that supports power management and expects automatic mounting of the device via the volume manager should export the boolean (zero length) property `removable-media`. This property enables the system to make the power state of the device dependent on the power state of the framebuffer and monitor.

Devices that behave like removable devices (such as PC ATA cards, where the controller and media both are removed at the same time) should also export this property.

Examples

**EXAMPLE 1 removable-media Entry**

An example of a `removable-media` entry from the `.conf` file of a driver is shown below.

```bash
# This entry keeps removable media from being powered down unless
# the console framebuffer and monitor are powered down
# removable-media=1;
```

**EXAMPLE 2 Implementation in `attach()`**

Below is an example of how the entry above would be implemented in the `attach(9E)` function of the driver.

```c
xxattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    ...
    if (ddi_prop_create(DDI_DEV_T_NONE, dip, DDI_PROP_CANSLEEP,
                        "removable-media", NULL, @)) != DDI_PROP_SUCCESS)
        goto failed;
    ...
}
```

*Writing Device Drivers*
**Name**  
scsi_address – SCSI address structure

**Synopsis**  
#include <sys/scsi/scsi.h>

**Interface Level**  
Solaris architecture specific (Solaris DDI)

**Description**  
A scsi_address structure defines the addressing components for a SCSI target device. The address of the target device is separated into two components: target number and logical unit number. The two addressing components are used to uniquely identify any type of SCSI device; however, most devices can be addressed with the target component of the address.

In the case where only the target component is used to address the device, the logical unit should be set to 0. If the SCSI target device supports logical units, then the HBA must interpret the logical units field of the data structure.

The pkt_address member of a scsi_pkt(9S) is initialized by scsi_init_pkt(9F).

**Structure Members**

```c
scsi_hba_tran_t  *a_hba_tran; /* Transport vectors for the SCSI bus */
ushort_t         a_target;   /* SCSI target id */
uchar_t          a_lun;      /* SCSI logical unit */
```

a_hba_tran is a pointer to the controlling HBA’s transport vector structure. The SCSA interface uses this field to pass any transport requests from the SCSI target device drivers to the HBA driver.

a_target is the target component of the SCSI address.

a_lun is the logical unit component of the SCSI address. The logical unit is used to further distinguish a SCSI target device that supports multiple logical units from one that does not. The makecom(9F) family of functions use the a_lun field to set the logical unit field in the SCSI CDB, for compatibility with SCSI-1.

*Writing Device Drivers*
Name  scsi_arq_status – SCSI auto request sense structure

Synopsis  #include <sys/scsi/scsi.h>

Interface Level  Solaris DDI specific (Solaris DDI)

Description  When auto request sense has been enabled using `scsi_ifsetcap(9F)` and the "auto-rqsense" capability, the target driver must allocate a status area in the SCSI packet structure for the auto request sense structure (see `scsi_pkt(9S)`). In the event of a check condition, the transport layer automatically executes a request sense command. This check ensures that the request sense information does not get lost. The auto request sense structure supplies the SCSI status of the original command, the transport information pertaining to the request sense command, and the request sense data.

```
struct scsi_status sts_status; /* SCSI status */
struct scsi_status sts_rqpkt_status; /* SCSI status of request sense cmd */
uchar_t sts_rqpkt_reason; /* reason completion */
uchar_t sts_rqpkt_resid; /* residue */
uint_t sts_rqpkt_state; /* state of command */
uint_t sts_rqpkt_statistics; /* statistics */
struct scsi_extended_sense sts_sensedata; /* actual sense data */
```

sts_status is the SCSI status of the original command. If the status indicates a check condition, the transport layer might have performed an auto request sense command.

sts_rqpkt_status is the SCSI status of the request sense command. sts_rqpkt_reason is the completion reason of the request sense command. If the reason is not CMD_CMPLT, then the request sense command did not complete normally.

sts_rqpkt_resid is the residual count of the data transfer and indicates the number of data bytes that have not been transferred. The auto request sense command requests SENSE_LENGTH bytes.

sts_rqpkt_state has bit positions representing the five most important statuses that a SCSI command can obtain.

sts_rqpkt_statistics maintains transport-related statistics of the request sense command.

sts_sensedata contains the actual sense data if the request sense command completed normally.

*Writing Device Drivers*
**Name**  
scsi_asc_key_strings – SCSI ASC ASCQ to message structure

**Synopsis**  
#include <sys/scsi/scsi.h>

**Interface Level**  
Solaris DDI specific (Solaris DDI).

**Description**  
The `scsi_asc_key_strings` structure stores the ASC and ASCQ codes and a pointer to the related ASCII string.

```c
ushort_t asc; /* ASC code */
ushort_t ascq; /* ASCQ code */
char *message; /* ASCII message string */
```

- `asc` Contains the ASC key code.
- `ascq` Contains the ASCQ code.
- `message` Points to the NULL terminated ASCII string describing the asc and ascq condition.

**See Also**  
scsi_vu_errmsg(9F)

**ANSI Small Computer System Interface-2 (SCSI-2)**

**Writing Device Drivers**
Name  
scsi_device – SCSI device structure

Synopsis  
#include <sys/scsi/scsi.h>

Interface Level  
Solaris DDI specific (Solaris DDI).

Description  
The scsi_device structure stores common information about each SCSI logical unit, including pointers to areas that contain both generic and device specific information. There is one scsi_device structure for each logical unit attached to the system. The host adapter driver initializes part of this structure prior to probe(9E) and destroys this structure after a probe failure or successful detach(9E).

Structure Members  
struct scsi_address  sd_address; /* Routing info. */  
  dev_info_t *sd_dev; /* Cross-ref. to */  
  /* dev_info_t */  
  kmutex_t sd_mutex; /* Mutex for this dev. */  
  struct scsi_inquiry *sd_inq; /* scsi_inquiry data struc. */  
  struct scsi_extended_sense *sd_sense; /* Optional request */  
  /* sense buffer ptr */  
  caddr_t sd_private; /* Target drivers */  
  private data */

sd_address contains the routing information that the target driver normally copies into a scsi_pkt(9S) structure using the collection of makecom(9F) functions. The SCSA library routines use this information to determine which host adapter, SCSI bus, and target/logical unit number ( lun ) a command is intended for. This structure is initialized by the host adapter driver.

sd_dev is a pointer to the corresponding dev_info structure. This pointer is initialized by the host adapter driver.

sd_mutex is a mutual exclusion lock for this device. It is used to serialize access to a device. The host adapter driver initializes this mutex. See mutex(9F).

sd_inq is initially NULL ( zero ). After executing scsi_probe(9F), this field contains the inquiry data associated with the particular device.

sd_sense is initially NULL ( zero ). If the target driver wants to use this field for storing REQUEST SENSE data, it should allocate an scsi_extended_sense(9S) buffer and set this field to the address of this buffer.

sd_private is reserved for the use of target drivers and should generally be used to point to target specific data structures.

Writing Device Drivers
scsi_extended_sense(9S)

Name

scsi_extended_sense – SCSI extended sense structure

Synopsis

#include <sys/scsi/scsi.h>

Interface Level

Solaris DDI specific (Solaris DDI).

Description

The scsi_extended_sense structure for error codes 0x70 (current errors) and 0x71 (deferred errors) is returned on a successful REQUEST SENSE command. SCSI-2 compliant targets are required to return at least the first 18 bytes of this structure. This structure is part of scsi_device(9S) structure.

Structure Members

uchar_t es_valid :1; /* Sense data is valid */
uchar_t es_class :3; /* Error Class- fixed at 0x7 */
uchar_t es_code :4; /* Vendor Unique error code */
uchar_t es_segunum; /* Segment number: for COPY cmd only */
uchar_t es_filmk :1; /* File Mark Detected */
uchar_t es_eom :1; /* End of Media */
uchar_t es_ili :1; /* Incorrect Length Indicator */
uchar_t es_key :4; /* Sense key */
uchar_t es_info_1; /* Information byte 1 */
uchar_t es_info_2; /* Information byte 2 */
uchar_t es_info_3; /* Information byte 3 */
uchar_t es_info_4; /* Information byte 4 */
uchar_t es_add_len; /* Number of additional bytes */
uchar_t es_cmd_info[4]; /* Command specific information */
uchar_t es_add_code; /* Additional Sense Code */
uchar_t es_qual_code; /* Additional Sense Code Qualifier */
uchar_t es_fru_code; /* Field Replaceable Unit Code */
uchar_t es_skey_specific[3]; /* Sense Key Specific information */

es_valid, if set, indicates that the information field contains valid information.

es_class should be 0x7.

es_code is either 0x0 or 0x1.

es_segnum contains the number of the current segment descriptor if the REQUEST SENSE command is in response to a COPY, COMPARE, and COPY AND VERIFY command.

es_filmk, if set, indicates that the current command had read a file mark or set mark (sequential access devices only).

es_eom, if set, indicates that an end-of-medium condition exists (sequential access and printer devices only).

es_ili, if set, indicates that the requested logical block length did not match the logical block length of the data on the medium.

es_key indicates generic information describing an error or exception condition. The following sense keys are defined:
<table>
<thead>
<tr>
<th>Sense Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEY_NO_SENSE</td>
<td>Indicates that there is no specific sense key information to be reported.</td>
</tr>
<tr>
<td>KEY_RECOVERABLE_ERROR</td>
<td>Indicates that the last command completed successfully with some recovery action performed by the target.</td>
</tr>
<tr>
<td>KEY_NOT_READY</td>
<td>Indicates that the logical unit addressed cannot be accessed.</td>
</tr>
<tr>
<td>KEY_MEDIUM_ERROR</td>
<td>Indicates that the command terminated with a non-recoverable error condition that was probably caused by a flaw on the medium or an error in the recorded data.</td>
</tr>
<tr>
<td>KEY_HARDWARE_ERROR</td>
<td>Indicates that the target detected a non-recoverable hardware failure while performing the command or during a self test.</td>
</tr>
<tr>
<td>KEY_ILLEGAL_REQUEST</td>
<td>Indicates that there was an illegal parameter in the CDB or in the additional parameters supplied as data for some commands.</td>
</tr>
<tr>
<td>KEY_UNIT_ATTENTION</td>
<td>Indicates that the removable medium might have been changed or the target has been reset.</td>
</tr>
<tr>
<td>KEY_WRITE_PROTECT/KEY_DATA_PROTECT</td>
<td>Indicates that a command that reads or writes the medium was attempted on a block that is protected from this operation.</td>
</tr>
<tr>
<td>KEY_BLANK_CHECK</td>
<td>Indicates that a write-once device or a sequential access device encountered blank medium or format-defined end-of-data indication while reading or a write-once device encountered a non-blank medium while writing.</td>
</tr>
<tr>
<td>KEY_VENDOR_UNIQUE</td>
<td>This sense key is available for reporting vendor-specific conditions.</td>
</tr>
<tr>
<td>KEY_COPY_ABORTED</td>
<td>Indicates that a COPY, COMPARE, and COPY AND VERIFY command was aborted.</td>
</tr>
<tr>
<td>KEY_ABORTED_COMMAND</td>
<td>Indicates that the target aborted the command.</td>
</tr>
<tr>
<td>KEY_EQUAL</td>
<td>Indicates that a SEARCH DATA command has satisfied an equal comparison.</td>
</tr>
</tbody>
</table>
KEY_VOLUME_OVERFLOW Indicates that a buffered peripheral device has reached the end-of-partition and data might remain in the buffer that has not been written to the medium.

KEY_MISCOMPARE Indicates that the source data did not match the data read from the medium.

KEY_reserve Indicates that the target is currently reserved by a different initiator.

es_info_{1,2,3,4} is device-type or command specific.

es_add_len indicates the number of additional sense bytes to follow.

es_cmd_info contains information that depends on the command that was executed.

es_add_code (ASC) indicates further information related to the error or exception condition reported in the sense key field.

es_qual_code (ASCQ) indicates detailed information related to the additional sense code.

es_fru_code (FRU) indicates a device-specific mechanism to unit that has failed.

es_skey_specific is defined when the value of the sense-key specific valid bit (bit 7) is 1. This field is reserved for sense keys not defined above.

ANSI Small Computer System Interface-2 (SCSI-2)

Writing Device Drivers
Name  scsi_hba_tran – SCSI Host Bus Adapter (HBA) driver transport vector structure

Synopsis  
#include <sys/scsi/scsi.h>

Interface Level  Solaris architecture specific (Solaris DDI).

Description  A `scsi_hba_tran_t` structure defines vectors that an HBA driver exports to SCSA interfaces so that HBA specific functions can be executed.

Structure Members  

dev_info_t *tran_hba_dip; /* HBAs dev_info pointer */

void *tran_hba_private; /* HBA softstate */

void *tran_tgt_private; /* HBA target private pointer */

struct scsi_device *tran_sd; /* scsi_device */

int (*tran_tgt_init)(); /* Transport target */
  Initialization */

int (*tran_tgt_probe)(); /* Transport target */

void (*tran_tgt_free)(); /* Transport target */
  free */

int (*tran_start)(); /* Transport start */

int (*tran_reset)(); /* Transport reset */

int (*tran_abort)(); /* Transport abort */

int (*tran_getcap)(); /* Capability */
  retrieval */

int (*tran_setcap)(); /* Capability */
  establishment */

struct scsi_pkt *(*tran_init_pkt)(); /* Packet and DMA */
  allocation */

void (*tran_destroy_pkt)(); /* Packet and DMA */
  deallocation */

void (*tran_dmafree)(); /* DMA deallocation */

void (*tran_sync_pkt)(); /* Sync DMA */

void (*tran_reset_notify)(); /* Bus reset */
  notification */

int (*tran_bus_reset)(); /* Reset bus only */

int (*tran_quiesce)(); /* Quiesce a bus */

int (*tran_unquiesce)(); /* Unquiesce a bus */

int (*tran_setup_pkt)(); /* Initialization */
  for pkt */

int (*tran_teardown_pkt)(); /* Deallocation */

int (*tran_pkt_constructor)(); /* Constructor */

int (*tran_pkt_destructor)(); /* Destructor */

int tran_hba_len; /* # bytes for pkt_ha_private */
int tran_interconnect_type; /* transport interconnect */

tran_hba_dip dev_info pointer to the HBA that supplies the scsi_hba_tran structure.

tran_hba_private Private pointer that the HBA driver can use to refer to the device's soft state structure.

tran_tgt_private Private pointer that the HBA can use to refer to per-target specific data. This field can only be used when the SCSI_HBA_TRAN_CLONE flag is specified in scsi_hba_attach(9F). In this case, the HBA driver must initialize this field in its tran_tgt_init(9E) entry point.

tran_sd Pointer to scsi_device(9S) structure if cloning; otherwise NULL.

tran_tgt_init Function entry that allows per-target HBA initialization, if necessary.

tran_tgt_probe Function entry that allows per-target scsi_probe(9F) customization, if necessary.

tran_tgt_free Function entry that allows per-target HBA deallocation, if necessary.

tran_start Function entry that starts a SCSI command execution on the HBA hardware.

tran_reset Function entry that resets a SCSI bus or target device.

tran_abort Function entry that aborts one SCSI command, or all pending SCSI commands.

tran_getcap Function entry that retrieves a SCSI capability.

tran_setcap Function entry that sets a SCSI capability.

tran_init_pkt Function entry that allocates a scsi_pkt structure.

tran_destroy_pkt Function entry that frees a scsi_pkt structure allocated by tran_init_pkt.

tran_dmafree Function entry that frees DMA resources that were previously allocated by tran_init_pkt. Not called for HBA drivers that provide a tran_setup_pkt entry point.

tran_sync_pkt Synchronizes data in pkt after a data transfer has been completed. Not called for HBA drivers that provide a tran_setup_pkt entry point.
tran_reset_notify
Function entry that allows a target to register a bus reset notification request with the HBA driver.

tran_bus_reset
Function entry that resets the SCSI bus without resetting targets.

tran_quiesce
Function entry that waits for all outstanding commands to complete and blocks (or queues) any I/O requests issued.

tran_unquiesce
Function entry that allows I/O activities to resume on the SCSI bus.

tran_setup_pkt
Optional entry point that initializes a scsi_pkt structure. See tran_setup_pkt(9E).

tran_teardown_pkt
Entry point that releases resources allocated by tran_setup_pkt.

tran_pkt_constructor
Additional optional entry point that performs the actions of a constructor. See tran_setup_pkt(9E).

tran_pkt_destructor
Additional optional entry point that performs the actions of a destructor. See tran_setup_pkt(9E).

tran_hba_len
Size of pkt_ha_private. See tran_setup_pkt(9E).

tran_interconnect_type
Integer value that denotes the interconnect type of the transport as defined in the services.h header file.

Data Structures for Drivers  121
inq _ dtype identifies the type of device. Bits 0 - 4 represent the Peripheral Device Type and bits 5 - 7 represent the Peripheral Qualifier. The following values are appropriate for Peripheral Device Type field:

- **DTYPE_DIRECT**: Direct-access device (for example, magnetic disk).
- **DTYPE_SEQUENTIAL**: Sequential-access device (for example, magnetic tape).
- **DTYPE_PRINTER**: Printer device.
- **DTYPE_PROCESSOR**: Processor device.
- **DTYPE_WORM**: Write-once device (for example, some optical disks).
- **DTYPE_RODIRECT**: CD-ROM device.
- **DTYPE_SCANNER**: Scanner device.
- **DTYPE_OPTICAL**: Optical memory device (for example, some optical disks).
- **DTYPE_CHANGER**: Medium Changer device (for example, jukeboxes).
- **DTYPE_COMM**: Communications device.
- **DTYPE_ARRAY_CTRL**: Array controller device (for example, RAID).
- **DTYPE_ESI**: Enclosure services device.
- **DTYPE_RBC**: Simplified direct-access device.
- **DTYPE_OCRW**: Optical card reader/writer device.
- **DTYPE_BRIDGE**: Bridge.
- **DTYPE_OSD**: Object-based storage device.
- **DTYPE_UNKNOWN**: Unknown or no device type.
- **DTYPE_MASK**: Mask to isolate Peripheral Device Type field.

The following values are appropriate for the Peripheral Qualifier field:

- **DPQ_POSSIBLE**: The specified peripheral device type is currently connected to this logical unit. If the target cannot determine whether or not a physical device is currently connected, it uses this peripheral qualifier when returning the INQUIRY data. This peripheral qualifier does not imply that the device is ready for access by the initiator.
- **DPQ_SUPPORTED**: The target is capable of supporting the specified peripheral device type on this logical unit. However, the physical device is not currently connected to this logical unit.
- **DPQ_NEVER**: The target is not capable of supporting a physical device on this logical unit. For this peripheral qualifier, the peripheral device type shall be set to
DTYPE_UNKNOWN to provide compatibility with previous versions of SCSI. For all other peripheral device type values, this peripheral qualifier is reserved.

DPQ_VUNIQ This is a vendor-unique qualifier.

DPQ_MASK Mask to isolate Peripheral Qualifier field.

DTYPE_NOTPRESENT is the peripheral qualifier DPQ_NEVER and the peripheral device type DTYPE_UNKNOWN combined.

inq_rmb, if set, indicates that the medium is removable.

inq_qual is a device type qualifier.

inq_iso indicates ISO version.

inq_ecma indicates ECMA version.

inq_ansi indicates ANSI version.

inq_aenc, if set, indicates that the device supports asynchronous event notification capability as defined in SCSI-2 specification.

inq_trmiop, if set, indicates that the device supports the TERMINATE I/O PROCESS message.

inq_normaca, if set, indicates that the device supports setting the NACA bit to 1 in CDB.

inq_hisip, if set, indicates the SCSI target device uses the hierarchical addressing model to assign LUNs to logical units.

inq_rdf, if set, indicates the INQUIRY data response data format: “RDF_LEVEL0” means that this structure complies with the SCSI-1 spec, “RDF_CCS” means that this structure complies with the CCS pseudo-spec, and “RDF_SCSI2” means that the structure complies with the SCSI-2/3 spec.

inq_len, if set, is the additional length field that specifies the length in bytes of the parameters.

inq_sccs, if set, indicates the target device contains an embedded storage array controller component.

inq_acc, if set, indicates that the logical unit contains an access controls coordinator (this structure member will be deleted before submission. It is being classified as unstable at this time).

inq_tpgse, if set, indicates that implicit asymmetric logical unit access is supported.

inq_tpgsi, if set, indicates that explicit asymmetric logical unit access is supported.
inq_3pc, if set, indicates that the SCSI target device supports third-party copy commands (this structure member will be deleted before submission. It is being classified as unstable at this time).

inq_protect, if set, indicates that the logical unit supports protection information (this structure member will be deleted before submission. It is being classified as unstable at this time).

inq_bque, if set, indicates that the logical unit supports basic task management.

inq_encserv, if set, indicates that the device contains an embedded enclosure services component (ses(7D)).

inq_dualp, if set, indicates that the SCSI target device supports two or more ports.

inq_mchngr, if set, indicates that the SCSI target device supports commands to control an attached media changer.

inq_addr16, if set, indicates that the device supports 16-bit wide SCSI addresses.

inq_wbus16, if set, indicates that the device supports 16-bit wide data transfers.

inq_sync, if set, indicates that the device supports synchronous data transfers.

inq_linked, if set, indicates that the device supports linked commands for this logical unit.

inq_cmdque, if set, indicates that the device supports tagged command queueing.

inq_sftre, if reset, indicates that the device responds to the RESET condition with the hard RESET alternative. If this bit is set, this indicates that the device responds with the soft RESET alternative.

inq_vid contains eight bytes of ASCII data identifying the vendor of the product.

inq_pid contains sixteen bytes of ASCII data as defined by the vendor.

inq_revision contains four bytes of ASCII data as defined by the vendor.

inq_clk clocking of the SPI3 target port.

inq_gas the SPI3 target port supports quick arbitration and selection.

inq_ius the SPI3 target device supports information unit transfers.

Writing Device Drivers
**Name**
scsi_pkt – SCSI packet structure

**Synopsis**
#include <sys/scsi/scsi.h>

**Interface Level**
Solaris DDI specific (Solaris DDI).

**Description**
A scsi_pkt structure defines the packet that is allocated by scsi_init_pkt(9F). The target driver fills in some information and passes it to scsi_transport(9F) for execution on the target. The host bus adapter (HBA) fills in other information as the command is processed. When the command completes or can be taken no further, the completion function specified in the packet is called with a pointer to the packet as its argument. From fields within the packet, the target driver can determine the success or failure of the command.

</tbody>
</table>
pkt_dma_flags DMA flags used, such as DDI_DMA_READ and DDI_DMA_WRITE. See tran_setup_pkt.

The host adapter driver will update the pkt_resid, pkt_reason, pkt_state, and pkt_statistics fields.

pkt_flags Definitions

The appropriate definitions for the structure member pkt_flags are:

- **FLAG_NOINTR** Run command with no command completion callback. Command is complete upon return from scsi_transport(9F).
- **FLAG_NODISCON** Run command without disconnects.
- **FLAG_NOPARITY** Run command without parity checking.
- **FLAG_HTAG** Run command as the head-of-queue-tagged command.
- **FLAG_OTAG** Run command as an ordered-queue-tagged command.
- **FLAG_STAG** Run command as a simple-queue-tagged command.
- **FLAG_SENSING** Indicates a request sense command.
- **FLAG HEAD** Place command at the head of the queue.
- **FLAG_RENEGOTIATE_WIDE_SYNC** Before transporting this command, the host adapter should initiate the renegotiation of wide mode and synchronous transfer speed. Normally, the HBA driver manages negotiations but under certain conditions forcing a renegotiation is appropriate. Renegotiation is recommended before Request Sense and Inquiry commands. Refer to the SCSI 2 standard, sections 6.6.21 and 6.6.23.

This flag should not be set for every packet as this will severely impact performance.

- **FLAG_TLR** Run command with Transport Layer Retries support.

pkt_reason Definitions

The appropriate definitions for the structure member pkt_reason are:

- **CMD_CMPLT** No transport errors; normal completion.
- **CMD_INCOMPLETE** Transport stopped with abnormal state.
- **CMD_DMA_DERR** DMA direction error.
- **CMD_TRAN_ERR** Unspecified transport error.
- **CMD_RESET** SCSI bus reset destroyed command.
CMD_ABORTED Command transport aborted on request.
CMD_TIMEOUT Command timed out.
CMD_DATA_OVR Data overrun.
CMD_CMD_OVR Command overrun.
CMD_STS_OVR Status overrun.
CMD_BADMSG Message not command complete.
CMD_NOMSGOUT Target refused to go to message out phase.
CMD_XID_FAIL Extended identify message rejected.
CMD_IDE_FAIL “Initiator Detected Error” message rejected.
CMD_ABORT_FAIL Abort message rejected.
CMD_REJECT_FAIL Reject message rejected.
CMD_NOP_FAIL “No Operation” message rejected.
CMD_PER_FAIL “Message Parity Error” message rejected.
CMD_BDR_FAIL “Bus Device Reset” message rejected.
CMD_ID_FAIL Identify message rejected.
CMD_UNX_BUS_FREE Unexpected bus free phase.
CMD_TAG_REJECT Target rejected the tag message.
CMD_DEV_GONE The device has been removed.
CMD_TLR_OFF Transport Layer Retries turn off.

 pkt_state Definitions

- STATE_GOT_BUS Bus arbitration succeeded.
- STATE_GOT_TARGET Target successfully selected.
- STATE_SENT_CMD Command successfully sent.
- STATE_XFERRED_DATA Data transfer took place.
- STATE_GOT_STATUS Status received.
- STATE_ARQ_DONE The command resulted in a check condition and the host adapter driver executed an automatic request sense command.
- STATE_XARQ_DONE The command requested in extra sense data using a PKT_XARQ flag got a check condition. The host adapter driver was able to successfully request and return this.
scsi_pkt.pkt_scbp->sts_rqpkt_resid returns the sense data residual based on the statuslen parameter of the `scsi_init_pkt(9F)` call. The sense data begins at `scsi_pkt.pkt_scbp->sts_sensedata`.

(pkt_statistics Definitions)

The definitions that are appropriate for the structure member `pkt_statistics` are:

- **STAT_DISCON**: Device disconnect.
- **STAT_SYNC**: Command did a synchronous data transfer.
- **STAT_PERR**: SCSI parity error.
- **STAT_BUS_RESET**: Bus reset.
- **STAT_DEV_RESET**: Device reset.
- **STAT_ABORTED**: Command was aborted.
- **STAT_TIMEOUT**: Command timed out.

scsi_transport(9F), scsi_status(9S), scsi_hba_pkt_comp(9F)`

(Writing Device Drivers)

(HBA drivers should signal `scsi_pkt` completion by calling `scsi_hba_pkt_comp(9F)`). This is mandatory for HBA drivers that implement `tran_setup_pkt(9E)`. Failure to comply results in undefined behavior.)
scsi_status – SCSI status structure

Synopsis
#include <sys/scsi/scsi.h>

Interface Level
Solaris DDI specific (Solaris DDI)

Description
The SCSI-2 standard defines a status byte that is normally sent by the target to the initiator during the status phase at the completion of each command.

Structure Members
uchar sts_scsi2 :1; /* SCSI-2 modifier bit */
uchar sts_is :1; /* intermediate status sent */
uchar sts_busy :1; /* device busy or reserved */
uchar sts_cm :1; /* condition met */
uchar sts_chk :1; /* check condition */

sts_chk indicates that a contingent allegiance condition has occurred.

sts_cm is returned whenever the requested operation is satisfied.

sts_busy indicates that the target is busy. This status is returned whenever a target is unable to accept a command from an otherwise acceptable initiator (that is, no reservation conflicts). The recommended initiator recovery action is to issue the command again later.

sts_is is returned for every successfully completed command in a series of linked commands (except the last command), unless the command is terminated with a check condition status, reservation conflict, or command terminated status. Note that host bus adapter drivers may not support linked commands (see scsi_ifsetcap(9F)). If sts_is and sts_busy are both set, then a reservation conflict has occurred.

sts_scsi2 is the SCSI-2 modifier bit. If sts_scsi2 and sts_chk are both set, this indicates a command terminated status. If sts_scsi2 and sts_busy are both set, this indicates that the command queue in the target is full.

For accessing the status as a byte, the following values are appropriate:

STATUS_GOOD
This status indicates that the target has successfully completed the command.

STATUS_CHECK
This status indicates that a contingent allegiance condition has occurred.

STATUS_MET
This status is returned when the requested operations are satisfied.

STATUS_BUSY
This status indicates that the target is busy.

STATUS_INTERMEDIATE
This status is returned for every successfully completed command in a series of linked commands.

STATUS_SCSI2
This is the SCSI-2 modifier bit.
<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATUS_INTERMEDIATE_MET</td>
<td>This status is a combination of STATUS_MET and STATUS_INTERMEDIATE.</td>
</tr>
<tr>
<td>STATUS_RESERVATION_CONFLICT</td>
<td>This status is a combination of STATUS_INTERMEDIATE and STATUS_BUSY, and it is returned whenever an initiator attempts to access a logical unit or an extent within a logical unit is reserved.</td>
</tr>
<tr>
<td>STATUS_TERMINATED</td>
<td>This status is a combination of STATUS_SCSI2 and STATUS_CHECK, and it is returned whenever the target terminates the current I/O process after receiving a terminate I/O process message.</td>
</tr>
<tr>
<td>STATUS_QFULL</td>
<td>This status is a combination of STATUS_SCSI2 and STATUS_BUSY, and it is returned when the command queue in the target is full.</td>
</tr>
</tbody>
</table>

Writing Device Drivers
A driver can communicate size information to the system by the values associated with following properties. Size information falls into two categories: device size associated with a dev_info_t node, and minor node size associated with a ddi_create_minor_node(9F) dev_t (partition).

**device size property names:**
- **device-nblocks**: An int64_t property representing device size in device-blksize blocks.
- **device-blksize**: An integer property representing the size in bytes of a logical block of device. If defined, the value must be a power of two. If not defined, DEV_BSIZE is implied.
- **device-pblksize**: An integer property representing the size in bytes of the physical sector of the device. If defined, the value must be a power of two. If not defined, device-blksize is implied. If neither is defined, DEV_BSIZE is implied.

**minor size property names:**
- **Size**: An int64_t property representing the size in bytes of a character minor device (S_IFCHR spec_type in ddi_create_minor_node()).
- **Nblocaks**: An int64_t property representing the number blocks, in device-blksize units, of a block minor device (S_IFBLK spec_type in ddi_create_minor_node()).
- **blksize**: An integer property representing the size in bytes of a logical block of a block minor device (S_IFBLK spec_type in ddi_create_minor_node()). If defined, the value must be a power of two. If not defined, DEV_BSIZE is implied.
- **pblksize**: An integer property representing the size in bytes of a physical block of a block minor device (S_IFBLK spec_type in ddi_create_minor_node()). If defined, the value must be a power of two. If not defined, blksize is implied. If neither is defined, DEV_BSIZE is implied.

A driver that implements both block and character minor device nodes should support both Size and Nblocaks. Typically, the following is true: Size = Nblocaks * blksize.

A driver where all ddi_create_minor_node(9F) calls for a given instance are associated with the same physical block device should implement device-nblocks. If the device has a fixed block size with a value other than DEV_BSIZE then device-blksize and device-pblksize should be implemented.

The driver is responsible for ensuring that property values are updated when device, media, or partition sizes change. For each represented item, if its size is know to be zero, the property value should be zero. If its size is unknown, the property should not be defined.
A driver may choose to implement size properties within its prop_op(9E) implementation. This reduces system memory since no space is used to store the properties.

The DDI property interfaces deal in signed numbers. For all interfaces described on this manual page, values should be considered unsigned. It is the responsibility of the code dealing with the property value to ensure that an unsigned interpretation occurs.

*Writing Device Drivers*
sof_ops–socketfilterentrypointsstructure

#include <sys/sockfilter.h>

The sof_ops structure defines a set of function entry points that a socket filter module exports to the socket filter framework. None of the entry points are required, and unused entry points should be set to NULL.

Filter instance are created and attached to sockets that match the requirements that were established when the filter was configured with soconfig(1M). A filter module can only have a single filter instance attached to a socket, but there may be multiple filter instance attached to a socket as a result of multiple filter modules being configured on the system.

The presence of multiple filter instance on a socket create a filter stack, which together with the source of the event determine the entry point execution order. Socket operations, such as connect(3SOCKET), traverse the stack top to bottom, while protocol events, such as incoming data, move bottom-up.

The order in which a filter is attached to a socket is undefined unless the filter specifies a placement hint when it is configured by soconfig.

The framework makes the following guarantees:

- sofop_attach_active(9E) or sofop_attach_passive(9E) is always called before any other entry point
- sofop_detach(9E) is always the final entry point to be called
- while a filter module is executing sofop_attach_active(), sofop_attach_passive(), or sofop_detach() for a socket, no other filter entry point will be called for the same socket.

In certain circumstances, a socket must be moved to legacy STREAMS mode to satisfy a STREAMS operation (streamio(7I)) issued by an application. Socket filters are incompatible with sockets operating in STREAMS mode, and a socket that has an active socket filter attached can not fall back to legacy mode, causing the STREAMS operation to fail. Therefore, the impact of enabling a socket filter should always be evaluated before it is deployed. A socket filter can minimize this impact by always marking itself inactive (using sof_bypass(9F)) if it is determined that it will not be used by a particular socket.

Socket filters are currently not supported by either AF_UNIX or SCTP sockets.

#streamtab—STREAMS entity declaration structure

```
#include <sys/stream.h>
```

Architectural independent level 1 (DDI/DKI).

Each STREAMS driver or module must have a streamtab structure.

Streamtab is made up of qinit structures for both the read and write queue portions of each module or driver. Multiplexing drivers require both upper and lower qinit structures. The qinit structure contains the entry points through which the module or driver routines are called.

Normally, the read QUEUE contains the open and close routines. Both the read and write queue can contain put and service procedures.

```
struct qinit *st_rdinit; /* read QUEUE */
struct qinit *st_wrinit; /* write QUEUE */
struct qinit *st_muxrinit; /* lower read QUEUE*/
struct qinit *st_muxwinit; /* lower write QUEUE*/
```

STREAMS Programming Guide
Name  stroptions – options structure for M_SETOPTS message

Synopsis  
#include <sys/stream.h>
#include <sys/stropts.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>

Architecture independent level 1 (DDI/DKI)

Description  The M_SETOPTS message contains a stroptions structure and is used to control options in the stream head.

Structure Members

uint_t  so_flags; /* options to set */
short  so_readopt; /* read option */
ushort_t  so_wroff; /* write offset */
ssize_t  so_minsz; /* minimum read packet size */
ssize_t  so_maxpsz; /* maximum read packet size */
size_t  so_hiwat; /* read queue high water mark */
size_t  so_lowat; /* read queue low water mark */
unsigned char  so_band; /* band for water marks */
ushort_t  so_errno; /* error option */

The following are the flags that can be set in the so_flags bitmask in the stroptions structure. Note that multiple flags can be set.

SO_READOPT  Set read option.
SO_WROFF  Set write offset.
SO_MINPSZ  Set minimum packet size
SO_MAXPSZ  Set maximum packet size.
SO_HIWAT  Set high water mark.
SO_LOWAT  Set low water mark.
SO_MREADON  Set read notification ON.
SO_MREADOFF  Set read notification OFF.
SO_NDELON  Old TTY semantics for NDELAY reads and writes.
SO_NDELOFFSTREAMS  Semantics for NDELAY reads and writes.
SO_TOSTOP  Stop on background writes to this stream.
SO_TONSTOP  Do not stop on background writes to this stream.
SO_BAND  Water marks affect band.
SO_ERROPT Set error option.

When SO_READOPT is set, the so_readopt field of the stroptions structure can take one of the following values. See read(2).

RNORM Read message normal.

RMSGD Read message discard.

RMSGN Read message, no discard.

When SO_BAND is set, so_band determines to which band so_hiwat and so_lowat apply.

When SO_ERROPT is set, the so_erropt field of the stroptions structure can take a value that is either none or one of:

RERRNORM Persistent read errors; default.

RERRNONPERSIST Non-persistent read errors.

OR'ed with either none or one of:

WERRNORM Persistent write errors; default.

WERRNONPERSIST Non-persistent write errors.

See Also  read(2), streamio(7I)

STREAMS Programming Guide
The tuple_t structure is the basic data structure provided by card services to manage PC card information. A PC card provides identification and configuration information through its card information structure (CIS). A PC card driver accesses a PC card’s CIS through various card services functions.

The CIS information allows PC cards to be self-identifying: the CIS provides information to the system so that it can identify the proper PC card driver for the PC card, and provides configuration information so that the driver can allocate appropriate resources to configure the PC card for proper operation in the system.

The CIS information is contained on the PC card in a linked list of tuple data structures called a CIS chain. Each tuple has a one-byte type and a one-byte link, an offset to the next tuple in the list. A PC card can have one or more CIS chains.

A multi-function PC card that complies with the PC Card 95 MultiFunction Metaformat specification will have one or more global CIS chains that collectively are referred to as the global CIS. These PC Cards will also have one or more per-function CIS chains. Each per-function collection of CIS chains is referred to as a function-specific CIS.

To examine a PC card’s CIS, first a PC card driver must locate the desired tuple by calling `csx_GetFirstTuple`. Once the first tuple is located, subsequent tuples may be located by calling `csx_GetNextTuple`. See `csx_GetFirstTuple`. The linked list of tuples may be inspected one by one, or the driver may narrow the search by requesting only tuples of a particular type.

Once a tuple has been located, the PC card driver may inspect the tuple data. The most convenient way to do this for standard tuples is by calling one of the number of tuple-parsing utility functions; for custom tuples, the driver may get access to the raw tuple data by calling `csx_GetTupleData`.

Solaris PC card drivers do not need to be concerned with which CIS chain a tuple appears in. On a multi-function PC card, the client will get the tuples from the global CIS followed by the tuples in the function-specific CIS. The caller will not get any tuples from a function-specific CIS that does not belong to the caller’s function.

The structure members of `tuple_t` are:

```
uint32_t Socket; /* socket number */
uint32_t Attributes; /* tuple attributes */
cisdata_t DesiredTuple; /* tuple to search for */
cisdata_t TupleOffset; /* tuple data offset */
```
The fields are defined as follows:

### Socket
Not used in Solaris, but for portability with other card services implementations, it should be set to the logical socket number.

### Attributes
This field is bit-mapped. The following bits are defined:

<table>
<thead>
<tr>
<th>Bit Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TUPLE_RETURN_LINK</td>
<td>Return link tuples if set.</td>
</tr>
<tr>
<td>TUPLE_RETURN_IGNORED_TUPLES</td>
<td>Return ignored tuples if set. Ignored tuples are those tuples in a multi-function PC card's global CIS chain that are duplicates of the same tuples in a function-specific CIS chain.</td>
</tr>
<tr>
<td>TUPLE_RETURN_NAME</td>
<td>Return tuple name string using the <code>csx_ParseTuple(9F)</code> function if set.</td>
</tr>
</tbody>
</table>

### DesiredTuple
This field is the requested tuple type code to be returned when calling `csx_GetFirstTuple(9F)` or `csx_GetNextTuple(9F)`.

- **RETURN_FIRST_TUPLE** is used to return the first tuple regardless of tuple type.
- **RETURN_NEXT_TUPLE** is used to return the next tuple regardless of tuple type.

### TupleOffset
This field allows partial tuple information to be retrieved, starting at the specified offset within the tuple. This field must only be set before calling `csx_GetTupleData(9F)`.

### TupleDataMax
This field is the size of the tuple data buffer that card services uses to return raw tuple data from `csx_GetTupleData(9F)`. It can be larger than the number of bytes in the tuple data body. Card services ignores any value placed here by the client.

### TupleDataLen
This field is the actual size of the tuple data body. It represents the number of tuple data body bytes returned by `csx_GetTupleData(9F)`.

### TupleData
This field is an array of bytes containing the raw tuple data body contents returned by `csx_GetTupleData(9F)`.

### TupleCode
This field is the tuple type code and is returned by `csx_GetFirstTuple(9F)` or `csx_GetNextTuple(9F)` when a tuple matching the DesiredTuple field is returned.
TupleLink

This field is the tuple link, the offset to the next tuple, and is returned by `csx_GetFirstTuple(9F)` or `csx_GetNextTuple(9F)` when a tuple matching the DesiredTuple field is returned.

*PC Card 95 Standard, PCMCIA/JEIDA*
Name    uio – scatter/gather I/O request structure

Synopsis    #include <sys/uio.h>

Interface Level    Architecture independent level 1 (DDI/DKI)

Description    A uio structure describes an I/O request that can be broken up into different data storage areas (scatter/gather I/O). A request is a list of iovec structures (base-length pairs) indicating where in user space or kernel space the I/O data is to be read or written.

The contents of uio structures passed to the driver through the entry points should not be written by the driver. The uiomove(9F) function takes care of all overhead related to maintaining the state of the uio structure.

uio structures allocated by the driver should be initialized to zero before use, by bzero(9F), kmem_zalloc(9F), or an equivalent.

Structure Members

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iovec_t *uio_iov;</td>
<td>/* pointer to start of iovec */</td>
</tr>
<tr>
<td>int uio_iovcnt;</td>
<td>/* number of iovecs in list */</td>
</tr>
<tr>
<td>off_t uio_offset;</td>
<td>/* 32-bit offset into file where data is xferred. See NOTES. */</td>
</tr>
<tr>
<td>offset_t uio_offset;</td>
<td>/* 64-bit offset into file where data is xferred. See NOTES. */</td>
</tr>
<tr>
<td>uio_seg_t uio_segflg;</td>
<td>/* ID’s type of I/O transfer: */</td>
</tr>
<tr>
<td>uint16_t uio_fmode;</td>
<td>/* file mode flags (not driver setable) */</td>
</tr>
<tr>
<td>daddr_t uio_limit;</td>
<td>/* 32-bit ulimit for file (max. block */</td>
</tr>
<tr>
<td>diskaddr_t uio_llimit;</td>
<td>/* 64-bit ulimit for file (max. block */</td>
</tr>
<tr>
<td>ssize_t uio_resid;</td>
<td>/* residual count */</td>
</tr>
</tbody>
</table>

The uio_iov member is a pointer to the beginning of the iovec(9S) list for the uio. When the uio structure is passed to the driver through an entry point, the driver should not set uio_iov. When the uio structure is created by the driver, uio_iov should be initialized by the driver and not written to afterward.

See Also    aread(9E), awrite(9E), read(9E), write(9E), bzero(9F), kmem_zalloc(9F), uiomove(9F), cb_ops(9S), iovec(9S)

Writing Device Drivers
Notes Only one structure, uio_offset or uio_loffset, should be interpreted by the driver. Which field the driver interprets is dependent upon the settings in the cb_ops(9S) structure.

Only one structure, uio_limit or uio_llimit, should be interpreted by the driver. Which field the driver interprets is dependent upon the settings in the cb_ops(9S) structure.

When performing I/O on a seekable device, the driver should not modify either the uio_offset or the uio_loffset field of the uio structure. I/O to such a device is constrained by the maximum offset value. When performing I/O on a device on which the concept of position has no relevance, the driver may preserve the uio_offset or uio_loffset, perform the I/O operation, then restore the uio_offset or uio_loffset to the field's initial value. I/O performed to a device in this manner is not constrained.
A bulk request (that is, a request sent through a bulk pipe) is used to transfer large amounts of data in reliable but non-time-critical fashion. Please refer to Section 5.8 of the USB 2.0 specification for information on bulk transfers. (The USB 2.0 specification is available at www.usb.org.)

The fields in the usb_bulk_req_t are used to format a bulk request. Please see below for acceptable combinations of flags and attributes.

The fields are:
- `uint_t bulk_len; /* number of bytes to xfer */`
- `mbblk_t *bulk_data; /* the data for the data phase */`
- `uint_t bulk_timeout; /* xfer timeout value in secs */`
- `usb_opaque_t bulk_client_private; /* Client specific information */`
- `usb_req_attrs_t bulk_attributes; /* xfer attributes */`
- `void (*bulk_cb)(usb_pipe_handle_t ph, struct usb_bulk_req *req);`
- `void (*bulk_exc_cb)(usb_pipe_handle_t ph, struct usb_bulk_req *req);`
- `usb_cr_t bulk_completion_reason; /* overall success status */`
- `usb_cb_flags_t bulk_cb_flags; /* recovery done by callback hndlr */`

Request attributes define special handling for transfers. The following attributes are valid for bulk requests:
- `USB_ATTRS_SHORT_XFER_OK`  USB framework accepts transfers where less data is received than expected.
- `USB_ATTRS_AUTOCLEARING`  USB framework resets pipe and clears functional stalls automatically on exception.
USB_ATTRS_PIPE_RESET

USB framework resets pipe automatically on exception.

Please see `usb_request_attributes(9S)` for more information.

Bulk transfers/requests are subject to the following constraints and caveats:

1) The following table indicates combinations of `usb_pipe.bulk.xfer()` flags argument and fields of the `usb.bulk_req_t` request argument (X = don’t care).

Table notes:

A). Fill buffer, no timeout, callback when `bulk_len` is transferred.
B). Fill buffer, with timeout; callback when `bulk_len` is transferred.
C). Fill buffer, no timeout, unblock when `bulk_len` is transferred; no callback.
D). Fill buffer, with timeout; unblock when bulk_len is transferred or a timeout occurs; no callback.
E). Fill buffer, no timeout, callback when bulk_len is transferred or first short packet is received.
F). Fill buffer, with timeout; callback when bulk_len is transferred or first short packet is received.
G). Fill buffer, no timeout, unblock when bulk_len is transferred or first short packet is received; no callback.
H). Fill buffer, with timeout; unblock when bulk_len is transferred, first short packet is received, or a timeout occurs; no callback.
I). Empty buffer, no timeout; callback when bulk_len is transferred.
J). Empty buffer, with timeout; callback when bulk_len is transferred or a timeout occurs.
K). Empty buffer, no timeout; unblock when bulk_len is transferred; no callback.
L). Empty buffer, with timeout; unblock when bulk_len is transferred or a timeout occurs; no callback.

2) bulk_len must be > 0. bulk_data must not be NULL.

3) Bulk_residue is set for both READ and WRITE. If it is set to 0, it means that all of the data was transferred successfully. In case of WRITE it contains data not written and in case of READ it contains the data NOT read so far. A residue can only occur because of timeout or bus/device error. (Note that a short transfer for a request where the USB_ATTRS_SHORT_XFER_OK attribute is not set is considered a device error.) An exception callback is made and completion_reason will be non-zero.

4) Splitting large Bulk xfers: Due to internal constraints, the USB A framework can only do a limited size bulk data xfer per request. A client driver may first determine this limitation by calling the USB interface (usb_pipe_get_max_bulk_xfer_size(9F)) and then restrict itself to doing transfers in multiples of this fixed size. This forces a client driver to do data xfers in a loop for a large request, splitting it into multiple chunks of fixed size.

The bulk_completion_reason indicates the status of the transfer. See
usb_completion_reason(9S) for usb_cr_t definitions.

The bulk_cb_flags are set prior to calling the exception callback handler to summarize recovery actions taken and errors encountered during recovery. See usb_callback_flags(9S) for usb_cb_flags_t definitions.

--- Callback handling ---

All usb request types share the same callback handling. See usb_callback_flags(9S) for details.

If the USB framework detects an error during a request execution, it calls the client driver’s exception callback handler to report what happened. Callback flags (which are set prior to calling the exception callback handler) detail errors discovered during the exception recovery process, and summarize recovery actions taken by the USBA framework.

Information from the callback flags supplements information from the original transport error. For transfers, the original transport error status is returned to the callback handler through the original request (whose completion reason field contains any transport error indication). For command completion callbacks, the callback’s rval argument contains the transport error status. A completion reason of USB_CR_OK means the transfer completed with no errors detected.

The `usb_cb_flags_t` enumerated type contains the following definitions:

- USB_CB_NO_INFO: No additional errors discovered or recovery actions taken.
- USB_CB_FUNCTIONAL_STALL: A functional stall occurred during the transfer. A functional stall is usually caused by a hardware error, and must be explicitly cleared. A functional stall is fatal if it cannot be cleared. The default control pipe never shows a functional stall.
- USB_CBSTALL_CLEARED: A functional stall has been cleared by the USBA framework. This can happen if `USB_ATTRS_AUTOCLEARING` is set in the request’s `xxxx_attributes` field.
- USB_CB_PROTOCOL_STALL: A protocol stall has occurred during the transfer. A protocol stall is caused usually by an invalid or misunderstood command. It is cleared automatically when the device is given its next command. The USBA framework treats stalls detected on default pipe transfers as protocol stalls.
- USB_CB_RESET_PIPE: A pipe with a stall has been reset automatically via autoclearing, or via an explicit call to `usb_pipe_reset(9F)`. Resetting a pipe consists of stopping all transactions on a pipe, setting the pipe to the idle state, and if the pipe is not the default pipe, flushing all pending requests. The request which has the error, plus all pending requests which are flushed,
show USB_CB_RESET_PIPE set in the usb_cb_flags_t when their exception callback is called.

**USB_CB_ASYNC_REQ_FAILED**

Resources could not be allocated to process callbacks asynchronously. Callbacks receiving this flag must not block, since those callbacks are executing in a context which holds resources shared by the rest of the system. Note that exception callbacks with USB_CB_ASYNC_REQ_FAILED set may execute out of order from the requests which preceded them. Normal callbacks may be already queued when an exception hits that the USB is unable to queue.

**USB_CB_SUBMIT_FAILED**

A queued request was submitted to the host controller driver and was rejected. The usb_completion_reason shows why the request was rejected by the host controller.

**USB_CB_NO_RESOURCES**

Insufficient resources were available for recovery to proceed.

**USB_CB_INTR_CONTEXT**

Callback is executing in interrupt context and should not block.

The usb_cb_flags_t enumerated type defines a bitmask. Multiple bits can be set, reporting back multiple statuses to the exception callback handler.

**CALLBACK HANDLER**

The USBA framework supports callback handling as a way of asynchronous client driver notification. There are three kinds of callbacks: Normal completion transfer callback, exception (error) completion transfer callback, and command completion callback, each described below.

Callback handlers are called whenever they are specified in a request or command, regardless of whether or not that request or command specifies the USB_FLAGS_SLEEP flag. (USB_FLAGS_SLEEP tells the request or command to block until completed.) Callback handlers must be specified whenever an asynchronous transfer is requested.

**PIPE POLICY**

Each pipe is associated with a pool of threads that are used to run callbacks associated with requests on that pipe. All transfer completion callbacks for a particular pipe are run serially by a single thread.

Pipes taking requests with callbacks which can block must have their pipe policy properly initialized. If a callback blocks on a condition that is only met by another thread associated with the same pipe, there must be sufficient threads available. Otherwise that callback thread will block forever. Similarly, problems will ensue when callbacks overlap and there are not enough threads to handle the number of overlapping callbacks.
The pp_max_async_reqs field of the pipe_policy provides a hint of how many threads to allocate for asynchronous processing of request callbacks on a pipe. Set this value high enough per pipe to accommodate all of the pipe's possible asynchronous conditions. The pipe_policy is passed to `usbPipeOpen(9F)`.

Transfer completion callbacks (normal completion and exception):

Most transfer completion callbacks are allowed to block, but only under certain conditions:

1. No callback is allowed to block if the callback flags show USB_CB_INTR_CONTEXT set, since that flag indicates that the callback is running in interrupt context instead of kernel context. Isochronous normal completion callbacks, plus those with USB_CB_ASYNC_REQ_FAILED set, execute in interrupt context.

2. Any callback except for isochronous normal completion can block for resources (for example to allocate memory).

3. No callback can block for synchronous completion of a command (for example, a call to `usbPipeClose(9F)` with the USB_FLAGS_SLEEP flag passed) done on the same pipe. The command could wait for all callbacks to complete, including the callback which issued that command, causing all operations on the pipe to deadlock. Note that asynchronous commands can start from a callback, providing that the pipe's policy pp_max_async_reqs field is initialized to accommodate them.

4. Avoid callbacks that block for synchronous completion of commands done on other pipes. Such conditions can cause complex dependencies and unpredictable results.

5. No callback can block waiting for a synchronous transfer request to complete. (Note that making an asynchronous request to start a new transfer or start polling does not block, and is OK.)

6. No callback can block waiting for another callback to complete. (This is because all callbacks are done by a single thread.)

7. Note that if a callback blocks, other callbacks awaiting processing can backup behind it, impacting system resources.

A transfer request can specify a non-null normal-completion callback. Such requests conclude by calling the normal-completion callback when the transfer completes normally. Similarly, a transfer request can specify a non-null exception callback. Such requests conclude by calling the exception callback when the transfer completes abnormally. Note that the same callback can be used for both normal completion and exception callback handling. A completion reason of USB_CR_OK defines normal completion.

All request callbacks take as arguments a `usbPipeHandle_t` and a pointer to the request:

```
xxxx_cb(usbPipeHandle_t ph, struct usbCtrlReq *req);
```
Such callbacks can retrieve saved state or other information from the private area of the pipe handle. (See `usb_pipe_set_private(9F)`.) Handlers also have access to the completion reason (`usb_cr_t`) and callback flags (`usb_cb_flags_t`) through the request argument they are passed.

Request information follows. In the data below, `xxxx` below represents the type of request (ctrl, intr, isoc or bulk.)

Request structure name is `usb_xxxxx_req_t`.

Normal completion callback handler field is `xxxx_cb`.

Exception callback handler field is `xxxx_exc_cb`.

Completion reason field is `xxxx_completion_reason`.

Callback flags field is `xxxx_cb_flags`.

Calls to some non-transfer functions can be set up for callback notification. These include `usb_pipe_close(9F)`, `usb_pipe_reset(9F)`, `usb_pipe_drain_reqs(9F)`, `usb_set_cfg(9F)`, `usb_set_alt_if(9F)` and `usb_clr_feature(9F)`.

The signature of a command completion callback is as follows:

```c
command_cb(
    usb_pipe_handle_t cb_pipe_handle,
    usb_opaque_t arg,
    int rval,
    usb_cb_flags_t flags);
```

As with transfer completion callbacks, command completion callbacks take a `usb_pipe_handle_t` to retrieve saved state or other information from the pipe's private area. Also, command completion callbacks are provided with an additional user-definable argument (`usb_opaque_t arg`), the return status of the executed command (int `rval`), and the callback flags (`usb_cb_flags_t flags`).

The `rval` argument is roughly equivalent to the completion reason of a transfer callback, indicating the overall status. See the return values of the relevant function for possible `rval` values which can be passed to the callback.

The callback flags can be checked when `rval` indicates failure status. Just as for transfer completion callbacks, callback flags return additional information on execution events.

usb_cfg_descr(9S)

**Name** usb_cfg_descr – USB configuration descriptor

**Synopsis** #include <sys/usb/usba.h>

**Interface Level** Solaris DDI specific (Solaris DDI)

**Description** The `usb_cfg_descr_t` configuration descriptor defines attributes of a configuration. A configuration contains one or more interfaces. A configuration descriptor acts as a header for the group of other descriptors describing the subcomponents (for example, interfaces and endpoints) of a configuration. Please refer to Section 9.6.3 of the USB 2.0 specification. The USB 2.0 specification is available at [www.usb.org](http://www.usb.org).

One or more configuration descriptors are retrieved from a USB device during device enumeration. They can be accessed via `usb_get_dev_data(9F)`.

A configuration descriptor has the following fields:

- `uint8_t bLength` Size of this descriptor in bytes.
- `uint8_t bDescriptorType` Set to USB_DESCR_TYPE_CFG.
- `uint16_t wTotalLength` Total length of data returned including this and all other descriptors in this configuration.
- `uint8_t bNumInterfaces` Number of interfaces in this configuration.
- `uint8_t bConfigurationValue` ID of this configuration (1-based).
- `uint8_t iConfiguration` Index of optional configuration string. Valid if > 0.
- `uint8_t bmAttributes` Configuration characteristics (See below).
- `uint8_t bMaxPower` Maximum power consumption, in 2mA units.

Configuration descriptors define the following `bmAttributes`:

- `USB_CFG_ATTR_SELFPPWR` - Set if config not using bus power.
- `USB_CFG_ATTR_REMOTE_WAKEUP` - Set if config supports rem wakeup.

**Name**  usb_client_dev_data – Device configuration information

**Synopsis**  
#include <sys/usb/usba.h>

**Interface Level**  Solaris DDI specific (Solaris DDI)

**Description**  The usb_client_dev_data_t structure carries all device configuration information. It is provided to a USB client driver through a call to usb_get_dev_data(9F). Most USBA functions require information which comes from this structure.

The usb_client_dev_data_t structure fields are:

```c
usb_pipe_handle_t dev_default_ph; /* deflt ctrl pipe handle */
ddi_iblock_cookie_t dev_iblock_cookie; /* for calls to mutex_init */
    /* for mutexes used by intr */
    /* context callbacks. */
usb_dev_descr_t *dev_descr; /* parsed* dev. descriptor */
char *dev_mfg; /* manufacturer's ID string */
char *dev_product; /* product ID string */
char *dev_serial; /* serial num. string */
usb_reg_parse_lvl_t dev_parse_level; /* Parse level */
    /* reflecting the tree */
    /* (if any) returned through */
    /* the dev_cfg array. */
usb_cfg_data_t *dev_cfg; /* parsed* descr tree.*/
uint_t dev_n_cfg; /* num cfgs in parsed descr. */
    /* tree, dev_cfg array below.*/
usb_cfg_data_t *dev_curr_cfg; /* Pointer to the tree config*/
    /* corresponding to the cfg */
    /* active at the time of the */
    /* usb_get_dev_data() call */
int dev_curr_if; /* First active interface in */
    /* tree under driver's control. */
    /* Always zero when driver */
    /* controls whole device. */
```

* A parsed descriptor is in a struct whose fields' have been adjusted to the host processor. This may include endianness adjustment (the USB
The default control pipe handle is used mainly for control commands and device setup.

The dev_iblock_cookie is used to initialize client driver mutexes which are used in interrupt-context callback handlers. (All callback handlers called with USB_CB_INTR_CONTEXT in their usb_cb_flags_t arg execute in interrupt context.) This cookie is used in lieu of one returned by ddi_get_iblock_cookie(9F). Mutexes used in other handlers or under other conditions should initialize per mutex_init(9F).

The parsed standard USB device descriptor is used for device type identification.

The several ID strings, including the manufacturer's ID, product ID, and serial number may be used to identify the device in messages or to compare it to other devices.

The descriptor tree, returned by dev_cfg, makes a device's parsed standard USB descriptors available to the driver. The tree is designed to be easily traversed to get any or all standard USB 2.0 descriptors. (See the "Tree Structure" section of this manpage below.) dev_n_cfg returns the number of configurations in the tree. Note that this value may differ from the number of configurations returned in the device descriptor.

A returned parse_level field of USB_PARSE_LVL_ALL indicates that all configurations are represented in the tree. This results when USB_PARSE_LVL_ALL is explicitly requested by the caller in the flags argument to usb_get_dev_data(), or when the whole device is seen by the system for the current OS device node (as opposed to only a single configuration for that OS device node). USB_PARSE_LVL_CFG is returned when one entire configuration is returned in the tree. USB_PARSE_LVL_IF is returned when one interface of one configuration is returned in the tree. In the latter two cases, the returned configuration is at
dev_cfg[USB_DEV_DEFAULT_CONFIG_INDEX].USB_PARSE_LVL_NONE is returned when no tree is returned. Note that the value of this field can differ from the parse_level requested as an argument to usb_get_dev_data().

The root of the tree is dev_cfg, an array of usb_cfg_data_t configuration nodes, each representing one device configuration. The array index does not correspond to a configuration’s value; use the bConfigurationValue field of the configuration descriptor within to find out the proper number for a given configuration.

The size of the array is returned in dev_n_cfg. The array itself is not NULL terminated.

When USB_PARSE_LVL_ALL is returned in dev_parse_level, index 0 pertains to the first valid configuration. This pertains to device configuration 1 as USB configuration 0 is not defined. When dev_parse_level returns USB_PARSE_LVL_CFG or USB_PARSE_LVL_IF, index 0 pertains to the device’s one configuration recognized by the system. (Note that the configuration level is the only descriptor level in the tree where the index value does not correspond to the descriptor’s value.)

Each usb_cfg_data_t configuration node contains a parsed usb configuration descriptor (usb_cfg_descr_t cfg_descr) a pointer to its string description (char *cfg_str) and string size (cfg_strsize), a pointer to an array of interface nodes (usb_if_data_t *cfg_if), and a pointer to an array of class/vendor (cv) descriptor nodes (usb_cvs_data_t *cfg_cvs). The interface node array size is kept in cfg_n_if, and the cv node array size is kept in cfg_n_cvs; neither array is NULL terminated. When USB_PARSE_LVL_IF is returned in dev_parse_level, the only interface (or alternate group) included in the tree is that which is recognized by the system for the current OS device node.

Each interface can present itself potentially in one of several alternate ways. An alternate tree node (usb_alt_if_data_t) represents an alternate representation. Each usb_if_data_t interface node points to an array of alternate nodes (usb_alt_if_data_t *if_alt) and contains the size of the array (if_n_alt).

Each interface alternate node holds an interface descriptor (usb_if_descr_t altif_descr), a pointer to its string description (char *altif_str), and has its own set of endpoints and bound cv descriptors. The pointer to the array of endpoints is usb_ep_data_t *altif_ep; the endpoint array size is altif_n_ep. The pointer to the array of cv descriptors is usb_cvs_data_t *altif_cvs; the cv descriptor array size is altif_n_cvs.

Each endpoint node holds an endpoint descriptor (usb_ep_descr_t ep_descr), a pointer to an array of cv descriptors for that endpoint (usb_cvs_data_t *ep_cvs), and the size of that array (ep_n_cvs). An endpoint descriptor may be passed to __usb_pipe_open(9F) to establish a logical connection for data transfer.

Class and vendor descriptors (cv descriptors) are grouped with the configuration, interface or endpoint descriptors they immediately follow in the raw data returned by the device. Tree
nodes representing such descriptors (usb_cvs_data_t) contain a pointer to the raw data (uchar_t*cvs_buf) and the size of the data (uint_t cvs_buf_len).

Configuration and interface alternate nodes return string descriptions. Note that all string descriptions returned have a maximum length of USB_MAXSTRINGLEN bytes and are in English ASCII.

**Examples** In the following example, a device’s configuration data, including the following descriptor tree, is retrieved by `usb_get_dev_data(9F)` into `usb_client_dev_data_t *reg_data`:

```c
config 1
  iface 0
    alt 0
    endpt 0
config 2
  iface 0
  iface 1
    alt 0
    endpt 0
    cv 0
    alt 1
      endpt 0
      endpt 1
      cv 0
      endpt 2
    alt 2
      endpt 0
      cv 0

and suppose that the C/V data is of the following format:

typedef struct cv_data {
  char char1;
  short short1;
  char char2;
} cv_data_t;

Parse the data of C/V descriptor 0, second configuration (index 1), iface 1, alt 2, endpt 0.

```c
usb_client_dev_data_t reg_data;
usb_cvs_data_t *cv_node;
```c
```
```c
parsed_data;
```c
```c
cv_node = &reg_data->dev_cfg[1].cfg_if[1].if_alt[2].altif_ep[0].ep_cvs[0];
(void)usb_parse_data("csc",
   (void *)(&cv_node->cvs_buf), cv_node->cvs_buf_len,

If an error occurs during execution of a USB request, the USBA framework calls a client driver’s exception callback handler to relay what happened. The host controller reports transport errors to the exception callback handler through the handler’s request argument’s completion reason (usb_cr_t) field. A completion reason of USB_CR_OK means the transfer completed with no errors detected.

The usb_cr_t enumerated type contains the following definitions:

- **USB_CR_OK**: The transfer completed without any errors being detected.
- **USB_CR_CRC**: CRC error was detected.
- **USB_CR_BITSTUFFING**: Bit stuffing violation was detected.
- **USB_CR_DATA_TOGGLE_MM**: Data toggle packet identifier did not match expected value.
- **USB_CR_STALL**: The device endpoint indicated that it is stalled. If autoclearing is enabled for the request (request attributes has USB_ATTRS_AUTOCLEARING set), check the callback flags (usb_cb_flags_t) in the callback handler to determine whether the stall is a functional stall (USB_CB_FUNCTIONALSTALL) or a protocol stall (USB_CB_PROTOCOLSTALL). Please see `usb_request_attributes(9S)` for more information on autoclearing.
- **USB_CR_DEV_NOT_RESP**: Host controller timed out while waiting for device to respond.
- **USB_CR_PID_CHECKFAILURE**: Check bits on the packet identifier returned from the device were not as expected.
- **USB_CR_UNEXP_PID**: Packet identifier received was not valid.
- **USB_CR_DATA_OVERRUN**: Amount of data returned exceeded either the maximum packet size of the endpoint or the remaining buffer size.
- **USB_CR_DATA_UNDERRUN**: Amount of data returned was not sufficient to fill the specified buffer and the USB_ATTRS_SHORT_XFER_OK attribute was not
set. Please see `usb_request_attributes(9S)` for more information on allowance of short transfers.

- **USB_CR_BUFFER_OVERRUN**: A device sent data faster than the system could digest it.
- **USB_CR_BUFFER_UNDERRUN**: The host controller could not get data from the system fast enough to keep up with the required USB data rate.
- **USB_CR_TIMEOUT**: A timeout specified in a control, bulk, or one-time interrupt request has expired.
- **USB_CR_NOT_ACCESSSED**: Request was not accessed nor processed by the host controller.
- **USB_CR_NO_RESOURCES**: No resources were available to continue servicing a periodic interrupt or isochronous request.
- **USB_CR_STOPPED_POLLING**: Servicing of the current periodic request cannot continue because polling on an interrupt-IN or isochronous-IN endpoint has stopped.
- **USB_CR_PIPE_CLOSING**: Request was not started because the pipe to which it was queued was closing or closed.
- **USB_CR_PIPE_RESET**: Request was not started because the pipe to which it was queued was reset.
- **USB_CR_NOT_SUPPORTED**: Request or command is not supported.
- **USB_CR_FLUSHED**: Request was not completed because the pipe to which it was queued went to an error state, became stalled, was reset or was closed.
- **USB_CR_HC_HARDWARE_ERR**: Request could not be completed due to a general host controller hardware error.

`usb_alloc_request(9F), usb_pipe_bulk_xfer(9F), usb_pipe_ctrl_xfer(9F),
usb_pipe_intr_xfer(9F), usb_pipe_isoc_xfer(9F), usb_bulk_request(9S),
usb_ctrl_request(9S), usb_intr_request(9S), usb_isoc_request(9S)`. 
A control request is used to send device commands (or requests) and to read status. Please refer to Section 5.5 of the USB 2.0 specification for information on control pipes. For information on formatting requests, see Section 9.3 of the USB 2.0 specification. The USB 2.0 specification is available at www.usb.org.

The fields in the usb_ctrl_req_t are used to format a control request:

- `uint8_t ctrl_bmRequestType; /* characteristics of request */`
- `uint8_t ctrl_bRequest; /* specific request */`
- `uint16_t ctrl_wValue; /* varies according to request */`
- `uint16_t ctrl_wIndex; /* index or offset */`
- `uint16_t ctrl_wLength; /* number of bytes to xfer */`
- `mblk_t *ctrl_data; /* data for the data phase */`
- `/* IN or OUT: allocated by client */`
- `uint_t ctrl_timeout; /* time until USBA framework */`
- `/* retries req, in seconds */`
- `/* If set to zero, defaults to 5 sec */`
- `usb_opaque_t ctrl_client_private; /* client private info */`
- `usb_req_attrs_t ctrl_attributes; /* attrib. for this req */`
- `/* Normal callback function, called upon completion. */`
  void (*ctrl_cb)(
    usb_pipe_handle_t ph, struct usb_ctrl_req *req);
- `/* Exception callback function, for error handling. */`
  void (*ctrl_exc_cb)(
    usb_pipe_handle_t ph, struct usb_ctrl_req *req);
- `usb_cr_t ctrl_completion_reason; /* overall success status */`
- `/* See usb_completion_reason(9S) */`
- `usb_cb_flags_t ctrl_cb_flags; /* recovery done by callback hndlr */`
- `/* See usb_callback_flags(9S) */`

Request attributes define special handling for transfers. The following attributes are valid for control requests:

- **USB_ATTRS_SHORT_XFER_OK** Accept transfers where less data is received than expected.
- **USB_ATTRS_AUTOCLEARING** Have USB framework reset pipe and clear functional stalls automatically on exception.
- **USB_ATTRSPIPE_RESET** Have USB framework reset pipe automatically on exception.

Please see **usb_request_attributes(9S)** for more information.
The following definitions directly pertain to fields in the USB control request structure. (See Section 9.3 of the USB 2.0 specification.)

Direction bitmasks of a control request's ctrl_bmRequestType field (USB 2.0 spec, section 9.3.1)

- USB_DEV_REQ_HOST_TO_DEV | Host to device direction
- USB_DEV_REQ_DEV_TO_HOST | Device to host direction
- USB_DEV_REQ_DIR_MASK | Bitmask of direction bits

Request type bitmasks of a control request's ctrl_bmRequestType field (USB 2.0 spec, section 9.3.1)

- USB_DEV_REQ_TYPE_STANDARD | USB 2.0 defined command for all USB devices
- USB_DEV_REQ_TYPE_CLASS | USB 2.0 defined class-specific command
- USB_DEV_REQ_TYPE_VENDOR | Vendor-specific command
- USB_DEV_REQ_TYPE_MASK | Bitmask of request type bits

Recipient bitmasks of a control request's ctrl_bmRequestType field (USB 2.0 spec, section 9.3.1)

- USB_DEV_REQ_RCPT_DEV | Request is for device
- USB_DEV_REQ_RCPT_IF | Request is for interface
- USB_DEV_REQ_RCPT_EP | Request is for endpoint
- USB_DEV_REQ_RCPT_OTHER | Req is for other than above
- USB_DEV_REQ_RCPT_MASK | Bitmask of request recipient bits

Standard requests (USB 2.0 spec, section 9.4)

- USB_REQ_GET_STATUS | Get status of device, endpoint or interface (9.4.5)
- USB_REQ_CLEAR_FEATURE | Clear feature specified by wValue field (9.4.1)
- USB_REQ_SET_FEATURE | Set feature specified by wValue field (9.4.9)
- USB_REQ_SET_ADDRESS | Set address specified by wValue field (9.4.6)
- USB_REQ_GET_DESCR | Get descr for item/idx in wValue field (9.4.3)
- USB_REQ_SET_DESCR | Set descr for item/idx in wValue field (9.4.8)
- USB_REQ_GET_CFG | Get current device configuration (9.4.2)
- USB_REQ_SET_CFG | Set current device configuration (9.4.7)
- USB_REQ_GET_IF | Get alternate interface setting (9.4.4)
USB_REQ_SET_IF | Set alternate interface setting (9.4.10)
USB_REQ_SYNC_FRAME | Set and report an endpoint's sync frame (9.4.11)

Unicode language ID, used as wIndex for USB_REQ_SET/GET_DESCRIPTOR

USB_LANG_ID | Unicode English Lang ID for parsing str descr

Name  usb_dev_descr – USB device descriptor

Synopsis  #include <sys/usb/usba.h>

Interface Level  Solaris DDI specific (Solaris DDI)

Description  The usb_dev_descr_t device descriptor defines device-wide attributes. Please refer to Section 9.6.1 of the USB 2.0 specification. The USB 2.0 specification is available at www.usb.org.

The device descriptor is retrieved from a USB device during device enumeration and can be accessed via usb_get_dev_data(9F).

A device descriptor contains the following fields:

- `uint8_t bLength`: Size of this descriptor, in bytes.
- `uint8_t bDescriptorType`: Set to USB_DESCR_TYPE_DEV.
- `uint16_t bcdUSB`: USB specification release number supported, in bcd.
- `uint8_t bDeviceClass`: Class code (see below).
- `uint8_t bDeviceSubClass`: Subclass code (see USB 2.0 specification of applicable device class for information.)
- `uint8_t bDeviceProtocol`: Protocol code (see USB 2.0 specification of applicable device class for information.)
- `uint8_t bMaxPacketSize0`: Maximum packet size of endpoint 0.
- `uint16_t idVendor`: vendor ID value.
- `uint16_t idProduct`: product ID value.
- `uint16_t bcdDevice`: Device release number in binary coded decimal.
- `uint8_t iManufacturer`: Index of optional manufacturer description string. Valid if > 0.
- `uint8_t iProduct`: Index of optional product description string. Valid if > 0.
uint8_t iSerialNumber  Index of optional serial number string. Valid if > 0.

uint8_t bNumConfigurations  Number of available configurations.

Device descriptors bDeviceClass values:
USB_CLASS_PER_INTERFACE  Class information is at interface level.
USB_CLASS_COMM  CDC control device class.
USB_CLASS_DIAG  Diagnostic device class.
USB_CLASS_HUB  HUB device class.
USB_CLASS_MISC  MISC device class.
USB_CLASS_VENDOR_SPEC  Vendor-specific class.
USB_CLASS_WIRELESS  Wireless controller device class.

**Name**  
usb_dev_qlf_descr – USB device qualifier descriptor

**Synopsis**  
#include <sys/usb/usba.h>

**Interface Level**  
Solaris DDI specific (Solaris DDI)

**Description**  
The device qualifier descriptor `usb_dev_qlf_descr` defines how fields of a high speed device's device descriptor would look if that device is run at a different speed. If a high-speed device is running currently at full/high speed, fields of this descriptor reflect how device descriptor fields would look if speed was changed to high/full. Please refer to section 9.6.2 of the USB 2.0 specification. The USB 2.0 specification is available at www.usb.org.

A device descriptor contains the following fields:

- **bLength**  
  Size of this descriptor.

- **bDescriptorType**  
  Set to USB_DESCR_TYPE_DEV_QLF.

- **bcdUSB**  
  USB specification release number in binary coded decimal.

- **bDeviceClass**  
  Device class code. (See `usb_dev_descr(9S)`.)

- **bDeviceSubClass**  
  Device subclass code. (See USB 2.0 specification of applicable device class for information.)

- **bDeviceProtocol**  
  Protocol code. (See USB 2.0 specification of applicable device class for information.)

- **bMaxPacketSize0**  
  Maximum packet size of endpoint 0.

- **bNumConfigurations**  
  Number of available configurations.

- **bReserved**  
  Reserved.

The `usb_ep_descr_t` endpoint descriptor defines endpoint attributes. An endpoint is a uniquely addressable portion of a USB device that is a source or sink of data.

Please refer to Section 9.6.6 of the USB 2.0 specification. The USB 2.0 specification is available at www.usb.org.

One or more endpoint descriptors are retrieved from a USB device during device enumeration. They can be accessed via `usb_get_dev_data(9F)`.

A endpoint descriptor has the following fields:

- `uint8_t bLength`: Size of this descriptor in bytes.
- `uint8_t bDescriptorType`: Set to USB_DESCR_TYPE_EP.
- `uint8_t bEndpointAddress`: Endpoint address.
- `uint8_t bmAttributes`: Endpoint attrib. (see below.)
- `uint16_t wMaxPacketSize`: Maximum pkt size.
- `uint8_t bInterval`: Polling interval for interrupt and isochro. endpoints. NAK rate for high-speed control and bulk endpoints.

Endpoint descriptor bEndpointAddress bitmasks contain address number and direction fields as follows:

- USB_EP_NUM_MASK: Address bits
- USB_EP_DIR_MASK: Direction bit
- USB_EP_DIR_OUT: OUT towards device
- USB_EP_DIR_IN: IN towards host

Endpoint descriptor transfer type bmAttributes values and mask:

- USB_EP_ATTR_CONTROL: Endpoint supports control transfers
- USB_EP_ATTR_ISOCH: Endpoint supports isochronous xfers
- USB_EP_ATTR_BULK: Endpoint supports bulk transfers
- USB_EP_ATTR_INTR: Endpoint supports interrupt transfers
- USB_EP_ATTR_MASK: bmAttributes transfer-type bit field

Endpoint descriptor synchronization type bmAttributes values and mask for isochronous endpoints:
USB_EP_SYNC_NONE   Endpoint supports no synchronization
USB_EP_SYNC_ASYNC  Endpoint supports asynchronous sync
USB_EP_SYNC_ADPT   Endpoint supports adaptive sync
USB_EP_SYNC_SYNC   Endpoint supports synchronous sync

Endpoint descriptor feedback type bmAttributes values and mask for
isochronous endpoints:

<table>
<thead>
<tr>
<th>Endpoint Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USB_EP_USAGE_DATA</td>
<td>Data endpoint</td>
</tr>
<tr>
<td>USB_EP_USAGE_FEED</td>
<td>Feedback endpoint</td>
</tr>
<tr>
<td>USB_EP_USAGE_IMPL</td>
<td>Implicit feedback data endpoint</td>
</tr>
<tr>
<td>USB_EP_USAGE_MASK</td>
<td>bmAttributes feedback type bit field</td>
</tr>
</tbody>
</table>

Endpoint descriptor additional-transaction-opportunities-per-microframe wMaxPacketSize values and mask for high speed
isochronous and interrupt endpoints:

<table>
<thead>
<tr>
<th>Endpoint Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USB_EP_MAX_PKT_SZ_MASK</td>
<td>Mask for packetsize bits</td>
</tr>
<tr>
<td>USB_EP_MAX_XACTS_MASK</td>
<td>Bits for additional transfers per microframe</td>
</tr>
<tr>
<td>USB_EP_MAX_XACTS_SHIFT</td>
<td>Left-shift this number of bits to get to additional-transfers-per-microframe bitfield</td>
</tr>
</tbody>
</table>

Endpoint descriptor polling bInterval range values:

<table>
<thead>
<tr>
<th>Endpoint Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USB_EP_MIN_HIGH_CONTROL_INTRVL</td>
<td>Min NAK rate for highspd ctrl e/p</td>
</tr>
<tr>
<td>USB_EP_MAX_HIGH_CONTROL_INTRVL</td>
<td>Max NAK rate for highspd ctrl e/p</td>
</tr>
<tr>
<td>USB_EP_MIN_HIGH_BULK_INTRVL</td>
<td>Min NAK rate for highspd bulk e/p</td>
</tr>
<tr>
<td>USB_EP_MAX_HIGH_BULK_INTRVL</td>
<td>Max NAK rate for highspd bulk e/p</td>
</tr>
<tr>
<td>USB_EP_MIN_LOW_INTR_INTRVL</td>
<td>Min poll interval, lowspd intr e/p</td>
</tr>
<tr>
<td>USB_EP_MAX_LOW_INTR_INTRVL</td>
<td>Max poll interval, lowspd intr e/p</td>
</tr>
<tr>
<td>USB_EP_MIN_FULL_INTR_INTRVL</td>
<td>Min poll interval, fullspd intr e/p</td>
</tr>
<tr>
<td>USB_EP_MAX_FULL_INTR_INTRVL</td>
<td>Max poll interval, fullspd intr e/p</td>
</tr>
</tbody>
</table>

Note that for the following polling bInterval range values, the interval is $2^{(value-1)}$. See Section 9.6.6 of the USB 2.0 specification.

The `usb_if_descr_t` interface descriptor defines attributes of an interface. A configuration contains one or more interfaces. An interface contains one or more endpoints. Please refer to Section 9.6.5 of the USB 2.0 specification. The USB 2.0 specification is available at [www.usb.org](http://www.usb.org).

One or more configuration descriptors are retrieved from a USB device during device enumeration. They can be accessed via `usb_get_dev_data(9F)`.

A interface descriptor has the following fields:

```c
uint8_t bLength Size of this descriptor in bytes.
uint8_t bDescriptorType Set to USB_DESCR_TYPE_IF.
uint8_t bInterfaceNumber Interface number (0-based).
uint8_t bAlternateSetting Alternate setting number for this interface and its endpoints (0-based).
uint8_t bNumEndpoints Number of endpoints, excluding endpoint 0.
uint8_t bInterfaceClass Interface Class code (see below).
uint8_t bInterfaceSubClass Sub class code. (See USB 2.0 specification of applicable interface class for information.)
uint8_t bInterfaceProtocol Protocol code. (See USB 2.0 specification of applicable interface class for information.)
uint8_t iInterface Index of optional string describing this interface. Valid if > 0. Pass to `usb_get_string_descr(9F)` to retrieve string.
```

USB 2.0 specification interface descriptor `bInterfaceClass` field
values are as follows:

<table>
<thead>
<tr>
<th>Class Code</th>
<th>Description</th>

### NAME

`usb_intr_request` – USB interrupt request structure

### Synopsis

```c
#include <sys/usb/usba.h>
```

### Interface Level

Solaris DDI specific (Solaris DDI)

### Description

An interrupt request (that is, a request sent through an interrupt pipe), is used to transfer small amounts of data infrequently, but with bounded service periods. (Data flows in either direction.) Please refer to Section 5.7 of the USB 2.0 specification for information on interrupt transfers. (The USB 2.0 specification is available at [www.usb.org](http://www.usb.org).)

The fields in the `usb_intr_req_t` are used to format an interrupt request. Please see below for acceptable combinations of flags and attributes.

The `usb_intr_req_t` fields are:

```c
struct usb_intr_req {
    ushort_t intr_len; /* Size of pkt. Must be set */
    /* Max size is 8K for low/full speed */
    /* Max size is 20K for high speed */
    mblk_t *intr_data; /* Data for the data phase */
    /* IN: zero-len mblk alloc by client */
    /* OUT: allocated by client */
    usb_opaque_t intr_client_private; /* client specific information */
    uint_t intr_timeout; /* only with ONE TIME POLL, in secs */
    /* If set to zero, defaults to 5 sec */
    usb_req_attrs_t intr_attributes;
    void (*intr_cb)(usb_pipe_handle_t ph, struct usb_intr_req *req);
    void (*intr_exc_cb)(usb_pipe_handle_t ph, struct usb_intr_req *req);
    usb_cr_t intr_completion_reason; /* overall completion status */
    /* See usb_completion_reason(9S) */
    usb_cb_flags_t intr_cb_flags; /* recovery done by callback hndlr */
    /* See usb_callback_flags(9S) */
};
```

Request attributes define special handling for transfers. The following attributes are valid for interrupt requests:

- **USB_ATTRS_SHORT_XFER_OK**: Accept transfers where less data is received than expected.
- **USB_ATTRS_AUTOCLEARING**: Have USB framework reset pipe and clear functional stalls automatically on exception.

---

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>USB_ATTRS_SHORT_XFER_OK</strong></td>
<td>Accept transfers where less data is received than expected.</td>
</tr>
<tr>
<td><strong>USB_ATTRS_AUTOCLEARING</strong></td>
<td>Have USB framework reset pipe and clear functional stalls automatically on exception.</td>
</tr>
</tbody>
</table>
USB_ATTRS_PIPE_RESET Have USB framework reset pipe automatically on exception.

USB_ATTRS_ONE_XFER Perform a single IN transfer. Do not start periodic transfers with this request.

Please see usb_request_attributes(9S) for more information.

Interrupt transfers/requests are subject to the following constraints and caveats:

1) The following table indicates combinations of
   usb_pipe_intr_xfer() flags argument and fields
   of the usb_intr_request_t request argument (X = don’t care):

   "none" as attributes in the table below indicates
   neither ONE_XFER nor SHORT_XFER_OK

<table>

<td></td>
</tr>
</tbody>
</table>
Table notes:

A) Continuous polling, new data is returned in cloned request structures via continuous callbacks, original request is returned on stop polling.

B) One time poll, no timeout, callback when data is received.

C) One time poll, with timeout, callback when data is received.

D) One time poll, no timeout, one callback, unblock when transfer completes.

E) One time poll, timeout, one callback, unblock when transfer completes or timeout occurs.

F) Transfer until data exhausted, no timeout, callback when done.

G) Transfer until data exhausted, timeout, callback when done.

H) Transfer until data exhausted, no timeout, unblock when data is received.

I) Transfer until data exhausted, timeout, unblock when data is received.

2) USB_FLAGS_SLEEP indicates here just to wait for resources, except when ONE_XFER is set, in which case it also waits for completion before returning.

3) Reads (IN):

a) The client driver does *not* provide a data buffer. By default, a READ request would mean continuous polling for data IN. The USBA framework allocates a new data buffer for each poll. intr_len specifies the amount of ‘periodic data’ for each poll.

b) The USBA framework issues a callback to the client at the end of a polling interval when there is data to return. Each callback returns its data in a new request cloned from the original. Note that the amount of data
read IN is either intr_len or "wMaxPacketSize" in length.

c) Normally, the HCD keeps polling the interrupt endpoint forever even if there is no data to be read IN. A client driver may stop this polling by calling `usb_pipe_stop_intr_polling(9F)`.

d) If a client driver chooses to pass `USB_ATTRS_ONE_XFER` as 'xfer_attributes' the HCD polls for data until some data is received. The USBA framework reads in the data, does a callback, and stops polling for any more data. In this case, the client driver need not explicitly call `usb_pipe_stop_intr_polling()`.

e) All requests with `USB_ATTRS_ONE_XFER` require callbacks to be specified.

f) When continuous polling is stopped, the original request is returned with `USB_CR_STOPPED_POLLING`.

g) If the `USB_ATTRS_SHORT_XFER_OK` attribute is not set and a short transfer is received while polling, an error is assumed and polling is stopped. In this case or the case of other errors, the error must be cleared and polling restarted by the client driver. Setting the `USB_ATTRS_AUTOCLEARING` attribute will clear the error but not restart polling. (NOTE: Polling can be restarted from an exception callback corresponding to an original request. Please see `usb_pipe_intr_xfer(9F)` for more information.

4) Writes (OUT):

a) A client driver provides the data buffer, and data, needed for intr write.

b) Unlike read (see previous section), there is no continuous write mode.

c) The `USB_ATTRS_ONE_XFER` attribute is illegal. By default USBA keeps writing intr data until the provided data buffer has been written out. The USBA framework does ONE callback to the client driver.

d) Queueing is supported.
The `intr_completion_reason` indicates the status of the transfer. See `usb_completion_reason(9S)` for `usb_cr_t` definitions.

The `intr_cb_flags` are set prior to calling the exception callback handler, to summarize recovery actions taken and errors encountered during recovery. See `usb_callback_flags(9S)` for `usb_cb_flags_t` definitions.

--- Callback handling ---

All USB request types share the same callback handling. Please see `usb_callback_flags(9S)` for a description of use and operation.

**Name**
usb_isoc_request – USB isochronous request structure

**Synopsis**
#include <sys/usb/usba.h>

**Interface Level**
Solaris DDI specific (Solaris DDI)

**Description**
A request sent through an isochronous pipe is used to transfer large amounts of packetized data with relative unreliability, but with bounded service periods. A packet is guaranteed to be tried within a bounded time period, but is not retried upon failure. Isochronous transfers are supported on both USB 1.1 and USB 2.0 devices. For further information, see section 5.6 of the USB 2.0 specification available at www.usb.org.

This section provides information on acceptable combinations of flags and attributes with additional details. The following fields of the usb_isoc_req_t are used to format an isochronous request.

```c
usb_frame_number_t
    isoc_frame_no;  /* frame num to start sending req. */
ushort_t isoc_pkts_count; /* num USB pkts in this request */
/*
   * The sum of all pkt lengths in an isoc request. Recommend to set it to
   * zero, so the sum of isoc_pkt_length in the isoc_pkt_descr list will be
   * used automatically and no check will be apply to this element.
   */
ushort_t isoc_pkts_length;
ushort_t isoc_error_count; /* num pkts completed w/errs */
usb_req_attrs_t isoc_attributes; /* request-specific attrs */
mblk_t *isoc_data; /* data to xfer */
    /* IN or OUT: alloc. by client. */
    /* Size=total of all pkt lengths. */
usbOpaque_t isoc_client_private; /* for client driver excl use. */
struct usb_isoc_pkt_descr /* (see below) */
    *isoc_pkt_descr;
/*
   * Normal callback function, called upon completion.
   * This function cannot block as it executes in soft interrupt context.
   */
void (*isoc_cb)(
    usbPipeHandle_t ph, struct usb_isoc_req *req);
/* Exception callback function, for error handling. */
void (*isoc_exc_cb)(
    usbPipeHandle_t ph, struct usb_isoc_req *req);
usb_cr_t isoc_completion_reason; /* overall completion status */
    /* set by USBA framework */
    /* See usb_completion_reason(9S) */
usb_cb_flags_t isoc_cb_flags; /* recovery done by callback hndlr */
```
A `usb_isoc_pkt_descr_t` describes the status of an isochronous packet transferred within a frame or microframe. The following fields of a `usb_isoc_pkt_descr_t` packet descriptor are used within an `usb_isoc_req_t`. The `isoc_pkt_length` is set by the client driver to the amount of data managed by the packet for input or output. The latter two fields are set by the USBA framework to indicate status. Any packets with an `isoc_completion_reason`, other than `USB_CR_OK`, are reflected in the `isoc_error_count` of the `usb_isoc_req_t`.

```c
ushort_t isoc_pkt_length; /* number bytes to transfer */
ushort_t isoc_pkt_actual_length; /* actual number transferred */
usb_cr_t isoc_pkt_status; /* completion status */
```

If two multi-frame isoc requests that both specify the `USB_ATTRS_ISOC_XFER_ASAP` attribute are scheduled closely together, the first frame of the second request is queued to start after the last frame of the first request.

No stalls are seen in isochronous transfer exception callbacks. Because transfers are not retried upon failure, isochronous transfers continue regardless of errors.

Request attributes define special handling for transfers. The following attributes are valid for isochronous requests:

- **USB_ATTRS_ISOC_START_FRAME**: Start transferring at the starting frame number specified in the `isoc_frame_no` field of the request.
- **USB_ATTRS_ISOC_XFER_ASAP**: Start transferring as soon as possible. The USBA framework picks an immediate frame number to map to the starting frame number.
- **USB_ATTRS_SHORT_XFER_OK**: Accept transfers where less data is received than expected.

The `usb_isoc_req_t` contains an array of descriptors that describe isochronous packets. One isochronous packet is sent per frame or microframe. Because packets that comprise a transfer are sent across consecutive frames or microframes, `USB_ATTRS_ONE_XFER` is invalid.

See `usb_request_attributes(9S)` for more information.

Isochronous transfers/requests are subject to the following constraints and caveats:

1) The following table indicates combinations of `usb_pipe_isoc_xfer` flags argument and fields of the `usb_isoc_req_t` request argument (X = don't care). (Note that attributes considered in this table are `ONE_XFER`, `START_FRAME`, `XFER_ASAP`, and `SHORT_XFER`, and that some transfer types are characterized by multiple table entries.)

<table>
<thead>
<tr>
<th>Flags Type</th>
<th>Attributes</th>
<th>Data</th>
<th>Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>X</td>
<td>X</td>
<td>NULL</td>
</tr>
</tbody>
</table>

---
**Table notes:**

A) continuous polling, new data is returned in cloned request structures via continuous callbacks, original request is returned on stop polling.

B) invalid if the current frame number is past "isoc_frame_no" or "isoc_frame_no" == 0

C) "isoc_frame_no" is ignored. The USBA framework determines which frame to insert and start the transfer.

2) **USB_FLAGS_SLEEP** indicates to wait for resources but not for completion.

3) For polled reads:

A. The USBA framework accepts a request which specifies the size and number of packets to fill with data. The packets get filled one packet per (1 ms) frame/(125 us) microframe. All requests have an implicit **USB_ATTRS_SHORT_XFER_OK** attribute set, since transfers continue in spite of any encountered. The amount of data read per packet will match the **isoc_pkt_length** field of the packet descriptor unless a short transfer occurs. The actual size is returned in the **isoc_pkt_actual_length** field of the packet descriptor. When all packets of the request have
been processed, a normal callback is done to signal the completion of the original request.

B. When continuous polling is stopped, the original request is returned in an exception callback with a completion reason of USB_CR_STOPPED_POLLING. (NOTE: Polling can be restarted from an exception callback corresponding to an original request. Please see usb_pipe_isoc_xfer(9F) for more information.

C. Callbacks must be specified.

The isoc_completion_reason indicates the status of the transfer. See usb_completion_reason(9s) for usb_cr_t definitions.

The isoc_cb_flags are set prior to calling the exception callback handler to summarize recovery actions taken and errors encountered during recovery. See usb_callback_flags(9s) for usb_cb_flags_t definitions.

--- Callback handling ---
All usb request types share the same callback handling. Please see usb_callback_flags(9s) for a description of use and operation.

The `usb_other_speed_cfg_descr_t` configuration descriptor defines how fields of a high speed device's configuration descriptor change if that device is run at its other speed. Fields of this descriptor reflect configuration descriptor field changes if a device's speed is changed from full to high speed, or from high to full speed.

Please refer to Section 9.6.4 of the USB 2.0 specification. The USB 2.0 specification is available at [www.usb.org](http://www.usb.org).

This descriptor has the following fields:

- `uint8_t bLength`: Size of this descriptor, in bytes.
- `uint8_t bDescriptorType`: Set to USB_DESCR_TYPE_OTHER_SPEED_CFG.
- `uint16_t wTotalLength`: Total length of data returned */ including all descriptors in the current other-speed configuration.
- `uint8_t bNumInterfaces`: Number of interfaces in the selected configuration.
- `uint8_t bConfigurationValue`: ID of the current other-speed configuration (1-based).
- `uint8_t iConfiguration`: Configuration value. Valid if > 0. Pass to `usb_get_string_descr(9F)` to retrieve string.
- `uint8_t bmAttributes`: Configuration characteristics [See `usb_cfg_descr(9S)`.]
- `uint8_t bMaxPower`: Maximum power consumption in 2mA units.

Solaris DDI specific (Solaris DDI)

Request attributes specify how the USBA framework handles request execution. Request attributes are specified in the request's *attributes field and belong to the enumerated type usb_req_attrs_t.

Supported request attributes are:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USB_ATTRS_SHORT_XFER_OK</td>
<td>Use this attribute when the maximum transfer size is known, but it is possible for the request to receive a smaller amount of data. This attribute tells the USBA framework to accept without error transfers which are shorter than expected.</td>
</tr>
<tr>
<td>USB_ATTRS_PIPE_RESET</td>
<td>Have the USB framework reset the pipe automatically if an error occurs during the transfer. Do not attempt to clear any stall. The USB_CB_RESETPIPE callback flag is passed to the client driver's exception handler to show the pipe has been reset. Pending requests on pipes which are reset are flushed unless the pipe is the default pipe.</td>
</tr>
<tr>
<td>USB_ATTRS_AUTOCLEARING</td>
<td>Have the USB framework reset the pipe and clear functional stalls automatically if an error occurs during the transfer. The callback flags passed to the client driver's exception handler show the status after the attempt to clear the stall. USB_CB_FUNCTIONALSTALL is set in the callback flags to indicate that a functional stall occurred. USB_CB_STALL_CLEARED is also set if the stall is cleared. The default pipe never shows a functional stall if the USB_ATTRS_AUTOCLEARING attribute is set. If USB_CB_FUNCTIONALSTALL is seen when autoclearing is enabled, the device has a fatal error. USB_CB_PROTOCOLSTALL is set without USB_CB_STALL_CLEARED in the callback flags to indicate that a protocol stall was seen but was</td>
</tr>
</tbody>
</table>
not explicitly cleared. Protocol stalls are cleared automatically when a subsequent command is issued.

Autoclearing a stalled default pipe is not allowed. The USB_CB_PROTOCOLSTALL callback flag is set in the callback flags to indicate the default pipe is stalled.

Autoclearing is not allowed when the request is USB_REQ_GET_STATUS on the default pipe.

**USB_ATTRS_ONE_XFER**

Applies only to interrupt-IN requests. Without this flag, interrupt-IN requests start periodic polling of the interrupt pipe. This flag specifies to perform only a single transfer. Do not start periodic transfers with this request.

**USB_ATTRS_ISO_CONT FRAME**

Applies only to isochronous requests and specifies that a request be started at a given frame number. The starting frame number is provided in the isoc_frame_no field of the usb_isoc_req_t. Please see `usb_isoc_request(9S)` for more information about isochronous requests.

USB_ATTRS_ISO_CONT FRAME can be used to delay a transfer by a few frames, allowing transfers to an endpoint to sync up with another source. (For example, synching up audio endpoints to a video source.) The number of a suitable starting frame in the near future can be found by adding an offset number of frames (usually between four and ten) to the current frame number returned from `usb_get_current_frame_number(9F)`.

Note that requests with starting frames which have passed are rejected.

**USB_ATTRS_ISO_CONT_XFER_ASP**

Applies only to isochronous requests and specifies that a request start as soon as possible. The host controller driver picks a starting frame number which immediately follows the last frame of the last queued request. The isoc_frame_no of the usb_isoc_req_t is ignored. Please see `usb_isoc_request(9S)` for more information about isochronous requests.
Examples
/*
* Allocate, initialize and issue a synchronous bulk-IN request.
* Allow for short transfers.
*/

struct buf *bp;
usb_bulk_req_t bulk_req;
mblk_t *mblk;

bulk_req = usb_alloc_bulk_req(dip, bp->b_count, USB_FLAGS_SLEEP);

bulk_req->bulk_attributes =
    USB_ATTRS_AUTOCLEARING | USB_ATTRS_SHORT_XFER_OK;

if ((rval = usb_pipe_bulk_xfer(pipe, bulk_req, USB_FLAGS_SLEEP)) !=
    USB_SUCCESS) {
    cmn_err (CE_WARN,
        "%s%d: Error reading bulk data."
        ,
        ddi_driver_name(dip), ddi_get_instance(dip));
}

mblk = bulk_req->bulk_data;
bcopy(mblk->rptr, buf->b_un.b_addr, mblk->wptr - mblk->rptr);
bp->b_resid = bp->b_count - (mblk->wptr = mblk->rptr);
...
...
....

usb_pipe_handle_t handle;
usb_frame_number_t offset = 10;
usb_isoc_req_t *isoc_req;

isoc_req = usb_alloc_isoc_req(...);
...
...

isoc_req->isoc_frame_no = usb_get_current_frame_number(dip) + offset;
isoc_req->isoc_attributes = USB_ATTRS_ISOC_START_FRAME;
...
...
if (usb_pipe_isoc_xfer(handle, isoc_req, 0) != USB_SUCCESS) {
    ...
}

Description

The `usb_string_descr_t` string descriptor defines the attributes of a string, including size and Unicode language ID. Other USB descriptors may have string descriptor index fields which refer to specific string descriptors retrieved as part of a device’s configuration.

Please refer to Section 9.6.7 of the USB 2.0 specification. The USB 2.0 specification is available at www.usb.org.

A string descriptor has the following fields:

```c
uint8_t  bLength        Size of this descriptor, in bytes.
uint8_t  bDescriptorType Set to USB_DESCR_TYPE_STRING.
uint16_t bString[1];   Variable length Unicode encoded string.
```
